## Type tree features

The type trees contained in the Pack for Financial Payments, FIX component serve to enforce FIX message structure, message syntax, as well as to enforce additional data validation rules.

- [FIX message structure](#)  
A FIX message consists of a header, a message body, and a trailer:
- [Message syntax](#)  
The type tree enforces strict message syntax that is based upon three variable values, <Tag>, <Value>, and <Delimiter>.
- [Additional validation](#)  
In addition to enforcing message structure and syntax, the type trees also enforce a number of other rules.

## FIX message structure

A FIX message consists of a header, a message body, and a trailer:

- Header - The FIX message header identifies the message type, length, sender/destination, sequence number, sending time etc.
- Body - The FIX message body contains specific session and application message content.
- Trailer - The FIX message trailer contains an optional digital signature and the required checksum value.

It should be noted that all fields within the message can be defined in any sequence with the following exceptions:

- tag number 8, 9, and 35 of the header block must be the first three fields in the message
- tag number 10 of the trailer block must be the last field in the message
- fields within a repeating block must appear in the same order as defined in the FIX standard documents
- the number of repeating group instances must immediately precede the repeating group contents
- binary fields must be preceded by corresponding length fields

## Message syntax

The type tree enforces strict message syntax that is based upon three variable values, <Tag>, <Value>, and <Delimiter>.

The field format is: <Tag>=<Value><Delimiter>. Values for these entities are described as follows:

- <Tag> - any integer with no leading zeros
- = (equal sign) - the separator between Tag and Value.
- <Value> - value that represents the actual content of the field
- <Delimiter> - a non-printing ASCII character that is called the SOH character

## Additional validation

In addition to enforcing message structure and syntax, the type trees also enforce a number of other rules.

Additional validation rules are defined in the following table.

| Rule                                 | Description                                                                                                              |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Restriction list verification        | Verifies the code list on FIX tags: examples are country codes, currency codes, exchange, and language data types.       |
| FIX tags numeric data types          | Enforces allowable numeric ranges for the following data types: int, float, Qty, Price, PriceOffset, Amt and Percentage. |
| Body length verification             | Validates that the actual body length is consistent with the value specified in tag number 9 of the FIX message.         |
| Message specific cross tag checking  | Validates the presence or absence of certain tags that depend on certain values of other tags within the same message.   |
| FIX tags without values verification | Verifies the FIX tags that have actual values specified. FIX tags without values fail the FIX type tree validation.      |

Checksum digit validation is no longer being enforced within the FIX type trees. See [Checksum integrity check](#).

The structure of the FIX tags allow restriction lists and numeric ranges to be implemented consistently across message types. These FIX fields are defined as "Group" class in the FIX type trees consisting of a common data type "Item" class. The data type items introduced in the FIX type trees are re-used in other FIX fields having the same data types. Maps built using FIX type trees from previous versions of the WebSphere Transformation Extender Pack for FIX require re-mapping of the FIX fields, specifically those fields that belong to the following data types:

- Country
- Currency
- Exchange
- Float (this includes data types, that is: Qty, Price, PriceOffset, Amt, and Percentage)

## Example message structure

The documentation provided here shows the FIX message structure by showing an example header, body and trailer.

These examples are taken from the example file that installs with the Pack for Financial Payments, FIX component.

- [\*\*Header example\*\*](#)  
The message header fields are shown below. These fields are taken from the example file that installs with the Pack for Financial Payments, FIX component.
- [\*\*Body example\*\*](#)  
The message header fields are shown below. These fields are taken from the example file that installs with the Pack for Financial Payments, FIX component.
- [\*\*Message trailer\*\*](#)  
The following conditions are not validated in the FIX type trees. You can extend the validation in your implementation through more mapping or lookups.
- [\*\*Additional validation recommendations\*\*](#)

## Header example

The message header fields are shown below. These fields are taken from the example file that installs with the Pack for Financial Payments, FIX component.

## Message trailer

The message trailer fields are shown in the example that is provided here. These fields are taken from the example file that installs with the Pack for Financial Payments, FIX component.

```
93=16
89=.....
10=235
```

- **Trailer fields**

The fields in the FIX message trailer are shown in the following table. These fields are taken from the example file that installs with the Pack for Financial Payments, FIX component.

## Trailer fields

The fields in the FIX message trailer are shown in the following table. These fields are taken from the example file that installs with the Pack for Financial Payments, FIX component.

| Tag Number | Value | Required | Header field    |
|------------|-------|----------|-----------------|
| 93         | 16    | No       | SignatureLength |
| 89         | ..... | No       | Signature       |
| 10         | 235   | Yes      | CheckSum        |

## Additional validation recommendations

The following conditions are not validated in the FIX type trees. You can extend the validation in your implementation through more mapping or lookups.

| Condition                                   | Explanation                                                                                                               |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| Uniqueness of sequence number.              | Every message must have a unique sequence number.                                                                         |
| Reference to fields from previous messages. | Certain conditional rules require field checks from message that is sent or previously processed.                         |
| ReservedXXXXPlus data types.                | Pattern data type used to allow additional bilaterally agreed upon enumerations to be defined starting at XXXX and above. |

| Condition                                                                                                                | Explanation                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| User-defined fields.                                                                                                     | Member firms can add their own custom fields, which are published on the FIX website.                                                                                                                                                                                                                                            |
| Bank Identifier Code (BIC), International Securities Identification Numbering System (ISINS) validation, or validations. | Certain fields require a BIC and an International ISINS number or numbers.                                                                                                                                                                                                                                                       |
| Encryption.                                                                                                              | Certain fields are encrypted, that is, tag #91 Secure Data.                                                                                                                                                                                                                                                                      |
| Checksum integrity check.                                                                                                | Verifies the check digit value that is specified in the field tag number 10 of the FIX message, against the computed checksum. The computed checksum is the actual sum of the binary value of each character of the message, up to but not including, the checksum field itself. This sum is then transformed into a modulo 256. |
| Fields that have a data type of UTCTimestamp.                                                                            | Leap Seconds are inserted to account for slowing of the rotation of the earth. During a leap second insertion, a UTCTimestamp field might read "19981231-23:59:59", "19981231-23:59:60", "19990101-00:00:00". Limitation is on Coordinated Universal Time (UTC) leap seconds set to a value of "60".                             |
| Coding schemes                                                                                                           | Restricted set of values that are associated with a URI. The URI can be assigned by an external body, or by FpML.                                                                                                                                                                                                                |
| XID data types                                                                                                           | The constraint added by this data type is that the values of all of the fields that have an ID data type in a FIX message must be unique.                                                                                                                                                                                        |
| XIDREF data types                                                                                                        | Defines a reference to an identifier that is defined by the XID data type.                                                                                                                                                                                                                                                       |

## FIXML type trees

The FIXML type trees are listed in [The trees subdirectory](#). The documentation provided here describes FIXML message protocol and defines message types by FIXML version number

- [FIXML message protocol](#)

The FIX protocol is defined at the application level.

---

## FIXML message protocol

The FIX protocol is defined at the application level.

The application level consists of:

- Pre-trade
- Trade
- Post-trade
- Other
- [Import source](#)  
The IBM Transformation Extender Schema Importer is used to generate the FIXML type trees.
- [Message types per FIXML version number](#)  
This documentation shows the message types that are supported in the Pack for Financial Payments, FIX component. Messages are listed by FIXML version.

---

## Import source

The IBM Transformation Extender Schema Importer is used to generate the FIXML type trees.

The type trees are based upon the following DTDs and schemas:

- fixml\_41.mtt - based from FIXML 4.1 DTD version 20000929
- fixml\_42.mtt - based from FIXML 4.2 DTD version 20010330
- fixml\_43.mtt - based from FIXML 4.3 DTD version 20020920
- fixml\_44.mtt - based from FIXML 4.4 schema version 20040109
- fixml\_50.mtt - based from FIXML 5.0 schema version 20070103
- fixml\_50\_sp1.mtt - based from FIXML 5.0 SP1 schema version 20080314
- fixml-main-Latest.mtt - based from FIXML Latest schema version 20240704

You must obtain these DTDs directly from FIX. The DTDs are copied to the DTDs to the same location where the compiled map that references any of the FIXML 4.1, 4.2 or 4.3 type trees is being executed.

Copies of the FIXML schemas are shipped with the Pack for Financial Payments, FIX component. The FIXML schemas are installed in the following directory:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/fix/schemas

The minimum version of the IBM Transformation Extender base product that is required by the Pack for Financial Payments, FIX component allows maps to work directly with "native" schemas. The pack does not ship "imported" type trees that are based on FIXML 5.0 SP2 schema. An example of such a scenario where FIXML schemas are being used directly in the maps is found in the sample conversion maps between FIX 5.0 SP2 and FIXML 5.0 SP2 under the <install\_dir>/packs/financial\_payments\_vn.n.n.n/fix/example folder.

---

## Message types per FIXML version number

This documentation shows the message types that are supported in the Pack for Financial Payments, FIX component. Messages are listed by FIXML version.

- [\*\*Session messages\*\*](#)  
The table shows a summary of the messages under the Session category. The messages are listed by FIX version number.
- [\*\*EventCommunication messages\*\*](#)  
The table shows a summary of the messages under the Event Communication category. The messages are listed by FIXML version number.
- [\*\*Indication messages\*\*](#)  
The table shows a summary of the messages under the Indication category. The messages are listed by FIXML version number.
- [\*\*QuotationNegotiation messages\*\*](#)  
The table shows a summary of the messages under the QuotationNegotiation category. The messages are listed by FIXML version number.
- [\*\*MarketData messages\*\*](#)  
The table shows a summary of the messages under the MarketData category. The message types are listed by FIXML version number.
- [\*\*SecuritiesReferenceData messages\*\*](#)  
The table shows a summary of the messages under the SecuritiesReferenceData category. The messages are listed by FIXML version number.
- [\*\*MarketStructureReferenceData messages\*\*](#)  
The table shows a summary of the messages under the MarketStructureReferenceData category. The messages are listed by FIXML version number.
- [\*\*PartiesAction messages\*\*](#)  
The table shows a summary of the messages under the PartiesAction category. The messages are listed by FIXML version number.
- [\*\*PartiesReferenceData messages\*\*](#)  
The table shows a summary of the messages under the PartiesReferenceData category. The messages are listed by FIXML version number.
- [\*\*SingleGeneralOrderHandling messages\*\*](#)  
The table shows a summary of the messages under the SingleGeneralOrderHandling category. The messages are listed by FIXML version number.
- [\*\*ProgramTrading messages\*\*](#)  
The table shows a summary of the messages under the ProgramTrading category. The messages are listed by FIXML version number.
- [\*\*OrderMassHandling messages\*\*](#)  
The table shows a summary of the messages under the OrderMassHandling category. The messages are listed by FIXML version number.
- [\*\*CrossOrders messages\*\*](#)  
The table shows a summary of the messages under the CrossOrders category. The messages are listed by FIXML version number.
- [\*\*MultilegOrders messages\*\*](#)  
The table shows a summary of the messages under the MultilegOrders category. The messages are listed by FIXML version number.
- [\*\*Allocation messages\*\*](#)  
The table shows a summary of the messages under the Allocation category. The messages are listed by FIXML version number.
- [\*\*SettlementInstruction messages\*\*](#)  
The table shows a summary of the messages under the SettlementInstruction category. The messages are listed by FIXML version number.
- [\*\*SettlementStatusManagement messages\*\*](#)  
The table shows a summary of the messages under the SettlementStatusManagement category. The messages are listed by FIXML version number.
- [\*\*RegistrationInstructions messages\*\*](#)  
The table shows a summary of the messages under the RegistrationInstructions category. The messages are listed by FIXML version number.
- [\*\*TradeCapture messages\*\*](#)  
The table shows a summary of the messages under the TradeCapture category. The message types are listed by FIXML version number.
- [\*\*TradeManagement messages\*\*](#)  
The table shows a summary of the messages under the TradeManagement category. The message types are listed by FIXML version number.
- [\*\*Confirmation messages\*\*](#)  
The table shows a summary of the messages under the Confirmation category. The message types are listed by FIXML version number.
- [\*\*PayManagement messages\*\*](#)  
The table shows a summary of the messages under the PayManagement category. The messages are listed by FIXML version number.
- [\*\*PositionMaintenance messages\*\*](#)  
The table shows a summary of the messages under the PositionMaintenance category. The messages are listed by FIXML version number.
- [\*\*CollateralManagement messages\*\*](#)  
The table shows a summary of the messages under the CollateralManagement category. The messages are listed by FIXML version number.
- [\*\*MarginRequirementManagement messages\*\*](#)  
The table shows a summary of the messages under the MarginRequirementManagement category. The messages are listed by FIXML version number.
- [\*\*AccountReporting messages\*\*](#)  
The table shows a summary of the messages under the AccountReporting category. The messages are listed by FIXML version number.
- [\*\*BusinessReject messages\*\*](#)  
The table shows a summary of the messages under the BusinessReject category. The messages are listed by FIXML version number.
- [\*\*Network messages\*\*](#)  
The table shows a summary of the messages under the Network category. The messages are listed by FIXML version number.
- [\*\*UserManagement messages\*\*](#)  
The table shows a summary of the messages under the UserManagement category. The messages are listed by FIXML version number.
- [\*\*Application messages\*\*](#)  
The table shows a summary of the messages under the Application category. The messages are listed by FIXML version number.

## Session messages

The table shows a summary of the messages under the Session category. The messages are listed by FIX version number.

| Session messages | FIX<br>4.0 | FIX<br>4.1 | FIX<br>4.2 | FIX<br>4.3 | FIX<br>4.4 | FIX<br>5.0 | FIX<br>SP1 | FIX<br>SP2 | FIX<br>(EP291)<br>LATEST |

## FIX component examples

The Pack for Financial Payments, FIX component contains examples to assist you in using the pack. Instructions for using the examples are included in the documentation provided here.

The following conversion examples that install with the pack:

- FIX 5.0 mapping from and to FIXML 5.0
- FIX 5.0 SP1 mapping from and to FIXML 5.0 SP1
- FIX 5.0 SP2 mapping from and to FIXML 5.0 SP2
- FIX 5.0 SP2 EP mapping from and to FIXML 5.0 SP2 EP

The mapping rules used between FIX and FIXML standards are not exhaustive. These rules are intended to give you a starting point in building your own transformations for your own business requirements.

It also includes the example scenarios on how to use the FIX checksum utility maps.

- FIX checksum validation
- FIX checksum generation

On UNIX platforms, be aware of file paths and case sensitivity for schemas and DTD's. Modifications might be needed to ensure that the naming conventions match the case. The input test data (\*.inp and \*.xml) must be posted as binary.

- [\*\*Running the examples\*\*](#)

The example conversion maps use the FIX checksum utility maps for generating a FIX checksum, and also for validating value set to FIX checksum tag 10.

- [\*\*Example for Advertisement message\*\*](#)

This example demonstrates the FIX Advertisement to FIXML translation and FIXML to FIX translation using maps only.

- [\*\*Example for Allocation Instruction message\*\*](#)

This example demonstrates the FIX AllocationInstruction to FIXML translation and FIXML to FIX translation using maps only.

- [\*\*Example for Allocation Instruction Ack message\*\*](#)

This example demonstrates the FIX AllocationInstructionAck to FIXML translation and FIXML to FIX translation using maps only.

- [\*\*Example for Don't Know Trade \(DK\) message\*\*](#)

This example demonstrates the FIX DontKnowTrade to FIXML translation and FIXML to FIX translation using maps only.

- [\*\*Example for Email message\*\*](#)

This example demonstrates the FIX OrderCancelReject to FIXML translation and FIXML to FIX translation using maps only.

- [\*\*Example for New Order message\*\*](#)

This example demonstrates the FIX NewOrderSingle to FIXML translation and FIXML to FIX translation using maps only.

- [\*\*Example for Order Status Request message\*\*](#)

This example demonstrates the FIX OrderStatusRequest to FIXML translation and FIXML to FIX translation using maps only.

- [\*\*Example for Quote message\*\*](#)

This example demonstrates the FIX Quote to FIXML translation and FIXML to FIX translation using maps only.

- [\*\*Example for Quote Request message\*\*](#)

This example demonstrates the FIX QuoteRequest to FIXML translation and FIXML to FIX translation using maps only.

## Running the examples

The example conversion maps use the FIX checksum utility maps for generating a FIX checksum, and also for validating value set to FIX checksum tag 10.

- [Before running the example](#)
- [FIX mapping from and to FIXML examples](#)
  - The FIX mapping from and to the FIXML example represents conversions from and to corresponding FIX protocol messages.
- [Running the examples on z/OS](#)
  - This documentation describes how to run this example on z/OS.
- [FIX checksum validation](#)
- [FIX checksum generation](#)

---

## Before running the example

### About this task

Complete the following steps to build the FIX checksum utility maps and have the utility maps ready for use by the example conversion maps.

### Procedure

1. Use IBM Sterling Transformation Extender Design Studio to open the FIX checksum utility map source file. The map source file is in the following location:  
`<install_dir>/packs/financial_payments_vn.n.n.n/fix/examples/fixFML<msg>/maps/fix_checksum.mms`  
Where `<msg>` is any of the FIX messages listed under the FIX component examples section.
  2. Build all of the maps in the FIX checksum utility map source file:
    - fxchksm1\_utility
    - fxchksm2\_validate
    - fxchksm3\_compute
- Note: On UNIX platforms, rename the compiled map extension to .mmc.

---

## FIX mapping from and to FIXML examples

The FIX mapping from and to the FIXML example represents conversions from and to corresponding FIX protocol messages.

### About this task

Run the example maps as described in the following steps:

Note: Throughout this documentation, `<install_dir>` is the installation location of the Pack for Financial Payments, and `n.n.n.n` is the current version of the Pack for Financial Payments.

### Procedure

1. Build the FIX checksum utility maps. See [Before running the example](#).
2. Use IBM Sterling Transformation Extender Design Studio to open the selected map source files in the  
`<install_dir>/packs/financial_payments_vn.n.n.n/fix/examples/fixFML<msg>/maps` directory.  
Where `<msg>` is any of the FIX messages listed under the FIX component examples section.
3. Build all the selected maps in the source files, and then run the transformation maps.
  - [Example scenarios](#)
  - [Example assumptions](#)
    - The following assumptions are made regarding FIX mapping from and to FIXML examples.
  - [Expected results](#)

---

## Example scenarios

The example maps illustrate the following conditions:

- How to convert to and from a FIX message and a FIXML message.
- How to validate a FIX checksum from a FIX message before conversion.
- How to populate a FIX checksum for a FIX message that is to be created.

---

## Example assumptions

The following assumptions are made regarding FIX mapping from and to FIXML examples.

The following assumptions are made when the FIX to FIXML maps are run:

- The example FIX input files are validated, for example, fix\_email\_50.inp, which is in the  
`<install_dir>/packs/financial_payments_vn.n.n.n/fix/examples/fixFMLemail/data` directory.

- The input file is validated against the corresponding FIX type trees, for example, fix\_50.mtt, which is in the `<install_dir>/packs/financial_payments_vn.n.n/n/fix/examples/fixFMLEmail/trees` directory.
- The input file FIX checksum in tag 10, is validated by calling one of the FIX checksum utility maps, for example, fxchksm2\_validate.mmc.

The following assumptions are made when the FIXML to FIX maps are run:

- The example input file is validated, for example, fixml\_email\_50.xml, which is in the `<install_dir>/packs/financial_payments_vn.n.n/n/fix/examples/fixFMLEmail/data` directory.
- The input file is validated against the FIXML type trees, for example, fixml\_50.mtt, that is in the `<install_dir>/packs/financial_payments_vn.n.n/n/fix/examples/fixFMLEmail/trees` directory.  
Note: The FIX 5.0 SP2 and FIX 5.0 SPE EP messages work directly with schemas without the need for a corresponding type tree.
- The FIXML input file message is a well-formed XML message and conforms against the FIXML schema called, for example, fixml-main-5-0.xsd, in the `<install_dir>/packs/financial_payments_vn.n.n/n/fix/examples/fixFMLE<msg>/schemas` directory.  
Where `<msg>` is any of the FIX messages listed under the FIX component examples section.
- Output file FIX checksum in tag 10, is populated by calling one of the FIX checksum utility maps, for example, fxchksm3\_compute.mmc.

## Expected results

The following results are expected when a FIX to FIXML map is run:

- The FIX input file contents are transformed to an XML file, for example, fixml\_email\_50\_out.xml, which is located in the `<install_dir>/packs/financial_payments_vn.n.n/n/fix/examples/fixFMLEmail/data` directory.
- The output XML is represented by the FIXML type tree, for example, fixml\_50.mtt, in the `<install_dir>/packs/financial_payments_vn.n.n/n/fix/examples/fixFMLEmail/trees` directory.  
Note: The FIX 5.0 SP2 and FIX 5.0 SPE EP messages work directly with schemas without the need for a corresponding type tree.
- The resulting output FIXML message is a well-formed XML message and conforms against an FIXML schema, for example, fixml-main-5-0.xsd, in the `<install_dir>/packs/financial_payments_vn.n.n/n/fix/examples/fixFMLEmail/schemas` directory.
- The output file corresponds to one valid FIX message.

## Running the examples on z/OS

This documentation describes how to run this example on z/OS.

### About this task

Be aware of the following points when these files are used on z/OS operating systems:

- When ported to z/OS, every map, schema, and file that is ported to z/OS must have a unique eight character DDNAME in the JCL.
- After you build the maps for the z/OS operating system, you must rename the \*.mvs compiled map to a unique eight character name.
- The compiled map file must be uploaded as a PDS member that contains maps. The schemas can either be uploaded as a traditional MVS data set to be referenced in a DSN option, or in a z/OS UNIX file, such as a Hierarchical File System (zFS or HFS) environment to be referenced in a PATH option. Both maps and schemas must be uploaded as binary.

Note: Throughout this documentation, `<install_dir>` is the installation location of the Pack for Financial Payments, and `n.n.n.n` is the current version of the Pack for Financial Payments.

### Procedure

1. Create a copy of the `<install_dir>/packs/financial_payments_vn.n.n/n/fix` directory to hold the z/OS modified files.
2. Review the FIX to FIXML conversion maps. The conversion maps are in the `<install_dir>/packs/financial_payments_vn.n.n/n/fix/examples/fixFMLE<msg>/maps` directory.  
Where `<msg>` is any of the FIX messages listed under the FIX component examples section.  
Resolve the input card for FIX to FIXML.

For example:

```
fxfm0001_email_fix_to_fixml from map source fixfml_50_email.mms.
```

The map uses one input card, called fix\_50. The fix\_50 card contains file email\_50.inp. This file is in the `<install_dir>/packs/financial_payments_vn.n.n/n/fix/examples/fixFMLEmail/data` directory.

The file resolves to **DD:fix#50** as the default **DD** name. This default **DD** name can be overridden through use of the execution command.

For example:

```
MAPDDS /IF1 FIX50IN /OF1 FIXML50T /TIO /AE
```

The values **FIX50IN** and **FIXML50T** are z/OS **DD** overrides for the input and output cards that are defined for the map.

3. Review the FIXML to FIX conversion maps. The conversion maps are in `<install_dir>/packs/financial_payments_vn.n.n/n/fix/examples/fixFMLE<msg>/maps` directory.  
Where `<msg>` is any of the FIX messages listed under the FIX component examples section.  
Resolve the input cards for FIXML to FIX map.

For example:

fmx0001\_email\_fixml\_to\_fix from map source fmlfix\_50\_email.mms.

The map uses one input card called fixml\_50. The fixml\_50 card contains the file fixml\_email\_50.xml. This file is in <install\_dir>/packs/financial\_payments\_vn.n.n/n/fix/examples/fixFMLEmail/data directory.

The file resolves to **DD:fixml#50** as the default **DD** name. This default **DD** name can be overridden through the execution command.

For example:

**MAPDDS /IF1 FXML50IN /OF6 FIX50OUT /TIO /AE**

The values **FXML50IN** and **FIX50OUT** are z/OS **DD** overrides for the input and output cards that are defined for the map.

Note: Running any of the FIXML to FIX example maps requires the FIX checksum utility RUN maps to be referenced within JCL.  
For example:

• **//FIXCHKSM1 DD DSN=&CHKSM1,DISP=SHR**

where

**&CHKSM1** refers to compiled map fxchksm1\_utility

• **//FIXCHKSM3 DD DSN=&CHKSM3,DISP=SHR**

where

**&CHKSM3** refers to compiled map fxchksm3\_compute

4. The example conversion maps references metadata values that specify the FIXML schemas. There are two options about how to reference the schemas within a JCL.

- [Option 1: Schemas on an MVS data set](#)
- [Option 2: Schemas on a UNIX hierarchical file system](#)

- [Option 1: Schemas on an MVS data set](#)
- [Option 2: Schemas on a UNIX hierarchical file system](#)

---

## Option 1: Schemas on an MVS data set

### About this task

The following steps describe how to use the schemas on an MVS data set.

### Procedure

1. Modify the cards with a Doc XSD element and specify a **DD** name for the primary schema.  
For example:

**Metadata=/DD:FIXML50**

An alternative is to remove the schema from the Map cards and to modify the target type tree attribute for the Doc group.

For example:

Modify the target type tree attributes for the Doc group as follows:

**Doc > Intent > Validate As > Metadata=/DD:FIXML50**

2. Build all of the maps for z/OS and rename the maps to short names for upload.

3. Copy the schemas to short names for upload.

For example:

**fixml-main-5-0.xsd = FIXML50**

4. Modify the schemas that you are going to upload and replace the import schema locations with the short names for the schemas.  
For example:

**<xsd:import namespace="http://www.w3.org/XML/1998/namespace" schemaLocation="/DD:xml#ns>**

5. Update JCL and add the DD statements for the schemas.

For example:

**//FIXML50 DD DSN\_USER.DSTX841.MAPLIB(FIXML50),DISP=SHR**

---

## Option 2: Schemas on a UNIX hierarchical file system

### About this task

The following steps describe how to use the schemas on a UNIX hierarchical file system.

## Procedure

---

1. Use the **M'filename'** execution command line option to override the metadata (XML schema or DTD) file location on the map card settings at run time.  
For example:

```
MAPPDS /IF1 INPUT /OF1 OUTPUT /O1M '/DD:FIXMLXSD' /AE /TIO
```

2. Build all maps for z/OS and rename the map names to short names for upload.
3. Modify the schemas that you are going to upload and replace the import schema locations to reference the full directory path of the schemas.  
For example:

```
<xs:include schemaLocation="/xsd/50/fixml-pretrade-5-0.xsd"/>
```

4. Update JCL and add the DD statements for the main schema.  
`//FIXML50 DD PATH=/xsd/50/fixml-main-5-0.xsd`

- [Reminders](#)
- 

## Reminders

Keep the following points in mind when you use Option 2:

- Upload maps and schemas as binary.
- Upload input data files as binary.
- The XML parser log file **DSTXXLOG** must be allocated to a data set.

For example:

```
//DSTXXLOG DD DSN=USER.DSTXXLOG.XML,DISP=(MOD,CATLG,DELETE),
// DCB=(RECFM=VB,LRECL=32500),
// UNIT=SYSDA,SPACE=(CYL,(20,1),RLSE)
```

---

## FIX checksum validation

### About this task

The IBM Sterling Transformation Extender Pack for Financial Payments ships with FIX checksum utility maps. The fxchksm2\_validate utility map is used to verify the computed FIX checksum value against the actual value that is set to the FIX message field tag 10.

Note: Throughout this documentation, `<install_dir>` is the installation location of the Pack for Financial Payments, and `n.n.n.n` is the current version of the Pack for Financial Payments.

The following steps describe how to use the FIX checksum validation example.

## Procedure

---

1. Compile the following maps under map source fix\_checksum.mms.
  - fxchksm1\_utility
  - fxchksm2\_validate

Note: For UNIX operating systems, assign a .mmc extension to the compiled maps.

2. Run the utility map fxchksm2\_validate.

- [Example scenarios](#)
  - [Example assumptions](#)
  - [Expected results](#)
- 

## Example scenarios

The example map illustrates validation of the value that is set in a FIX tag 10 checksum.

## Example assumptions

The following assumptions are made regarding the FIX checksum validation example:

Example assumptions when the fxchksm2\_validate map is run:

- The example map validates the checksum of a FIX input file, fix\_40.inp, that is in the `<install_dir>/packs/financial_payments_vn.n.n.n/fix/utilities/data` directory.  
Note: On a z/OS environment, use fix\_40\_MVS.inp located in the same directory.
- The example map accepts any FIX message as input, and uses a general purpose type tree called, fix\_checksum.mtt, that is in the `<install_dir>/packs/financial_payments_vn.n.n.n/fix/utilities/trees` directory.

- The example map returns a value of PASS or FAIL. A value of PASS means that the tag 10 value is correct, and it matches the computed FIX checksum value. If not, the map returns a FAIL value.

## Expected results

The expected results, when the fxchksm2\_validate map is run, is PASS.

## FIX checksum generation

### About this task

The IBM Sterling Transformation Extender Pack for Financial Payments ships with FIX checksum utility maps. The fxchksm3\_compute utility map is used to generate the FIX tag 10 value by applying a FIX checksum computation value against the actual FIX message, ignoring the FIX tag 10 on the FIX message. The utility map also computes the FIX message body length. It ignores the FIX tag 9 value of the actual FIX message.

Note: Throughout this documentation, *<install\_dir>* is the installation location of the Pack for Financial Payments, and *n.n.n.n* is the current version of the Pack for Financial Payments.

### Procedure

- Compile the following maps under map source fix\_checksum.mms.
  - fxchksm1\_utility
  - fxchksm3\_compute

Note: For UNIX operating systems, assign a .mmc extension to the compiled maps.

- Run the utility map fxchksm3\_compute.

- [Example scenarios](#)
- [Example assumptions](#)
- [Expected results](#)

## Example scenarios

The example map illustrates the following:

- The creation of a FIX checksum based on a FIX message.
- The creation of a FIX message length based on a FIX message.

## Example assumptions

The following assumptions are made regarding the FIX checksum generation example:

Example assumptions when the fxchksm3\_compute map is run:

- The example map returns the checksum of a FIX input file, fix\_40.inp, that is in the *<install\_dir>/packs/financial\_payments\_vn.n.n.n/fix/utilities/data* directory.  
Note: On the z/OS operating system, use fix\_40\_MVS.inp located in the same directory.
- The example map accepts any FIX message as input, and uses a general-purpose type tree called, fix\_checksum.mtt, that is in the *<install\_dir>/packs/financial\_payments\_vn.n.n.n/fix/utilities/trees* directory.
- The example map also returns the computed message body length of a FIX message.

## Expected results

The expected results when the fxchksm3\_compute map is run:

- The expected checksum result is 34 on the first output card.
- The expected message body length is 335.

Note: For the MVS environment, the expected checksum is 207. The expected message body length is 335 on the second output card. The optional message length is configured to use the **SINK** adapter, but can be overridden, that is, changed to a **FILE** adapter if a FIX message body length is needed.

## Example for Advertisement message

This example demonstrates the FIX Advertisement to FIXML translation and FIXML to FIX translation using maps only.

Advertisement messages are used to announce completed transactions.

- [What the example contains](#)

This example contains the following directories and files:

- [How to run the example in Design Studio](#)

- [How to run the example in Design Server](#)

---

## What the example contains

This example contains the following directories and files:

### Maps

The maps directory contains the following map sources:

- fixfml\_<FIX\_version>\_adv.mms - Map to transform FIX format into FIXML format.
- fmlfix\_<FIX\_version>\_adv.mms - Map to transform FIXML format into FIX format.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

### Schemas

The schemas directory contains the following main files:

- fixml-main-5-0.xsd
- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd

### Trees

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0
- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

### Data

The data directory contains the following file.

Sample FIX and FIXML valid file:

- fix\_adv\_50.inp
- fix\_adv\_50\_sp1.inp
- fix\_adv\_50\_sp2.inp
- fixml\_adv\_50.xml
- fixml\_adv\_50\_sp1.xml
- fixml\_adv\_50\_sp2.xml
- fix\_adv\_50\_MVS.inp
- fix\_adv\_50\_sp1\_MVS.inp
- fix\_adv\_50\_sp2\_MVS.inp

---

## How to run the example in Design Studio

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixfml\_<FIX\_version>\_adv.mms with desired input file.
3. Run main example map, fixfml\_<FIX\_version>\_adv.mms
4. See output file, on data folder called fixml\_adv\_<FIX\_version>.out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_adv.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_adv.mms
4. See output file, on data folder called fix\_adv\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

# How to run the example in Design Server

## About this task

Use the following steps to run the example from the Design Server:

## Procedure

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixFMLadv.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixfml\_<FIX\_version>\_adv
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_adv
8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## Example for Allocation Instruction message

This example demonstrates the FIX AllocationInstruction to FIXML translation and FIXML to FIX translation using maps only.

The Allocation Instruction message provides the ability to specify how an order or set of orders should be subdivided amongst one or more accounts.

## What the example contains

This example contains the following directories and files:

### Maps

The maps directory contains the following map sources:

- fixfml\_<FIX\_version>\_allocinstrtn.mms - Map to transform FIX format into FIXML format.
- fmlfix\_<FIX\_version>\_allocinstrtn.mms - Map to transform FIXML format into FIX format.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'.

### Schemas

The schemas directory contains the following main files:

- fixml-main-5-0.xsd
- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd

### Trees

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0
- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

### Data

The data directory contains the following file:

Sample FIX and FIXML valid files:

- fix\_allocinstrctn\_50.inp
- fix\_allocinstrctn\_50\_sp1.inp
- fix\_allocinstrctn\_50\_sp2.inp
- fixml\_allocinstrctn\_50.xml
- fixml\_allocinstrctn\_50\_sp1.xml
- fixml\_allocinstrctn\_50\_sp2.xml
- fix\_allocinstrctn\_50\_MVS.inp
- fix\_allocinstrctn\_50\_sp1\_MVS.inp
- fix\_allocinstrctn\_50\_sp2\_MVS.inp

## How to run the example in Design Studio

Running FIX to FIXML translation map:

1. Build all maps in the .mms files.
  2. Replace input card 1 in example map fixfml\_<FIX\_version>\_allocinstrctn.mms with desired input file.
  3. Run main example map, fixfml\_<FIX\_version>\_allocinstrctn.mms
  4. See output file, on data folder called fixml\_allocinstrctn\_<FIX\_version>\_out.xml
- Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'.

Running FIXML to FIX translation map:

1. Build all maps in the .mms files.
  2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_allocinstrctn.mms with desired input file.
  3. Run main example map, fmlfix\_<FIX\_version>\_allocinstrctn.mms
  4. See output file, on data folder called fix\_allocinstrctn\_<FIX\_version>.out
- Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## How to run the example in Design Server

### About this task

Use the following steps to run the example from the Design Server:

### Procedure

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
  2. Enter user and password credentials.
  3. If project does not exist, import fixFMLallocinstrctn.zip
  4. If absent, create a package containing all Maps, Files and Flows.
  5. Build package in desired server (to build all maps).
  6. Open project.
  7. In Maps tab, open map based on translation and version:
    - For FIX to FIXML use map - fixfml\_<FIX\_version>\_allocinstrctn
    - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_allocinstrctn
  8. Modify settings for input card 1 on design canvas to point to the desired test file.
  9. Save, build and run the map.
  10. Right click on the output card on canvas and select View data.
- Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## Example for Allocation Instruction Ack message

This example demonstrates the FIX AllocationInstructionAck to FIXML translation and FIXML to FIX translation using maps only.

The Allocation Instruction Ack message is used to acknowledge the receipt of and provide status for an Allocation Instruction message.

- [What the example contains](#)  
This example contains the following directories and files:

### What the example contains

This example contains the following directories and files:

### Maps

The maps directory contains the following map sources:

- fixfml\_<FIX\_version>\_allocinstrcnack.mms - Map to transform FIX format into FIXML format.
- fmlfix\_<FIX\_version>\_allocinstrcnack.mms - Map to transform FIXML format into FIX format.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## Schemas

---

The schemas directory contains the following main files:

- fixml-main-5-0.xsd
- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd

## Trees

---

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0
- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

## Data

---

The data directory contains the following file.

Sample FIX and FIXML valid file:

- fix\_allocinstrcnack\_50.inp
- fix\_allocinstrcnack\_50\_sp1.inp
- fix\_allocinstrcnack\_50\_sp2.inp
- fixml\_allocinstrcnack\_50.xml
- fixml\_allocinstrcnack\_50\_sp1.xml
- fixml\_allocinstrcnack\_50\_sp2.xml
- fix\_allocinstrcnack\_50\_MVS.inp
- fix\_allocinstrcnack\_50\_sp1\_MVS.inp
- fix\_allocinstrcnack\_50\_sp2\_MVS.inp

## How to run the example in Design Studio

---

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixfml\_<FIX\_version>\_allocinstrcnack.mms with desired input file.
3. Run main example map, fixfml\_<FIX\_version>\_allocinstrcnack.mms
4. See output file, on data folder called fixml\_allocinstrcnack\_<FIX\_version>\_out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_allocinstrcnack.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_allocinstrcnack.mms
4. See output file, on data folder called fix\_allocinstrcnack\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## How to run the example in Design Server

---

### About this task

---

Use the following steps to run the example from the Design Server:

### Procedure

---

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixFMLallocinstrcnack.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.

7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixfml\_<FIX\_version>\_allocinstrcnack
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_allocinstrcnack
8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.  
Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

---

## Example for Don't Know Trade (DK) message

This example demonstrates the FIX DontKnowTrade to FIXML translation and FIXML to FIX translation using maps only.

The Don't Know Trade (DK) message notifies a trading partner that an electronically received execution has been rejected.

- [What the example contains](#)  
This example contains the following directories and files:
- [How to run the example in Design Studio](#)
- [How to run the example in Design Server](#)

---

## What the example contains

This example contains the following directories and files:

### Maps

The maps directory contains the following map sources:

- fixfml\_<FIX\_version>\_dktrd.mms - Map to transform FIX format into FIXML format.
- fmlfix\_<FIX\_version>\_dktrd.mms - Map to transform FIXML format into FIX format.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

### Schemas

The schemas directory contains the following main files:

- fixml-main-5-0.xsd
- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd

### Trees

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0
- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

### Data

The data directory contains the following file.

Sample FIX and FIXML valid file:

- fix\_dktrd\_50.inp
- fix\_dktrd\_50\_sp1.inp
- fix\_dktrd\_50\_sp2.inp
- fixml\_dktrd\_50.xml
- fixml\_dktrd\_50\_sp1.xml
- fixml\_dktrd\_50\_sp2.xml
- fix\_dktrd\_50\_MVS.inp
- fix\_dktrd\_50\_sp1\_MVS.inp
- fix\_dktrd\_50\_sp2\_MVS.inp

---

## How to run the example in Design Studio

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixfml\_<FIX\_version>\_dktrd.mms with desired input file.
3. Run main example map, fixfml\_<FIX\_version>\_dktrd.mms
4. See output file, on data folder called fixxml\_dktrd\_<FIX\_version>\_out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_dktrd.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_dktrd.mms
4. See output file, on data folder called fix\_dktrd\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## How to run the example in Design Server

### About this task

Use the following steps to run the example from the Design Server:

### Procedure

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixFMLdktrd.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixfml\_<FIX\_version>\_dktrd
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_dktrd
8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## Example for Email message

This example demonstrates the FIX Email to FIXML translation and FIXML to FIX translation using maps only.

The email message is similar to the format and purpose of the News message, however, it is intended for private use between two parties.

This example contains the following directories and files:
- [How to run the example in Design Studio](#)
- [How to run the example in Design Server](#)

## What the example contains

This example contains the following directories and files:

### Maps

The maps directory contains the following map sources:

- fixfml\_<FIX\_version>\_email.mms - Map to transform FIX format into FIXML format.
- fmlfix\_<FIX\_version>\_email.mms - Map to transform FIXML format into FIX format.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2' or '50\_sp2\_ep'

### Schemas

The schemas directory contains the following main files:

- fixml-main-5-0.xsd
- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd
- fixml-main-Latest.xsd

## Trees

---

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0
- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fix\_50\_sp2\_ep.mtt - metadata that represents the FIX version 5.0 SP2 EP / Latest EP
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fixml-main-Latest.mtt - metadata that represents the FIXML compatible with FIX version 5.0 SP2 EP / Latest EP
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

## Data

---

The data directory contains the following file.

Sample FIX and FIXML valid file:

- fix\_email\_50.inp
- fix\_email\_50\_sp1.inp
- fix\_email\_50\_sp2.inp
- fix\_email\_50\_sp2\_ep.inp
- fixml\_email\_50.xml
- fixml\_email\_50\_sp1.xml
- fixml\_email\_50\_sp2.xml
- fixml\_email\_50\_sp2\_ep.xml
- fix\_email\_50\_MVS.inp
- fix\_email\_50\_sp1\_MVS.inp
- fix\_email\_50\_sp2\_MVS.inp
- fix\_email\_50\_sp2\_ep\_MVS.inp

## How to run the example in Design Studio

---

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixfml\_<FIX\_version>\_email.mms with desired input file.
3. Run main example map, fixfml\_<FIX\_version>\_email.mms
4. See output file, on data folder called fixml\_email\_<FIX\_version>\_out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2' or '50\_sp2\_ep'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_email.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_email.mms
4. See output file, on data folder called fix\_email\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2' or '50\_sp2\_ep'

## How to run the example in Design Server

---

### About this task

---

Use the following steps to run the example from the Design Server:

### Procedure

---

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixFMLEmail.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixfml\_<FIX\_version>\_email
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_email
8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.  
Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2' or '50\_sp2\_ep'

## Example for Execution Report message

This example demonstrates the FIX ExecutionReport to FIXML translation and FIXML to FIX translation using maps only.

The execution report message is used to:

- Confirm the receipt of an order
  - Confirm changes to an existing order (accept, cancel, and replace requests)
  - Relay order status information
  - Relay fill information on working orders
  - Relay fill information on tradeable or restricted tradeable quotes
  - Reject orders
  - Report post-trade fees calculations associated with a trade
- [What the example contains](#)  
This example contains the following directories and files:
- [How to run the example in Design Studio](#)
  - [How to run the example in Design Server](#)

## What the example contains

This example contains the following directories and files:

### Maps

The maps directory contains the following map sources:

- fixml\_<FIX\_version>\_execrpt.mms - Map to transform FIX format into FIXML format.
- fmlfix\_<FIX\_version>\_execrpt.mms - Map to transform FIXML format into FIX format.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

### Schemas

The schemas directory contains the following main files:

- fixml-main-5-0.xsd
- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd

### Trees

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0
- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

### Data

The data directory contains the following file.

Sample FIX and FIXML valid file:

- fix\_execrpt\_50.inp
- fix\_execrpt\_50\_sp1.inp
- fix\_execrpt\_50\_sp2.inp
- fixml\_execrpt\_50.xml
- fixml\_execrpt\_50\_sp1.xml
- fixml\_execrpt\_50\_sp2.xml
- fix\_execrpt\_50\_MVS.inp
- fix\_execrpt\_50\_sp1\_MVS.inp
- fix\_execrpt\_50\_sp2\_MVS.inp

## How to run the example in Design Studio

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.

2. Replace input card 1 in example map fixfml\_<FIX\_version>\_execrpt.mms with desired input file.
3. Run main example map, fixfml\_<FIX\_version>\_execrpt.mms
4. See output file, on data folder called fixxml\_execrpt\_<FIX\_version>.out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'  
Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_execrpt.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_execrpt.mms
4. See output file, on data folder called fix\_execrpt\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

---

## How to run the example in Design Server

### About this task

Use the following steps to run the example from the Design Server:

### Procedure

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixFMLExecrpt.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixfml\_<FIX\_version>\_execrpt
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_execrpt
8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

---

## Example for Indication of interest message

This example demonstrates the FIX IOI to FIXML translation and FIXML to FIX translation using maps only.

Indication of interest messages are used to market merchandise which the broker is buying or selling in either a proprietary or agency capacity.

- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

## Data

---

The data directory contains the following file.

Sample FIX and FIXML valid file:

- fix\_ioi\_50.inp
- fix\_ioi\_50\_sp1.inp
- fix\_ioi\_50\_sp2.inp
- fixml\_ioi\_50.xml
- fixml\_ioi\_50\_sp1.xml
- fixml\_ioi\_50\_sp2.xml
- fix\_ioi\_50\_MVS.inp
- fix\_ioi\_50\_sp1\_MVS.inp
- fix\_ioi\_50\_sp2\_MVS.inp

## How to run the example in Design Studio

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixfml\_<FIX\_version>\_ioi.mms with desired input file.
3. Run main example map, fixfml\_<FIX\_version>\_ioi.mms
4. See output file, on data folder called fixml\_ioi\_<FIX\_version>\_out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_ioi.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_ioi.mms
4. See output file, on data folder called fix\_ioi\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## How to run the example in Design Server

### About this task

---

Use the following steps to run the example from the Design Server:

### Procedure

---

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixFMLioi.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixfml\_<FIX\_version>\_ioi
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_ioi
8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.  
Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## Example for List Cancel Request message

---

This example demonstrates the FIX ListCancelRequest to FIXML translation and FIXML to FIX translation using maps only.

The List Cancel Request message type is used by institutions wishing to cancel previously submitted lists either before or during execution.

- fix\_listextc\_50\_sp2\_MVS.inp

---

## How to run the example in Design Studio

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixml\_<FIX\_version>\_listextc.mms with desired input file.
3. Run main example map, fixml\_<FIX\_version>\_listextc.mms
4. See output file, on data folder called fixml\_listextc\_<FIX\_version>.out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_listextc.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_listextc.mms
4. See output file, on data folder called fix\_listextc\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

---

## How to run the example in Design Server

### About this task

Use the following steps to run the example from the Design Server:

### Procedure

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixFMLlistextc.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixml\_<FIX\_version>\_listextc
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_listextc
8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

---

## Example for List Status message

This example demonstrates the FIX ListStatus to FIXML translation and FIXML to FIX translation using maps only.

The list status message is issued as the response to a List Status Request message sent in an unsolicited fashion by the sell-side.

---

## What the example contains

This example contains the following directories and files:

### Maps

The maps directory contains the following map sources:

- fixml\_<FIX\_version>\_liststat.mms - Map to transform FIX format into FIXML format.
- fmlfix\_<FIX\_version>\_liststat.mms - Map to transform FIXML format into FIX format.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## Schemas

---

The schemas directory contains the following main files:

- fixml-main-5-0.xsd
- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd

## Trees

---

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0
- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

## Data

---

The data directory contains the following file.

Sample FIX and FIXML valid file:

- fix\_liststat\_50.inp
- fix\_liststat\_50\_sp1.inp
- fix\_liststat\_50\_sp2.inp
- fixml\_liststat\_50.xml
- fixml\_liststat\_50\_sp1.xml
- fixml\_liststat\_50\_sp2.xml
- fix\_liststat\_50\_MVS.inp
- fix\_liststat\_50\_sp1\_MVS.inp
- fix\_liststat\_50\_sp2\_MVS.inp

## How to run the example in Design Studio

---

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixfml\_<FIX\_version>\_liststat.mms with desired input file.
3. Run main example map, fixfml\_<FIX\_version>\_liststat.mms
4. See output file, on data folder called fixml\_liststat\_<FIX\_version>.out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_liststat.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_liststat.mms
4. See output file, on data folder called fix\_liststat\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## How to run the example in Design Server

---

### About this task

---

Use the following steps to run the example from the Design Server:

### Procedure

---

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixFMLliststat.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixfml\_<FIX\_version>\_liststat
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_liststat

8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.  
Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

---

## Example for List Status Request message

This example demonstrates the FIX ListStatusRequest to FIXML translation and FIXML to FIX translation using maps only.

The list status request message type is used by institutions to instruct the broker to generate status messages for a list.

- [What the example contains](#)  
This example contains the following directories and files:
- [How to run the example in Design Studio](#)
- [How to run the example in Design Server](#)

---

## What the example contains

This example contains the following directories and files:

### Maps

The maps directory contains the following map sources:

- fixfml\_<FIX\_version>\_liststatreq.mms - Map to transform FIX format into FIXML format.
- fmlfix\_<FIX\_version>\_liststatreq.mms - Map to transform FIXML format into FIX format.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

### Schemas

The schemas directory contains the following main files:

- fixml-main-5-0.xsd
- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd

### Trees

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0
- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

### Data

The data directory contains the following file.

Sample FIX and FIXML valid file:

- fix\_liststatreq\_50.inp
- fix\_liststatreq\_50\_sp1.inp
- fix\_liststatreq\_50\_sp2.inp
- fixml\_liststatreq\_50.xml
- fixml\_liststatreq\_50\_sp1.xml
- fixml\_liststatreq\_50\_sp2.xml
- fix\_liststatreq\_50\_MVS.inp
- fix\_liststatreq\_50\_sp1\_MVS.inp
- fix\_liststatreq\_50\_sp2\_MVS.inp

---

## How to run the example in Design Studio

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixfml\_<FIX\_version>\_liststatreq.mms with desired input file.
3. Run main example map, fixfml\_<FIX\_version>\_liststatreq.mms

4. See output file, on data folder called fixml\_liststareq\_<FIX\_version>.out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_liststareq.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_liststareq.mms
4. See output file, on data folder called fix\_liststareq\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## How to run the example in Design Server

### About this task

Use the following steps to run the example from the Design Server:

### Procedure

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixFMLliststareq.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixfml\_<FIX\_version>\_liststareq
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_liststareq
8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## Example for New Order List message

This example demonstrates the FIX NewOrderList to FIXML translation and FIXML to FIX translation using maps only.

The NewOrderList Message can be used in one of two ways depending on which market conventions are being followed.

This example contains the following directories and files:
  - [How to run the example in Design Studio](#)
  - [How to run the example in Design Server](#)

## What the example contains

This example contains the following directories and files:

### Maps

The maps directory contains the following map sources:

- fixfml\_<FIX\_version>\_newordlist.mms - Map to transform FIX format into FIXML format.
- fmlfix\_<FIX\_version>\_newordlist.mms - Map to transform FIXML format into FIX format.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

### Schemas

The schemas directory contains the following main files:

- fixml-main-5-0.xsd
- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd

### Trees

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0

- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

## Data

---

The data directory contains the following file.

Sample FIX and FIXML valid file:

- fix\_newordlist\_50.inp
- fix\_newordlist\_50\_sp1.inp
- fix\_newordlist\_50\_sp2.inp
- fixml\_newordlist\_50.xml
- fixml\_newordlist\_50\_sp1.xml
- fixml\_newordlist\_50\_sp2.xml
- fix\_newordlist\_50\_MVS.inp
- fix\_newordlist\_50\_sp1\_MVS.inp
- fix\_newordlist\_50\_sp2\_MVS.inp

## How to run the example in Design Studio

---

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixml\_<FIX\_version>\_newordlist.mms with desired input file.
3. Run main example map, fixml\_<FIX\_version>\_newordlist.mms
4. See output file, on data folder called fixml\_newordlist\_<FIX\_version>.out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_newordlist.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_newordlist.mms
4. See output file, on data folder called fix\_newordlist\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## How to run the example in Design Server

---

### About this task

---

Use the following steps to run the example from the Design Server:

### Procedure

---

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixMLnewordlist.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixml\_<FIX\_version>\_newordlist
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_newordlist
8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## Example for News message

---

This example demonstrates the FIX News to FIXML translation and FIXML to FIX translation using maps only.

The news message is a general free format message between the broker and institution.

- [What the example contains](#)

This example contains the following directories and files:

- [How to run the example in Design Server](#)

## What the example contains

This example contains the following directories and files:

### Maps

The maps directory contains the following map sources:

- fixfml\_<FIX\_version>\_news.mms - Map to transform FIX format into FIXML format.
- fmlfix\_<FIX\_version>\_news.mms - Map to transform FIXML format into FIX format.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

### Schemas

The schemas directory contains the following main files:

- fixml-main-5-0.xsd
- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd

### Trees

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0
- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

### Data

The data directory contains the following file.

Sample FIX and FIXML valid file:

- fix\_news\_50.inp
- fix\_news\_50\_sp1.inp
- fix\_news\_50\_sp2.inp
- fixml\_news\_50.xml
- fixml\_news\_50\_sp1.xml
- fixml\_news\_50\_sp2.xml
- fix\_news\_50\_MVS.inp
- fix\_news\_50\_sp1\_MVS.inp
- fix\_news\_50\_sp2\_MVS.inp

## How to run the example in Design Studio

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixfml\_<FIX\_version>\_news.mms with desired input file.
3. Run main example map, fixfml\_<FIX\_version>\_news.mms
4. See output file, on data folder called fixml\_news\_<FIX\_version>\_out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_news.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_news.mms
4. See output file, on data folder called fix\_news\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## How to run the example in Design Server

## About this task

---

Use the following steps to run the example from the Design Server:

## Procedure

---

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixFMLnews.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixfml\_<FIX\_version>\_news
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_news
8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.  
Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## Example for Order Cancel Reject message

---

This example demonstrates the FIX OrderCancelReject to FIXML translation and FIXML to FIX translation using maps only.

The order cancel reject message is issued by the broker upon receipt of a cancel request or cancel/replace request message which cannot be honored.

- [What the example contains](#)  
This example contains the following directories and files:
- [How to run the example in Design Studio](#)
- [How to run the example in Design Server](#)

## What the example contains

---

This example contains the following directories and files:

### Maps

---

The maps directory contains the following map sources:

- fixfml\_<FIX\_version>\_ordcxlrej.mms - Map to transform FIX format into FIXML format.
- fmlfix\_<FIX\_version>\_ordcxlrej.mms - Map to transform FIXML format into FIX format.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

### Schemas

---

The schemas directory contains the following main files:

- fixml-main-5-0.xsd
- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd

### Trees

---

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0
- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

### Data

---

The data directory contains the following file:

Sample FIX and FIXML valid file:

- fix\_ordcxlrej\_50.inp
- fix\_ordcxlrej\_50\_sp1.inp
- fix\_ordcxlrej\_50\_sp2.inp
- fixml\_ordcxlrej\_50.xml

- fixml\_ordcxlrej\_50\_sp1.xml
- fixml\_ordcxlrej\_50\_sp2.xml
- fix\_ordcxlrej\_50\_MVS.inp
- fix\_ordcxlrej\_50\_sp1\_MVS.inp
- fix\_ordcxlrej\_50\_sp2\_MVS.inp

---

## How to run the example in Design Studio

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixml\_<FIX\_version>\_ordcxlrej.mms with desired input file.
3. Run main example map, fixml\_<FIX\_version>\_ordcxlrej.mms
4. See output file, on data folder called fixml\_<FIX\_version>\_out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_ordcxlrej.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_ordcxlrej.mms
4. See output file, on data folder called fix\_ordcxlrej\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

---

- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd

---

### Trees

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0
- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

---

### Data

The data directory contains the following file.

Sample FIX and FIXML valid file:

- fix\_orderstatreq\_50.inp
- fix\_orderstatreq\_50\_sp1.inp
- fix\_orderstatreq\_50\_sp2.inp
- fixml\_orderstatreq\_50.xml
- fixml\_orderstatreq\_50\_sp1.xml
- fixml\_orderstatreq\_50\_sp2.xml
- fix\_orderstatreq\_50\_MVS.inp
- fix\_orderstatreq\_50\_sp1\_MVS.inp
- fix\_orderstatreq\_50\_sp2\_MVS.inp

---

## How to run the example in Design Studio

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixfml\_<FIX\_version>\_orderstatreq.mms with desired input file.
3. Run main example map, fixfml\_<FIX\_version>\_orderstatreq.mms

4. See output file, on data folder called fixml\_orderstatreq\_<FIX\_version>.out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_orderstatreq.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_orderstatreq.mms
4. See output file, on data folder called fix\_orderstatreq\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## How to run the example in Design Server

### About this task

Use the following steps to run the example from the Design Server:

### Procedure

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixFMLorderstatreq.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixfml\_<FIX\_version>\_orderstatreq
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_orderstatreq
8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## Example for Quote message

This example demonstrates the FIX Quote to FIXML translation and FIXML to FIX translation using maps only.

The Quote message is used as the response to a Quote Request or a Quote Response message in both indicative, tradeable, and restricted tradeable quoting markets.

- [What the example contains](#)

This example contains the following directories and files:

- [How to run the example in Design Studio](#)
- [How to run the example in Design Server](#)

## What the example contains

This example contains the following directories and files:

### Maps

The maps directory contains the following map sources:

- fixfml\_<FIX\_version>\_quot.mms - Map to transform FIX format into FIXML format.
- fmlfix\_<FIX\_version>\_quot.mms - Map to transform FIXML format into FIX format.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

### Schemas

The schemas directory contains the following main files:

- fixml-main-5-0.xsd
- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd

### Trees

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0

- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

## Data

---

The data directory contains the following file.

Sample FIX and FIXML valid file:

- fix\_quot\_50.inp
- fix\_quot\_50\_sp1.inp
- fix\_quot\_50\_sp2.inp
- fixml\_quot\_50.xml
- fixml\_quot\_50\_sp1.xml
- fixml\_quot\_50\_sp2.xml
- fix\_quot\_50\_MVS.inp
- fix\_quot\_50\_sp1\_MVS.inp
- fix\_quot\_50\_sp2\_MVS.inp

## How to run the example in Design Studio

---

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixml\_<FIX\_version>\_quot.mms with desired input file.
3. Run main example map, fixml\_<FIX\_version>\_quot.mms
4. See output file, on data folder called fixml\_quot\_<FIX\_version>\_out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_quot.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_quot.mms
4. See output file, on data folder called fix\_quot\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## How to run the example in Design Server

---

### About this task

---

Use the following steps to run the example from the Design Server:

### Procedure

---

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixFMLquot.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixml\_<FIX\_version>\_quot
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_quot
8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## Example for Quote Request message

---

This example demonstrates the FIX QuoteRequest to FIXML translation and FIXML to FIX translation using maps only.

In some markets it is the practice to request quotes from brokers prior to placement of an order. The quote request message is used for this purpose.

- [What the example contains](#)

This example contains the following directories and files:

- [How to run the example in Design Studio](#)

- [How to run the example in Design Server](#)
- 

## What the example contains

This example contains the following directories and files:

### Maps

---

The maps directory contains the following map sources:

- fixfml\_<FIX\_version>\_quotreq.mms - Map to transform FIX format into FIXML format.
- fmlfix\_<FIX\_version>\_quotreq.mms - Map to transform FIXML format into FIX format.

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

### Schemas

---

The schemas directory contains the following main files:

- fixml-main-5-0.xsd
- fixml-main-5-0-SP1.xsd
- fixml-main-5-0-SP2.xsd

### Trees

---

The trees directory contains the following files:

- fix\_50.mtt - Metadata that represents the FIX version 5.0
- fix\_50\_sp1.mtt - Metadata that represents the FIX version 5.0 SP1
- fix\_50\_sp2.mtt - Metadata that represents the FIX version 5.0 SP2
- fixml\_50.mtt - Metadata that represents the FIXML compatible with FIX version 5.0
- fixml\_50\_sp1.mtt - Metadata that represents the FIXML compatible with FIX version 5.0 SP1
- fix\_checksum.mtt - Metadata that represents fields for checksum and body length

### Data

---

The data directory contains the following file.

Sample FIX and FIXML valid file:

- fix\_quotreq\_50.inp
- fix\_quotreq\_50\_sp1.inp
- fix\_quotreq\_50\_sp2.inp
- fixml\_quotreq\_50.xml
- fixml\_quotreq\_50\_sp1.xml
- fixml\_quotreq\_50\_sp2.xml
- fix\_quotreq\_50\_MVS.inp
- fix\_quotreq\_50\_sp1\_MVS.inp
- fix\_quotreq\_50\_sp2\_MVS.inp

## How to run the example in Design Studio

Running FIX to FIXML translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fixfml\_<FIX\_version>\_quotreq.mms with desired input file.
3. Run main example map, fixfml\_<FIX\_version>\_quotreq.mms
4. See output file, on data folder called fixml\_quotreq\_<FIX\_version>.out.xml

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

Running FIXML to FIX translation map:

1. Build all maps in the .mms files listed.
2. Replace input card 1 in example map fmlfix\_<FIX\_version>\_quotreq.mms with desired input file.
3. Run main example map, fmlfix\_<FIX\_version>\_quotreq.mms
4. See output file, on data folder called fix\_quotreq\_<FIX\_version>.out

Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

## How to run the example in Design Server

## About this task

---

Use the following steps to run the example from the Design Server:

## Procedure

---

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If project does not exist, import fixFMLquotreq.zip
4. If absent, create a package containing all Maps, Files and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In Maps tab, open map based on translation and version:
  - For FIX to FIXML use map - fixfml\_<FIX\_version>\_quotreq
  - For FIXML to FIX use map - fmlfix\_<FIX\_version>\_quotreq
8. Modify settings for input card 1 on design canvas to point to the desired test file.
9. Save, build and run the map.
10. Right click on the output card on canvas and select View data.  
Note: <FIX\_version> = '50' or '50\_sp1' or '50\_sp2'

---

## Overview of the NACHA component

NACHA is a national, not-for-profit organization that develops operating rules and business practices for electronic payments. The Pack for Financial Payments, NACHA component provides support for the exchange of ACH payments.

### Introduction to the Pack for Financial Payments NACHA component

---

The Pack for Financial Payments NACHA component is used for validation and mapping of files that conform to the National Automated Clearing House Association (NACHA) Operating Rules. The NACHA component can be integrated into larger solutions.

The NACHA component includes a ITX type tree that complies with the ACH file. It also includes record and field level specifications and example maps to help you use the type tree.

The pack delivers extensive compliance by use of the validation rules and content restrictions included in the type tree definitions.

Maps are included for conversion on the following ACH entries:

- Corporate Credit or Debit (CCD)
- Corporate Trade Exchange (CTX)
- Death Notification Entry (DNE)
- International ACH Transaction (IAT)
- Prearranged Payments and Deposits (PPD)
- Returns
- Notification of Change
- Refused Notification of Change
- Contested Dishonored Returns

Maps are included to support the NACHA endorsed banking conventions for ACH entries with payment-related information.

It further includes examples that can be executed in the IBM Sterling B2B Integrator ACH service.

Introductory and reference documentation is included to implement the Pack for Financial Payments NACHA component as part of an overall electronics payments solution.

## The NACHA standard

---

Members of the NACHA organization define the rules that cover the Automated Clearing House (ACH) network in the United States. The ACH Network is a nationwide electronic funds transfer system that is a batch-oriented store and forward system. In this system, transactions received by financial institutions are stored and processed later in the day in a batch mode, rather than receiving and processing each payment individually.

- [\*\*ACH network terminology\*\*](#)  
Participants that are involved in electronic payments are the individuals or companies that request the payment transaction, the banks that are involved, and clearing houses. Clearing houses are central facilities through which the banks can send or receive the transaction information.
- [\*\*NACHA credit transfer and direct debit processes\*\*](#)  
This documentation describes the credit transfer and direct debit processes that are used with NACHA.
- [\*\*The ACH file\*\*](#)  
An ACH transaction flows through the portions of the processes in an ACH file. The ACH file has a format as defined in the technical specifications of the NACHA Operating Rules.

---

## ACH network terminology

Participants that are involved in electronic payments are the individuals or companies that request the payment transaction, the banks that are involved, and clearing houses. Clearing houses are central facilities through which the banks can send or receive the transaction information.

The following list introduces the specific terminology that NACHA uses to define these roles.

- *Originator*. – The company or individual that initiates the transaction. The transaction can be either credit or debit.
- *Originating Depository Financial Institution (ODFI)*. – This institution receives transaction information from the Originator and forwards the transaction information to ACH Operator.
- *ACH Operator* – Federal Reserve Bank (FRB) or private organization.
- *Receiving Depository Financial Institution (RDFI)*. – Any financial institution that is qualified to receive ACH entries that agree to abide by the NACHA Operating Rules and Guidelines. The RDFI is responsible for posting entries and for providing funds availability, which are determined by the Settlement Date in the Company Batch Header Record.
- *Receiver* – The company or individual that authorizes the originator to initiate ACH to the receiver's account.
- *Third Party Service Provider* – The Third Party Service Provider provides services on behalf of the originator, ODFI or RDFI.

## NACHA credit transfer and direct debit processes

This documentation describes the credit transfer and direct debit processes that are used with NACHA.

- **Credit processes**  
Within the credit process, the initiator is always crediting the receiver's account with funds. The credit process includes both consumer and corporate payments.
- **Debit process**  
Within the debit process, the initiator always collects funds from the receiver's account and transfers funds to the originator's account.

## Credit processes

Within the credit process, the initiator is always crediting the receiver's account with funds. The credit process includes both consumer and corporate payments.

This list shows some types (but not all types) of credits:

- Annuities
- Dividends
- Payroll - direct deposit

## Debit process

Within the debit process, the initiator always collects funds from the receiver's account and transfers funds to the originator's account.

This list shows types debits:

- Club dues
- Cash concentration
- Mortgage payments
- Utility payments

## The ACH file

An ACH transaction flows through the portions of the processes in an ACH file. The ACH file has a format as defined in the technical specifications of the NACHA Operating Rules.

This file can consist of multiple ACH entries that are defined by an application type. The NACHA rules support a number of Consumer and Corporate payment application types.

## Configuration

This documentation describes the system configuration.

- **Directory structure**  
When you install the Pack for Financial Payments NACHA component, the examples, and trees directories are created.

## Directory structure

When you install the Pack for Financial Payments NACHA component, the examples, and trees directories are created.

The directories are installed at this location:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/nacha

where <install\_dir> is the installation location of the Pack for Financial Payments, and n.n.n indicates the current version of the Pack for Financial Payments.

- [examples directory](#)  
Under the examples directory are subdirectories that contain examples that show how to use the pack.
- [trees directory](#)  
The type tree that is contained in the trees directory represents the technical specifications of the ACH rules. These rules are defined in the appendixes of the *Operating Rules of the National Automated Clearing House Association*.

## examples directory

Under the examples directory are subdirectories that contain examples that show how to use the pack.

For a complete description of how to run the examples, see [NACHA component examples](#).

This table shows the directory structure of the examples.

| Directory structure                                         | Description                                                                                                 |
|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| ACH Contested Dishonored Return Entry example               |                                                                                                             |
| ..examples/ach_cntstd_dshnrd_rtrn                           | Top level folder for the example.                                                                           |
| ..examples/ach_cntstd_dshnrd_rtrn/data                      | Placeholder for the input test data.                                                                        |
| ..examples/ach_cntstd_dshnrd_rtrn/maps                      | Placeholder for the maps.                                                                                   |
| ACH Dishonored Return Entry example                         |                                                                                                             |
| ..examples/ach_dshnrd_rtrn                                  | Top level folder for the example.                                                                           |
| ..examples/ach_dshnrd_rtrn/data                             | Placeholder for the input test data.                                                                        |
| ..examples/ach_dshnrd_rtrn/maps                             | Placeholder for the maps.                                                                                   |
| ACH conversion from/to EDI example                          |                                                                                                             |
| ..examples/ach_edi                                          | Top level folder for the example.                                                                           |
| ..examples/ach_edi/data                                     | Placeholder for the input test data.                                                                        |
| ..examples/ach_edi/maps                                     | Placeholder for the maps.                                                                                   |
| ACH mapping from and to ISO 20022 examples                  |                                                                                                             |
| ..examples/ach_iso20002                                     | Contains the ACH conversion from/to ISO 20022 examples, assumptions tables, and shared maps and type trees. |
| ..examples/ach_iso20002/data                                | Placeholder for the input test data for multiple examples.                                                  |
| ..examples/ach_iso20002/trees                               | Placeholder for the type trees used by multiple examples.                                                   |
| ..examples/ach_iso20002/scenarios                           | Contains the examples and assumptions tables.                                                               |
| ACH to ISO 20022 example assumptions tables                 |                                                                                                             |
| ..examples/ach_iso20002/scenarios/assumptions               | Contains assumptions tables used with the ACH/ISO 20022 examples                                            |
| ACH to ISO 20022 Payment Initiation Credit Transfer example |                                                                                                             |

## trees directory

The type tree that is contained in the trees directory represents the technical specifications of the ACH rules. These rules are defined in the appendixes of the *Operating Rules of the National Automated Clearing House Association*.

The ach\_vccyy.mtt type trees and the ach\_vccyy\_sfmt.mtt (streaming-format) type trees are contained in this directory.

In the file names mentioned here, ccyy indicates the version of the ACH rules. The ACH technical specifications for the year 2010 are supported by the 2009 type tree. For details, see the release notes.

- **[Support for streaming format messages](#)**

Support is provided for ACH messages without any record terminators. This format is referred to as streaming-format, and is supported by the ach\_vccyy\_sfmc.mtt type trees.

## Support for streaming format messages

Support is provided for ACH messages without any record terminators. This format is referred to as streaming-format, and is supported by the ach\_vccyy\_sfmc.mtt type trees.

The difference between ach\_vccyy.mtt and ach\_vccyy\_sfmc.mtt is support for record terminators. For ACH files with record terminators, it is recommended that you use the ach\_vccyy.mtt type tree. For ACH files without any record terminators, it is recommended that you use the ach\_vccyy\_sfmc.mtt type tree.

A list of the streaming-format type trees that are contained in the trees directory is provided in the release notes.

## NACHA type trees

This documentation describes the type trees that are included with the Pack for Financial Payments NACHA component.

- **[Overview of the NACHA type trees](#)**

The primary type trees that are provided in the Pack for Financial Payments NACHA component provide a full definition of the records and fields that are needed to create or validate an ACH file.

- **[Summary of ACH applications](#)**

A single batch can contain only one ACH application type. Supported ACH applications with brief descriptions are listed here. The *ACH Rulebook* summarizes the application types and groups them by type: consumer, corporate, or other.

- **[Return entries](#)**  
Return entries are generated by an ACH operator when data acceptance rules are violated. They are also generated by an RDFI for any reason with an appropriate return reason code specified by the ACH rules.
- **[Notification of change entries \(COR\)](#)**  
A notification of change entry is created in a Batch with an SEC code of COR.
- **[Acknowledgement records](#)**  
An acknowledgement (ACK or ATX) entry is created by an RDFI to notify ODFI of receipt of CCD or CTX, if such is requested by the CCD or CTX entry.
- **[Analysis errors](#)**  
There are no expected analysis errors for the type trees. They are analyzed for the supported ITX base product platforms, but the .dbe file is not delivered.
- **[Additional validation recommendations](#)**  
Most of the exceptions to validations affect multiple ACH types. If something is specific to one particular application type, that type is noted by its SEC code.

---

## Overview of the NACHA type trees

The primary type trees that are provided in the Pack for Financial Payments NACHA component provide a full definition of the records and fields that are needed to create or validate an ACH file.

An ACH file consists of one or more application batches. Each batch has a header record and batch control record. Each batch can have one or more entry detail records and in some cases, one or more addenda records. The entire file also has a single file header record at the beginning, a file control record and one or more filler records. The tree defines the groups that are needed for each record type, and also the sequencing of batches in the file.

The type names in the type trees are consistent with the terminology used in the NACHA published rules. The root of each tree is called ACH. Each tree has the following categories:

- Element
  - File
  - Group
  - Record - a partitioned group at the same level as the categories
- **[Data elements](#)**  
The types that are defined in this category element comprise the full set of data elements that are needed for any ACH record format.
- **[File category](#)**  
The File category defines the groups that define the full ACH file.
- **[Groups and records](#)**  
In the Group category, groups include all of the subsets and record groups that comprise the ACH file.

---

## Data elements

The types that are defined in this category element comprise the full set of data elements that are needed for any ACH record format.

There are more subcategories, and elements with inherited properties, to set the data definition in a way to allow adequate validation and mapping support when used in the context of a full ACH file.

The type names of data elements are abbreviated versions of the element descriptions. For example, the name of the type that defines the data element Addenda Record Indicator is *Addenda\_Ind*. If you find these, or other names inappropriate for your use, rename the type. Every reference to that type is renamed for you automatically.

Coded values for coded fields in records are implemented in the type tree as restriction lists, and component rules. These coded values are described in detail in the *ACH Rulebook; Appendix 2, Section 2.2*.

---

## File category

The File category defines the groups that define the full ACH file.

The starting point of a full mapping of an ACH file is to select either one of the following from the layout in the type tree structure: ACH/File/ACH/ADV\_Entries or ACH/File/ACH/ALL\_Entries.

---

## Groups and records

In the Group category, groups include all of the subsets and record groups that comprise the ACH file.

These subsets and record groups include the batch types that are needed to represent the supported application types. Many of the batches contain entry detail records with one or more addenda records. Because of this, groups are defined to cover one instance of a full entry in the ACH transaction.

In the type tree, these groups are named so that the validation takes place in the correct order to be able to properly distinguish between similar applications, types, and returns. The ACH rules do not allow for mixed SEC codes, or mixed applications, in a single batch. However, the file can contain multiple batches, each of a different application type.

When a new ACH file is created by use of the type tree, the batch control record for each batch must be mapped with correct counts/total amounts for all included entries.

Finally, the partitioned group Record contains all of the definitions of the individual records that might be used in the ACH file. There are extra partitions for addenda, BatchHeader, EntryDetail, and Returns records.

## Summary of ACH applications

A single batch can contain only one ACH application type. Supported ACH applications with brief descriptions are listed here. The *ACH Rulebook* summarizes the application types and groups them by type: consumer, corporate, or other.

In the following table, application types are listed alphabetically as they appear in the type tree, as groups defined in the partitioned group Batch in the category Group.

Table 1. ACH applications

| Application | Description                                          |
|-------------|------------------------------------------------------|
| ACK         | ACH Payment Acknowledgement (with addenda)           |
| ADV         | Automated Accounting Device                          |
| ARC         | Accounts Receivable Entry                            |
| ATX         | Financial EDI Acknowledgement (with Addenda)         |
| BOC         | Back Office Conversion Entries                       |
| CCD         | Corporate Credit or Debit Entry (with Addenda)       |
| CIE         | Customer-Initiated Entry (with Addenda)              |
| COR         | Notification of Change (with Addenda)                |
| CTX         | Corporate Trade Exchange (with Addenda)              |
| DNE         | Death Notification Entry (with Addenda)              |
| ENR         | Automated Enrollment Entry (with Addenda)            |
| IAT         | International ACH entries (with Addenda)             |
| POP         | Point of Purchase Entry                              |
| POS         | Point of Sale Entry (with Addenda)                   |
| SHR         | Shared Network Transaction (with Addenda)            |
| MTE         | Machine Transfer Entry (with Addenda)                |
| PPD         | Prearranged Payment and Deposit Entry (with Addenda) |
| RCK         | Represented Check Entry                              |
| TEL         | Telephone-Initiated Entry                            |
| TRC         | Check Truncation Entry                               |
| TRX         | Check Truncation Entries Exchange (with Addenda)     |
| WEB         | Internet-Initiated Entry (with Addenda)              |
| XCK         | Destroyed Check Entry                                |

## Return entries

Return entries are generated by an ACH operator when data acceptance rules are violated. They are also generated by an ODFI for any reason with an appropriate return reason code specified by the ACH rules.

The pack includes examples of how to populate a return, dishonored return, and contested dishonored return entries.

After a Return is sent, the ODFI can then dishonor that return, and as one final step, the RDFI can then contest the dishonored return. These have different reason codes and thus are defined separately in the type trees. The names for the groups that define the format of a batch or returns, dishonored returns, and contested dishonored returns are not abbreviated, and thus appear in the type tree as

- Returns
- DishonoredReturns
- ContestedDishonoredReturns

In the partitioned group, Batch Group, there are different formats for the returns that are related to cross border entries. For this reason, the following groups are also defined in the ACH type trees.

## Notification of change entries (COR)

A notification of change entry is created in a Batch with an SEC code of COR.

This type of entry is created by the Receiving Depository Financial Institution (RDFI) to notify the Originating Depository Financial Institution (ODFI) that previously valid information in an entry is now outdated or erroneous, and must be changed. Specifications for creating the Notification of Change records are detailed in the *ACH Rulebook; Appendix 6*. The ODFI can refuse the notification of Change and generate a Refused COR entry with an appropriate reason.

Although the Batch header for a batch that contains COR entries is the same for notification of changes for both consumer and corporate application types, the entry detail records are different. Thus the group that is defined in the type tree for COR contains a partitioned group COR Entry Detail Record to support either type of application.

The Pack for Financial Payments NACHA component comes with examples that show how to populate a Notification of Change and a Refused Notification of Change entry.

These are the names for the groups that define batches or Notification of Change entries and refused Notification of Change entries:

- COR
- RefusedCOR

As with returns, different formats are required for cross border entries. The ACH type trees also contain the following groups:

## Acknowledgement records

An acknowledgement (ACK or ATX) entry is created by an RDFI to notify ODFI of receipt of CCD or CTX, if such is requested by the CCD or CTX entry.

A refused acknowledgement entry is created by the ODFI to refuse an ACK that is incorrectly routed, incorrect, or incomplete.

The Pack for Financial Payments does not generate these automatically, but the type tree provides the appropriate definition to allow you to create your own map for them. These entries are defined by specific SEC codes, ACK and ATX. They are listed in the partitioned group, Batch Group, as the standard application types that are defined by this three letter code.

The NACHA component examples for IBM Sterling B2B Integrator come with an ACH Deenvelope service scenario to generate an ATX message from an Inbound CTX.

## Analysis errors

There are no expected analysis errors for the type trees. They are analyzed for the supported ITX base product platforms, but the .dbe file is not delivered.

For better performance in building any maps that are based on type trees that are delivered with the pack, analyze and save the type tree before you use it in a map. If the type tree is used in any maps, any of the IBM Transformation Extender map execution errors might apply, depending upon your application architecture.

## Additional validation recommendations

Most of the exceptions to validations affect multiple ACH types. If something is specific to one particular application type, that type is noted by its SEC code.

The following table shows the ACH rule, or field that is involved in the exception along with a detailed description.

Table 1. Exceptions to validations.

| ACH rule or field                                                                                                                                                                                                         | Explanation of exception and potential action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| In all fields that are defined as alphanumeric, in the rules, the characters that are allowed are restricted to a subset of ASCII or EBCDIC.                                                                              | Because of performance concerns, a restriction list is not defined in the type tree to exclude the special ASCII or EBCDIC values. Fields will be left justified, space filled, and defined to the correct fixed size. Mandatory fields are checked to ensure that content is present. Required fields that only include spaces are considered valid by the tree.                                                                                                                                                                                            |
| Total Debit Entry Dollar Amount field and Total Credit Entry Dollar Amount field in Batch Control Record                                                                                                                  | If a message can be either a credit or a debit, the only way to enforce the debit/credit totals is through a map.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Check Digit field                                                                                                                                                                                                         | The type tree does not contain a rule to ensure that the value for this field was computed correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Effective Entry Date field, Settlement Date field in Batch Header                                                                                                                                                         | Checks against processing turnaround times and other date related rules need to be done as part of the overall implementation.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Identification number field in ENR                                                                                                                                                                                        | The type tree validation has no means to determine whether this is a Federal Government enrollment. Would need to be implemented in a validation map through lookups, or other means of confirmation.                                                                                                                                                                                                                                                                                                                                                        |
| Payment related information in the addenda records for various application types                                                                                                                                          | The rules call for an asterisk (*) to be the delimiter between data elements, and a backward slash (\), or a tilde (~) to be the terminator between data segments, but this validation must be done in a map. For more information, see the <a href="#">ACH Payment Related Information example</a> . The Payment Related Information field in all of the addenda records must be parsed to validate the data. Similarly, to ensure that the content in this field is ANSI X12 or NACHA, endorsed banking conventions must be validated separately in a map. |
| Rules regarding valid sending point, valid routing numbers                                                                                                                                                                | Other than data format validation, the type tree validation does not provide lookup capabilities against tables of valid ACH participant information.                                                                                                                                                                                                                                                                                                                                                                                                        |
| Rules regarding matching field values (for example, Immediate Origin, File Creation Date, File Creation Time and File ID Modifier) back to original entries or related ACH files in a particular application process flow | The rules must be included in the overall application. In other words, the type tree does not perform records matching within the content of the data, whereas the validation map performs this matching task and reports any duplicates                                                                                                                                                                                                                                                                                                                     |
| Originator City field and State/Province field in the Third IAT addenda record, and the Receiver City field and State/Province field in the Seventh IAT addenda record.                                                   | The State/Province portion of these fields is not mandatory in all cases, but only "if applicable". If the overall implementation is limited to situations where this is applicable, then additional validation could be implemented in a validation map.                                                                                                                                                                                                                                                                                                    |
| Currency Codes                                                                                                                                                                                                            | The type tree does not restrict the value to a valid ISO Currency Code. To make certain the Currency Code is valid, the ISO Currency Code values must be added as restrictions to all Currency Code elements.                                                                                                                                                                                                                                                                                                                                                |
| DFI Account Number field                                                                                                                                                                                                  | The type tree does not provide look up capabilities against validation of the DFI Account number                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Rules regarding TRC Entries and TRX Entries                                                                                                                                                                               | TRC Entries and TRX Entries are permitted only to eligible participants. An ODFI may transmit a TRC entry or TRX entry to an RDFI only if the ODFI and RDFI each are participants in the same Check Truncation Program. The type tree does not contain rules to ensure that ODFI or RDFI are both participants in the same Check Truncation Program. If the overall implementation is limited to situations where this is applicable, then additional validation could be implemented in a validation map.                                                   |
| Rules regarding loan accounts                                                                                                                                                                                             | Originators may transmit ACH credit entries to loan accounts belonging to a Receiver. Originators must be aware that, with the exception of reversals to correct erroneous credit, debit entries to loan accounts are prohibited. The type tree does not contain rules that enforce this entry detail rejection criteria.                                                                                                                                                                                                                                    |
| Rules regarding Office of Foreign Assets Control (OFAC) enforced sanctions policies.                                                                                                                                      | The type tree does not have rules to enforce OFAC sanctions policies, such as reporting entities referred to as "Specially Designated Nationals and Blocked Person" acting as ACH participants.                                                                                                                                                                                                                                                                                                                                                              |

## Creating an application specific type tree

These procedures describe how to create NACHA type trees for your specific application.

Using a subset type tree, as described here, can improve mapping run-time performance, as there are fewer application group partitions to test during validation. In addition, the size (disk space required) of the type tree source file can be reduced (minimized). Data validation of a type tree starts at the top, and moves down the list of SEC subtypes, attempting validation of each subtype against the data until a match is found. Use the procedures in this section to "prune" the appropriate version of the Automated Clearing House (ACH) type tree to meet your needs.

Instead of merely deleting the unneeded types directly in the type tree, there is a two-step process that is required to "prune" the tree in order to make it the most efficient:

- First, create a tree by copying the current ach\_vccyy, or ach\_vccyy\_sfmt file and deleting unnecessary application types.  
Note: In the file names above, ccyy indicates the year of the application standards, for example, 2009, or 2015.
- To remove unused components from the type tree that was created in the previous step, create another tree and merge the File type into it.
- **[Copying NACHA type trees](#)**  
To copy standard NACHA type trees:
- **[Removing unnecessary application types](#)**  
In this procedure, only the required application types are retained.
- **[Creating the target type tree](#)**  
The type tree that is created in this procedure is the type tree that contains the industry subsets.
- **[Merging the application type to the new type tree](#)**  
The types that are retained in the type tree are merged into the target type tree to create the industry subsets.

---

## Copying NACHA type trees

To copy standard NACHA type trees:

1. Open the NACHA type tree that you want to copy.
2. From the File menu, choose Save As.
3. Enter a new name in the File name field. For example: myach\_vccyy.mtt, where ccyy is the year of the ACH Standards being copied.
4. Click Ok.

---

## Removing unnecessary application types

In this procedure, only the required application types are retained.

In addition, when you map using the new NACHA type tree, only the necessary batch types appear in the Map Designer. In this example, the assumed application is the WEB application, a consumer application for origination of debit entries via the internet. To remove unnecessary application types:

1. In the new type tree, select Group.
2. Right click on the type and choose the Expand All Subsystems from the context menu.
3. Right-click on the group Batch and choose Select All Subtypes. All NACHA application subtypes are selected (highlighted).
4. For each application type to be retained in the subset tree, locate the subtype for that functional group. For example, locate the type WEB under Batch.
5. Hold down the Ctrl key, and then click each subtype that you want to retain. All the items to be deleted remain selected.
6. After all application subtypes that remain in the subset tree are no longer selected, press the Delete key (or choose Delete from the Type menu).
7. Remove the ADV under the Group category and ADV\_Entries under File category if the ADV\_Batch was deleted in the preceding steps. Save the type tree.

---

## Creating the target type tree

The type tree that is created in this procedure is the type tree that contains the industry subsets.

To create the new type tree, and name the root type:

1. From the File menu, choose the New-Type Tree.
2. In the New Type Tree window, select the parent folder and the file name for the new type tree, and then click Finish.
3. A new type tree is created in the window, with the Root type.
4. In the Properties window, in the Name field, change the name of the root type from Root to ACH.
5. From the File menu, choose Save.

---

## Merging the application type to the new type tree

The types that are retained in the type tree are merged into the target type tree to create the industry subsets.

To merge the application type to the new type tree:

1. Right-click the File category in the type tree that you modified in the [Copying NACHA type trees](#) steps (myach\_vccyy.mtt), then select Merge from the context menu. When the Merge window opens, the Merge Sub-Tree check box is grayed out.
2. Go to the new type tree that you created in [Creating the target type tree](#) and click anywhere in the new type tree window to populate the To field in the Merge window.
3. When the name of the new tree shows in the To Tree box, click Merge, and then click Close.

For scenarios where the application subtype, or subtypes selected are all non-return entries, on the second component of ACH\Group\ALL, edit the rule on Batch(s) by commenting out a specific line in the rule as follows:

```
/*COUNT(EntryDetail Returns Record IN $) */
```

For scenarios where the application subtype, or subtypes selected are all return entries (Contested Dishonored Return, Dishonored Returns, Refused Notification of Change, Returns), on the second component of ACH\Group\ALL , edit rule on Batch(s) by commenting out a specific line in the rule as follows:

```
/*COUNT(EntryDetail Record IN $) */
```

You can now save and begin to use the type tree.

## NACHA component examples

The Pack for Financial Payments NACHA component contains examples to assist you in using the pack. Instructions for using these examples are contained in this documentation. The ACH examples that install with the pack include the following:

- ACH mapping from and to EDI
- ACH mapping from and to SWIFT
- ACH to ISO 20022 Payment Initiation Credit Transfer
- ACH to ISO 20022 Payment Initiation Direct Debit
- ACH Reject to ISO 20022 Transformation
- ACH Returns to ISO 20022 Transformation
- XML to ACH Prearrange Payment and Deposit Entry (PPD)
- ACH Returns and Notification of Change (COR)
- ACH Refused Notification of Change
- ACH Dishonored Return Entry
- ACH Contested Dishonored Return Entry
- ACH Payment Related Information (PRI) validation
- ACH Return Entries Report
- ACH Validation

Other examples are included to be executed within IBM Sterling B2B Integrator ACH service.

The following are example scenarios:

- ACH Deenvelope - Corporate Trade Exchange Entries (CTX)
- ACH Deenvelope - Death Notification Entries (DNE)
- ACH Envelope - Corporate Trade Exchange Entries (CTX)
- ACH Envelope - Death Notification Entries (DNE)

Note: IBM Sterling B2B Integrator examples are available only when the pack is used with the Transformation Extender version 8.4 (and later) base product.

- **[ACH EDI example](#)**

The ACH mapping from and to EDI example represents conversions from and to the Corporate Credit or Debit (CCD), as well as the Corporate Trade Exchange (CTX) ACH entries.

- **[ACH SWIFT example](#)**

The example represents conversions to and from the International ACH Transaction (IAT) and the SWIFT MT103+ Single Customer Credit Transfer.

- **[ACH to ISO 20022 Credit Transfer example](#)**

The ACH to ISO 20022 example demonstrates how to transform an ACH file to an ISO 20022 XML document, as well as how to transform an ISO 20022 XML document to an ACH file.

- **[ACH to ISO 20022 Direct Debit example](#)**

The ACH to ISO 20022 Payment Initiation Direct Debit example demonstrates how to transform an ACH file to an ISO 20022 XML document, as well as how to transform an ISO 20022 document to an ACH file.

- **[ACH ISO 20022 Rejects example](#)**

The ACH ISO 20022 Rejects example demonstrates how to transform an ACH file to an ISO 20022 XML document, as well as how to transform an ISO 20022 XML document to an ACH file.

- **[ACH ISO 20022 Returns example](#)**

The ACH ISO 20022 Returns example demonstrates how to transform an ACH file to an ISO 20022 XML document, as well as how to transform an ISO 20022 XML document to an ACH file.

- **[XML to ACH PPD example](#)**

The example map illustrates how information is mapped from a back-office XYZ Trust XML file into the ACH PPD record layouts.

- **[ACH Returns and Notification of Change \(COR\) example](#)**

The example map illustrates how a return and notification of change is prepared.

- **[ACH Refused Notification of Change Entry example](#)**

The example map shows how a Refused Notification of Change (COR) entry is prepared.

- **[ACH Dishonored Return example](#)**

The ACH Dishonored Return example map shows how a dishonored return entry is prepared.

- **[ACH Contested Dishonored Return Entry example](#)**

The example map shows how an ACH contested dishonored return entry is prepared.

- **[ACH Payment Related Information example](#)**

The ACH Payment Related Information example demonstrates how to validate the content of the Payment Related Information field on the Addenda record, if it conforms to NACHA endorsed banking conventions.

- **[ACH Return Entries Report example](#)**

The example map shows how ACH return entries are extracted from an ACH file. The return entries are reported in categories that are returned due to administrative, unauthorized reasons and all other reasons (except for returned RCK entries).

- **[ACH Validation example](#)**

The ACH Validation example demonstrates how to validate an ACH file if it conforms to NACHA Operating Rules. The base implementations are derived from the ACH type treerules and are not designed to replace the use of the ACH type tree.

- [How to download output files](#)  
Download the output files.
  - [IBM Sterling B2B Integrator examples](#)  
See IBM Sterling B2B Integrator for a complete description of these examples, including deployment instructions.
- 

## ACH EDI example

The ACH mapping from and to EDI example represents conversions from and to the Corporate Credit or Debit (CCD), as well as the Corporate Trade Exchange (CTX) ACH entries.

- [What the example contains](#)  
The ACH EDI example contains these files, schemas, and maps.
  - [How to run the example in Design Studio](#)  
These steps describe how to run the ACH EDI example.
  - [How to run the example in Design Server](#)  
Run instructions for the ACH EDI example.
  - [Scenarios](#)  
The example maps will illustrate the following:
  - [Assumptions](#)  
The following assumptions are made regarding the ACH Mapping from and to EDI example:
- 

## What the example contains

The ACH EDI example contains these files, schemas, and maps.

### Files

These files are contained in the example:

- 820\_for\_ccd.in - input to the x12raccd transformation map which contains remittance advice (820) transactions.
- ccd\_valid.in - input to the ccdx12ra transformation map which contains ACH Corporate Credit (CCD+) entries.
- 820\_for\_ctx.in - input to the x12ractx transformation map which contains remittance advice (820) transactions.
- ctx\_valid.in - input to the ctxx12ra transformation map which contains ACH Corporate Trade Exchange (CTX) entries.

### Schemas

These schemas are contained in the example:

- 5010\_820 - type tree that represents an EDI 820 X12 version 5010X218.
- utility - miscellaneous schema used in sample maps.
- ach\_v2024 - current version of NACHA type tree.

### Maps

These maps are contained in the example:

- addenda - utility map that is called by x12ractx map to populate the ACH Corporate Trade Exchange (CTX) addenda records.
  - ccdx12ra - used to transform a valid ACH Corporate Credit (CCD+) entry to a valid X12 5010X218 820 Payment Advice Order/Remittance.
  - ctxx12ra - used to transform a valid ACH Corporate Trade Exchange (CTX) entry to a valid X12 5010X218 820 Payment Order/Remittance Advice.
  - x12raccd - used to transform a valid X12 5010X218 820 Payment Order/Remittance Advice to a valid ACH Corporate Credit (CCD+) entry.
- 

## How to run the example in Design Studio

These steps describe how to run the ACH EDI example.

### Procedure

1. Use the Design Studio to open the following map source file: ach\_edi.mms
2. Build all the maps in the source file, and then run the following transformation maps:  
Note: Comments which are associated with the rules are based upon situations which are illustrated by the example.
  - x12raccd and ccdx12ra
  - x12ractx and ctxx12ra

# How to run the example in Design Server

Run instructions for the ACH EDI example.

## About this task

These steps describe how to run the ACH EDI example in Design Server.

## Procedure

1. Import the nachaEDI.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the nachaEDI project in the Design Server UI.
4. Run the following maps:
  - x12ractx
  - ctxx12ra
  - ccdx12ra
  - x12raccd
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).

## Scenarios

The example maps will illustrate the following:

- How a Corporate Credit or Debit (CCD) entry is converted from an EDI X12 820 Payment Order/Remittance Advice, and conversely, how an EDI X12 820 Payment Order Remittance Advice is converted from a CCD entry.
- How a Corporate Trade Exchange (CTX) entry is converted from an EDI X12 820 Payment Order/Remittance Advice and conversely, how an EDI X12 820 Payment Order/Remittance Advice is converted from a CTX entry.

## Assumptions

The following assumptions are made regarding the ACH Mapping from and to EDI example:

- The ccdx12ra example map transforms a valid Corporate Credit or Debit (CCD) entry to a valid EDI X12 5010X218 820 Payment Order/Remittance Advice. For mapping data from the CCD to the EDI X12 820 (Remittance Advice), the CCD plus addenda format is necessary. The Payment Related Information element in the addenda record of a CCD can contain either NACHA endorsed banking conventions or Payment Related EDI X12 Segments. This example has been implemented with the payment related information in the CCD containing EDI X12 RMR Segments. The RMR Segment in the EDI X12 820 is populated with the payment related information from the CCD addenda record.
- The x12raccd example map transforms a valid EDI X12 5010X218 820 Payment Order/Remittance Advice to a valid Corporate Credit or Debit (CCD) entry. Calculations at the Batch Control and File levels are performed. This example maps the TRN Segment in the EDI X12 5010X218 820 to the Payment Related Information element in the CCD Addenda record.
- The x12ractx example map transforms a valid EDI X12 5010X218 820 Payment Order/Remittance Advice to a valid Corporate Trade Exchange (CTX) entry. Calculations at the Batch Control and File levels are performed.
- The ctxx12ra example map transforms a valid Corporate Trade Exchange (CTX) entry to a valid EDI X12 5010X218 820 Payment Order/Remittance Advice.

## ACH SWIFT example

The example represents conversions to and from the International ACH Transaction (IAT) and the SWIFT MT103+ Single Customer Credit Transfer.

- [What the example contains](#)  
The ACH SWIFT example contains these files, schemas, and maps.
- [How to run the example in Design Studio](#)  
Run the map example as follows.
- [How to run the example in Design Server](#)  
Run instructions for the ACH SWIFT example.
- [Scenarios](#)  
The example maps show how an International ACH Transaction (IAT) entry is converted from a SWIFT MT103+ Single customer Credit Transfer.
- [Assumptions](#)  
This example makes the following assumptions:

## What the example contains

The ACH SWIFT example contains these files, schemas, and maps.

## Files

---

These files are contained in the example:

- ach\_iat\_example.in - input to the iatmt103 transformation map which contains a valid International ACH Transaction (IAT) entry.
- mt103\_plus\_example.in - input to the mt103iat transformation map which contains a valid SWIFT MT103 message.

## Schemas

---

These schemas are contained in the example:

- swift\_mt103 - type tree that represents a SWIFT MT103+ message.
- ach\_v2024 - current version of NACHA type tree.

## Maps

---

These maps are contained in the example:

- iatmt103 - used to transform a valid International ACH Transaction (IAT) entry to a valid SWIFT MT103+ Single Customer Credit Transfer.
- mt103iat - used to transform a valid MT103+ Single Customer Credit Transfer to a valid International ACH Transaction (IAT) entry.

## How to run the example in Design Studio

Run the map example as follows.

### Procedure

---

1. Use the Design Studio to open the following map source file: ach\_swift.mms.
2. Build all the maps in the source file and then run the transformation maps iatmt103 and mt103iat.  
Note: Comments that are associated with the rules are based on situations that are illustrated by the example.

## How to run the example in Design Server

Run instructions for the ACH SWIFT example.

### About this task

---

Follow these steps to run the ACH SWIFT example.

### Procedure

---

1. Import the nachaSWIFT.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the **nachaSWIFT** project in the Design Server UI.
4. Run the following maps:
  - mt103iat
  - iatmt103
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).

## Scenarios

---

The example maps show how an International ACH Transaction (IAT) entry is converted from a SWIFT MT103+ Single customer Credit Transfer.

### About this task

---

The maps also show how a SWIFT MT103+ Single customer Credit transfer is converted to an IAT entry.

## Assumptions

---

This example makes the following assumptions:

- The iatmt103 example map transforms a valid International ACH Transaction (IAT) with a single batch and entry detail records. There are seven addenda records to a SWIFT MT103+ Single Customer Credit Transfer. Information provided on the addenda records is mapped to the closest equivalent SWIFT MT103+ fields.
- The mt103iat example map transforms a valid SWIFT MT103+ Single Customer Credit Transfer to an International ACH Transaction (IAT) entry. Calculations at the Batch Control and File levels are performed.

## ACH to ISO 20022 Credit Transfer example

The ACH to ISO 20022 example demonstrates how to transform an ACH file to an ISO 20022 XML document, as well as how to transform an ISO 20022 XML document to an ACH file.

The transformation is limited to the following Standard Entry Class (SEC) code being transformed into an ISO 20022 Payment Initiation (pain.001.001.03) Credit Transfer file.

- Corporate Credit or Debit (CCD)
- Prearranged Payment and Deposit (PPD)
- Corporate Trade Exchange (CTX)
- International ACH Transaction (IAT)

The implementations are based from the NACHA ISO 20022 Tool for pain.001 (credit transfer) Nov 2016.xlsx document

The example references the *ACH\_ISO\_Mapping\_Assumptions\_Table (Credit Transfer).xlsx* table. These tables install with the nachaISO20022MappingDoc.zip file.

- **What the example contains**  
The ACH ISO 20022 Credit Transfer example contains these files, schemas, and maps.
- **How to run the example in Design Studio**  
These steps describe how to run the ACH to ISO 20022 Credit Transfer example.
- **How to run the example in Design Server**  
Run instructions for the ACH ISO20022 Credit Transfer example.
- **Scenarios**  
The ACH to ISO 20022 Payment Initiation Credit Transfer example maps demonstrate file validation prior to transformation to a pain.001.001.03 document. Predefined rules must be followed to ensure valuation.
- **Assumptions**  
The example maps enforce the pre-conversion rules and, given that no rules are violated, the maps proceed to the transformation phase.

## What the example contains

The ACH ISO 20022 Credit Transfer example contains these files, schemas, and maps.

### Files

These files are contained in the example:

- ach\_ccd\_ct\_input.txt - input to the ccdiso01 map which contains a total of 5 CCD batch entries.
- ach\_ppd\_ct\_input.txt - input to the ppdiso01 map which contains a total of 1 PPD batch entry.
- ach\_ctx\_ct\_input.txt - input to the ctxiso01 map which contains a total of 2 CTX batch entries.
- ach\_iat\_ct\_input.txt - input to the iatiso01 map which contains a total of 2 IAT batch entries.
- iso\_pain001\_to\_ccd\_ct\_input.xml - input to the isoccd01 map which contains a total of 5 Payment Information level records.
- iso\_pain001\_to\_ppd\_ct\_input.xml - input to the isoppd01 map which contains a total of 1 Payment Information level record.
- iso\_pain001\_to\_ctx\_ct\_input.xml - input to the isoctx01 map which contains a total of 2 Payment Information level records.
- iso\_pain001\_to\_iat\_ct\_input.xml - input to the isoiat01 map which contains a total of 2 Payment Information level records.
- ach\_error\_codes.txt - list of error messages used in the pre-conversion rule verification step.

### Schemas

These schemas are contained in the example:

- pre\_conv\_rules- type tree that serves as a placeholder for the pre-conversion rules that are enforced in the transformation maps.
- ach\_error\_codes- metadata that represents the ach\_error\_codes.txt file which lists all error codes.
- ach\_v2024 - current version of NACHA type tree.
- pain.001.001.03.xsd - XML schema that represents the ISO 20022 Payment Initiation document.

### Maps

These maps are contained in the example:

- ccdiso01 - map used to transform an ACH Corporate Credit or Debit (CCD) file to an xml Payment Initiation (pain.001.001.03) Credit Transfer.

- ppdiso01 - map used to transform an ACH Prearranged Payment and Deposit (PPD) file to an xml Payment Initiation (pain.001.001.03) Credit Transfer.
- ctxiso01 - map used to transform an ACH Corporate Trade Exchange (CTX) file to an xml Payment Initiation (pain.001.001.03) Credit Transfer.
- iatiso01 - map used to transform an ACH International ACH Transaction (IAT) file to an xml Payment Initiation (pain.001.001.03) Credit Transfer.
- isoccd01 - map used to transform an xml Payment Initiation (pain.001.001.03) Credit Transfer to an ACH Corporate Credit or Debit (CCD) file.
- isoppd01 - map used to transform an xml Payment Initiation (pain.001.001.03) Credit Transfer to an ACH Prearranged Payment and Deposit (PPD) file.
- isoctx01 - map used to transform an xml Payment Initiation (pain.001.001.03) Credit Transfer to an ACH Corporate Trade Exchange (CTX) file.
- isoiat01 - map used to transform an xml Payment Initiation (pain.001.001.03) Credit Transfer to an ACH International ACH Transaction (IAT) file.

## How to run the example in Design Studio

These steps describe how to run the ACH to ISO 20022 Credit Transfer example.

### About this task

Run the map example as follows:

### Procedure

1. Use the Design Studio to open the following map source files:
  - a. ACH to ISO 20022
    - achiso\_ccd\_ct.mms
    - achiso\_ppd\_ct.mms
    - achiso\_ctx\_ct.mms
    - achiso\_iat\_ct.mms
  - b. ISO 20022 to ACH
    - isoach\_ccd\_ct.mms
    - isoach\_ppd\_ct.mms
    - isoach\_ctx\_ct.mms
    - isoach\_iat\_ct.mms
2. Build all the following maps in the source file:
  - ccdiso01 (transforms CCD to pain.001.001.03)
  - ppdiso01 (transforms PPD to pain.001.001.03)
  - ctxiso01 (transforms CTX to pain.001.001.03)
  - iatiso01 (transforms IAT to pain.001.001.03)
  - isoccd01 (transforms pain.001.001.03 to CCD)
  - isoppd01 (transforms pain.001.001.03 to PPD)
  - isoctx01 (transforms pain.001.001.03 to CTX)
  - isoiat01 (transforms pain.001.001.03 to IAT)
3. Set all compiled maps with a .mmc extension.
4. Define the following directories for those operating systems other than Windows:
  - data
  - maps
  - schemas
5. When the artifacts listed here are copied to operating systems other than Windows, make certain that the FTP settings are set as described sub-steps a and b, below:
  - a. FTP settings must be set to TEXT mode for the following input data:
    - ach\_ccd\_ct\_input.txt
    - ach\_ppd\_ct\_input.txt
    - ach\_ctx\_ct\_input.txt
    - ach\_iat\_ct\_input.txt
    - ach\_error\_codes.txt
  - b. FTP settings must be set to BINARY mode for the following:
    - all compiled maps
    - all xml schema files
    - iso\_pain001\_to\_ccd\_ct\_input.xml
    - iso\_pain001\_to\_ppd\_ct\_input.xml
    - iso\_pain001\_to\_ctx\_ct\_input.xml
    - iso\_pain001\_to\_iat\_ct\_input.xml

Note: MVS users, perform both step 6 and step 7. Non-MVS users go directly to step 7.
6. **MVS only:** Edit the following map card setting of the Schema > Type > Metadata to the //DD:ddname where ddname references the XML schema, pain.001.001.03.xsd:
  - a. Edit the ddname references on output card #2 for the following maps:
    - ccdiso01
    - ppdiso01
    - ctxiso01
    - iatiso01
  - b. Edit the ddname references on input card #1 for the following maps:
    - isoccd01
    - isoppd01
    - isoctx01
    - isoiat01

7. Run the maps listed in step 2 of this procedure.

## How to run the example in Design Server

Run instructions for the ACH ISO20022 Credit Transfer example.

### About this task

These steps describe how to run the ACH ISO20022 Credit Transfer example.

### Procedure

1. Import the nachaISO20022CreditTransfer.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the **nachaISO20022CreditTransfer** project in the Design Server UI.
4. Run the following maps:
  - ctxiso01
  - ccdiso01
  - ppdiso01
  - isoccd01
  - isoppd01
  - isoctx01
  - iatiso01
  - isoiat01
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).

### Scenarios

The ACH to ISO 20022 Payment Initiation Credit Transfer example maps demonstrate file validation prior to transformation to a pain.001.001.03 document. Predefined rules must be followed to ensure valuation.

The rules are defined in the *ACH\_ISO\_Mapping\_Assumptions\_Table (Credit Transfer).xlsx* table. This table includes the pre-conversion rules needed to validate between ACH to ISO 20022, and ISO 20022 to ACH.

The *ACH\_ISO\_Mapping\_Assumptions\_Table (Credit Transfer).xlsx* table installs with the pack in the following directory:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/nacha/examples/ach\_iso20022/scenario/assumptions

The table is also available on the Support website: <http://www.ibm.com/support/docview.wss?uid=ibm10716007>

### Assumptions

The example maps enforce the pre-conversion rules and, given that no rules are violated, the maps proceed to the transformation phase.

Mapping is done based on the *NACHA ISO 20022 Tool for pain.001 (credit transfer) Nov 2016.xlsx* document.

The *ACH\_ISO\_Mapping\_Assumptions\_Table (Credit Transfer).xlsx* includes some implementation specifics about mapping to and from ACH and ISO pain.001.001.03.

These tables are installed with the nachaISO20022MappingDoc.zip file.

### Expected results

- The ACH to ISO example maps generate an XML document that passes pain.001.001.03 XML schema validation.
- The ISO to ACH example maps generate an ACH file that passes ACH type tree validation.

## ACH to ISO 20022 Direct Debit example

The ACH to ISO 20022 Payment Initiation Direct Debit example demonstrates how to transform an ACH file to an ISO 20022 XML document, as well as how to transform an ISO 20022 document to an ACH file.

The transformation is limited to the following Standard Entry Class (SEC) code being transformed into an ISO 20022 Payment Initiation (pain.008.001.02) Direct Debit file:

- Corporate Credit or Debit (CCD)
- Prearranged Payment and Deposit (PPD)

The implementations are based on the *NACHA ISO 20022 Tool for pain.008 (Direct Debit) Nov 2016.xlsx* document.

The example references the *ACH\_ISO\_Mapping\_Assumptions\_Table (Direct Debit).xlsx* table. These tables install with the nachaISO20022MappingDoc.zip file.

- [What the example contains](#)  
The ACH ISO 20022 Direct Debit example contains these files, schemas, and maps.
- [How to run the example in Design Studio](#)  
These steps describe how to run the ACH to ISO 20022 Payment Initiation Direct Debit example.
- [How to run the example in Design Server](#)  
Run instructions for the ACH ISO20022 Direct Debit example.
- [Scenarios](#)  
The ACH to ISO 20022 Payment Initiation Direct Debit example maps show an ACH file being validated if the file conforms to predefined rules, prior to transformation to a pain.008.001.02 document.
- [Assumptions](#)  
The example maps enforce the pre-conversion rules and if no rules are violated, the maps proceed to the transformation phase.

---

## What the example contains

The ACH ISO 20022 Direct Debit example contains these files, schemas, and maps.

### Files

---

These files are contained in the example:

- ach\_ccd\_dd\_input.txt - input to the ccdiso08 map which contains a total of 5 CCD batch entries.
- ach\_ppd\_dd\_input.txt - input to the ppdiso08 map which contains a total of 1 PPD batch entry.
- iso\_pain008\_to\_ccd\_dd\_input.xml - input to the isoccd08 map which contains a total of 5 Payment Information level records.
- iso\_pain008\_to\_ppd\_dd\_input.xml - input to the isoppd08 map which contains a total of 1 Payment Information level record.
- ach\_error\_codes.txt - list of error messages used in the pre-conversion rule verification step.

### Schemas

---

These schemas are contained in the example:

- pre\_conv\_rules- type tree that serves as place holder for pre-conversion rules enforced in the transformation maps.
- ach\_error\_codes- type tree that represents the ach\_error\_codes.txt file which lists all error codes.
- ach\_v2024 - current version of NACHA type tree.
- pain.008.001.02.xsd - XML schema that represents the ISO 20022 Payment Initiation document.

### Maps

---

These maps are contained in the example:

- ccdiso08 - map used to transform an ACH Corporate Credit or Debit (CCD) file to an xml Payment Initiation (pain.008.001.02) Direct Debit.
- ppdiso08 - map used to transform an ACH Prearranged Payment and Deposit (PPD) file to an xml Payment Initiation (pain.008.001.02) Direct Debit.
- isoccd08 - map used to transform an xml Payment Initiation (pain.008.001.02) Direct Debit to an ACH Corporate Credit or Debit (CCD) file.
- isoppd08 - map used to transform an xml Payment Initiation (pain.008.001.02) Direct Debit to an ACH Prearranged Payment and Deposit (PPD) file.

---

## How to run the example in Design Studio

These steps describe how to run the ACH to ISO 20022 Payment Initiation Direct Debit example.

### About this task

---

Run the map example as follows:

### Procedure

---

1. Use the Design Studio to open the following map source files:
  - a. ACH to ISO 20022
    - achiso\_ccd\_dd.mms
    - achiso\_ppd\_dd.mms
  - b. ISO 20022 to ACH
    - isoach\_ccd\_dd.mms
    - isoach\_ppd\_dd.mms
2. Build all the following maps in the source file:
  - ccdiso08 (transforms CCD to pain.008.001.02)
  - pdiso08 (transforms PPD to pain.008.001.02)

- isoccd08 (transforms pain.008.001.02 to CCD)
  - isoppd08 (transforms pain.008.001.02 to PPD)
3. Set all compiled maps with a .mmc extension.
4. Define the following directories for those operating systems other than Windows:
- data
  - maps
  - schemas
5. When the artifacts listed here are copied to operating systems other than Windows, make certain that the FTP settings are set as described in sub-steps a and b:
- a. FTP settings must be set to TEXT mode for the following input data:
    - ach\_ccd\_dd\_input.txt
    - ach\_ppd\_dd\_input.txt
    - ach\_error\_codes.txt
  - b. FTP settings must be set to BINARY mode for the following:
    - all compiled maps
    - all xml schema files
    - iso\_pain008\_to\_ccd\_dd\_input.xml
    - iso\_pain008\_to\_ppd\_dd\_input.xml
- Note: MVS users, perform both step 6 and step 7. Non-MVS users go directly to step 7.
6. **MVS only:** Edit the following map card setting of the Schema > Type > Metadata to the //DD:ddname where ddname references the XML schema, pain.008.001.02.xsd.
- a. Edit the ddname references on output card #2 (pain.008.001.02.xsd) for the following maps:
    - ccdiso08
    - ppdiso08
  - b. Edit the ddname references on input card #1 (pain.008.001.02.xsd) for the following maps:
    - isoccd08
    - isoppd08
7. Run the maps listed in step 2 of this procedure.

## How to run the example in Design Server

Run instructions for the ACH ISO20022 Direct Debit example.

### About this task

These steps describe how to run the ACH ISO20022 Direct Debit example.

### Procedure

1. Import the nachaISO20022DirectDebit.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the **nachaISO20022DirectDebit** project in the Design Server UI.
4. Run the following maps:
  - ccdiso08
  - ppdiso08
  - isoccd08
  - isoppd08
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).

## Scenarios

The ACH to ISO 20022 Payment Initiation Direct Debit example maps show an ACH file being validated if the file conforms to predefined rules, prior to transformation to a pain.008.001.02 document.

The rules are defined in the *ACH\_ISO\_Mapping\_Assumptions\_Table (Direct Debit).xlsx* table. This table includes pre-conversion rules needed between ACH to and from ISO pain.008.001.02.

The *ACH\_ISO\_Mapping\_Assumptions\_Table (Direct Debit).xlsx* installs with the pack in the following directory:

<install\_dir>/packs/financial\_payments\_vn.n.n/nacha/examples/ach\_iso20022/scenario/assumptions

The table is also available on the Support website: <http://www.ibm.com/support/docview.wss?uid=ibm10716007>

## Assumptions

The example maps enforce the pre-conversion rules and if no rules are violated, the maps proceed to the transformation phase.

- Mapping is done based on the *NACHA ISO 20022 Tool for pain.008 (Direct Debit) Nov 2016.xlsx* document. These tables install with the nachaISO20022MappingDoc.zip file.
- The *ACH\_ISO\_Mapping\_Assumptions\_Table (Direct Debit).xlsx* document includes implementation specifics on the mapping between ACH, to and from ISO pain.008.

## Expected results

---

- The ACH to ISO example maps generate an XML document which passes pain.008.001.02 XML schema validation.
  - The ISO to ACH example map generates an ACH file which passes ACH type tree validation.
- 

## ACH ISO 20022 Rejects example

The ACH ISO 20022 Rejects example demonstrates how to transform an ACH file to an ISO 20022 XML document, as well as how to transform an ISO 20022 XML document to an ACH file.

The transformation is limited to the following Standard Entry Class (SEC) code being transformed into an ISO 20022 Customer Payment Status Report message (pain.002.001.03) Credit Transfer and Direct Debit file.

- Corporate Credit or Debit (CCD)
- Prearranged Payment and Deposit (PPD)
- Corporate Trade Exchange (CTX)
- ACH International ACH Transaction (IAT)

The implementations are based on the *NACHA ISO 20022 Tool for pain.002.001.03 (Reject) Nov 2016.xlsx* document.

The example references the *ACH\_ISO\_Mapping\_Assumptions\_Table (Reject).xlsx* table. These tables install with the *nachaISO20022MappingDoc.zip* file.

- [\*\*What the example contains\*\*](#)  
The ACH Rejects example contains these files, schemas, and maps.

Run instructions for the ACH ISO20022 Rejects example.
- [\*\*Scenarios\*\*](#)  
The ACH to ISO 20022 and ISO 20022 to ACH example maps show ACH and ISO 20022 files being validated if the files conforms to specific rules, prior to transformation to a pain.002 document.
- [\*\*Assumptions\*\*](#)

---

## What the example contains

The ACH Rejects example contains these files, schemas, and maps.

## Files

---

These files are contained in the example:

- ach\_reject\_ccd\_ct\_input.txt - input to the rjtiso01 map which contains a total of 2 Reject CCD batch entries for Credit Transfer.
- ach\_reject\_ccd\_dd\_input.txt - input to the rjtiso01 map which contains a total of 2 Reject CCD batch entries for Direct Debit.
- ach\_reject\_ppd\_ct\_input.txt - input to the rjtiso01 map which contains a total of 1 Reject PPD batch entries for Credit Transfer.
- ach\_reject\_ppd\_dd\_input.txt - input to the rjtiso01 map which contains a total of 1 Reject PPD batch entries for Direct Debit.
- ach\_reject\_ctx\_ct\_input.txt - input to the rjtiso01 map which contains a total of 2 Reject CTX batch entries for Credit Transfer.
- ach\_reject\_ctx\_dd\_input.txt - input to the rjtiso01 map which contains a total of 2 Reject CTX batch entries for Direct Debit.
- ach\_reject\_iat\_ct\_input.txt - input to the rjtiso01 map which contains a total of 1 Reject IAT batch entries for Credit Transfer.
- ach\_reject\_iat\_dd\_input.txt - input to the rjtiso01 map which contains a total of 1 Reject IAT batch entries for Direct Debit.
- iso\_pain002\_to\_reject\_ccd\_ct\_input.xml - input to the isorj01 map which contains a total of 2 OriginalPaymentAndStatus message level records for Credit Transfer.
- iso\_pain002\_to\_reject\_ccd\_dd\_input.xml - input to the isorj01 map which contains a total of 2 OriginalPaymentAndStatus message level records for Direct Debit.
- iso\_pain002\_to\_reject\_ppd\_ct\_input.xml - input to the isorj01 map which contains a total of 1 OriginalPaymentAndStatus message level records for Credit Transfer.
- iso\_pain002\_to\_reject\_ppd\_dd\_input.xml - input to the isorj01 map which contains a total of 1 OriginalPaymentAndStatus message level records for Direct Debit.
- iso\_pain002\_to\_reject\_ctx\_ct\_input.xml - input to the isorj01 map which contains a total of 2 OriginalPaymentAndStatus message level records for Credit Transfer.
- iso\_pain002\_to\_reject\_ctx\_dd\_input.xml - input to the isorj01 map which contains a total of 2 OriginalPaymentAndStatus message level records for Direct Debit.
- iso\_pain002\_to\_reject\_iat\_ct\_input.xml - input to the isorj01 map which contains a total of 1 OriginalPaymentAndStatus message level records for Credit Transfer.
- iso\_pain002\_to\_reject\_iat\_dd\_input.xml - input to the isorj01 map which contains a total of 1 OriginalPaymentAndStatus message level records for Direct Debit.
- ach\_error\_codes.txt - list of error messages used in the pre-conversion rule verification step.
- rtrn\_reason\_codes.txt - Lists of CH return reason code and their equivalent ISO ExternalStatusReason1 Codes.

## Schemas

---

These schemas are contained in the example:

- pain.002.001.03.xsd - XML schema that represents the ISO 20022 Customer Payment Status Report message document.
- pre\_conv\_rules - type tree that serves as place holder for pre-conversion rules enforced in the transformation maps.
- rtrn\_reason\_codes - type tree that represents the rtrn\_reason\_codes.txt file which lists ACH return reason code and their equivalent ISO ExternalStatusReason1 Codes
- ach\_error\_codes - type tree that represents the ach\_error\_codes.txt file which lists all error codes.
- ach\_v2024 - current version of NACHA type tree.

## Maps

---

These maps are contained in the example:

- rjtniso01 - map used to transform an ACH Reject for Corporate Credit or Debit (CCD), Prearranged Payment and Deposit (PPD), ACH International ACH Transaction (IAT), and Corporate Trade Exchange (CTX) file to an xml Customer Payment Status Report message (pain.002.001.03).
- isorjtn01 - map used to transform an xml Customer Payment Status Report message (pain.002.001.03) to an ACH Reject Corporate Credit or Debit (CCD), Prearranged Payment and Deposit (PPD), ACH International ACH Transaction (IAT) and Corporate Trade Exchange (CTX) file.

## How to run the example in Design Studio

---

These steps describe how to run the ACH Reject to ISO 20022 transformation example.

### About this task

---

Run the map example as follows:

### Procedure

---

1. Use the Design Studio to open the following map source file:
  - a. ACH to ISO 20022
    - achiso\_rjct.mms
  - b. ISO 20022 to ACH
    - isoach\_rjct.mms
2. Build all the following maps in the source file:
  - rjtniso01 (transforms Reject to pain.002.001.03)
  - isorjtn01 (transforms pain.002.001.03 to Reject)
3. Set all compiled maps with a .mmc extension.
4. Define the following directories for those operating systems other than Windows:
  - data
  - maps
  - schemas
5. When the artifacts listed here are copied to operating systems other than Windows, make certain that the FTP settings are set as described in sub-steps a and b:
  - a. FTP settings must be set to TEXT mode for the following input data:
    - ach\_reject\_ccd\_ct\_input.txt
    - ach\_reject\_ccd\_dd\_input.txt
    - ach\_reject\_ppd\_ct\_input.txt
    - ach\_reject\_ppd\_dd\_input.txt
    - ach\_reject\_ctx\_ct\_input.txt
    - ach\_reject\_ctx\_dd\_input.txt
    - ach\_reject\_iat\_ct\_input.txt
    - ach\_reject\_iat\_dd\_input.txt
    - rtrn\_reason\_codes.txt
    - ach\_error\_codes.txt
  - b. FTP settings must be set to BINARY mode for the following:
    - all compiled maps
    - all xml schema files
    - iso\_pain002\_to\_reject\_ccd\_ct\_input.xml
    - iso\_pain002\_to\_reject\_ccd\_dd\_input.xml
    - iso\_pain002\_to\_reject\_ppd\_ct\_input.xml
    - iso\_pain002\_to\_reject\_ppd\_dd\_input.xml
    - iso\_pain002\_to\_reject\_ctx\_ct\_input.xml
    - iso\_pain002\_to\_reject\_ctx\_dd\_input.xml
    - iso\_pain002\_to\_reject\_iat\_ct\_input.xml
    - iso\_pain002\_to\_reject\_iat\_dd\_input.xml
- Note: MVS users, perform both step 6 and step 7. Non-MVS users go directly to step 7.
6. **MVS only:** Edit the following map card setting of the Schema > Type > Metadata to the //DD:ddname where ddname references the XML schema, pain.002.001.03.xsd
  - a. Edit the ddname references on output card #2 (pain.002.001.03.xsd) for the following map:
    - rjtniso01

- b. Edit the ddname references on input card #1 (pain.002.001.03.xsd) for the following maps:
- isorjt01
7. Run the maps listed in step 2 of this procedure.

---

## How to run the example in Design Server

Run instructions for the ACH ISO20022 Rejects example.

### About this task

These steps describe how to run the ACH ISO20022 Rejects example.

### Procedure

1. Import the nachaISO20022Rejects.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the nachaISO20022Rejects project in the Design Server UI.
4. Run the following maps:
  - isorjt01
  - rjtiso01
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).

---

## Scenarios

The ACH to ISO 20022 and ISO 20022 to ACH example maps show ACH and ISO 20022 files being validated if the files conforms to specific rules, prior to transformation to a pain.002 document.

The rules are defined in the *ACH\_ISO\_Mapping\_Assumptions\_Table (Reject).xlsx* table. This table includes pre-conversion rules needed between ACH to and from ISO pain.002.001.03.

The *ACH\_ISO\_Mapping\_Assumptions\_Table (Direct Debit).xlsx* installs with the pack in the following directory:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/nacha/examples/ach\_iso20022/scenario/assumptions

The table is also available on the Support website: <http://www.ibm.com/support/docview.wss?uid=ibm10716007>

---

## Assumptions

- The example maps enforce the pre-conversion rules and if no rules are violated, the maps proceed to the transformation phase.
- Mapping is done based on the *NACHA ISO 20022 Tool for pain.002 (reject) Nov 2016.xlsx* document.
- The *ACH\_ISO\_Mapping\_Assumptions\_Table (Reject).xlsx* includes implementation specifics on the mapping to and from ACH and ISO pain.002.

---

## Expected results

- The ACH to ISO example maps generate an XML document which passes pain.002.001.03 XML schema validation
- The ISO to ACH example maps generate an ACH file which passes ACH type tree validation.

---

## ACH ISO 20022 Returns example

The ACH ISO 20022 Returns example demonstrates how to transform an ACH file to an ISO 20022 XML document, as well as how to transform an ISO 20022 XML document to an ACH file.

The transformation will be limited to the following Standard Entry Class (SEC) code being transformed into an ISO 20022 Bank To Customer Statement message (camt.053.001.02) Credit Transfer and Direct Debit file.

- Corporate Credit or Debit (CCD)
- Prearranged Payment and Deposit (PPD)
- Corporate Trade Exchange (CTX)

The implementations are based on the *NACHA ISO 20022 Tool for camt.053 (returns) Nov 2016.xlsx* document.

The example references the *ACH\_ISO\_Mapping\_Assumptions\_Table (returns).xlsx* table. These tables install with the nachaISO20022MappingDoc.zip file.

- [What the example contains](#)  
The ACH returns example contains these files, schemas, and maps.

The ACH Returns to ISO 20022 transformation example maps enforce pre-conversion rules.

---

## What the example contains

The ACH returns example contains these files, schemas, and maps.

### Files

These files are contained in the example:

- ach\_return\_ccd\_ct\_input.txt - input to the rtniso01 map which contains a total of 2 Returns CCD batch entries for Credit Transfer.
- ach\_return\_ccd\_dd\_input.txt - input to the rtniso01 map which contains a total of 2 Returns CCD batch entries for Direct Debit.
- ach\_return\_ppd\_ct\_input.txt - input to the rtniso01 map which contains a total of 1 Returns PPD batch entries for Credit Transfer.
- ach\_return\_ppd\_dd\_input.txt - input to the rtniso01 map which contains a total of 1 Returns PPD batch entries for Direct Debit.
- ach\_return\_ctx\_ct\_input.txt - input to the rtniso01 map which contains a total of 2 Returns CTX batch entries for Credit Transfer.
- ach\_return\_ctx\_dd\_input.txt - input to the rtniso01 map which contains a total of 2 Returns CTX batch entries for Direct Debit.
- iso\_camt053\_to\_returns\_ccd\_ct\_input.xml - input to the isortn01 map which contains a total of 2 Statement message level records for Credit Transfer.
- iso\_camt053\_to\_returns\_ccd\_dd\_input.xml - input to the isortn01 map which contains a total of 2 Statement message level records for Direct Debit.
- iso\_camt053\_to\_returns\_ppd\_ct\_input.xml - input to the isortn01 map which contains a total of 1 Statement message level records for Credit Transfer.
- iso\_camt053\_to\_returns\_ppd\_dd\_input.xml - input to the isortn01 map which contains a total of 1 Statement message level records for Direct Debit.
- iso\_camt053\_to\_returns\_ctx\_ct\_input.xml - input to the isortn01 map which contains a total of 2 Statement message level records for Credit Transfer.
- iso\_camt053\_to\_returns\_ctx\_dd\_input.xml - input to the isortn01 map which contains a total of 2 Statement message level records for Direct Debit.
- ach\_error\_codes.txt - list of error messages used in the pre-conversion rule verification step.
- rtrn\_reason\_codes.txt - lists of CH return reason code and their equivalent ISO ExternalStatusReason1 Codes.

### Schemas

These schemas are contained in the example:

- camt.053.001.02.xsd - XML schema that represents the ISO 20022 Bank To Customer Statement message document.
- pre\_conv\_rules - type tree that serves as place holder for pre-conversion rules enforced in the transformation maps.
- rtrn\_reason\_codes - type tree that represents the rtrn\_reason\_codes.txt file which lists ACH return reason code and their equivalent ISO ExternalStatusReason1 Codes.
- ach\_error\_codes - type tree that represents the ach\_error\_codes.txt file which lists all error codes.
- ach\_v2024 - current version of NACHA type tree.

### Maps

These maps are contained in the example:

- rtniso01 - map used to transform an ACH Returns for Corporate Credit or Debit (CCD), Prearranged Payment and Deposit (PPD) and Corporate Trade Exchange (CTX) file to an XML Bank To Customer Statement message (camt.053.001.02).
  - isortn01 - map used to transform an XML Bank To Customer Statement message (camt.053.001.02) to an ACH Returns Corporate Credit or Debit (CCD), Prearranged Payment and Deposit (PPD) and Corporate Trade Exchange (CTX) file.
- 

## How to run the example in Design Studio

These steps describe how to run the ACH Returns to ISO 20022 transformation example.

### About this task

Run the map example as follows:

### Procedure

1. Use the Design Studio to open the following map source file:
    - a. ACH to ISO 20022
      - achiso\_rtrn.mms
    - b. ISO 20022 to ACH
      - isoach\_rtrn.mms
  2. Build all the following maps in the source file:
    - rtniso01 (transforms Returns to camt.053.001.02)
    - isortn01 (transforms camt.053.001.02 to Returns)
  3. Set all compiled maps with a .mmc extension.
  4. Define the following directories for those operating systems other than Windows:
    - data
    - maps
    - schemas
  5. When the artifacts listed here are copied to operating systems other than Windows, make certain that the FTP settings are set as described in sub-steps a and b:
    - a. FTP settings must be set to TEXT mode for the following input data:
      - ach\_return\_ccd\_ct\_input.txt
      - ach\_return\_ccd\_dd\_input.txt
      - ach\_return\_ppd\_ct\_input.txt
      - ach\_return\_ppd\_dd\_input.txt
      - ach\_return\_ctx\_ct\_input.txt
      - ach\_return\_ctx\_dd\_input.txt
      - rtrn\_reason\_codes.txt
      - ach\_error\_codes.txt
    - b. FTP settings must be set to BINARY mode for the following:
      - all compiled maps
      - all xml schema files
      - iso\_camt053\_to\_returns\_ccd\_ct\_input.xml
      - iso\_camt053\_to\_returns\_ccd\_dd\_input.xml
      - iso\_camt053\_to\_returns\_ppd\_ct\_input.xml
      - iso\_camt053\_to\_returns\_ppd\_dd\_input.xml
      - iso\_camt053\_to\_returns\_ctx\_ct\_input.xml
      - iso\_camt053\_to\_returns\_ctx\_dd\_input.xml
- Note: MVS users, perform step 6 and step 7. Non-MVS users go directly to step 7.
6. **MVS only:** Edit the following map card setting of the Schema > Type > Metadata to the //DD:ddname where ddname reference the XML schema camt.053.001.02.xsd.
- a. Edit the ddname references on output card #2 (camt.053.001.02.xsd) for the following map:
    - rtniso01
  - b. Edit the ddname references on input card #1 (camt.053.001.02.xsd) for the following map:
    - isortn01
7. Run the maps listed in step 2 of this procedure.

## How to run the example in Design Server

Run instructions for the ACH ISO20022 Returns example.

### About this task

These steps describe how to run the ACH ISO20022 Returns example.

### Procedure

1. Import the nachaISO20022Returns.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the nachaISO20022Returns project in the Design Server UI.
4. Run the following maps:
  - isortn01
  - rtniso01
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).

### Scenarios

The ACH Returns to ISO 20022 and ISO 20022 to ACH Returns example demonstrates file validation prior to transformation to a camt.053.001.02 document. Validation is dependent upon predefined rules being followed.

The *ACH\_ISO\_Mapping\_Assumptions\_Table (Returns).xlsx* table includes the pre-conversion rules needed for validation between ACH and ISO camt.053.

The *ACH\_ISO\_Mapping\_Assumptions\_Table (Returns).xlsx* installs with the pack in the following directory:

The table is also available on the Support website: <http://www.ibm.com/support/docview.wss?uid=ibm10716007>

### Assumptions

The ACH Returns to ISO 20022 transformation example maps enforce pre-conversion rules.

The following are assumed if no rules are violated:

- The maps proceed to the transformation phase.
- Mapping is based on the *NACHA ISO 20022 Tool for camt.053 (returns) Nov 2016.xlsx* document.

The *ACH\_ISO\_Mapping\_Assumptions\_Table (Returns).xlsx* table includes implementation specifics on the mapping between ACH and ISO camt.053.

## Expected results

---

- The ACH Returns to ISO 20022 example maps generate an XML document that passes camt.053.001.02 XML schema validation.
  - The ISO to ACH example maps generate an ACH file that passes ACH schema validation.
- 

## XML to ACH PPD example

The example map illustrates how information is mapped from a back-office XYZ Trust XML file into the ACH PPD record layouts.

- [\*\*What the example contains\*\*](#)  
The XML to ACH example contains these files, schemas, and maps.
  - [\*\*How to run the example in Design Studio\*\*](#)  
Run the map example as follows:
  - [\*\*How to run the example in Design Server\*\*](#)  
Run instructions for the XML to ACH PPD example.
  - [\*\*Scenarios\*\*](#)  
The sample application consists of a payroll application (a batch of consumer credit entries) and a monthly dues application (a batch of consumer debit entries).
  - [\*\*Assumptions\*\*](#)  
The XML to ACH PPD example has these assumptions.
- 

## What the example contains

The XML to ACH example contains these files, schemas, and maps.

### Files

---

These files are contained in the example:

- xyz\_trust\_file.xml - input to the transformation map which contains payroll transactions and membership dues from two originating customers.

### Schemas

---

These schemas are contained in the example:

- xyz.trst.001.xsd - XML schema describing the format of the XML document which holds information required by the sample originating depository institution to format an ACH PPD file.
- xyz.trst.001 - type tree derived from the sample XML schema called xyz.trst.001.xsd.
- ach\_v2024 - current version of NACHA type tree.

### Maps

---

These maps are contained in the example:

- xml\_to\_ppd - used to convert a non-industry specific XML file to an ACH Prearrange Payment and Deposit Entries (PPD) file.
- 

## How to run the example in Design Studio

Run the map example as follows:

### Procedure

---

1. Use the Design Studio to open the following map source file: `xml_to_ppd.mms`
2. Build the map in the source file, and then run the following transformation map:  
Note: Comments which are associated with the rules are based upon situations which are illustrated by the example.
  - `xml_to_ppd`

## How to run the example in Design Server

Run instructions for the XML to ACH PPD example.

## About this task

---

These steps describe how to run the XML to ACH PPD example.

## Procedure

---

1. Import the nachaXML.zip file into the Design Server UI. See the release notes for import instructions.
  2. Create a package for the project and build all the maps.
  3. Open the nachaXML project in the Design Server UI.
  4. Run the following map:
    - `xml_to_ppd`
  5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
  6. To download the output file, see [How to download output files](#).
- 

## Scenarios

---

The sample application consists of a payroll application (a batch of consumer credit entries) and a monthly dues application (a batch of consumer debit entries).

Based on the sample applications and certain assumptions, this example illustrates how the PPD ACH records are formatted.

---

## Assumptions

---

The XML to ACH PPD example has these assumptions.

Note: The XML to ACH PPD example relates to specific applications outlined in this documentation. The example is not intended to depict situations that are always appropriate.

XYZ Trust originates ACH payments. Presently, it has two originating customers, BEL, Incorporated, and AM Club.

## Application #1

---

BEL, Incorporated pays its employees monthly by direct deposit. On June 25, BEL, Incorporated prepared an ACH file on its PC software package for delivery to XYZ Trust.

The file contains the information for the pay date of June 27. Three individuals are being paid a total of \$90,000. Payroll information for BEL Incorporated is shown here:

|             |                         |
|-------------|-------------------------|
| NAME        | Donn, John              |
| EMPLOYEE ID | 787-87-8787             |
| NET PAY     | \$30,000.00             |
| FI          | QRS S&L                 |
| RTN         | 43655655                |
| ACT. #      | 34-567 890 (checking)   |
|             |                         |
| NAME        | Rees, Jaycee            |
| EMPLOYEE ID | 133-13-3133             |

| ACT. #      | 10987654343 (savings)   |
|             |                         |
| NAME        | Ainge, Roy              |
| EMPLOYEE ID | 343-34-3434             |
| NET PAY     | \$30,000.00             |
| FI          | WXY Bank                |
| RTN         | 34513093                |
| ACT. #      | 7 78 0-87 69 (checking) |

## Application #2

---

AM Club collects some of its monthly dues by ACH debit. On June 25, AM Club prepares an ACH file on its PC software package and delivers it to XYZ Trust by modem. The file contains three collections for July dues. The entries total \$1,800.00. The ID number for AM Club is its tax ID: 249999991.

Customer information for AM Club is listed here:

|              |              |
|--------------|--------------|
| NAME         | Connor, Beth |
| MEMBERSHIP # | 5130         |

| ACCT. #      | 675718 0-83-55 (checking)  |

The ID number (Routing and ABA Number) for XYZ Trust is 27111111.

XYZ Trust receives the information from its two Originators and prepares a file for delivery to its ACH Operator, LOL services. The Routing Number for LOL Services is 27322225. The file contains one batch of credits and one batch of debits. Each batch carries three PPD entries.

## ACH Returns and Notification of Change (COR) example

The example map illustrates how a return and notification of change is prepared.

The example application shows the preparation of a file which consists of two batches. The first batch carries a single return entry, and the second batch contains a single notification of change entry.

- [What the example contains](#)  
The ACH Return Notification of Change example contains these files, schemas, and maps.
- [How to run the example in Design Studio](#)  
Run the map example as follows.
- [How to run the example in Design Server](#)  
Run instructions for the ACH Return Notification of Change example.
- [Scenarios](#)  
The original entries are received by the RDFI.
- [Assumptions](#)  
These are the assumptions for the ACH Returns and Notifications of Change (COR) example.

## What the example contains

The ACH Return Notification of Change example contains these files, schemas, and maps.

### Files

This file is contained in the example:

- ach\_ppd\_from\_xyz\_trust.in - input to the transformation map which contains payroll transaction with and membership due from two originating customers.

### Schemas

This schema is contained in the example:

- ach\_v2024 - current version of NACHA type tree.

### Maps

This map is contained in the example:

- ach\_return\_cor - map that creates an ACH Return entry and an ACH Notification of Change (COR) entry from an ACH Prearrange Payment and Deposit Entries (PPD) file.

## How to run the example in Design Studio

Run the map example as follows.

### Procedure

1. Use the Design Studio to open the following map source file: ach\_return\_cor.mms.

- Build the map in the source file, and then run the transformation map.
- Comments that are associated with the rules are based on situations that are illustrated by the example.

- ach\_return\_cor

## How to run the example in Design Server

Run instructions for the ACH Return Notification of Change example.

### About this task

These steps describe how to run the ACH Return Notification of Change example.

### Procedure

- Import the nachaReturnNotificationOfChange.zip file into the Design Server UI. See the release notes for import instructions.
- Create a package for the project and build all the maps.
- Open the nachaReturnNotificationOfChange project in the Design Server UI.
- Run the following map:
  - ach\_return\_cor
- View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
- To download the output file, see [How to download output files](#).

### Scenarios

The original entries are received by the RDFI.

However, WXY Bank, Routing Number 34513093, cannot post a \$600 entry for Beth Connor, account # 31872-76 54 8. The reason is because the account does not have sufficient funds to cover the debit (return reason code 'R01').

The DEF Bank also prepares a notification of change. The change notifies XYZ Trust, which is the ODFI, that the DFI Account Number for Roy Ainge is incorrect and must be changed. The Original Entry carried a DFI Account Number of 7780-8769, but the correct DFI Account Number is 80-8769.

### Assumptions

These are the assumptions for the ACH Returns and Notifications of Change (COR) example.

Note: The ACH Returns and Notifications of Change (COR) example relates to specific applications outlined in the documentation provided here. The example is not intended to depict situations that are always appropriate.

The WXY Bank received the following PPD entries from XYZ Trust. XYZ trust has started originating ACH payments and it presently has two originating customers: Application #1 and Application #2.

### Application #1

The AM Club collects some of its monthly dues through ACH debit. On June 25, UVW Club prepared an ACH file on its PC software package and delivered it to XYZ Trust by modem.

The file contains one collection for July dues. The entries total \$600.00. AM Club's ID number is its tax ID - 249999991. AM Club's customer information is listed as follows:

|              |                          |
|--------------|--------------------------|
| NAME         | Connor, Beth             |
| MEMBERSHIP # | 5130                     |
| DUES         | \$600.00                 |
| FI           | WXY Bank                 |
| RTN          | 34513093                 |
| ACCT. #      | 31872-76 54 8 (checking) |

### Application #2

BEL, Incorporated pays its employees monthly by direct deposit. On June 25, BEL, Incorporated prepared an ACH file on its PC software package for delivery to XYZ Trust. The file contains the information for the pay date of June 27.

The individual is being paid a total of \$30,000. Payroll information for BEL is listed below.

|              |             |
|--------------|-------------|
| NAME         | Ainge, Roy  |
| MEMBERSHIP # | 343-34-3434 |
| DUES         | \$30,000.00 |
| FI           | WXY Bank    |
| RTN          | 34513093    |

ACCT. # 7 78 0-87 69 (checking)

The ID number for BEL, Incorporated is a user assigned number: 333333331 The ID (Routing and ABA Number) for XYZ Trust is 27111111.

- WXY Bank responds to ACH PPD entries received, and prepares an ACH file with a batch that contains a single RETURN entry due to insufficient funds. It prepares another batch that contains a Notification of Change (COR) entry.
- The ACH file is delivered to the ACH Operator - TTY Services at WXY Bank which has a Routing Number of 34223222.

## ACH Refused Notification of Change Entry example

The example map shows how a Refused Notification of Change (COR) entry is prepared.

The example application shows the preparation of a file which consists of one batch. The batch carries one Refused Notification of Change entry.

- [What the example contains](#)  
The ACH Refused Notification of Change example contains these files, schemas, and maps.
- [How to run the example in Design Studio](#)  
Run the example map as follows.
- [How to run the example in Design Server](#)  
Run instructions for the ACH Refused Notification of Change example.
- [Scenarios](#)  
The Notification of Change (COR) entry is received by XYZ Trust.
- [Assumptions](#)  
These are the assumptions for the ACH Refused Notification of Change Entry example.

## What the example contains

The ACH Refused Notification of Change example contains these files, schemas, and maps.

### Files

This file is contained in the example:

- ach\_cor.in - input to the transformation map which contains a notification about a payroll transaction and corrected account information.

### Schemas

This schema is contained in the example:

- ach\_v2024 - current version of NACHA metadata.

### Maps

This map is contained in the example:

- ach\_refused\_cor - map that creates an ACH Refused Notification of Change entry from an ACH Notification of Change (COR) entry file.

## How to run the example in Design Studio

Run the example map as follows.

### Procedure

1. Use the Design Studio to open the following map source file: ach\_refused\_cor.mms
2. Build the map in the source file, and then run the transformation map.  
Comments that are associated with the rules are based on situations that are illustrated by the example.

- ach\_refused\_cor

## How to run the example in Design Server

Run instructions for the ACH Refused Notification of Change example.

### About this task

These steps describe how to run the ACH Refused Notification of Change example.

### Procedure

- 
1. Import the nachaRefusedNotificationOfChange.zip file into the Design Server UI. See the release notes for import instructions.
  2. Create a package for the project and build all the maps.
  3. Open the nachaRefusedNotificationOfChange project in the Design Server UI.
  4. Run the following map:
    - ach\_refused\_cor
  5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
  6. To download the output file, see [How to download output files](#).
- 

## Scenarios

The Notification of Change (COR) entry is received by XYZ Trust.

It contains one batch that carries a single COR entry. The COR entry sent by WXY Bank (the RDFI) sends the wrong Original Entry Trace Number. The Trace Number expected was 2711111000003 but it was sent as 27111110000303. XYZ Trust (the ODFI) receives the Notification of Change and cannot identify the original entry because of the error. The ODFI prepares a Refused Notification of Change.

---

## Assumptions

These are the assumptions for the ACH Refused Notification of Change Entry example.

Note: The ACH Refused Notification of Change Entry example relates to specific applications outlined here, and are not intended to depict situations which are always appropriate.

BEL, Incorporated pays its employees monthly by direct deposit. On June 25, BEL, Incorporated prepared an ACH file on its PC software package for delivery to XYZ Trust. The file contains the information for the pay date of June 27. One individual is being paid a total of \$30,000. Payroll information for BEL Incorporated is listed here:

|             |                         |
|-------------|-------------------------|
| NAME        | Ainge, Roy              |
| EMPLOYEE ID | 343-34-3434             |
| NET PAY     | \$30,000.00             |
| FI          | WXY Bank                |
| RTN         | 34513093                |
| ACCT. #     | 7 78 0-87 69 (checking) |

- The ID number for BEL, Corporation is a user assigned number: 333333331
  - The Routing and ABA Number for XYZ Trust is: 27111111. The Routing Number for its ACH Operator, LOL Services is: 27322225.
  - WXY Bank received the entry from XYZ Trust. The Original Entry carried a DFI Account Number of 7780-8769, but the correct DFI Account Number is 80-8769.
  - WXY Bank determines that the Roy Ainge account number was incorrect and prepares an ACH file with a batch that contains a single Notification of Change (COR) entry.
  - However, the Notification of Change contained an incorrect Original Entry Trace Number. The expected number was 2711111000003 but it was sent as 27111110000303. XYZ Trust was unable to reference the original entry with the incorrect Trace Number and responded with an ACH Refused Notification of Change entry.
- 

## ACH Dishonored Return example

The ACH Dishonored Return example map shows how a dishonored return entry is prepared.

The example application shows the preparation of a file which consists of one batch. The batch carries one dishonored return entry.

- [What the example contains](#)  
The ACH Dishonored Return example contains these files, schemas, and maps.
  - [How to run the example in Design Studio](#)  
Run the map example as follows.
  - [How to run the example in Design Server](#)  
Run instructions for the ACH Dishonored Return example.
  - [Scenarios](#)  
The following describes the scenario depicted in the ACH Dishonored Return Entry example.
  - [Assumptions](#)  
These are the assumptions for the ACH Dishonored Return entry example.
- 

## What the example contains

The ACH Dishonored Return example contains these files, schemas, and maps.

## Files

This file is contained in the example:

- ach\_return.in - input to the transformation map which contains membership due transaction that is being returned due to insufficient funds on the account holder.

## Schemas

---

This schema is contained in the example:

- ach\_v2024 - current version of NACHA type tree

## Maps

---

This map is contained in the example:

- ach\_dishonored\_return - map that creates an ACH Dishonored Return entry from an ACH Return entry file.

## How to run the example in Design Studio

---

Run the map example as follows.

### Procedure

---

1. Use the Design Studio to open the following map source file: ach\_dishonored\_return.mms
2. Build the map in the source file, and then run the transformation map.

Note: Comments that are associated with the rules are based upon situations that are illustrated by the example.

- ach\_dishonored\_return

## How to run the example in Design Server

---

Run instructions for the ACH Dishonored Return example.

### About this task

---

These steps describe how to run the ACH Dishonored Return example.

### Procedure

---

1. Import the nachaDishonoredReturn.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the nachaDishonoredReturn project in the Design Server UI.
4. Run the following map:
  - ach\_dishonored\_return
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).

## Scenarios

---

The following describes the scenario depicted in the ACH Dishonored Return Entry example.

The return entry is received by XYZ Trust, it contains one batch that carries a single return entry. The return had to be made available to the ODFI by opening of business on June 28 in order to be considered on time. For the purpose of this example, assume that the return was on June 27. However, due to ACH Operator hardware problems, XYZ Trust did not receive the return until June 29, instead of June 28. XYZ Trust is unable to post the return to AM Club's account because AM Club has declared bankruptcy. Thus, XYZ Trust suffers a loss and dishonors the return as untimely.

## Assumptions

---

These are the assumptions for the ACH Dishonored Return entry example.

Note: The ACH Dishonored Return entry example relates to specific applications that are outlined in the documentation provided here, and are not intended to depict situations that are always appropriate.

AM Club collects some of its monthly dues through ACH debit. On June 25, AM Club prepared an ACH file on its PC software package and delivered it to XYZ Trust over a modem. The file contains one collection for July dues. The entry total is \$600.00. AM Club's ID number is its tax ID, which is: 249999991

AM Club's customer information is listed below:

|              |              |
|--------------|--------------|
| NAME         | Connor, Beth |
| MEMBERSHIP # | 5130         |
| DUES         | \$600.00     |
| FI           | WXY Bank     |
| RTN          | 34513093     |

ACT. # 31872-76 54 8 (checking)

- XYZ Trust's ID, Routing and ABA Number, is 27111111. Its ACH Operator, LOL services' Routing Number is 27322225.
- WXY Bank received the following PPD entry from XYZ Trust. WXY Bank determined that Beth Connor's account has insufficient funds to cover the membership dues and sent back an ACH return entry on June 27.
- Due to a hardware problem, the ACH Operator was only able to deliver the ACH return to XYZ Trust on June 29 instead of the required June 28 date. At this point AM Club declared bankruptcy. The loss was, therefore, suffered by XYZ Trust. XYZ Trust then responds to the ACH return entry received with a Dishonored Return entry.

## ACH Contested Dishonored Return Entry example

The example map shows how an ACH contested dishonored return entry is prepared.

The example application shows the preparation of a file that consists of one batch. The batch carries one Contested Dishonored Return entry.

- [What the example contains](#)

The ACH Contested Dishonored Return example contains these files, schemas, and maps.

- [How to run the example in Design Studio](#)

Run the map example as follows:

- [How to run the example in Design Server](#)

Run instructions for the ACH Contested Dishonored Return example.

- [Scenarios](#)

The following scenario is depicted in the ACH Contested Dishonored Return Entry example.

- [Assumptions](#)

In the ACH Contested Dishonored Return Entry example, WXY Bank received the following PPD entries from XYZ Trust, which has started to originate ACH payments from customer AM Club.

## What the example contains

The ACH Contested Dishonored Return example contains these files, schemas, and maps.

### Files

This file is contained in the example:

- ach\_dshnrd\_rtrn.in - This file is the input to the transformation map which contains an ACH Dishonored Return entry.

### Schemas

This schema is contained in the example:

- ach\_v2024 - current version of NACHA type tree.

### Maps

This map is contained in the example:

- ach\_cntstd\_dshnrd\_rtrn - This map creates an ACH Contested Dishonored Return entry from an ACH Dishonored Return entry file.

## How to run the example in Design Studio

Run the map example as follows:

### Procedure

1. Use the Design Studio to open the following map source file: ach\_cntstd\_dshnrd\_rtrn.mms
2. Build the map in the source file, and then run the transformation map.

Note: Comments that are associated with the rules are based on situations that are illustrated by the example.

- ach\_cntstd\_dshnrd\_rtrn

## How to run the example in Design Server

Run instructions for the ACH Contested Dishonored Return example.

### About this task

These steps describe how to run the ACH Contested Dishonored Return example.

## Procedure

---

1. Import the nachaContestedDishonoredReturn.zip file into the Design Server UI. See the release notes for import instructions.
  2. Create a package for the project and build all the maps.
  3. Open the nachaContestedDishonoredReturn project in the Design Server UI.
  4. Run the following map:
    - ach\_cntstd\_dshnd\_rtrn
  5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
  6. To download the output file, see [How to download output files](#).
- 

## Scenarios

The following scenario is depicted in the ACH Contested Dishonored Return Entry example.

The dishonored return entry is received by WXY Bank. It disputes the fact that the original return was untimely. The return had to be made available to the ODFI by the opening of business on June 28 in order to be considered timely. WXY Bank transmitted the return on June 27, but due to hardware problems at the Receiving ACH Operator, the return was not settled until June 29. Thus, XYZ Trust, the originator of the dishonored return, considers the return to be untimely.

---

## Assumptions

In the ACH Contested Dishonored Return Entry example, WXY Bank received the following PPD entries from XYZ Trust, which has started to originate ACH payments from customer AM Club.

Note: The ACH Contested Dishonored Return entry example relates to specific applications that are outlined in the documentation provided here, and is not intended to depict situations that are always appropriate.

## Application 1

---

AM Club collects some of its monthly dues through use of ACH debit. On June 25, AM Club prepared an ACH file on its PC software package and delivered it to XYZ Trust by using a modem. The file contains one collection for July dues. The entries total \$600.00. AM Club's ID number is its tax ID - 249999991.

|              |                          |
|--------------|--------------------------|
| NAME         | Connor, Beth             |
| MEMBERSHIP # | 5130                     |
| DUES         | \$600.00                 |
| FI           | WXY Bank                 |
| RTN          | 34513093                 |
| ACT. #       | 31872-76 54 8 (checking) |

- XYZ Trust's ID (Routing and ABA Number) is 27111111.
  - WXY Bank received the following PPD entry from XYZ Trust. WXY Bank determined that Beth Connor account has insufficient funds to cover the membership dues and sent back an ACH return entry on June 27.
  - Due to a hardware problem, the ACH Operator was only able to deliver the ACH return to XYZ Trust on June 29 instead of the required June 28 date. At this point, AM Club declared bankruptcy. XYZ Trust suffered the loss and responded to the ACH return entry received with a Dishonored Return entry.
  - WXY Bank received the Dishonored Return entry and disputes the fact that the return was untimely, since it transmitted the return on June 27. Because of hardware problems at the Receiving ACH Operator, the return was not settled until June 29.
  - The ACH Contested Dishonored Return file will be delivered to WXY Bank's ACH Operator - TTY Services which has a Routing Number of 34223222.
- 

## ACH Payment Related Information example

The ACH Payment Related Information example demonstrates how to validate the content of the Payment Related Information field on the Addenda record, if it conforms to NACHA endorsed banking conventions.

The conventions are guides to participants involved in electronic payments as to the type of formats, definitions and implementation recommendations to facilitate processing of payment information electronically through the Automated Clearing House (ACH) Network.

- [What the example contains](#)  
The ACH Payment Related Information (PRI) example contains these files, schemas, and maps.
  - [How to run the example in Design Studio](#)  
Run the map example as follows:
  - [How to run the example in Design Server](#)  
Run instructions for the ACH Payment Related Information example.
  - [Scenarios](#)  
The example map shows an ACH file being validated with regard to the formatting of the Payment Related Information field on the Addenda Records if it conforms to the NACHA endorsed banking conventions.
  - [Assumptions](#)  
These are the assumptions for the examples.
- 

## What the example contains

The ACH Payment Related Information (PRI) example contains these files, schemas, and maps.

## Files

---

These files are contained in the example:

- pri.tst.rslt.001.xsd - metadata that represents the XML output reported by the example PRI validation map.
- ach\_pri\_example.in - input to the achpri01\_validate map which contains a total of 20 ACH batch records with various supported Payment Related Information field formats.
- ach\_error\_codes.txt - a resource file that consists of all error codes and descriptions used by the PRI validation map when generating XML output.

## Schemas

---

This schema is contained in the example:

- pri\_tst\_rslt - type tree that represents the place holder used by the example utility maps for each of the PRI validation results.
- pri\_fmt - type tree that represents different payment related information field formats based on NACHA endorsed banking conventions, and ANSI ASC X12 data segments.
- ach\_v2024 - current version of NACHA type tree.
- ach\_error\_codes - type tree that represents the ach\_error\_codes.txt file which lists all error codes.
- pri.tst.rslt.001.xsd - metadata that represents the XML output reported by the example PRI validation map.

## Maps

---

These maps are contained in the example:

- achpri02\_validate\_ack\_atx - utility map called by main map achpri01\_validate to validate the PRI field of ACH Payment Acknowledgement (ACK) and Financial EDI Acknowledgement (ATX) entries.
- achpri05\_validate\_dne - utility map called by main map achpri01\_validate to validate the PRI field of Death Notification Entry (DNE) entries.
- achpri03\_validate\_ccd - utility map called by main map achpri01\_validate to validate the PRI field of Corporate Credit or Debit Entry (CCD) entries.
- achpri06\_validate\_enr - utility map called by main map achpri01\_validate to validate the PRI field of Automated Enrollment Entry (ENR) entries.
- achpri08\_validate\_web - utility map called by main map achpri01\_validate to validate the PRI field of Internet-Initiated or Mobile Entry (WEB) entries.
- achpri07\_validate\_iat - utility map called by main map achpri01\_validate to validate the PRI field of International ACH Entry (IAT) entries.
- achpri04\_validate\_cie\_ppd - utility map called by main map achpri01\_validate to validate the PRI field of Customer Initiated Entry (CIE) and Prearranged Payment and Deposit Entries (PPD) entries.
- achpri01\_validate - the PRI main map used to validate the Addenda Record's PRI field.

## How to run the example in Design Studio

---

Run the map example as follows:

### Procedure

---

1. Use the Design Studio to open the following map source file: pri\_validation.mms.
2. Build all the maps in the source file and then run the map that is called achpri01\_validate.
3. Set all compiled maps with a .mmc extension.
4. Define the following directories for those operating systems other than Windows:
  - data
  - maps
  - schemas
5. When the artifacts listed here are copied to operating systems other than Windows, make certain that the FTP settings are set as described here.
  - a. FTP settings must be set to TEXT mode for the following input data:
    - ach\_pri\_example.in
    - ach\_error\_codes.txt
  - b. FTP settings must be set to BINARY mode for the following:
    - all compiled maps
    - pri.tst.rslt.001.xsd

## How to run the example in Design Server

---

Run instructions for the ACH Payment Related Information example.

## About this task

---

These steps describe how to run the ACH Payment Related Information example.

## Procedure

---

1. Import the nachaPaymentRelatedInfo.zip file into the Design Server UI. See the release notes for import instructions.
  2. Create a package for the project and build all the maps.
  3. Open the nachaPaymentRelatedInfo project in the Design Server UI.
  4. Run the following map:
    - achpri01\_validate
  5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
  6. To download the output file, see [How to run the example in Design Server](#).
- 

## Scenarios

---

The example map shows an ACH file being validated with regard to the formatting of the Payment Related Information field on the Addenda Records if it conforms to the NACHA endorsed banking conventions.

---

## Assumptions

---

These are the assumptions for the examples.

- The achpri01\_validate example map processes an ACH file with 20 batch records. The example map goes through each batch record. Depending upon the Standard Entry Class (SEC) codes, the example map verifies the format of the Payment Related Information field on the Addenda Record.
- For ACH Payment Acknowledgement (ACK) and Financial EDI Acknowledgement (ATX) entries, the Payment Related Information field must contain an ANSI version release 5010 ASC X12 REF (Reference) data segment.
- For Corporate Credit or Debit Entry (CCD) entries, Payment Related Information field must contain an ANSI ASC X12 data segment, or NACHA endorsed banking conventions (that is Tax Payment, Third-Party Tax Payments, or Child Support).
- For Corporate Credit or Debit Entry (CCD) entries that are used for Healthcare EFT transactions, the Company Entry Description field on the Batch Record has a value that is set to HCCLAIMPMT. Also, the Payment Related Information field must contain an ANSI version release 5010 ASC X12 TRN (Re-association Trace Number) data segment.
- For Corporate Credit or Debit Entry (CCD) entries that are used for Tax Payment, the Payment Related Information field must contain a variant of the ANSI version release 3060 ASC X12 TXP (Tax Payment) data segment. For more information, see the NACHA endorsed, *Tax Payment (TXP) Banking Convention* implementation guide. This implementation guide is available at the following website: <https://www.nacha.org/bankingconvention>
- For Corporate Credit or Debit Entry (CCD) entries that are used for Third-Party Tax Payment, the Payment Related Information field must contain an ASC X12 TPP (Third-Party Tax Payment) data segment. For more information, see the NACHA endorsed, *Third-Party Tax Payment (TPP) Banking Convention* implementation guide. This implementation guide is available on the following website: <https://www.nacha.org/bankingconvention>
- For Corporate Credit or Debit Entry (CCD) entries that are used for Child Support, the Payment Related Information field must contain a variant of ANSI version release 4010 ASC X12 DED (Child Support) data segment. For more information, see the NACHA endorsed, *Child Support (DED) Banking Convention* implementation guide. This implementation guide is available on the following website: <https://www.nacha.org/bankingconvention>
- For Customer Initiated Entry (CIE), Pre-arranged Payment and Deposit Entries (PPD), *Internet-Initiated/Mobile Entries* (WEB debit entries), the Payment Related Information field must contain ANSI ASC X12 data segments.
- For *Internet-Initiated/Mobile Entries* (WEB credit entries), the Payment Related Information field content does not have any formatting requirements.
- For Death Notification Entries (DNE) entries, the Payment Related Information field must contain one of either of the following two NACHA endorsed banking conventions.
  - DATE OF DEATH\*MMDDYY\*CUSTOMERSSN\*#####\*AMOUNT\*\$\$\$\$.cc~
  - DATE OF DEATH\*MMDDYY\*CUSTOMERSSN\*#####\*AMOUNT\*\$\$\$\$.cc~
- In Automated Enrollment Entry (ENR) entries, the Payment Related Information field must contain one of either of the following two NACHA endorsed banking conventions.
  - TRANSACTION CODE (2 CHARS)\*RECEIVING DFI IDENTIFICATION NUMBER (8 CHARS)\*CHECK DIGIT (1 CHAR)\*DFI ACCOUNT NUMBER (MAX 17 CHARS)\*INDIVIDUAL ID NUMBER OR ID NUMBER (9 CHARS)\*INDIVIDUAL SURNAME OR COMPANY NAME(MAX 15 CHARS)\*INDIVIDUAL FIRST NAME OR COMPANY NAME(MAX 7 CHAR)\*REPRESENTATIVE PAYEE INDICATOR/ENROLLEE CLASSIFICATION CODE(1 CHAR)\
  - TRANSACTION CODE (2 CHARS)\*RECEIVING DFI IDENTIFICATION NUMBER (8 CHARS)\*CHECK DIGIT (1 CHAR)\*DFI ACCOUNT NUMBER (MAX 17 CHARS)\*INDIVIDUAL ID NUMBER OR ID NUMBER (9 CHARS)\*INDIVIDUAL SURNAME OR COMPANY NAME(MAX 15 CHARS)\*INDIVIDUAL FIRST NAME OR COMPANY NAME(MAX 7 CHAR)\*REPRESENTATIVE PAYEE INDICATOR/ENROLLEE CLASSIFICATION CODE(1 CHAR)~
- For International ACH Entry (IAT) entries with the Transaction Type Code field within the First IAT Addenda Record. If this field contains ARC, BOC, or RCK, the Payment Related Information field must contain either of the following NACHA endorsed banking conventions:
  - CHECK SERIAL NUMBER
  - CHECK SERIAL NUMBER~
- For International ACH Entry (IAT) entries with the Transaction Type Code field within the First IAT Addenda Record. If this field contains POP, the Payment Related Information field must contain one of either of the following two NACHA endorsed banking conventions.
  - CHECK SERIAL NUMBER (MAX 9 CHARS)\*TERMINAL CITY (MAX 4 CHARS)\*TERMINAL STATE/FOREIGN COUNTRY (2 CHARS)\
  - CHECK SERIAL NUMBER (MAX 9 CHARS)\*TERMINAL CITY (MAX 4 CHARS)\*TERMINAL STATE/FOREIGN COUNTRY (2 CHARS)~
- For International ACH Entry (IAT) entries with the Transaction Type Code field within the First IAT Addenda Record. If this field contains MTE, POS, or SHR, the Payment Related Information field must contain one of the following two NACHA endorsed banking conventions.
  - TERMINAL IDENTIFICATION CODE(MAX 6 CHARS)\*TERMINAL LOCATION (MAX 27 CHARS)\*TERMINAL CITY (MAX 15 CHARS)\*TERMINAL STATE or FOREIGN COUNTRY (2 CHARS)\
  - TERMINAL IDENTIFICATION CODE(MAX 6 CHARS)\*TERMINAL LOCATION (MAX 27 CHARS)\*TERMINAL CITY (MAX 15 CHARS)\*TERMINAL STATE or FOREIGN COUNTRY (2 CHARS)~
- The example map supports only the following SEC codes, ACK, ATX, CCD, CIE, PPD, DNE, ENR, IAT, and WEB entries.
- The example map requires an input ACH file that passes the ACH 2024 type tree validation.
- The achpri01\_validate example map generates an XML output document that consists of the following information about the ACH file.

- File record information
  - Immediate Origin
  - Immediate Origin Name
  - File Creation Date
  - File Creation Time
  - File ID Modifier
  - File Entry / Addenda Count
  - File Total Debit Entry Dollar Amount
  - File Total Credit Entry Dollar Amount
  - File Batch Count
  - File Date / Time Processed
- Batch record information
  - Batch Number
  - Originating DFI Id
  - Company Name
  - Company Id
  - Effective Entry Data
  - Batch Entry/Addenda Count
  - Batch Total Debit Entry Dollar Amount
  - Batch Total Credit entry Dollar Amount
- Entry detail record information
  - Receiving DFI ID
  - Receiving Company Name/Id Number
  - Trace Number
  - ACH (SEC) Entry Code
  - ACH (SEC) Entry Is Supported Flag (true or false)
- Addenda Record Information
  - Entry Detail Sequence Number
  - Addenda Sequence Number
  - Payment Related Information (PRI)
- PRI Validation Information
  - Reason of Failure
  - Status (PASS or FAIL)
- Out of the 20 batch records contained in the input ACH file (ach\_pri\_example.in), the example map detects two batch records with a Payment Related Information field that is not compliant with NACHA endorsed banking conventions. The two batch records are listed here:
  - Batch Number: 4444442, due to a missing TRN data segment on the Payment Related Information field on a Healthcare EFT CCD entry.
  - Batch Number: 4444445, due to a mismatch between the value that is set on the amount field of the Entry Detail Record and the TPP04 amount data element on the Payment Related Information field.

## ACH Return Entries Report example

The example map shows how ACH return entries are extracted from an ACH file. The return entries are reported in categories that are returned due to administrative, unauthorized reasons and all other reasons (except for returned RCK entries).

The example application shows an ACH file input that has two batch entries that contain CCD return entries, and two batch entries that contain BOC return entries.

- [What the example contains](#)  
The ACH Return Entries Report example contains these files, schemas, and maps.
- [How to run the example in Design Studio](#)  
This documentation describes how to run the ACH Return Entries Report example.
- [How to run the example in Design Server](#)  
Run instructions for the ACH Returned Entries Report example.
- [Example scenario](#)  
The example map shows ACH Return entries that are extracted from an ACH file and reported per category.
- [Example assumptions](#)  
The ACH Return Entries Report example contains four applications.

## What the example contains

The ACH Return Entries Report example contains these files, schemas, and maps.

### Files

This file is contained in the example:

- ach\_rtrn\_report\_example.in - input to the map which contains ACH Returns of both corporate and consumer entities.

### Schemas

These schemas are contained in the example:

- ach\_v2024 - current version of NACHA type tree.
- ach\_rtrn\_csv - metadata describing the format of an arbitrary report generated by the map.

## Maps

---

This map is contained in the example:

- ach\_rtrn\_report - map that creates distinct reports for ACH entries returned due to unauthorized, administrative, and other reasons from an ACH Return entry file.
- 

## How to run the example in Design Studio

This documentation describes how to run the ACH Return Entries Report example.

### About this task

---

Follow these procedures to run the map example:

### Procedure

---

1. Use the Design Studio to open the following map source file: ach\_rtrn\_report.mms
2. Build the map in the source file, and then run the transformation map.

Note: Comments that are associated with the rules are based on situations that are illustrated by the example.

- achrtn01\_reports
- 

## How to run the example in Design Server

Run instructions for the ACH Returned Entries Report example.

### About this task

---

These steps describe how to run the ACH Returned Entries Report example.

### Procedure

---

1. Import the nachaReturnedEntriesReport.zip file into the Design Server UI. See the release notes for import instructions.
  2. Create a package for the project and build all the maps.
  3. Open the nachaReturnedEntriesReport project in the Design Server UI.
  4. Run the following map:
    - achrtn01\_reports
  5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
  6. To download the output file, see [How to download output files](#).
- 

## Example scenario

The example map shows ACH Return entries that are extracted from an ACH file and reported per category.

These categories are reported:

- Administrative (with reason codes R02, R03, R04).
  - Unauthorized (with reason codes R05, R07, R10, R29, R51)
  - Others (all other reason codes except for returned RCK entries, that is, R50, R51, R52, R53). The reports are formatted by using comma-separated values (CSV).
- 

## Example assumptions

The ACH Return Entries Report example contains four applications.

- [Application 1](#)  
COC Export (tax ID: 1006999991) collects corporate receivables from the trading partners that are shown here.
  - [Application 2](#)  
NWNW Import (tax id : 1394440909) collects corporate donations from trading partners.
  - [Application 3](#)  
ACE University (tax ID: 1889383922) collects tuition fees from students and prepares an ACH file.
  - [Application 4](#)  
WOW Gym (tax ID: 1129988333) collects monthly dues from members and prepares an ACH file.
- 

## Application 1

COC Export (tax ID: 1006999991) collects corporate receivables from the trading partners that are shown here.

An ACH file is prepared and sent to COC Export's financial institution, DDD Trust (routing number: 839289911). DDD Trust receives the information and prepares the ACH file for delivery to its ACH Operator (III Services).

|                    |                   |
|--------------------|-------------------|
| NAME:              | Foo Inc.          |
| TRADING PARTNER ID | 475784R           |
| DUES               | \$500.00          |
| FI                 | EEE Bank          |
| RTN                | 14300390          |
| ACCT #             | 49857-80494-33397 |
| NAME               | Mr West LLC       |
| TRADING PARTNER ID | 384107R           |
| DUES               | \$500.00          |
| FI                 | EEE Bank          |
| RTN                | 14300390          |
| ACCT #             | 04942-94873-92843 |

Original entries are received by the RDFI, but EEE Bank cannot post the \$500.00 entry for Foo Inc's account because of return reason code 'R05' (Unauthorized Debit to Consumer Account Using Corporate SEC Code).

EEE Bank also failed to post the \$500.00 for Mr West LLC's account because of return reason code 'R14' (Representative Payee Deceased or Unable to Continue in That Capacity).

---

## Application 2

NWNW Import (tax id : 1394440909) collects corporate donations from trading partners.

An ACH file is prepared and sent to NWNW Import's financial institution, ZZZ Trust (routing number : 012344110). ZZZ Trust receives the information and prepares the ACH file for delivery to its ACH Operator (IV Services).

|                    |                   |
|--------------------|-------------------|
| NAME               | GGG Limited       |
| TRADING PARTNER ID | G933984           |
| DUES               | \$500.00          |
| FI                 | EEE Bank          |
| RTN                | 14300390          |
| ACCT #             | 38738-93838-34747 |
| NAME               | HOGS Meat Inc.    |
| TRADING PARTNER ID | G983988           |
| DUES               | \$500.00          |
| FI                 | EEE Bank          |
| RTN                | 14300390          |
| ACCT #             | 56533-00930-53636 |

Original entries are received by the RDFI, but EEE Bank cannot post the \$500.00 entry for GGG Limited's account because of the return reason code 'R07' (Authorization Revoked by Customer).

EEE Bank also failed to post the \$500.00 to the Hogs Meat Inc. account because of the return reason code 'R03' (No Account/Unable to Locate Account).

---

## Application 3

ACE University (tax ID: 1889383922) collects tuition fees from students and prepares an ACH file.

This ACH file is sent to ACE University's financial institution, SOS Trust (routing number: 039042217). SOS Trust receives the information and prepares the ACH file for delivery to its ACH Operator (VI Services).

|            |                   |
|------------|-------------------|
| NAME       | Fisher, Timothy   |
| STUDENT ID | 15309384-MS       |
| DUES       | \$500.00          |
| FI         | EEE Bank          |
| RTN        | 14300390          |
| ACCT #     | 33339-84844-88859 |
| NAME       | Hooper, Edmond    |
| STUDENT ID | 49349875-CS       |
| DUES       | \$500.00          |
| FI         | EEE Bank          |
| RTN        | 14300390          |
| ACCT #     | 66637-00933-55598 |

Original entries are received by the RDFI, but EEE Bank cannot post the \$500.00 entry to the Timothy Fisher account, because of return reason code 'R10' (Customer Advises Not Authorized, Improper, Ineligible, or part of an Incomplete Transaction).

EEE Bank also failed to post the \$500.00 for Edmond Hooper's account because of return reason code 'R04' (Invalid Account Number)

## Application 4

WOW Gym (tax ID: 1129988333) collects monthly dues from members and prepares an ACH file.

The ACH file is sent to WOW Gym's financial institution, PPP Trust (routing number: 112300478). PPP Trust receives the information and prepares the ACH file for delivery to its ACH Operator (VII Services).

|           |                   |
|-----------|-------------------|
| NAME      | McPearson, Jessie |
| MEMBER ID | M39987432         |
| DUES      | \$500.00          |
| FI        | EEE Bank          |
| RTN       | 14300390          |
| ACCT #    | 63636-18273-03287 |
| NAME      | Oneil, Sharon     |
| MEMBER ID | Y40984303         |
| DUES      | \$500.00          |
| FI        | EEE Bank          |
| RTN       | 14300390          |
| ACCT #    | 87490-29743-84787 |

Original entries are received by the RDFI, but EEE Bank cannot post the \$500.00 entry for Jessie McPearson's account because of the return reason code 'R02' (Account Closed).

EEE Bank also failed to post the \$500.00 for Sharon Oneil's account because of the return reason code 'R01' (Insufficient Funds).

## ACH Validation example

The ACH Validation example demonstrates how to validate an ACH file if it conforms to NACHA Operating Rules. The base implementations are derived from the ACH type treerules and are not designed to replace the use of the ACH type tree.

The ACH validation example can be used to further investigate ACH type tree failures.

- [What the example contains](#)  
The ACH Validation example contains these files, schemas, and maps.
- [How to run the example in Design Studio](#)  
The ACH validation example demonstrates how to validate whether an ACH file conforms to NACHA operating rules.
- [How to run the example in Design Server](#)  
Run instructions for the ACH Validation example.
- [Scenarios](#)  
The ACH validation example demonstrates how to validate whether an ACH file conforms to NACHA operating rules.
- [Assumptions](#)  
These are the assumptions for the validation scenario.

## What the example contains

The ACH Validation example contains these files, schemas, and maps.

### Files

These files are contained in the example:

- ach\_sec\_example.in - input to the achval01 map which contains a total of 13 supported ACH Standard Entry Class codes.
- ach\_config.xml - input to the achval01 map which contains the ACH record/field properties, and attributes to configure validation and reporting.
- ach\_error\_codes.txt - a resource file that consists of all error codes and descriptions used by the maps when generating XML output.

### Schemas

These schemas are contained in the example:

- ach\_v2024 - current version of NACHA type tree.
- ach\_v2024\_sfmt - current version of NACHA sfmt type tree.
- ach\_config.xsd - XML schema that represents the ACH Standard Entry Class records. Also contains user configurable property settings. In this file you should:
  - Treat required fields as optional.
  - Generate compliance report for exceptions only.
- ach\_parse\_info.xsd - XML schema that is used to enforce validation rules on the ACH file.
- ach\_validation\_report.xsd - XML schema that represents the layout of the validation report.
- ach\_generic - metadata that represents the ACH records which are valid, out-of-sequence, and unknown ACH record types.

- ach\_error\_codes - metadata that represents the ach\_error\_codes.txt file which lists all error codes.

## Maps

---

These maps are contained in the example:

- achval01 - the main map used to validate an ACH File.
- achval02 - utility map called by main map which handles unknown ACH record types, and ACH records that are out-of-sequence.
- achval03 - utility map called by main map to generate a report of ACH records and fields which have validation exceptions.
- achval04 - utility map called by main map to generate a report of duplicate ACH records.

---

## How to run the example in Design Studio

The ACH validation example demonstrates how to validate whether an ACH file conforms to NACHA operating rules.

### About this task

---

The base implementations are based on the ACH type tree rules and are not designed to replace the use of the ACH type tree. This ACH validation example can be used to further investigate any ACH type tree failures.

### Procedure

---

1. Use the Design Studio to open the following map source file: ach\_validation.mms
2. Build all maps that are contained in the source file. Run the achval01 map.
3. Set all compiled maps with the .mmc extension.
4. Define the following directories for operating systems other than Windows:
  - data
  - maps
  - schemas
5. When the artifacts listed here are copied to operating systems other than Windows, make certain that the FTP settings are set as described in a and b:
  - a. Set FTP settings to TEXT mode for the following input data:
    - ach\_sec\_example.in
    - ach\_error\_codes.txt
  - b. Set FTP settings to BINARY mode for the following items:
    - All compiled maps
    - All XML schema files
    - ach\_config.xml
6. For MVS, edit the following map card setting of the Schema->Type->Metadata to //DD:ddname where ddname references the XML schema ach\_config.xsd
  - a. achval01asf
    - input card #2 (ach\_config.xsd)
    - output card #1 (ach\_parse\_info.xsd)
  - b. achval02
    - output card #1 (ach\_parse\_info.xsd)
  - c. achval03
    - input card #1 (ach\_validation\_report.xsd)
    - output card #1 (ach\_validation\_report.xsd)

---

## How to run the example in Design Server

Run instructions for the ACH Validation example.

### About this task

---

These steps describe how to run the ACH Validation example.

### Procedure

---

1. Import the nachaValidation.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the nachaValidation project in the Design Server UI.
4. Run the following map:
  - achval01
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).

---

## Scenarios

The ACH validation example demonstrates how to validate whether an ACH file conforms to NACHA operating rules.

## Assumptions

These are the assumptions for the validation scenario.

- The achval01 example map processes an ACH file with 13 batch records. The example map goes through each ACH record and verifies the format of the File Header, Batch Header, Entry Detail, Addenda, Batch Control and File Control record formats.

The input file contains the following:

- Standard Entry Class (SEC)
- CCD (Corporate Credit or Debit)
- CIE (Customer Initiated Entry)
- CTX (Corporate Trade Exchange)
- MTE (Machine Transfer Entry)
- POS (Point of Sale)
- PPD (Pre-arrange Payment and Deposit Entry)
- RCK (Re-presented Check Entry)
- SHR (Shared Network Transaction)
- TEL (Telephone-Initiated Entry)
- WEB (Internet-Initiated/Mobile Entry)

- The configuration file ach\_config.xml can be edited for these actions:

- Treat the required field as optional. Default is 'YES.'
- Generate a report for ACH fields that have exceptions. Default is 'YES.'
- Enforce validation on an ACH field. Default is 'true.'

Note: Note: Keeping the rest of the settings is recommended, since they are used internally by the maps to process ACH records as defined in the NACHA rule book.

- The achval01 example map generates an XML output document that consists of the following information about the ACH file:

1. ACH record info

- name
- value
- line number

2. ACH field info

- name
- value

3. ACH configuration info

- column number
- length
- attribute type
- validation flag
- requirement attribute

4. Exception info

- description of reason of failure
- status (Pass or Fail)

Note: Of the 13 batch records contained in the input ACH file (ach\_sec\_example.in), the example map detects the last batch record with a WEB SEC code which is noncompliant with NACHA Operating rules. The invalid batch record is listed here:

- Batch Number: 2222800, due to a mismatch of the Company Identification field between the value set on the Batch Header record and Batch Control record.

## How to download output files

Download the output files.

### About this task

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

### Procedure

1. Click the output Card Settings you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:

```
data/ach_contested_dishonored_return.out
```

copy only:

```
ach_contested_dishonored_return.out
```

3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.
6. Click Ok.
7. Build and run the map.
8. Go to Files and select Download to view the data.

# IBM Sterling B2B Integrator examples

See IBM Sterling B2B Integrator for a complete description of these examples, including deployment instructions.

## Related concepts

- [IBM Sterling B2B Integrator](#)

## IBM Sterling B2B Integrator

In IBM Sterling B2B Integrator, a service is a resource that you can configure to carry out an activity.

A typical activity scenario is one where ACH files must be sent to a trading partner. In preparation for this, the data must be enveloped in order to provide identifying batch and interchange data. The IBM Sterling B2B Integrator business process calls the ACH Envelope process to perform enveloping services, while the ACH Deenvelope process provides de-enveloping services.

A document envelope consists of control information that enables organizations to effectively exchange documents. The document envelope takes the original document, assigns a control number, and packages header and trailer information with it prior to submitting it to a trading partner. Creating document envelopes are necessary if you want to do electronic exchange of data with your trading partners.

The pack examples for IBM Sterling B2B Integrator demonstrate the following:

- Creates fully enveloped ACH outbound messages.
- Processes inbound ACH messages.
- Uses Transformation Extender maps for data transformation.

Transformation Extender maps can run within the IBM Sterling B2B Integrator services on some, but not all, versions of the Transformation Extender base product. See the product release notes for those versions of the base product that support IBM Sterling B2B Integrator.

- [Directory structure of the IBM Sterling B2B Integrator examples](#)

The examples for use of IBM Sterling B2B Integrator with the NACHA component include transformation maps, corresponding type trees, test data, and exported IBM Sterling B2B Integrator artifacts.

These procedures describe how to run the ACH Deenvelope and ACH Envelope services examples from Transformation Extender, and from IBM Sterling B2B Integrator.

- [Design considerations of the examples](#)

The documentation provided here describes design features and concepts that were taken into account when building the example transformation maps invoked by the ACH Deenvelope and ACH Envelope services

## Directory structure of the IBM Sterling B2B Integrator examples

The examples for use of IBM Sterling B2B Integrator with the NACHA component include transformation maps, corresponding type trees, test data, and exported IBM Sterling B2B Integrator artifacts.

The IBM Sterling B2B Integrator artifacts include trading partner envelopes, business processes and schemas that are relevant when executing the Transformation Extender map within IBM Sterling B2B Integrator.

The table shows the directory structure used for processing ACH CTX data using both IBM Sterling B2B Integrator ACH Deenvelope and ACH Envelope services.

Table 1. Directory structure for the ACH Deenvelope service examples

| Directory structure                             | Description                                                      |
|-------------------------------------------------|------------------------------------------------------------------|
| ./examples/sterling/services/ach_deenvelope/ctx | Contains the ACH Deenvelope service CTX example.                 |
| ./data                                          | Placeholder for input test data.                                 |
| ./maps                                          | Placeholder for the transformation maps.                         |
| ./platform_support                              | Placeholder for IBM Sterling B2B Integrator import(.xml) files.  |
| ./examples/sterling/services/ach_deenvelope/dne | Contains the ACH Deenvelope service DNE example.                 |
| ./data                                          | Placeholder for input test data.                                 |
| ./maps                                          | Placeholder for the transformation maps.                         |
| ./platform_support                              | Placeholder for IBM Sterling B2B Integrator import (.xml) files. |

Table 2. Directory structure for the ACH Envelope service examples

| Directory structure                          | Description                                    |
|----------------------------------------------|------------------------------------------------|
| /examples/sterling/services/ach_envelope/ctx | Contains the ACH Envelope service CTX example. |
| ./data                                       | Placeholder for input test data.               |

| Directory structure                          | Description                                                      |
|----------------------------------------------|------------------------------------------------------------------|
| ..maps                                       | Placeholder for the transformation maps.                         |
| ..platform_support                           | Placeholder for IBM Sterling B2B Integrator import (.xml) files. |
| /examples/sterling/services/ach_envelope/dne | Contains the ACH Envelope service DNE example.                   |
| ..data                                       | Placeholder for the input test data.                             |
| ..maps                                       | Placeholder for the transformation maps.                         |
| ..platform_support                           | Placeholder for IBM Sterling B2B Integrator import (.xml) files. |

Table 3. CTX and DNE trees and schemas

| Directory structure                 | Description                                                                                           |
|-------------------------------------|-------------------------------------------------------------------------------------------------------|
| /examples/sterling/services/schemas | Placeholder for the schemas used to represent IBM Sterling B2B Integrator proprietary ACH xml format. |
| /examples/sterling/services/trees   | Placeholder for the type trees used in the examples.                                                  |

## ACH Deenvelope CTX example

The inbound\_ach\_ctx.mms file is the map source for this example.

The map source installs into the following directory location:

```
<install_dir>/packs/financial_payments_vn.n.n.n/nacha/examples/sterling/services/ach_deenvelope/ctx/maps
```

The following maps are contained in this map source:

- x12\_ra\_to\_xml\_ctx - This map transforms an X12 5010X218 820 Payment/Order Remittance Advice (RA) file to the IBM Sterling B2B Integrator XML format that represents CTX record format. This XML format is based from custom IBM Sterling B2B Integrator transformation maps.
- x12\_ra\_to\_flat\_rpt - This map is a post-processing map that transforms an X12 5010X218 820 Payment Order/Remittance Advice (RA) file to an arbitrary back office flat file which corresponds to a payment order report.
- x12\_ra\_to\_atx\_pri - This map extracts, from the X12 5010X218 820 Payment Order/Remittance Advice (RA) file, the main REF segment and populates this as the Payment Related Information of the addenda record of the ATX acknowledgement entry.
- xml\_ctx\_to\_csv\_ctx - This map converts an ACH CTX message in XML format into a comma-separated value file format. This XML format is based from the ACH service and is included as part of the process data of the IBM Sterling B2B Integrator.

XML schemas are generated to represent the IBM Sterling B2B Integrator ACH XML format.

Note: The NACHA component of the Pack for Financial Payments is delivered with XML schemas to represent the IBM Sterling B2B Integrator proprietary XML format. See [ACH service XML schemas](#).

## ACH Envelope CTX example

The outbound\_ach\_ctx.mms file is the map source for this example.

The maps source installs into the following directory location:

```
<install_dir>/packs/financial_payments_vn.n.n.n/nacha/examples/sterling/services/ach_envelope/ctx/maps
```

The following map is contained in this map source:

- x12\_ra\_to\_xml\_ctx - This map transforms an X12 5010X218 820 Payment Order/Remittance Advice (RA) file to the IBM Sterling B2B Integrator proprietary XML format that represents CTX record format. This XML format is based on custom IBM Sterling B2B Integrator maps.

Note: This map is the same as the map used in the ACH Deenvelope example, but the purpose of its use in the ACH envelope and deenvelope services are different. This map is used for validation in the ACH Deenvelope service, while for the ACH Envelope service, it is used for transformation.

## ACH Deenvelope DNE example

The inbound\_ach\_dne.mms file is the map source for this example.

The map source installs into the following directory location:

```
<install_dir>/packs/financial_payments_vn.n.n.n/nacha/examples/sterling/services/ach_deenvelope/dne/maps
```

The following files are contained in this map source:

- inbound\_dne\_pri\_to\_xml - This map is used to transform payment related information (PRI) from an ACH DNE addenda record into an XML format. The output of this map will be appended to the IBM Sterling B2B Integrator proprietary XML format of the ACH message, as translated payment related information of the addenda records.
- xml\_dne\_to\_dne\_flat - This map is used to transform proprietary, IBM Sterling B2B Integrator XML format, to an arbitrary back office DNE flat file with fixed length positional elements, that corresponds to an ACH DNE addenda record format.
- create\_dne\_pri - This miscellaneous map is used to generate payment information for a ACH DNE addenda record.
- validate\_dne\_pri - This is a miscellaneous map that is used to validate a file consisting of payment related information of an ACH DNE addenda record.

## ACH Envelope DNE example

The outbound\_ach\_dne.mms file is the map source for this example.

The map source installs into the following directory location:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/nacha/examples/sterling/services/ach\_envelope/dne/maps

The following maps are contained in this map source:

- **outbound\_dne\_entryDtls** - This map is used to extract an arbitrary back office ACH DNE flat file with fixed length positional elements that corresponds to an ACH DNE entry detail record format. The back-office DNE record excludes the following fields: **record type code**, **AddendaRecordIndicator**, and **TraceNumber**. These fields are populated by the ACH Envelope service.
- **outbound\_dne\_addenda** - This map is used to extract an arbitrary back office ACH DNE flat file with fixed length positional elements that corresponds to an ACH DNE addenda record format. The back-office DNE record excludes the following fields: **record type code**, **addenda sequence number**, and **entry detail sequence number**. These fields are populated by the ACH Envelope service.
- **create\_dne\_flat** - This is a miscellaneous map that is used to generate an arbitrary back office DNE flat file with fixed length positional elements.
- **validate\_dne\_flat** - This is a miscellaneous map that is used to validate an arbitrary back office DNE flat file with fixed length positional elements.

## Deploying and executing the IBM Sterling B2B Integrator examples

These procedures describe how to run the ACH Deenvelope and ACH Envelope services examples from Transformation Extender, and from IBM Sterling B2B Integrator.

The example maps call the IBM Sterling B2B Integrator adapter to write values to IBM Sterling B2B Integrator tables. Because of this, the map fails if you attempt to run the map outside of IBM Sterling B2B Integrator. You can, however, test the map from Design Studio by using the Run on Sterling B2B Integrator option.

Design Studio preferences must be configured to connect to the IBM Sterling B2B Integrator. See the Transformation Extender Map Designer documentation for more information.

- [Deploying the example maps to IBM Sterling B2B Integrator](#)

Maps are deployed using either Design Studio, or through use of the IBM Sterling B2B Integrator.

- [Running the ACH service examples](#)

The documentation provided here describes how to run the ACH Deenvelope service and the ACH Envelope service examples.

- [Expected results](#)

The documentation provided here describes the results returned from the ACH Deenvelope CTX and DNE examples, and the ACH Envelope CTX and DNE examples.

## Deploying the example maps to IBM Sterling B2B Integrator

Maps are deployed using either Design Studio, or through use of the IBM Sterling B2B Integrator.

- [Deploying the map using the Design Studio](#)

This documentation describes how to deploy the map to IBM Sterling B2B Integrator using Design Studio.

- [Deploying the map using IBM Sterling B2B Integrator](#)

The following procedures describe an alternate method of checking in the map by using the IBM Sterling B2B Integrator dashboard.

## Deploying the map using the Design Studio

This documentation describes how to deploy the map to IBM Sterling B2B Integrator using Design Studio.

### Procedure

1. Configure the Design Studio preferences before you attempt to connect to the IBM Sterling B2B Integrator server. See the Design Studio documentation for more information.
2. Open the source map in Design Studio.
3. Right click on the map, then choose Deploy to Sterling B2B Integrator. Enter your ID and password if you are prompted.

## Deploying the map using IBM Sterling B2B Integrator

The following procedures describe an alternate method of checking in the map by using the IBM Sterling B2B Integrator dashboard.

### Procedure

1. Compile the source maps for the correct platform on which the IBM Sterling B2B Integrator is installed.
2. From the IBM Sterling B2B Integrator dashboard, go to Deployment > Maps, then select the Check in new Map from Map Editor option.  
If the map has already been deployed to the IBM Sterling B2B Integrator, you can update it by first searching for, and locating the map. You can then use the Map Source Manager to check out the map and check in the new version.

## Running the ACH service examples

The documentation provided here describes how to run the ACH Deenvelope service and the ACH Envelope service examples.

To run the examples, you must first perform the following activities:

- Import IBM Sterling B2B Integrator artifacts
- Deploy the map to IBM Sterling B2B Integrator
- **[Importing IBM Sterling B2B Integrator artifacts for ACH service examples](#)**  
From the IBM Sterling B2B Integrator dashboard, import one of the following files from the platform\_support directory of the example.
- **[Running the ACH service examples from the Transformation Extender](#)**  
The following procedures describe how to run the ACH Deenvelope and ACH Envelope examples from the Transformation Extender.
- **[Running the ACH service examples from IBM Sterling B2B Integrator](#)**  
The following procedures describe how to run the ACH Deenvelope and ACH Envelope examples using the IBM Sterling B2B Integrator dashboard.

## Importing IBM Sterling B2B Integrator artifacts for ACH service examples

From the IBM Sterling B2B Integrator dashboard, import one of the following files from the platform\_support directory of the example.

### About this task

- If you are running the CTX Deenvelope example, import: ExportACHctxDeenvSIOBJECTS.xml
- If you are running the CTX Envelope example, import: ExportACHctxEnvSIOBJECTS.xml
- If you are running the DNE Deenvelope example, import: ExportACHdneDeenvSIOBJECTS.xml
- If you are running the DNE Envelope example, import: ExportACHdneEnvSIOBJECTS.xml

### Procedure

1. Log in to the IBM Sterling B2B Integrator dashboard.
2. From the Administration menu, expand the Deployment and Resource Manager sections, and then select the Import/Export option.
3. Choose the Import Resources option.
  - a. For the ACH Deenvelope services example for CTX, select: ExportACHctxDeenvSIOBJECTS.xml
  - b. For the ACH Envelope services example for CTX, select: ExportACHctxEnvSIOBJECTS.xml
  - c. For the ACH Deenvelope services example for DNE, select: ExportACHdneDeenvSIOBJECTS.xml
  - d. For the ACH Envelope services example for DNE, select: ExportACHdneEnvSIOBJECTS.xml
4. Enter "password" as the Passphrase, and then check the Import All Resources check box.
5. Click Next.
6. In the Create Resource Tag window, leave the Tag Name and Tag Description entries blank and then click Next.
7. In the Update Objects window, select Yes to update objects if they exist in the system, and then click Next.
8. In the Confirm window, click Finish.
9. View the Import and Performance reports. When finished, click Return.

## Running the ACH service examples from the Transformation Extender

The following procedures describe how to run the ACH Deenvelope and ACH Envelope examples from the Transformation Extender.

### Procedure

1. Use the Design Studio to open the source map for the example that you want to run:
  - a. If you are running the ACH Deenvelope service CTX example, open the inbound\_ach\_ctx.mms source map and then open these maps:
    - x12\_ra\_to\_atx\_pri
    - x12\_ra\_to\_flat\_rpt
    - x12\_ra\_to\_xml\_ctx
    - xml\_ctx\_to\_csv\_ctx
  - b. If you are running the ACH Envelope service CTX example, open the outbound\_ach\_ctx.mms source map and then open x12\_ra\_to\_xml\_ctx.
  - c. If you are running the ACH Deenvelope service DNE example, open the inbound\_ach\_dne.mms source map and then open these maps:
    - inbound\_dne\_pri\_to\_xml
    - xml\_dne\_to\_dne\_flat
  - d. If you are running the ACH Envelope service DNE example, open the outbound\_ach\_dne.mms source map and then open these maps:
    - outbound\_dne\_addenda
    - outbound\_dne\_entryDtls
2. Right click on the map, and then choose Run on IBM Sterling B2B Integrator. Enter the ID and password if you are prompted.  
The processing completes.
3. The following output files are created in each corresponding ACH service example scenario data directory:
  - a. If you are running the ACH Deenvelope service CTX example, these output files are created:
    - ach\_atx\_pri.out - (from the x12\_ra\_to\_atx\_pri map)
    - pymt\_ordr\_rpt.out - (from the x12\_ra\_to\_flat\_rpt map)
    - ach\_ctx\_out.xml (from the x12\_ra\_to\_xml\_ctx map)
    - ctx\_xml\_to\_csv.out (from the xml\_ctx\_to\_csv\_ctx map)
  - b. If you are running the ACH Envelope service CTX example, this output file is created:
    - ach\_ctx\_out.xml - (from the x12\_ra\_to\_xml\_ctx map)
  - c. If you are running the ACH Deenvelope service DNE example, these output files are created:
    - pri\_out.xml (from the inbound\_dne\_pri\_to\_xml map)
    - ach\_dne\_flat.out (from the xml\_dne\_to\_dne\_flat map)

d. If you are running the ACH Envelope service DNE example, these output files are created:

- ach\_dne\_entry\_dtls.out (from outbound\_dne\_entryDtls map)
- ach\_dne\_addenda.out (from outbound\_dne\_addenda map)

## Results

---

Other files might be generated in the maps directory: *map\_name\_MapTestRequest.msg*, and *map\_name\_MapResponse.msg*. These files include the results returned by the web service that runs the map, including the output data and other status information.

## Running the ACH service examples from IBM Sterling B2B Integrator

The following procedures describe how to run the ACH Deenvelope and ACH Envelope examples using the IBM Sterling B2B Integrator dashboard.

## Procedure

---

1. Import IBM Sterling B2B Integrator artifacts as described in [Importing IBM Sterling B2B Integrator artifacts for ACH service examples](#).
2. Deploy the example maps as described in [Deploying the example maps to IBM Sterling B2B Integrator](#).
3. From the Administration menu, go to the Business Process Manager page.
4. Search for a Business Process:
  - a. If you are running the IBM Sterling B2B Integrator ACH Deenvelope service CTX example, search for the EDIDeveloppe business process.
  - b. If you are running the IBM Sterling B2B Integrator ACH Envelope service CTX example, search for the ACH\_CTX\_EnvelopeUsingWTX business process.
  - c. If you are running the IBM Sterling B2B Integrator ACH Deenvelope service DNE example, search for the EDIDeveloppe business process.
  - d. If you are running the IBM Sterling B2B Integrator ACH Envelope service DNE example, search for the ACH\_DNE\_EnvelopeUsingWTX business process.
5. Select the execution manager for the Business Process, then select the Execute option.
6. On the Local Desktop filename, browse, and then select, the appropriate input file from the data folder.
  - If you are running the ACH Deenvelope service CTX example, select the ach\_ctx\_inbound.inp file.
  - If you are running the ACH Envelope service CTX example, select the x12\_ra\_to\_ctx.inp file.
  - If you are running the ACH Deenvelope service DNE example, select the ach\_dne\_inbound.inp file.
  - If you are running the ACH Envelope service DNE example, select the ach\_dne\_flat.inp file.  
Note: If the IBM Sterling B2B Integrator server is operating on UNIX, use ach\_dne\_flat\_LNX.inp as the input file.
7. Select the Go option.
8. The Execute Business Process results show a status of Success for all steps in the Business Process. You can view more details, such as Status Report, document, and Instance Data by going to Business Process > Monitor > Current Process. The translated output of the examples can be viewed by going to: Business > Monitor > Current Documents. The document information shows the translated output of the generic de-envelope and envelope service. The Document Instance Data shows the Process data values that are set by the service, including the traceNo values set by the map.

## Expected results

---

The documentation provided here describes the results returned from the ACH Deenvelope CTX and DNE examples, and the ACH Envelope CTX and DNE examples.

- [\*\*CTX Deenvelope example expected results\*\*](#)

Expected results for the CTX Deenvelope example are provide here.

- [\*\*DNE Deenvelope example expected results\*\*](#)

Expected results for the DNE Deenvelope example are provided here.

- [\*\*CTX Envelope example expected results\*\*](#)

Expected results for the CTX Envelope example are provided here.

- [\*\*DNE Envelope example expected results\*\*](#)

Expected results for the DNE Envelope example are provided here.

## CTX Deenvelope example expected results

---

Expected results for the CTX Deenvelope example are provide here.

- When analyzing the 5010\_820.mtt type tree, Warnings are not expected. Errors are not expected.
- The xml\_ctx\_to\_csv\_ctx translation map creates a comma separated file based on the ACH CTX message.
- The x12\_ra\_to\_flat\_rpt translation map creates a back office payment order report file based on the ACH CTX message.
- The x12\_ra\_to\_xml\_ctx transformation map creates an XML equivalent of the X12 EDI 820 used by the ACH service for validation.
- The service creates an acknowledgement for the CTX message, an ACH ATX message. The payment related information of the ATX message is based on the result of the x12\_ra\_to\_atx\_pri translation map .
- The entry for trace number, traceNo, exists in both the ProcessData and Correlation tables.

## DNE Deenvelope example expected results

---

Expected results for the DNE Deenvelope example are provided here.

- When analyzing the ach\_pyamtRltdInfo.mtt type tree, Warnings are not expected. Errors are not expected.
- The xml\_dne\_to\_dne\_flat translation map will extract one Addenda record and one Entry detail record.

- The inbound\_dne\_pri\_to\_xml translation map will transform the DNE Payment Related information into XML format. This XML payment related information will be used by the service to complete its internal XML representation of the DNE message.
  - The entry for trace number, traceNo, exists in both the ProcessData and Correlation tables.
- 

## CTX Envelope example expected results

Expected results for the CTX Envelope example are provided here.

- When analyzing the 5010\_820.mtt type tree, Warnings are not expected. Errors are not expected.
  - The x12\_ra\_to\_xml\_ctx transformation map creates an XML equivalent of the X12 EDI 820 used by the ACH service for building an ACH CTX message.
  - The service creates an ACH CTX message with Addenda records based from the input X12 EDI 820 data.
  - The entry for trace number, traceNo, exists in both the ProcessData and Correlation tables.
- 

## DNE Envelope example expected results

Expected results for the DNE Envelope example are provided here.

- When analyzing the ach\_dne\_flat.mtt type tree, Warnings are not expected. Errors are not expected.
  - The outbound\_dne\_entryDtls translation map extracts entry detail records from a back office file which holds both addenda and entry detail information.
  - The outbound\_dne\_addenda translation map extracts addenda records from a back office file which holds both addenda and entry detail information.
  - The service creates an ACH DNE message consisting of three entry detail records with three corresponding addenda records.
  - The entry for trace number, traceNo, exists in both the ProcessData and Correlation tables.
- 

## Design considerations of the examples

The documentation provided here describes design features and concepts that were taken into account when building the example transformation maps invoked by the ACH Deenvelope and ACH Envelope services

- **[IBM Sterling B2B Integrator data harness](#)**  
Some Transformation Extender maps share information with the IBM Sterling B2B Integrator processes.
  - **[Thread safety](#)**  
A thread-safe map can run in a multi-threaded environment.
  - **[Specific map and type tree settings](#)**  
These are the map and type tree settings used with IBM Sterling B2B Integrator.
  - **[Custom type trees](#)**  
The custom type trees described here are provided with the ACH Deenvelope and ACH Envelope examples.
  - **[ACH service XML schemas](#)**  
The ACH Deenvelope service has features that transform ACH messages into intermediary XML formats. The Pack for Financial Payments NACHA component provides XML schemas that describe content and constraints on the IBM Sterling B2B Integrator proprietary XML documents.
- 

## IBM Sterling B2B Integrator data harness

Some Transformation Extender maps share information with the IBM Sterling B2B Integrator processes.

For example, the maps can perform one of the following activities:

- Store information about the data, for example, a document ID, or other key field, that can be used by IBM Sterling B2B Integrator to track the data.
- Get information from IBM Sterling B2B Integrator tables, such as trading partner information, or code list table data. The maps read and write this information to IBM Sterling B2B Integrator database tables using the IBM Sterling B2B Integrator adapter. This is referred to as the IBM Sterling B2B Integrator Data Harness which provides access to these tables.

The IBM Sterling B2B Integrator adapter is used to get and to set certain values that are maintained in the IBM Sterling B2B Integrator adapter database tables.

- The setProcessData call is used to set values such as reference ids in the processData table. This value can be used by other services in the Business Process flow.
- The setCorrelation call is used to set the values such as reference ids in the correlation data table. This value can be used to help search for documents processed by the map.

The ACH Deenvelope service and ACH Envelope service example maps use PUT calls to the IBM Sterling B2B Integrator adapter in order to set the TraceNo with the following values in the IBM Sterling B2B Integrator database called ProcessData and Correlation tables:

- For CTX scenarios, and for DNE inbound scenario - Originating DFI Identification
- For DNE outbound scenario - Receiving DFI Identification

For more information about the IBM Sterling B2B Integrator Data Harness, see the Transformation Extender IBM Sterling B2B Integrator documentation.

---

## Thread safety

A thread-safe map can run in a multi-threaded environment.

One of the attributes a map needs in order to run in a multi-threaded environment is that when multiple occurrences of the map are instantiated, none of the resources used by an individual instance of the map are used by another instance of the map.

For example, the map's work files, audit logs, backup files, and trace logs are individually named, that is, they are unique within each instance of the map.

For more information, about thread safety, including how you can verify that the map meets at least the basic thread-safe checks, see the Transformation Extender Map Designer documentation.

## Specific map and type tree settings

These are the map and type tree settings used with IBM Sterling B2B Integrator.

- **Burst**  
The *burst* concept deals with the scope of the data that is processed in one run of the map. ACH Envelope service example maps are set to execute in burst mode.
- **Audit settings**  
Certain map settings allow the Transformation Extender map to generate data audit information that can be used by the Generic service in business process reports.
- **Restart**  
These are the Restart flag settings.

## Burst

The *burst* concept deals with the scope of the data that is processed in one run of the map. ACH Envelope service example maps are set to execute in burst mode.

The ACH Envelope service runs a portion of the input with each iteration of the map. This is expected behavior in several IBM Sterling B2B Integrator services.

In the ACH Envelope service example, in the map input card, the FetchAs property is set to Burst, with a FetchUnit of 1. This allows the Transformation Extender map to generate data audit information that can be used by the ACH.

## Audit settings

Certain map settings allow the Transformation Extender map to generate data audit information that can be used by the Generic service in business process reports.

In the map settings, the MapAudit switch is set to ON, the BurstAudit and SummaryAudit settings are set to Always, and the AuditLocation is set to Memory.

- **ACH Deenvelope service data audit settings**  
In the ACH Deenvelope service examples, the Data Audit Settings for the maps in the CTX and DNE examples are set as listed here.
- **ACH Envelope service data audit settings**  
These are the data audit settings for the maps in the ACH Envelope examples.

## ACH Deenvelope service data audit settings

In the ACH Deenvelope service examples, the Data Audit Settings for the maps in the CTX and DNE examples are set as listed here.

The following are the data audit settings for the x12\_ra\_to\_flat\_rpt, the x12\_ra\_to\_flat\_rpt, and the x12\_ra\_to\_xml\_ctx maps in the ACH Deenvelope CTX example.

|           |                                                                                                                         |

| Item Data | Occurrence           |

## Restart

These are the Restart flag settings.

- [ACH Deenvelope service](#)  
The Restart flag on the 5010\_820.mtt and ach\_pyamtRltInfo.mtt type trees are specified on the following components.
- [ACH Envelope service](#)  
The Restart flags on the 5010\_820.mtt and the ach\_dne\_flat.mtt type trees are specified on the following components.

## ACH Deenvelope service

The Restart flag on the 5010\_820.mtt and ach\_pyamtRltInfo.mtt type trees are specified on the following components.

- CTX example - The Restart flag on the 5010\_820.mtt type tree is specified on the following components:
  - Partner X12 Inbound Interchange (s)
  - Transaction #820 Inbound Partner Set 5010X218 (s)
  - Inbound Partner Funct'lGroup ANSI (0:99999)
- DNE example- The Restart flag on the ach\_pyamtRltInfo.mtt type tree is specified on the following component:
  - PRI Record (1:s)

## ACH Envelope service

The Restart flags on the 5010\_820.mtt and the ach\_dne\_flat.mtt type trees are specified on the following components.

- CTX example - The Restart flag on the 5010\_820.mtt type tree are specified on the following components
  - Partner X12 Inbound Interchange (s)
  - Transaction #820 Inbound Partner Set 5010X218 (s)
  - Inbound partner Funct'lGroup ANSI (0:99999)
- DNE example - The Restart flag on the ach\_dne\_flat.mtt type tree is specified on the following component:
  - group batch (1:s)

## Custom type trees

The custom type trees described here are provided with the ACH Deenvelope and ACH Envelope examples.

- [5010\\_820.mtt type tree](#)  
On both the ACH Deenvelope service and the ACH Envelope service CTX examples, the service extracts the EDI X12 820 from the CTX Addenda records and inputs it to the transformation maps configured within the service.
- [ach\\_pyamtRltInfo.mtt type tree](#)  
On the ACH Deenvelope service DNE example, the service extracts the Payment Related Information from the DNE message and inputs it to a transformation map that is configured within the service.
- [ach\\_dne\\_flat.mtt type tree](#)  
On the ACH Envelope service DNE example, the service has a back-office input file which has two record formats, entry details and addenda records.
- [pyamt\\_ordr\\_rpt.mtt](#)  
On the ACH Deenvelope service CTX example, this type tree is used by the service post-processing map, x12\_ra\_to\_flat\_rpt , when transforming the X12 820 into a back office payment order report format.
- [ach\\_ctx\\_csv.mtt](#)  
After the ACH Deenvelope service CTX example completes, the service generates a IBM Sterling B2B Integrator process data which contains an XML representation

of the CTX message.

## 5010\_820.mtt type tree

On both the ACH Deenvelope service and the ACH Envelope service CTX examples, the service extracts the EDI X12 820 from the CTX Addenda records and inputs it to the transformation maps configured within the service.

The NACHA component of the Pack for Financial Payments ships a type tree that represents the EDI ANSI 5010X218 X12 820 message syntax. This type tree is used by the map x12\_ra\_to\_xml\_ctx to validate the X12 820 and transform it to IBM Sterling B2B Integrator proprietary XML format. This type tree is used by the ACH Deenvelope service post processing map x12\_ra\_to\_flat\_rpt to transform the X12 820 to a back office payment order report. This type tree is used by the ACH Deenvelope ACK Addenda Record map x12\_ra\_to\_atx\_pri which extracts the REF segment and is used by the service to generate the Payment Related Information on the acknowledgement ATX message.

## ach\_pymtRltdInfo.mtt type tree

On the ACH Deenvelope service DNE example, the service extracts the Payment Related Information from the DNE message and inputs it to a transformation map that is configured within the service.

The NACHA component of the Pack for Financial Payments includes a type tree that represents the 80 character Payment Related Information syntax. This type tree is used by the map inbound\_dne\_pri\_to\_xml which converts the PRI into XML. The XML formatted PRI is embedded by the service to the IBM Sterling B2B Integrator proprietary XML representation of the DNE message. The same type tree is used in the ACH Deenvelope service CTX example, ACK Addenda Record map x12\_ra\_to\_atx\_pri when populating the contents of the PRI of the ATX message.

## ach\_dne\_flat.mtt type tree

On the ACH Envelope service DNE example, the service has a back-office input file which has two record formats, entry details and addenda records.

The Pack for Financial Payments NACHA component ships a type tree that represents the 77 character Entry Detail Record and 80 character Addenda record syntax. This type tree is used by the service Entry Detail map outbound\_dne\_entryDtls to extract the entry detail record. The type tree is used by the service Addenda map outbound\_dne\_addenda to extract the addenda record. Output from both maps is used by the service to populate a DNE message. The same type tree is used in the ACH Deenvelope service DNE example, post-processing map xml\_dne\_to\_dne\_flat when transforming IBM Sterling B2B Integrator proprietary XML format to a back office format.

## pymt\_ordr\_rpt.mtt

On the ACH Deenvelope service CTX example, this type tree is used by the service post-processing map, x12\_ra\_to\_flat\_rpt , when transforming the X12 820 into a back office payment order report format.

## ach\_ctx\_csv.mtt

After the ACH Deenvelope service CTX example completes, the service generates a IBM Sterling B2B Integrator process data which contains an XML representation of the CTX message.

This type tree is used by an example map called xml\_ctx\_to\_csv\_ctx to transform the XML file extracted from IBM Sterling B2B Integrator process data which represents a CTX message into a comma-separated value file format.

## ACH service XML schemas

The ACH Deenvelope service has features that transform ACH messages into intermediary XML formats. The Pack for Financial Payments NACHA component provides XML schemas that describe content and constraints on the IBM Sterling B2B Integrator proprietary XML documents.

The XML schemas allow Transformation Extender maps that are configured within ACH service to work directly with the service XML representation of ACH messages.

These XML schemas are provided.

- ach.ack.001.xsd
- ach.adv.001.xsd
- ach.arc.001.xsd
- ach.atx.001.xsd
- ach.boc.001.xsd
- ach.ccd.001.xsd
- ach.cie.001.xsd
- ach.cmn.001.xsd ( common base types shared by the different XML schemas)
- ach.cntstd.dshnrd.rtrn.001.xsd
- ach.cor.001.xsd

- ach.ctx.001.xsd
- ach.ctx.002.xsd
- ach.dne.001.xsd
- ach.dshnrd.rtrn.001.xsd
- ach.enr.001.xsd
- ach.iat.001.xsd
- ach.iat.cor.001.xsd
- ach.iat.rtrn.001.xsd
- ach.mte.001.xsd
- ach.pop.001.xsd
- ach.pos.001.xsd
- ach.ppd.001.xsd
- ach.rck.001.xsd
- ach.rfsd.ack.001.xsd
- ach.rfsd.atx.001.xsd
- ach.rfsd.cor.001.xsd
- ach.rtrn.001.xsd
- ach.shr.001.xsd
- ach.tel.001.xsd
- ach.trc.001.xsd
- ach trx.001.xsd
- ach.web.001.xsd
- ach.xck.001.xsd

For examples of how to use the XML schema, see the ACH Deenvelope service CTX and DNE examples.

## Overview of the SEPA component

The SEPA component of the Pack for Financial Payments supports validation of the Single European Payments Area (SEPA) scheme datasets, transformation samples between SEPA, and individual domestic formats.

The SEPA component can link your current payments systems and operations in their current mode to SEPA validation, providing processing and enrichment for your back office and intermediary systems.

This documentation provides introductory and reference material needed to implement the SEPA component of the Pack for Financial Payments as part of an overall SEPA solution. This documentation contains background on SEPA, including the following topics:

- A description of how the SEPA component fits into your SEPA processing for credit transfer and direct debit transactions
- Configuration of the SEPA component, including specifics of deploying the component on z/OS
- A description of the SEPA message validation framework
- A discussion of the domestic format converters.

For a description of installation and uninstallation procedures for this product, refer to the release notes.

- **[Principal components](#)**

The SEPA component of the Pack for Financial Payments contains the following principal components:

- **[The SEPA initiative](#)**

In today's financial marketplace, customers are demanding improved services and want a prompt payment processing system that is consistent both within their home country, and in other European markets.

## Principal components

The SEPA component of the Pack for Financial Payments contains the following principal components:

- ISO 20022 (UNIFI) message schemas for credit transfer and direct debit (.xsd files) and the type trees for credit transfer and direct debit formats.
- Additional validation maps used to validate the general usage rules as defined in the EPC rule books.
- Example converter maps for the following domestic credit transfer and direct debit messages:
  - United Kingdom - BACS, see [Example for the UK](#).
  - Germany - DTAS, see [Example for Germany](#).
  - France - MINOS and CFONB, see [Example for France](#).
  - Italy - SIA Rete Interbacaria (RNI), see [Example for Italy](#).
- Type trees for the SWIFTNet FIN MT 1nn message, as well as the transformation maps used to convert between SEPA formats and the SWIFTNet FIN MT101 MT102, MT102+, MT103 and MT103+ messages.
- z/OS example with sample JCL for a SEPA pass through map. See [Running the SEPA component on z/OS](#).
- Reference data templates (bic.xml, and currencycodedecimals.xml files).
- An example validation map that uses the European Payments Council (EPC) schemas for the relevant payments clearing and settlement messages that use native schema mapping. These maps can be used as a replacement for the main validation maps to improve performance, since these maps use the EPC schema subset of the ISO20022 schema.

## The SEPA initiative

In today's financial marketplace, customers are demanding improved services and want a prompt payment processing system that is consistent both within their home country, and in other European markets.

Each European country has developed its own banking and payment system in accordance with local market requirements. The result has been a varying level of payment service for customers. This is particularly noticeable to citizens who cross borders regularly to shop and holiday within Europe.

To address this problem, the EPC, in 2002, proposed a single payment process. At that time, 42 banks, and three European Credit Sector Associations (ECSAs), came together to release a proposal formally launching the SEPA concept.

The definition of SEPA was approved by the EPC in December of 2004 and states that:

*"SEPA will be the area where citizens, companies and other economic actors will be able to make and receive payments in euro, within Europe (currently defined as consisting of the 28 European Union (EU) member states plus Iceland, Norway, Liechtenstein and Switzerland), whether between or within national boundaries under the same basic conditions, rights and obligations, regardless of their location."*

- **[SEPA message standards](#)**

This section describes SEPA message standards and provides an overview of the UNIFI ISO 20022 (UNIFI) standard upon which the SEPA standard is based.

- **[EPC rulebook validation of SEPA messages](#)**

The EPC publishes various documents related to SEPA, including a data model reference, rulebooks, and implementation guides for both credit transfers and direct debits.

---

## SEPA message standards

This section describes SEPA message standards and provides an overview of the UNIFI ISO 20022 (UNIFI) standard upon which the SEPA standard is based.

Note: The terms "UNIFI" and "ISO 20022" are used interchangeably throughout this and other SEPA documentation. Both refer to the ISO 20022 Universal Financial Industry message scheme.

This platform was proposed by the International Standards Organization (ISO) to be used to develop all financial industry messages. It must be understood that UNIFI by itself does not describe messages. Rather, it can be thought of as a recipe to be used to develop financial industry message standards. The main ingredients of this recipe are a development methodology, a registration process, and a central repository.

- **[Message overview](#)**

The core messages defined for use by the EPC comprise a subset of the ISO 20022 Payments Clearing and Settlement (pacs.nnn.nnn.nn), Cash Management (camt.nnn.nnn.nn), and Payments Initiation (pain.nnn.nnn.nn) business areas.

- **[About the UNIFI message standard](#)**

---

## Message overview

The core messages defined for use by the EPC comprise a subset of the ISO 20022 Payments Clearing and Settlement (pacs.nnn.nnn.nn), Cash Management (camt.nnn.nnn.nn), and Payments Initiation (pain.nnn.nnn.nn) business areas.

The **pacs** and **camt** messages are for use in the PSP-to-PSP processing space, and have been designated mandatory by the EPC and they must be used by all SEPA participants. The **pain** messages are recommended for use in the customer-to-PSP space.

It should be noted that, within SEPA, there are numerous terms that can be used interchangeably. In addition to the terms UNIFI and ISO 20022 XML which are nearly synonymous, a SEPA message can be referred to either by its UNIFI message number, or by a dataset identified in the EPC rulebook. For example, the following terms mean the same:

- FI to FI Customer Credit Transfer
- pacs.008.001.08
- Inter-PSP Payment Dataset – DS-02

- **[Credit Transfer messages](#)**

Credit transfer SEPA messages include Inter-PSP (PSP-to-PSP) and Customer to PSP messages.

- **[Credit Transfer - Inter-PSP messages](#)**

SEPA Credit Transfer Inter-PSP messages are defined in the following table.

- **[Credit Transfer - Customer-to-PSP messages](#)**

SEPA Credit Transfer, Customer-to-PSP messages, are defined in the following table:

---

## Credit Transfer messages

Credit transfer SEPA messages include Inter-PSP (PSP-to-PSP) and Customer to PSP messages.

- **[Credit Transfer - Inter-PSP messages](#)**

SEPA Credit Transfer Inter-PSP messages are defined in the following table.

- **[Credit Transfer - Customer-to-PSP messages](#)**

SEPA Credit Transfer, Customer-to-PSP messages, are defined in the following table:

---

## Credit Transfer - Inter-PSP messages

SEPA Credit Transfer Inter-PSP messages are defined in the following table.

| Message ID      | Description              | Dataset designation                                         | Purpose                                                                                                      |
|-----------------|--------------------------|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|

| pain.009.001.0<br>6 | Mandate Initiation Request   | DS-12 - E-Mandate Proposal/Request Message - Issuing   | Transports the request to use the validation service from the Creditor to the Debtor PSP. The message caters for a single request.                                                                                                                       |
| pain.010.001.0<br>6 | Mandate Amendment Request    | DS-12 - E-Mandate Proposal/Request Message - Amendment | Transports the amendment of a mandate sent by the Creditor to the Debtor PSP. The message caters for a single amendment request.                                                                                                                         |
| pain.011.001.0<br>6 | Mandate Cancellation Request | E-Mandate Proposal/Request Message – Cancellation      | Transports the cancellation request of a mandate sent by the Creditor to the Debtor PSP. The message caters for a single cancellation request.                                                                                                           |
| pain.012.001.0<br>6 | Mandate Acceptance Report    | DS-13 - E-Mandate Validation Message                   | Transports the confirmation of the acceptance or rejection of a mandate request (initiation, amendment or cancellation) sent by the Debtor PSP to the Creditor. The message caters for a single confirmation of rejection of a specific Mandate Request. |

## Direct Debit - E-Mandate Core messages

The SEPA, Direct Debit, E-Mandate, Core messages are defined in this table.

| Message ID          | Description                  | Dataset designation                                       | Purpose                                                                                                                                                                                                                                                 |
|---------------------|------------------------------|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pain.009.001.0<br>6 | Mandate Initiation Request   | DS-12 - E-Mandate Proposal/Request Message – Issuing      | Transports the request to use the validation service from the Creditor to the Debtor PSP. The message caters for a single request                                                                                                                       |
| pain.010.001.0<br>6 | Mandate Amendment Request    | DS-12 - E-Mandate Proposal/Request Message – Amendment    | Transports the amendment of a mandate sent by the Creditor to the Debtor PSP. The message caters for a single amendment request.                                                                                                                        |
| pain.011.001.0<br>6 | Mandate Cancellation Request | DS-12 - E-Mandate Proposal/Request Message – Cancellation | Transports the cancellation request of a mandate sent by the Creditor to the Debtor PSP. The message caters for a single cancellation request.                                                                                                          |
| pain.012.001.0<br>6 | Mandate Acceptance Report    | DS-13 - E-Mandate Validation Message                      | Transports the confirmation of the acceptance or rejection of a mandate request (initiation, amendment or cancellation) sent by the Debtor PSP to the Creditor. The message caters for a single confirmation of rejection of a specific Mandate Request |

## About the UNIFI message standard

At the beginning of the decade, the general interest in Internet Protocol (IP) and XML was perceived as a unique opportunity for the industry to move to a common XML-based language. There was a problem, however, because XML is not a language at all, but rather a meta-language which everyone can use to define their own dialect. As a result, several standardization initiatives grew from the common XML concept, each with messages using their own dialect, or adaptation of XML. This led to not only an increased risk of yet more 'languages' being introduced, but a waste of resources in the form of duplicated effort, and a further risk of divergence when more than one initiative is brought to focus on the same business area.

To solve this problem, ISO proposed a single standardization approach, or "recipe" which includes a common development methodology, a common process, and a common repository, that would be used by all financial standards initiatives. This recipe, called UNIFI or ISO 20022 is the message standard around which the SEPA component is developed.

For a complete description of ISO 20022 message flow, refer to the International Standardization Organization, ISO 20022 UNIversal Financial Industry message scheme. This information is available at:

[www.iso20022.org/](http://www.iso20022.org/)

## EPC rulebook validation of SEPA messages

The EPC publishes various documents related to SEPA, including a data model reference, rulebooks, and implementation guides for both credit transfers and direct debits.

The SEPA data model describes how three layers are recognized:

- A business process layer.
- A logical data layer to define the datasets and their attributes.
- The physical layer which specifies the actual document formats and messages.

The rulebooks contain the business requirements and rules for the operation of the SEPA schemes.

The implementation guides contain detailed specifications on the physical layer of the data model, and thus define SEPA-specific validation that is applied to ISO 20022 (UNIFI) messages to ensure compliance with the SEPA.

The SEPA component of the Pack for Financial Payments includes maps to apply these validation rules to the various ISO 20022 SEPA messages so that customers can validate their messages to ensure compliance. These messages are listed in the [Credit Transfer messages](#) and in the [Direct debit messages](#).

The maps provide a check-digit validation of the following fields:

- IBAN
- Identification of the Creditor (AT-02) - direct debit only

They also conduct validation checks against XML lookup files to verify the following items:

- Bank Identification Code (BIC)
- Currency codes
- Country codes
- [Business to Business direct debit implementation](#)  
The original SEPA scheme is the SEPA core direct debit scheme.
- [External Purpose Code List](#)  
The SEPA component of the Pack for Financial Payments contains an External Purpose Code List. This code list contains values that define the reason for payment transactions between customers.

## Business to Business direct debit implementation

The original SEPA scheme is the SEPA core direct debit scheme.

There is one difference in the actual data for the two schemas:

Payment Information – Local Instrument – The code is CORE for the Core Direct Debit Schema and B2B for the Business to Business schema.

## External Purpose Code List

The SEPA component of the Pack for Financial Payments contains an External Purpose Code List. This code list contains values that define the reason for payment transactions between customers.

This code list was developed within the framework of some of the ISO 20022 Payment messages. The code values can be used in specific elements of the Payments messages, and are required in order to validate all Customer to PSP messages. Although Pub code values can be used in specific elements of the Payments messages, the External Purpose Code List is not part of the ISO 20022 standard, as it is not a standalone ISO standard such as BIC, or Currency Codes. To access the current code values, go to the ISO 20022 website, [www.iso20022.org](http://www.iso20022.org).

## Configuration

The documentation provided here describes SEPA system configuration.

This includes a detailed description of the major components that comprise the SEPA component for the Pack for Financial Payments, followed by detailed instructions on how to run the SEPA component on z/OS®. The z/OS section includes sample batch scripts and JCL.

- [Major components of the SEPA component](#)
- [Running the SEPA component on z/OS](#)
- [Working with the default project](#)

The SEPA component is supplied with a default Transformation Extender project to help you configure the component into the ECLIPSE-based Design Studio.

## Major components of the SEPA component

When you install the Transformation Extender Pack for Financial Payments SEPA component, the following subdirectories are created under the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa directory: examples, mapsandschemas,res, and type\_trees.

- [Examples](#)  
The examples directory contains examples for converting between SEPA formats and various national formats, as well as other parts of the SEPA component of the Pack for Financial Payments.
- [mapsandschemas](#)  
The **mapsandschemas** directory contains validation framework maps, schemas, and reference data files and maps.
- [res](#)  
The res directory contains files that can be used to display SEPA validation and error messages in alternate languages.

- [type trees](#)

The type\_trees directory contains type trees for the validation framework and corresponding BICPlusIBAN directory structures.

---

## Examples

The examples directory contains examples for converting between SEPA formats and various national formats, as well as other parts of the SEPA component of the Pack for Financial Payments.

These are the formats for the countries that are supported by examples in the SEPA component:

- Germany, DTAUS – see /examples/germany
- France, MINOS, CFONB – see /examples/france
- United Kingdom, BACS – see /examples/uk
- Italy, RNI – see /examples/italy

In addition to the format subdirectories, the examples subdirectory also contains the following subdirectories:

- passthrough subdirectory – see /examples/passthrough. Contains an example for validating a message against a schema in the z/OS® environment along with a sample of the JCL required to run it.
- pain\_pacs subdirectory – see /examples/pain\_pacs. Contains example maps used to create inter-PSP messages from customer-to-PSP messages and PSP-to-customer messages.
- sample\_jcl subdirectory – see /examples/sample\_jcl. Contains an example that shows how to run the SEPA component validation maps on z/OS.
- swiftfin subdirectory – see /examples/swiftfin. Contains an example that describes the SEPA component format converter for the SWIFTNet FIN format.
- epc\_mapsandschemas subdirectory. Contains an example validation map source that uses the EPC published schemas for the relevant payments clearing and settlement messages by using native schema mapping. These maps can be used as a replacement for the main validation maps to improve performance, since these maps use the EPC schema subset of the ISO20022 schema.
- bundle/unbundle - contains examples that demonstrate working with aggregate (bundle) SEPA data.

Note the following points about the examples:

- They are supplied as examples only, and are not to be considered a full set of all possible conversions. The domestic type trees that are supplied with the SEPA component support basic syntactic validation, but do not provide for full validation.
- The SEPA type trees that are used in the converters are the ISO20022 type trees. The transformation rules are best estimates. Pay particular attention to BIC and IBAN conversions, since these conversions might require the use of extra reference data that only you can access.

Instructions for running the examples are provided in the [SEPA component examples](#) documentation.

---

## mapsandschemas

The **mapsandschemas** directory contains validation framework maps, schemas, and reference data files and maps.

The components of the **mapsandschemas** subdirectory are described in this list:

- xliff.dtd file – Not included as part of the pack, and must be copied from ITX install directory into the **mapsandschemas** directory.
- epcl.txt file – contains the latest External Purpose Code List that is used to validate all Customer to PSP messages.
- eeaSEPACTryCd.txt file - contains the list of countries and territories which are part of the jurisdictional scope of the SEPA Schemes and their ISO country codes.
- errc.txt file - contains the latest External Reversal Reason Code that is used to validate all Customer to PSP Payment Reversal messages.
- **Validation framework maps** - perform validation of the SEPA message by checking for: 1) Basic UNIFI compliance and 2) EPC-mandated usage rules for Credit Transfer and Direct Debit. The main map for the validation framework (sepavalid) resides under the sepa\_validation.mms. All of the validation maps reside within this source file, so they can all be built at the same time, by using the Build All option in the Map Designer.
- **ISO 20022 Schemas** - All needed schemas are provided for the validation of all the different message types and levels (UNIFI, SEPA, CORE, and AOS). Any new or modified schema must be located here. Also, there is a SEPA generic schema (sepagen.xsd) that contains a list of all messages that are supported by the validation framework maps.
- sepa\_library.mms file – includes additional utility maps to work with the **BICPlusIBAN** directory.
- **Dependent EPC** - All dependent EPC are validated based on the Local Instrument Code.
- **Reference data files and maps** - The SEPA component comes with XML templates used by the validation framework for validating BICs, currency code, country code and allowed decimal places for currency amounts information. The SEPA component also contains maps to populate these templates with live data supplied by SWIFT (sepa\_library.mms).
- [BICPlusIBAN Utility](#)

---

## BICPlusIBAN Utility

The SWIFT BICPlusIBAN is a collection of institution identifiers from International, National directory providers and Financial institutions. This directory was created to improve straight-through processing (STP) by identifying correspondents and counterparties accurately. Additional utility maps are included in the sepa\_library.mms file to work with the **BICPlusIBAN** directory.

---

## res

The res directory contains files that can be used to display SEPA validation and error messages in alternate languages.

To display messages in one of the supported languages, refer to the following procedures:

1. Rename the existing sepamsgs.xml file located in the **mapsandschemas** directory to sepamsgs\_en.xml.
2. Copy the sepamsgs\_<language>.xml file for the desired language from the **res** directory to the **mapsandschemas** directory, naming the file to sepamsgs.xml.
3. Update the type tree errorxml.mtt located in the **type\_trees** directory. Change the property '**Data Language**' from '**Native**' to '**UTF-8**' for the following items:
  - Error/fields/action
  - Error/fields/explanation
  - Error/fields/msgText
4. Analyze and save the type tree.
5. Update the map **seplib05\_extract\_error\_msg** on sepa\_validation.mms located in the **mapsandschemas** directory. On output card#1 update the map rules on the following to replace TEXT function with CTEXT function using '**UTF-8**' as character set.
  - msgText
  - explanation fields
  - action fields

Re-build all the maps under sepa\_validation.mms

The following language files are available:

- sepamsgs\_de.xml - German
- sepamsgs\_es.xml - Spanish
- sepamsgs\_fr.xml - French
- sepamsgs\_it.xml - Italian
- sepamsgs\_ja.xml - Japanese
- sepamsgs\_ko.xml - Korean
- sepamsgs\_pt.xml - Portuguese
- sepamsgs\_zh-CN.xml - Simplified Chinese
- sepamsgs\_zh-TW.xml - Traditional Chinese

---

## type\_trees

The type\_trees directory contains type trees for the validation framework and corresponding BICPlusIBAN directory structures.

All schemas required for the validation framework have a corresponding tree in this subdirectory. These schema type trees are created using the type tree schema importer. A tree for the SEPA generic schema (sepagen.mtt) is also provided.

These type trees were imported using both the Xerces and the Classic importer.

---

## Running the SEPA component on z/OS

Before deploying the SEPA component of the Transformation Extender Pack for Financial Payments on the z/OS® platform, make note of the following factors:

- The SEPA framework consists of a main map and several executable run maps that use several schemas to validate UNIFI and SEPA.  
Note: EBA functionality is deprecated in this version of the Pack for Financial Payments.
- All compiled maps and schemas, as well as input XML files, must be ported in binary to the z/OS platform. The schemas and maps should reside in the same location, like a library dataset.
- The xliff.dtd from the base product directory must be ported in binary to the z/OS environment.
- All of the type trees in the type\_trees subdirectory that are related to a schema or DTD must be (manually) modified to include the DDNAME which will point to the corresponding schema or DTD.
- After modification of the type trees, the maps have to be built and then ported to z/OS.
- Every map, schema, and file that is ported to z/OS must have a unique 8-character DDNAME in the JCL.
- **Preparing work for execution on z/OS**  
In order to view the XML error log produced on z/OS, you can use 'ICONV', if available, or you can modify the JCL for the map run command to add '/VX15 name of third output card for the sepalid map'

---

## Preparing work for execution on z/OS

In order to view the XML error log produced on z/OS, you can use 'ICONV', if available, or you can modify the JCL for the map run command to add '/VX15 name of third output card for the sepalid map'

You might want to create a list of the maps, files, and schemas that will reside on z/OS. In the list, indicate the original file name, the type of file, the name that the file on z/OS, and the DDNAME. The following table shows how a typical list can be constructed. For a more complete description of all of the maps, files and schemas being deployed on z/OS, refer to the example FTP script and the example JCL contained in the examples/sample\_jcl directory.

| Original file name  | Type | File name on z/OS     | DDNAME   |
|---------------------|------|-----------------------|----------|
| pacs.002.001.10.xsd | map  | sepa.maplib(SE1B002C) | SE1B002C |
| xliff.dtd           | dtd  | xliff.dtd             | XLIFF    |

| Original file name       | Type       | File name on z/OS | DDNAME   |
|--------------------------|------------|-------------------|----------|
| currencycodedecimals.xml | INPUT CARD | currency.xml      | CURRENCY |

## Working with the default project

The SEPA component is supplied with a default Transformation Extender project to help you configure the component into the ECLIPSE-based Design Studio.

Perform the following steps to import the default project into your Transformation Extender Design Studio workspace:

1. From the Transformation Extender Design Studio menu bar, select File > Import. The Import window opens.
2. From the General folder, select Existing Projects into Workspace. Choose Next.
3. In the Import window, choose the Select root directory option, then use the Browse option to navigate to <install\_dir>/ packs.
4. From the list of existing projects, select financial\_payments\_vn.n.n.n/sepa, where n.n.n.n represents the current version of the Pack for Financial Payments. Select Ok.
5. Ensure that the Copy project to workspace check box is not checked. Choose Finish.

## Validation overview

One of the primary objects of the SEPA component is the validation framework map.

The validation framework map is designed to simplify the calling of validation steps that are provided by IBM and the optional integration of custom validation steps. This map orchestrates the validation flow and enables the logging to debug validation flow.

This validation framework map will take in any UNIFI 20022 formatted XML message and validate the set of rules published by the EPC. Default setting for UNIFI validation is OFF, that is '0'. To enable UNIFI validation, change input card 3 ValidateUNIFI on property SourceRule > GET > Source > Data from '0' to '1'. The validation framework is completely operated by the call of one map, **sepvalid**, which is discussed in detail in the following section.

It should be noted that no matter what the SEPA message type, the validation framework map passes correct data.

In order for a SEPA message to pass through the validation framework without error, the following conditions must be met:

- the XML must be well-formed
- all published applicable UNIFI rules must be followed
- all published applicable SEPA IGs and rulebooks must be enforced
- XML must validate against the published UNIFI/SEPA schemas

Optionally, the validation framework allows for validation of a message against an original SEPA message, where appropriate. The SEPA implementation guides have rules that require the original payment information to be validated in the current data document. Specifically, the contents of the Original Transaction Reference must match the original transaction information. For example the **pacs004** return refund and **pacs002** reject, for both credit transfer transactions and direct debit collections. The **pacs007** direct debit reversal also has this requirement. For all of these cases, the original message is the **pacs008** FI to FI customer transfer, or the **pacs003** FI to FI customer direct debit.

- **sepvalid**

This validation framework will take in any UNIFI 20022 formatted XML message and validate the set of rules published by the EPC. Default setting for UNIFI validation is OFF, that is '0'. To enable UNIFI validation, change input card 3 ValidateUNIFI on property SourceRule > GET > Source > Data from '0' to '1'.

- **SEPA validation customization**

Within the SEPA validation framework maps, you can customize validation for the following:

- **Unenforced usage rules**

The Validation Framework does not enforce usage rules that involve uniqueness over time, because the SEPA component does not provide a full end-to-end view of all the messages handled.

## sepvalid

This validation framework will take in any UNIFI 20022 formatted XML message and validate the set of rules published by the EPC. Default setting for UNIFI validation is OFF, that is '0'. To enable UNIFI validation, change input card 3 ValidateUNIFI on property SourceRule > GET > Source > Data from '0' to '1'.

The framework is completely operated by the call of one map, **sepvalid**. No matter what SEPA message type, this map will pass the data through the validation framework. The framework has the ability to determine if the data is ISO 20022 UNIFI schema data, or if the data is part of the EPC Technical Validation Set, which has two sets of schemas, CORE schemas, which allow only the fields that are required by SEPA, and the CORE plus AOS, which allow additional elements. Custom schemas can also be added.

The main map that is called is **sepvalid**. Three inputs are allowed:

- The first input will be the SEPA message that needs to be validated.
- The second input will be the original message. If no original data file is provided, then the matching rules in the SEPA implementation guide will not be processed.
- The third input will be to enable or disable the UNIFI rule validation. Default setting for UNIFI validation is OFF, that is '0'. To enable UNIFI validation, change input card 3 ValidateUNIFI on property SourceRule > GET > Source > Data from '0' to '1'.

There are 3 Output cards for the **sepvalid** map. Cards one and two do not produce output files, and card three produces the **seperror.xml** file that allows you to see all of the validation errors and framework messages produced from the data file. If debugging of the process is required, change the output for card 1 from SINK to File and assign it a file name. This debug file will then serve as a debugging tool, as it contains steps that document where in the process it has been, and what was performed.

## SEPA validation customization

Within the SEPA validation framework maps, you can customize validation for the following:

- Add additional error reporting, or add checks that are outside of the scope of the SEPA or UNIFI schemas
- Add validation for a custom schema
- Change individual validation rules, which is especially useful for those rules in the customer-to-PSP messages that are only "recommended" by SEPA

## Unenforced usage rules

The Validation Framework does not enforce usage rules that involve uniqueness over time, because the SEPA component does not provide a full end-to-end view of all the messages handled.

Rules that imply that a field can only be used if there is agreement between originator and beneficiary are also not enforced. The following SEPA rules are involved:

| SEPA message  | Element                               | Rule                                                                                                                                                                              |
|---------------|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pacs.008.(CT) | Transaction Identification            | Must contain a reference that is meaningful to the Originators PSP and is unique over time.                                                                                       |
| pacs.008.(CT) | Remittance Information - Unstructured | Unstructured may carry structured remittance information, as agreed between the Originator and the Beneficiary.                                                                   |
| pacs.002(CT)  | Original Transaction Identification   | Must contain a reference that is unique over time.                                                                                                                                |
| pacs.004(CT)  | End To End Identification             | A customer reference that must be passed on in the end-to-end payment chain. If no reference was given, 'NOTPROVIDED' must be used.                                               |
| pain.001(CT)  | Remittance Information - Unstructured | Unstructured may carry structured remittance information, as agreed between the Originator and the Beneficiary.                                                                   |
| pacs.003.(DD) | Transaction Identification            | Must contain a reference that is meaningful to the Creditors PSP and is unique over time.                                                                                         |
| pacs.003.(DD) | Remittance Information - Unstructured | Unstructured may carry structured remittance information, as agreed between the Creditor and the Debtor.                                                                          |
| pacs.003(DD)  | End-To-End Identification             | A customer reference that must be passed on in the end-to-end payment chain. If no reference was given, 'NOTPROVIDED' must be used.                                               |
| pacs.004.(DD) | Transaction Identification            | Must contain a reference that is meaningful to the Creditors PSP and is unique over time.                                                                                         |
| pacs.004(DD)  | Original Transaction Identification   | Must contain a reference that is meaningful to the Creditor's PSP and is unique over time.                                                                                        |
| pacs.007.(DD) | Original Transaction Identification   | Must contain a reference that is meaningful to the Creditors PSP and is unique over time.                                                                                         |
| pain.008(DD)  | Remittance Information - Unstructured | Unstructured may carry structured remittance information, as agreed between the Creditor and the Debtor.                                                                          |
| camt.029(CT)  | Additional Information                | Assumption is Additional Information (AddtlInf) coming in camt.029 is based on original message camt.056. Cross verification to original/associated camt.056 cannot be performed. |

## Validation details

The following topics contain a detailed discussion of the SEPA component validation processes. It provides:

- a description of the maps inside the validation framework
  - a detailed description of validation framework map naming conventions
  - instructions on customizing validation steps
  - a discussion of how failures and unexpected results should be handled.
- [\*\*Maps inside the validation framework\*\*](#)  
One purpose of the validation framework is to simplify the calling of the IBM-provided validation steps in the SEPA component of the Pack for Financial Payments.
- [\*\*Validation framework map naming conventions\*\*](#)  
To navigate easily through the maps in the validation framework, it is important that you understand the map naming conventions.

- [\*\*How to run the SEPA Compliance in Design Server\*\*](#)
- [\*\*Types of customization for SEPA validation\*\*](#)  
This section describes how to add a new schema or validation step, modify a validation step, and modify or add validation rules.
- [\*\*Handling failures and unexpected results\*\*](#)  
Between the validation framework built-in debugging tools, and general ITX debugging techniques, it is possible to obtain information about map and data format failures, as well as and unexpected results.
- [\*\*BIC plus IBAN validation and lookup\*\*](#)  
Proper handling of bank identification with either the Bank Identification Code (BIC), or International Bank Account Number (IBAN) is required throughout the SEPA process, a process that includes validation, domestic format conversion, and client data mapping..

## Maps inside the validation framework

One purpose of the validation framework is to simplify the calling of the IBM-provided validation steps in the SEPA component of the Pack for Financial Payments.

In the world of SEPA/XML, the information needed to determine the cause of invalid data may not always be straightforward, and at times, it might require several levels of checking in order to achieve meaningful error reporting.

- [Stepped map process](#)

## Stepped map process

The stepped map process validates the data against different criteria. For example, the first step may be to validate against a schema and the second step may be to validate against some additional rules. Each map step reports any errors that are found. If the data is good, according to all the map steps performed, then no output is produced by the validation framework. If the data fails a map step, one or more errors will be produced from that step. It is important to understand the independent nature of the map steps, and that each step is designed to look for certain failures. In some cases, data may fail on multiple mapsteps; a failure of an enumeration value in a schema may also present itself as a failure in the map rules.

For example, to process a **pacs\_008\_001\_08** message, the message is validated against the following:

- **pacs\_008\_001\_08 schema**
- SEPA rules not in the schema
- UNIFI rules (Optional feature)

## Validation framework map naming conventions

To navigate easily through the maps in the validation framework, it is important that you understand the map naming conventions.

The naming convention used in the validation framework maps is a combination of an eight character coded reference, plus a string that matches the SEPA schema naming convention. When looking at the validation framework map names, notice that periods are replaced by underscores (`_`).

The first eight characters are significant, as they must be unique for mainframe processing. The naming scheme for the first eight characters in the validation framework map names is as follows:

**"se" + map level + PSP/customer + message + ct/dd**

This is illustrated in the following example. Data conforming to **pacs\_002\_001\_10 FIToFIPmtStsRpt** schema to be validated against the Credit Transfer Implementation Guide would first pass through the level one map named:

**se1b002c\_FIToFIPmtStsRpt**

**"se" + map level="1" + PSP/customer="PSP"="b" + message = "002" + ct/dd="ct"="c"**

The map name is shown below with the first eight characters indicated:

Characters 1 through 8 are defined as follows:

- **Characters 1 and 2** – These characters always begin with the literal **se**.
- **Character 3** – This character indicates the validation framework mapping level. It may be a **0**, or a **1**. There are two validation framework mapping levels:
  - **Level-zero maps** – At the highest level are framework level maps, called level-zero maps. A level-zero map always contains a **0**.
  - **Level-one maps** – At the next level of detail are validation level maps, or level-one maps. These maps perform specific validation for the messages. A level-one map always contains a **1**.
- **Character 4** – This will be character **b** to indicate the message is PSP-to-PSP. Character **c** to indicate the message is customer-to-PSP and character **e** to indicate the message is an e-Mandate.
- **Character 5, 6 and 7** – These characters indicate the UNIFI message name.
- **Character 8** – This character indicates whether the message is used for a credit transfer, or for a direct debit. Credit transfers are indicated when a **c** appears in this character position. A direct debit is indicated when a **d** appears in character position 8. Characters **e**, **f**, **g**, **h**, **i**, **j** and **m** are variations of map names.

The remainder of the map name (i.e., `_FIToFIPmtStsRpt`) is a direct transformation of the primary schema name.

## How to run SEPA Compliance in Design Studio

These steps describe how to run the SEPA Compliance component in Design Studio.

1. Copy xliff.dtd file from ITX install directory into the mapsandschemas directory.
2. Use the Design Studio to open and build the maps on the following map source files.
  - sepa\_error\_parser.mms
  - sepa\_library.mms
  - sepa\_validation.mms
3. Run the following map from sepa\_validation.mms map source file.
  - sepalid

# How to run the SEPA Compliance in Design Server

These steps describe how to run the SEPA Compliance component in Design Server.

1. Import the sepaCompliance.zip file into the Design Server UI. See the release notes for import instructions.
  2. Create a package for the project and build all the maps.
  3. Open the sepaCompliance project in the Design Server UI.
  4. Run the sepalid
  5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select **View Data**.
  6. To download the output file, see [How to download output files](#).
- [How to download output files](#)  
After you build/run maps, download the output files.

## How to download output files

After you build/run maps, download the output files.

### About this task

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

### Procedure

1. Click the output Card Settings you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:  
  
data/pain008d.xml  
  
copy only:  
  
pain008d.xml
3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

## Types of customization for SEPA validation

This section describes how to add a new schema or validation step, modify a validation step, and modify or add validation rules.

Note: Customization requires modification of the SEPA component validation maps. Make a copy of the validation maps prior to customization to avoid the need to reinstall the SEPA component of the Pack for Financial Payments, if you need to go back to the original maps.

- [Adding new schemas](#)  
If you are not using the published ISO 20022 UNIFI schemas or the EPC revised schemas published for SEPA, you will have to add any customized schemas to the framework.
- [Adding new validation steps](#)  
If you are using customized SEPA schemas, you must customize the framework, and possibly the validation maps, that the validation framework calls.
- [Modifying validation steps](#)  
These steps describe how to modify validation steps.
- [Modify or add validation rules](#)  
In many cases, you will have to either add additional validation rules, or perhaps in the case of the **pain.xx** message types, where all of the recommended rules in the SEPA implementation guidelines are included, you may need to remove some rules.

## Adding new schemas

If you are not using the published ISO 20022 UNIFI schemas or the EPC revised schemas published for SEPA, you will have to add any customized schemas to the framework.

This might be necessary if you are implementing recommended and mandatory fields in the customer-to bank messages. It might also be appropriate if the message is being sent to another member of an AOS community, and the schema has been modified to more specifically define those message element fields that are permitted by SEPA. This process requires tree and map modifications.

Follow these procedures to add a new schema:

1. Add the new schema name to the seagen.xsd schema located in the mapsandschemas directory, and save the file. This is a simple schema, and contains a choice group with the list of schemas currently used by SEPA. A new element can be inserted as follows:

```
<xss:element name="custom_schema_name" type="xs:string">
```

2. Open the Type Designer and modify the existing seagen file by importing the seagen.xsd schema that you edited in step 1 as a Classic type tree.

3. Place the modified type tree in the type\_trees directory.

4. Check to make certain that your customized schema is located in the mapsandschemas directory.

Note: You must edit seagen after it is created to remove any restriction lists that may have been created by the import process. At this point in the validation, we need to treat the bulk of the instance document as a blob of data (disregarding XML tags), until it is passed to the lower level maps that perform the validation

The previous steps will allow an instance document based on your new schema to be processed by the validation framework. However, to perform specific validation, you must add a new validation step for this schema. See [Adding new validation steps](#).

## Adding new validation steps

If you are using customized SEPA schemas, you must customize the framework, and possibly the validation maps, that the validation framework calls.

Here you will find a description of how to add new schemas or customize existing ones. Even if you are using only the existing SEPA schemas, you may want to add a new map step. One example could be that your overall implementation requires you to process SEPA messages that only contain a certain number of payment transactions, which is less than the number allowed by SEPA.

Creating a new map step involves updating the validation framework maps to:

- Optionally extract a subset of information from the message to make downstream mapping more straightforward, with the use of a NVP WorkTemp. See [About NVP WorkTemps\(s\)](#).
- Set up the new step as a call to a functional map.
- [About NVP WorkTemps\(s\)](#)  
The NVP WorkTemp(s) are used to extract information from the data, and from previous steps, without the need for excess hierarchical functional map calling structure.
- [Add a custom schema](#)

## About NVP WorkTemps(s)

The NVP WorkTemp(s) are used to extract information from the data, and from previous steps, without the need for excess hierarchical functional map calling structure.

In other words, there are some things that you cannot easily do all on one map rule. NVP WorkTemp(s) are found at both the **sevalid** map level and the zero level maps (for example, **se0b002d\_FIToFIPmtStsRpt**). As a general rule, if the information being extracted in a NVP WorkTemp(s) is useful to most of the messages, it should be extracted at the sevalid map level and passed into the zero level maps as parameters. In the case of adding new custom mapsteps, if you are adding multiple steps, and this information will be used in all the validation maps for those steps, extract at the **sevalid** map level. For new steps, however, many of the anticipated new pieces of information needed are expected to pertain just to that new mapstep. In this case the NVP WorkTemp(s) in the new step should be used.

## Add a custom schema

The process for adding a custom schema uses the **sevalid** map. This process adds a new run map call to the existing validation maps, or could call a new or modified validation map. Follow the procedures below to add a validation step.

1. Open **sepa\_validation** in the map designer, then select output card 1 of the **sevalid** map.
2. If desired, create a new NVP WorkTemp under the Global WorkArea. This can then be passed to any of the new validation steps created.
3. Add an index to the FileType(s) group. To do this, first go to the bottom of the **sevalid** map. Right click on the **FileType(s)** and add an index. This index will have a corresponding call to a level zero (se0) functional map that will call the validation level one (se1) run map for validation. The corresponding level zero map can also contain framework rules.
4. In the FileTypes element group, complete all elements as needed for the new FileType. The following table provides a description of the table groups and associated elements.
5. Create the required functional maps and run maps to perform the validation required. You may want to copy other maps within the validation framework as a starting point.
6. If you want to use an NVP WorkTemp at the functional map level, these are found in the output card as an indexed group under the Step WorkArea element.

| Group                         | Action                                                                                                                                                                                                                                          |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| StepDescription Element Group | Add a description of the step.                                                                                                                                                                                                                  |
| StepWorkArea Element Group    | Create indexes as needed in the <b>NVP WorkTemp</b> .                                                                                                                                                                                           |
| Operation Group               | <b>RUNCall</b> Element = Used for running map commands.<br><b>PUTCall</b> Element = Used for putting files or queues etc., using an ITX adapter.<br><b>DBCall</b> Element = Used for connecting to an external database for framework activity. |
| Step Results Element Group    | Used for reporting step results.                                                                                                                                                                                                                |

## Modifying validation steps

These steps describe how to modify validation steps.

1. Navigate to the desired functional map in **sevalid** that needs to be updated. Notice that the functional map names begin with **se0**. The framework maps all have this naming convention, while the validation run maps all start with **se1**. These maps are also referred to as level zero and level one maps.  
Note: The 8 character prefix name for all of the maps must be consistent in order to facilitate deployment to z/OS.
2. Add an index to the **STEP(s)** element. The **STEP (s)** element is always at the bottom of the output card in the functional map.
3. In the **STEP [n]** element, complete the following groups and associated group elements as described in the table in the **Adding a validation step** section.

## Modify or add validation rules

In many cases, you will have to either add additional validation rules, or perhaps in the case of the **pain.xx** message types, where all of the recommended rules in the SEPA implementation guidelines are included, you may need to remove some rules.

Refer to the following section **Guidelines for modifying or adding validation rules** when modifying or adding validation rules. To add error messages, refer to the **Adding error messages** section.

- [Guidelines for modifying or adding validation rules](#)  
Observe these guidelines when modifying or adding validation rules.
- [Adding error messages](#)  
All of the rules call the **seplib05\_extract\_error\_msg** functional map. This map is used for the framework and the validation maps to create error messages in the **seperror.xml** output file.

## Guidelines for modifying or adding validation rules

Observe these guidelines when modifying or adding validation rules.

- All of the rules are in the **se1\*** run maps.
- Rules are added by creating a 'Rule' index.
- Rules are organized in the order that they appear in the SEPA Implementation Guides.
- Comments in each existing rule refer to the correct index in the SEPA Implementation Guides.

## Adding error messages

All of the rules call the **seplib05\_extract\_error\_msg** functional map. This map is used for the framework and the validation maps to create error messages in the **seperror.xml** output file.

Two values are echoed. The first value in this rule, for example **SEP0019E**, corresponds to the error number in the **sepamsgs.xml** file that contains all of the error messages used in the framework and validation maps. The second value is passed into the {0} variable in the **sepamsgs.xml**, and can be any text string data.

When you want to add additional error messages to the **sepamsgs.xml**, make certain that you add them in the same format as the existing messages. Each message will have 3 trans-unit-ids:

- Error Message (EM)
- Extended Error (EE)
- Error Action (EA)

String values from the map are passed into the EM id using the {0} variable. Any additions to this file must be added in ascending trans-unit id order.

## Handling failures and unexpected results

Between the validation framework built-in debugging tools, and general ITX debugging techniques, it is possible to obtain information about map and data format failures, as well as and unexpected results.

The first step that should be taken if any unexpected results are encountered, is to consult output card 3 (**seperror.xml** by default). This output contains an XML structure that describes any framework or validation errors in end-user terms. The next section describes output card 3 validation errors. If output card 3 is checked, and the reason for the failure is not apparent, consult output card 1. Refer to the Output card 1 section for details of this procedure.

For a description of the SEPA error parser and instructions on how to run the **sepa\_error\_parser** utility map, see [SEPA schema error parser \(Deprecated\)](#).

- [Checking output card 1](#)
- [Checking output card 3](#)
- [SEPA schema error parser \(Deprecated\)](#)

## Checking output card 1

If the reason for the failure is still not apparent after consulting output card 3, check output card one. First, create this file, if calling **sevalid** from outside of Map Designer, or in the Map Designer change the output card settings from **sink** to **file** and specify an output file location (a suggested name is **out.xml**). By default, this card is suppressed (card setting of **sink**) from creation. This XML instance document will contain a log of all processing during the run of the **sevalid** map. It will also list all of the temporary variables used and show the various map steps performed and their results.

You will be able to use this output to track the steps of the framework and determine on which map the failure is occurring, or the unexpected results are being introduced.

## Checking output card 3

Output card 3 shows the name of the file being validated, the name of the (optional) original file to be validated, the start and end date/times and any errors. If there are no errors reported by the validation framework for a map run then this output will not be created.

- [Example of output card 3 validation errors](#)

## Example of output card 3 validation errors

Output card 3 validation errors are illustrated in the following example:

```
<MapInfo>
<FileToValidate>/opt/data/hipfiles/5bd883af2ab79c00a1168c0b/5c07ea2c2ab79c00272650f0/maps/./data/pacs812c.xml</FileToValidate>
<OriginalFile>/opt/data/hipfiles/5bd883af2ab79c00a1168c0b/5c07ea2c2ab79c00272650f0/maps/./data/sep000.xml</OriginalFile>
 <Start>20181206154248</Start>
 <End>20181206154248</End>
 <Validation>
 <Description refId="PmtInfId:SUB - EndToEndId:SUB">

 <Action>Ensure the Payment Type Information is present either in Payment Information level or the
Credit Transfer Transaction Information level, but not in both levels</Action>
 </Description>
 </Validation>
</MapInfo>
```

## SEPA schema error parser (Deprecated)

If you encounter a SEPA schema validation error when SEPA validation is performed using the maps in sepa\_validation, you are presented with a SEP0300E or SEP0301 error message in the error log. There are many elements in these schemas that SEPA does not use. In this event, only the SEP0300E or SEP0301E errors will appear in the error log. To help to determine what these errors are, you can use the sepa\_error\_parser utility map.

The sepa\_error\_parser runs the SEPA data file through schema validation with the TX trace option turned on. In order to expedite diagnosis of errors, this map will create a subset data file containing only the bad transactions. The XML trace log will be parsed, which will then be used by this framework to retrieve the error data information for the input data. The list of data errors will be presented as the output to the framework, which will show the line numbers of the data that is in error, as well as the element that failed validation. After the framework completes the process, refer to the subset bad data file which will be presented as card 4 in the utility map (errordat.xml) and the error log to correct schema errors in the data.

- [Running the error parser](#)

## Running the error parser

Follow these instructions to run the **sepa\_error\_parser** map:

1. Pass your SEPA data file into the **errparse** run map with an override to input card 1.
2. Retrieve the error log, which will be output card 3. The contents will refer to the subset data file that was used to create the error log. Use this subset data file to locate and correct the schema errors.

Note: If you are a z/OS user, you must modify the **sepa\_error\_parser.jcl** located in the **mapsandschemas** directory. You can then deploy to your system.

## BIC plus IBAN validation and lookup

Proper handling of bank identification with either the Bank Identification Code (BIC), or International Bank Account Number (IBAN) is required throughout the SEPA process, a process that includes validation, domestic format conversion, and client data mapping..

Although the IBAM has the same function in multiple countries, the components that comprise the IBAN can vary in length, or in other requirements. This increases the complexity involved in SEPA implementations.

- [The BICPlusIBAN directory](#)

In January 2008, SWIFT enhanced the BIC Database Plus directory to include IBAN information and published a revised directory structure with additional fields. The BIC Database Plus directory is now called the BICPlusIBAN directory.

- [The BICPlusIBAN utility](#)

The BICPlusIBAN utility provides a way to look-up BIC or IBAN information in the published directory. This utility can be used within domestic converter maps based on the samples provided in the pack, or implemented in an application map separate from individual message processing.

- [Turning BIC and IBAN checking on and off](#)

You are able to disable both the BIC and the IBAN checking from within the SEPA validation framework.

## The BICPlusIBAN directory

In January 2008, SWIFT enhanced the BIC Database Plus directory to include IBAN information and published a revised directory structure with additional fields. The BIC Database Plus directory is now called the BICPlusIBAN directory.

The BICPlusIBAN directory provides data for financial institutions in all SEPA countries. Through this directory, all BICs and IBANs are systematically checked against the latest versions of both the ISO BIC directory and the ISO IBAN registry, for which SWIFT is the registration authority. SWIFT validates the data with financial institutions, national banks and banking institutions. Additionally, cross checks against data from multiple sources improve the quality and consistency.

The BICPlusIBAN directory helps you to perform the following tasks:

- increase STP rates
- lower the cost associated with handling rejected messages
- comply with SEPA mandate requiring the use of IBAN and BIC
- provide better service to your clients by repairing incomplete messages

## The BICPlusIBAN utility

The BICPlusIBAN utility provides a way to look-up BIC or IBAN information in the published directory. This utility can be used within domestic converter maps based on the samples provided in the pack, or implemented in an application map separate from individual message processing.

For example, the utility could be used within an application map to prepare, in advance, a subset of the BIC-IBAN information if not all of the countries or institutions represented in the directory were required in a particular SEPA implementation.

For any IBAN specified in a payment, directed to any SEPA country, by using the utility along with the BICPlusIBAN directory you are able to lookup the associated BIC to be used in the SEPA payment. The lookup function also returns those BICs that cannot be simply derived from the national bank code included in the IBAN. You can also validate the BICs, and the IBANs and their relationships in your outgoing SEPA payments. The utility is based on the specifications provided by SWIFT to accommodate the varying lengths and other requirements of the fields within the IBAN. Conversely, you can also use the utility to do a BIC lookup based on a particular IBAN.

- [BICPlusIBAN support](#)

These are the BICPlusIBAN files in the SEPA component, with a description, related type trees, and scenarios illustrating which maps to use.

## BICPlusIBAN support

These are the BICPlusIBAN files in the SEPA component, with a description, related type trees, and scenarios illustrating which maps to use.

## BICPlusIBAN files

BICPlusIBAN file name	Description	Type trees
bi.txt	BI (BICPlusIBAN) file, gives information about financial institutions and their IBAN-related data	bi
is.txt	IS (IBAN structure) file, gives information about IBAN structure applicable in the countries	is
ct.txt	CT (Countries) file, gives information about ISO countries	ct
cu.txt	CU (Currencies) file, gives information about ISO currencies	cu

Note: The files defined above are examples used to show the capabilities of the BICPlusIBAN utility maps. For complete and current versions of the BICPlusIBAN files, download the files from SWIFT.

## Scenarios

The table below presents various scenarios and shows which map to use.

Map name	Scenario
seplib07_derive_bic_from_iban	IBAN is present but BIC is missing in a SEPA payment instruction.
seplib08_validate_bank_id	Ordering customer has constructed the IBAN, and the Bank ID contained in the IBAN needs to be validated.
seplib09_validate_bic	Ordering customer attempted to derive the BIC itself from financial institution's name and address and needs to validate that the BIC is a valid BIC.
seplib10_validate_bic_ibancomb	Verify if the BIC and IBAN belong to one and the same institution
seplib11_validate_ct	Lookup country codes.
seplib12_validate_cu	Lookup currency codes.

## Technical specification for BICPlusIBAN

A technical specification called TECH\_SPEC\_BI.pdf can be downloaded from SWIFT. The information in this specification is the basis of the functions of the BICPlusIBAN utility maps.

## Turning BIC and IBAN checking on and off

You are able to disable both the BIC and the IBAN checking from within the SEPA validation framework.

The following sections describe how to disable these validations.

- [Disabling BIC validations](#)

Perform the following steps to disable BIC validations.

- [Disabling IBAN validations](#)

Perform the following steps to disable IBAN validations,

## Disabling BIC validations

Perform the following steps to disable BIC validations.

### Procedure

1. Open the sepa\_validation source file and locate the following f functional maps:
  - f\_bic\_searchup
  - f\_bic\_searchup\_unifi
2. Change the map rule to =NONE.
3. Comment out the remainder of the rule as noted below:

### Example

```
=NONE
/*f_bic_level2
 ("SEP0002E", EITHER (SEARCHUP (subtype Attr:AttrList:ElemDecl BIC:BICCodes Element:Global:BicList, id
 Attr:AttrList:ElemDecl BIC:BICCodes Element:Global:BicList, CTEXT (BIC, "NATIVE")), "n/a"),
 CTEXT (BIC, "NATIVE") ,
 BicList ,
 path,
 refId)*/
```

## Disabling IBAN validations

Perform the following steps to disable IBAN validations,

### Procedure

1. Open the sepa\_validation source file and locate the f\_format\_IBAN functional map.
2. Change the map rule to =NONE.
3. Comment out the remainder of the rule as noted below:

### Example

```
= NONE
/*f_sub_letter(MID (IBAN, 5, SIZE(IBAN)) + MID (IBAN , 1, 4),
ErrMsg,
path,
CTEXT (OriginalIBAN , "NATIVE"),
RefIds)*/
```

## Domestic format support

The Transformation Extender SEPA component provides domestic support for the following countries.

- the United Kingdom

- Germany

- Italy

- France

- [Domestic format for the United Kingdom](#)

This section describes the BACS domestic format converter for the United Kingdom (U.K.).

- [Domestic format for Germany](#)

The DTAUS data format was defined within the overall online banking standard that was announced in 1995 by the German banks represented by their associations participating in the Central Banking Committee (ZKA - Zentraler Kreditausschuss).

- [Domestic format for France](#)

There are two domestic format converters for France:

- [\*\*Domestic format for Italy\*\*](#)

The domestic format example for Italy includes maps, trees, and data used to convert SEPA data to SIA Rete Interbacaria (RNI) Italian domestic format, and conversion from the domestic formats to SEPA.

- [\*\*SEPA format converters for SWIFTNet FIN\*\*](#)

This documentation describes the SEPA format converter for the SWIFTNet FIN format.

---

## Domestic format for the United Kingdom

This section describes the BACS domestic format converter for the United Kingdom (U.K.).

Note: This format is available for purchase from APACS at [www.apacs.org.uk](http://www.apacs.org.uk), and references Standard 18 - 1 October 2002.pdf BACS Interchange Standards (v18/9 dated 1 October 2002)

The BACS standard contains two formats for data records: BACS input and BACS output. Both of these formats have the same basic field structure of 100 bytes, but the BACS output format is extended by additional fields. The BACS standard also defines Volume and File and User Header records which vary in size. The BACS input and output formats are described in as follows:

- **BACS input** - This format is used by Banks, and their customers, to send payment data to BACS by electronic transfer, or other means. After initial validation, the data is forwarded to the relevant bank(s) using BACS output format. The BACS input format can be either 100 or 106 bytes. The additional 6 bytes are used to specify individual processing dates within BACS. For full details on this process, refer to the BACS User Manual.
- **BACS output** - The BACS output is always 120 bytes. The additional 20 bytes contain fields added after validation by BACS: Error Code, BACS User Number and BACS Reference (unique reference for each payment; used by BACS for query purposes).

The SEPA type tree and converter maps are based upon the output format. If conversion to and from the input format is required, it can be easily achieved since the base 100-byte format is identical, although the extra data provided by the BACS output format is useful in providing additional unique identifiers for each transaction.

There are several types of data records in BACS format. These data records are identified by Transaction Code (TX Code) and vary depending upon whether the sender is a Bank or a Bank's Customer. The SEPA type tree contains a single file description containing all possible record types.

- [\*\*Domestic format example for the United Kingdom\*\*](#)

Example files that describe the United Kingdom domestic format are located in the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/uk directory.

---

## Domestic format example for the United Kingdom

Example files that describe the United Kingdom domestic format are located in the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/uk directory.

See the [Example for the UK](#) documentation for more information.

---

## Domestic format for Germany

The DTAUS data format was defined within the overall online banking standard that was announced in 1995 by the German banks represented by their associations participating in the Central Banking Committee (ZKA - Zentraler Kreditausschuss).

The full standard is the "Homebanking Computer Interface (HBCI)". This format is used for both interbank and customer-bank payments processing in Germany.

In the DTAUS format, a physical file contains:

- a single file header also called Record A
- one or more payment exchange messages called Record C
- a single file trailer called Record E

There is a single format used for both direct debit or credit transfer, identified by Record A (File Header) Field 3 (Identifier). However, a logical file must contain only credits or only direct debits (no mixed payment records). Record A contains the sender and receiver of the file, and is a fixed length of 128 bytes. Each Record C contains details of the orders to be executed (credits or debits) and contains a constant and a variable length section. Record E is used for performing checks.

- [\*\*Domestic format example for Germany\*\*](#)

Example files that describe the domestic format for Germany are located in the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/germany directory.

---

## Domestic format example for Germany

Example files that describe the domestic format for Germany are located in the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/germany directory.

See the [Example for Germany](#) documentation for more information.

---

## Domestic format for France

There are two domestic format converters for France:

- MINOS

- CFONB
  - [\*\*CFONB domestic format converter for France\*\*](#)  
The CFONB organization defines additional formats used in payments processing for the Customer-Bank processes.
  - [\*\*MINOS format converter for France\*\*](#)  
The MINOS domestic format converter for France is defined in the Handbook of SIT Interbank Transaction Standards, and is administered by GSIT, the French Interbank Teleclearing System.
  - [\*\*Domestic format example for France\*\*](#)  
For the SEPA converter examples for France, in which two type trees are provided.
- 

## CFONB domestic format converter for France

The CFONB organization defines additional formats used in payments processing for the Customer-Bank processes.

This format, used in the examples for France, is described in *Remises informatisees d'ordres de paiement International, au format 320 caractères*. This document is available through a catalogue on the web site: [www.revue-banque.fr/editionCatalogue.do?shortcut=edition\\_catalogue](http://www.revue-banque.fr/editionCatalogue.do?shortcut=edition_catalogue). This format will be replaced by an XML based format on which the French banking community works currently, and by the SEPA PAIN (payments initiation) format in the case of SEPA payment operations.

It should be noted that the CFONB format is close to the MINOS format, but each bank has the freedom to adapt the format to its specific needs.

- [\*\*Payment message record types\*\*](#)  
Each CFONB320\_PI payment message is identified by the value of PI in positions 3 to 4 of each record and is composed of the following record types.
- 

## Payment message record types

Each CFONB320\_PI payment message is identified by the value of PI in positions 3 to 4 of each record and is composed of the following record types.

- Mandatory header line identified by the first two characters of: 03.
- Group(s) of detail records consisting of the following:
  - Mandatory detail line identified by the first two characters of: 04.
  - Optional (dependent) line for details related to the Beneficiary Bank. The first two characters are: 05.
  - Optional line for details related to the Intermediate Bank. The first two characters are: 06.
  - Optional line for additional information related to the transfer. The first two characters are: 07.
- Mandatory total line. The first two characters are: 08.

## MINOS format converter for France

The MINOS domestic format converter for France is defined in the Handbook of SIT Interbank Transaction Standards, and is administered by GSIT, the French Interbank Teleclearing System.

This handbook contains the structure of the transactions used for interbank payment information. This document is available to order from the web site: [www.gsit.fr/Gb/information/minos.htm](http://www.gsit.fr/Gb/information/minos.htm).

For the MINOS format, there are various payment types handled through the current system, but only a very few correspond to the payments processing defined by the SEPA rules and datasets. The first payment types of interest are the Virements (sweeps, credit transfers), which are the most common kind of operations handled through the interbanking in France. These map to SEPA Credit Transfer processing. The credit transfer is identified by the 'code opération' in the SIT part of the record = 120. The second payment type of interest is the Prelevement (direct debit) which corresponds to SEPA Direct Debit processing. Different types of direct debits exist, however, the direct debit example included with the SEPA component of the Transformation Extender Pack for Financial Payments uses the message with a 'code operation' = 180 ('Prélèvements 4 jours').

MINOS distinguishes two message directions:

- 'Aller' – from the Bank to the Clearing House (ACH)
- 'Retour' – from the Clearing House to the Bank

Each of these directions can handle different types of operations (Credit transfer, Direct Debit)

'Remise aller' is a payment file containing the following:

- A header record
- 1-N payment operations of a same category and for the same settlement date:
  - Same category means: same type of operation (credit/debit), same currency, same urgency, same end of day (time period)
- A summary record containing control information:
  - Number of operations
  - Total amount
  - Signature

'Remise retour' (remittance ACH to bank): a payment file containing:

- A header record
- 1-N payment messages to be posted in the same basket, composed of:
  - A header record containing the installation number of the issuer
  - 1-N operations issued by the same sender
  - A summary record (number of operations, total amount)
- A summary record containing control information

- Number of messages
  - Total amount
  - Signatures
- 

## Domestic format example for France

For the SEPA converter examples for France, in which two type trees are provided.

- CFONB320, which contains the type tree definitions for the formats that can be defined by “Remises Informatisées D’Ordres de Paiement International” (CFONB320\_PI), and “Remises Informatisées D’Ordres de Virement National France” (CFONB320\_VF). Only the CFONB\_PI format is used in the example maps.
- MINOS, which contains the type tree definitions for many of the MINOS formats

Example files that describe the domestic format for France are located in the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/france directory.

See the [Example for France](#) documentation for more information.

---

## Domestic format for Italy

The domestic format example for Italy includes maps, trees, and data used to convert SEPA data to SIA Rete Interbacaria (RNI) Italian domestic format, and conversion from the domestic formats to SEPA.

RNI Is a proprietary message format from SIA Interbank Company for Automation (Società Interbancaria per l'Automazione). These messages are used to carry out banking operations such as the following:

- Exchange accounting information
- Determining the balance of each participant
- Procedures for truncated cheques
- Electronic collection orders (RIBAs)
- Direct debits
- Retail credit transfers

These procedures are managed by service providers, or *centri applicativi*, which are bank-owned software companies that carry out a number of activities on the banks' behalf in connection with the exchange of accounting information on interbank payments.

- [Domestic format example for Italy](#)

Example files that describe the domestic format for Italy are located in the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/italy directory.

---

## Domestic format example for Italy

Example files that describe the domestic format for Italy are located in the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/italy directory.

See the [Example for Italy](#) documentation for more information.

---

## SEPA format converters for SWIFTNet FIN

This documentation describes the SEPA format converter for the SWIFTNet FIN format.

Mapping guidelines exist for the SWIFTNet FIN MT 101, MT 102, MT 102+, MT 103, MT 103+message.

- [SWIFTNet FIN format example](#)

Example files that describe the SWIFTNet FIN format are located in the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/swiftfin directory.

---

## SWIFTNet FIN format example

Example files that describe the SWIFTNet FIN format are located in the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/swiftfin directory.

See the [SWIFTNet FIN / SEPA example](#) documentation for more information.

---

## SEPA component examples

Examples are included in the pack installation to assist you in using the SEPA component.

- [Validation using the EPC schemas example](#)

The Validation using the EPC schemas example is used to replace the existing validation framework maps that use the ISO20022 published XML schemas with maps that use the abbreviated Technical Validation Subset (TVS) published by the EPC.

- [Example for France](#)

The CFONB organization defines additional formats used in payments processing for the Customer-Bank processes.

- [\*\*Example for Germany\*\*](#)  
The DTAUS data format was defined within the overall online banking standard that was announced in 1995 by the German banks represented by their associations participating in the Central Banking Committee (ZKA - Zentraler Kreditausschuss).
- [\*\*Example for the UK\*\*](#)  
The Example for the UK demonstrates how to use the BACS / SEPA converter maps.
- [\*\*Example for Italy\*\*](#)  
The domestic format example for Italy includes maps, type trees, and data used to convert SEPA data to SIA Rete Interbacarria (RNI) Italian domestic format, and conversion from the domestic formats to SEPA.
- [\*\*PAIN / PACS example\*\*](#)  
This example shows how to use the PACS to PAIN message and the PAIN to PACS message converter maps.
- [\*\*Passthrough Example for z/OS\*\*](#)  
The Passthrough Example for z/OS, validates a message against a schema in the z/OS environment and contains a sample of the JCL required to run it.
- [\*\*Sample JCL for the validation framework maps example\*\*](#)  
This example demonstrates how to deploy and execute the SEPA validation maps on z/OS batch.
- [\*\*SWIFTNet FIN / SEPA example\*\*](#)  
This example demonstrates how to use the SWIFTNet FIN / SEPA example.

## Validation using the EPC schemas example

The Validation using the EPC schemas example is used to replace the existing validation framework maps that use the ISO20022 published XML schemas with maps that use the abbreviated Technical Validation Subset (TVS) published by the EPC.

- [\*\*Download the EPC schemas\*\*](#)  
Before you can use the EPC Validation example, you must download the EPC schemas from SEPA. Instructions for downloading the schemas are available in the IBM Transformation Extender Pack for Financial Payments release notes.
- [\*\*Example maps and schemas\*\*](#)  
The maps included in the epc\_mapsandschemas.mms source file are identically named as the SEPA validation map source, sepa\_validation in the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/epc\_mapsandschemas/mapsandschemas directory.
- [\*\*How to run the example in Design Studio\*\*](#)  
These steps describe how to run the Validation using the EPC schemas example.
- [\*\*How to run the example in Design Server\*\*](#)  
Run instructions for the EPC SEPA Validation example.

## Download the EPC schemas

Before you can use the EPC Validation example, you must download the EPC schemas from SEPA. Instructions for downloading the schemas are available in the IBM Transformation Extender Pack for Financial Payments release notes.

Download instructions for the Direct Debit and Credit Transfer implementations for this example are provided in a readme file that installs with the pack. Go to the following location and follow the instructions contained in the readme file:

```
<install_dir>/packs/financial_payments_vn.n.n.n/sepa/examples/epc_mapsandschemas/readme_epc_mapsandschemas.txt
```

## Example maps and schemas

The maps included in the epc\_mapsandschemas.mms source file are identically named as the SEPA validation map source, sepa\_validation in the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/epc\_mapsandschemas/mapsandschemas directory.

The example maps replace the sepa\_validation maps, and achieve better performance because of the use of the abbreviated EPC schemas.

The <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/epc\_mapsandschemas/mapsandschemas directory includes a batch script called build\_epc\_mapsandschemas.bat. This batch script deploys all of the necessary files to the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/epc\_mapsandschemas/mapsandschemas directory and compiles the epc\_sepa\_validation.mms maps. Instructions for running the batch script are provided below.

## How to run the batch script

1. Open a command prompt window and navigate to the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/epc\_mapsandschemas/mapsandschemas directory.
2. Determine the parameters you want to use. The script uses two mandatory parameters:
  - a. The platform for building the maps. The choices available would be the same as the platforms supported by the corresponding TX version installed
  - b. The type of SEPA map to compile:
    - ct
    - dd
    - both
  - c. The TX install directory path
3. At the prompt, type in: build\_epc\_mapsandschemas.bat followed by the platform choice listed above, the SEPA type choice, and the TX install directory path.

Examples:

- To build both the credit transfer and direct debit maps for Windows operating system, enter the following at the command prompt:

build\_epc\_mapsandschemas.bat WINDOWS both and <TX\_install\_dir>

- To build the credit transfer maps for ZOS operating system, enter the following at the command prompt:  
build\_epc\_mapsandschemas.bat ZOS ct and <TX\_install\_dir>
- To build the direct debit maps for ZLINUX operating system:  
build\_epc\_mapsandschemas.bat ZLINUX dd and <TX\_install\_dir>

---

## How to run the example in Design Studio

These steps describe how to run the Validation using the EPC schemas example.

### About this task

If you use the deploy script, the example maps are deployed to  
<install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/epc\_mapsandschemas/mapsandschemas from the example directory. The deployed maps replace any existing compiles of the sepa\_validation map source. The maps are run using sepalid.mmc the same way as instructed in the Pack for Financial Payments user documentation.

### Procedure

1. Copy the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/type\_trees directory to the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/epc\_mapsandschemas/mapsandschemas directory.
2. Use the Design Studio to open the following map source file:  
<install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/epc\_mapsandschemas/mapsandschemas/epc\_sepa\_validation.mms
3. Verify the input and output card settings to ensure the correct files are being used.
4. Build the map in the source file, and then run the following transformation map:
  - sepalid
  - [Notes about the maps](#)

---

## Notes about the maps

Note these points about the maps:

- It is assumed that the schemas have been downloaded from the EPC website, unzipped, renamed, and placed in the correct location. See the release notes for instructions on downloading schemas.
- These maps differ from the main validation maps in that they have much more schema validation than the main validation maps due to the EPC schemas having more restrictions in place. As a result, error messages generated from these maps will be different in many cases, but will produce an error message if the main map has produced an error for the same data.
- The EPC schemas only allow fields that are shaded in yellow in the implementation guides. Using other fields will result in input validation errors, so if other fields are needed, then these maps should not be used.

---

## How to run the example in Design Server

Run instructions for the EPC SEPA Validation example.

### Before you begin

Before you can run the SEPA EPC Validation example, you must add the schemas that you download from SEPA with the schemas that are contained in the **sepaEPC.zip** file. Before you import the **sepaEPC.zip** into the Design Server.

### About this task

These steps describe how to run the EPC SEPA Validation example.

### Procedure

1. Download the schemas from SEPA.
2. Unzip the contents of the **sepaEPC.zip**.
3. Add the schemas that you downloaded from SEPA to  
filedata/schemas/ct  
filedata/schemas/dd  
schemadata/schemas/ct

- schemadata/schemas/dd
4. Compress the following folders into a compressed file called: sepaEPC\_upd.zip.
    - filedata
    - files
    - maps
    - schemadata
    - schemas
  5. Import into the Design Server as described in Importing projects.
  6. Create a package for the project and build all the maps.
  7. Open the sepaEPC\_upd.zip project.
  8. Run the following map:
    - sepalid
  9. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
  10. To download the output file, see [How to download output files](#).
- **[Building multiple maps using Deploy](#)**  
To deploy large numbers of maps (generally, when a project contains more than 10 maps), use the instructions provided here.
  - **[How to download output files](#)**  
Download the output files.
  - **[Notes about the maps](#)**  
Additional points to note about the maps.

---

## Building multiple maps using Deploy

To deploy large numbers of maps (generally, when a project contains more than 10 maps), use the instructions provided here.

### About this task

---

Follow these steps to deploy large numbers of maps:

### Procedure

---

1. From the Design Server UI, click on the Deploy drop down, and click Packages.
2. Define a new Package, then click Add icon.
3. Define a Name field on the Edit Package dialog.
4. From the Project drop down, select the project.
5. Check top level box on Maps and Files drop down, this select all maps and files in the project
6. Save the Package.
7. Return to Design Server UI, main page, click Deploy drop down, scroll down and select Deploy from the list on the left.
8. Select the desired server (see the Server definition on Deployment > Deployment overview) and select the package.
9. Click Deploy.
10. Return to the Design Server UI, main page, click Design, select project (one just deployed).
11. Open the map.

---

## How to download output files

Download the output files.

### About this task

---

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

### Procedure

---

1. Click the output Card Settings you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:

data/ach\_contested\_dishonored\_return.out

copy only:

ach\_contested\_dishonored\_return.out

3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.

6. Click Ok.
  7. Build and re-run the map.
  8. Go to Files and select Download to view the data.
- 

## Notes about the maps

Additional points to note about the maps.

- It is assumed that the schemas have been downloaded from the EPC website, unzipped, renamed and placed in the correct location.
  - These maps differ from the main validation maps in that they have much more schema validation than the main validation maps due to the EPC schemas having more restrictions in place. As a result, error messages generated from these maps will be different in many cases, but will produce an error message if the main map has produced an error for the same data.
  - The EPC schemas only allow fields that are shaded in yellow in the implementation guides. Using other fields will result in input validation errors, so if other fields are needed, then these maps should not be used.
- 

## Example for France

The CFONB organization defines additional formats used in payments processing for the Customer-Bank processes.

This format, used in the examples for France, is described in *Remises informatisees d'ordres de paiement International, au format 320 caracteres*. This document is available through a catalogue on the web site: [www.revue-banque.fr/editionCatalogue.do?shortcut=edition\\_catalogue](http://www.revue-banque.fr/editionCatalogue.do?shortcut=edition_catalogue). This format will be replaced by an XML based format on which the French banking community works currently, and by the SEPA PAIN (payments initiation) format in the case of SEPA payment operations.

It should be noted that the CFONB format is close to the MINOS format, but each bank has the freedom to adapt the format to its specific needs.

- [Directory structure](#)
  - [Example for France components](#)  
Example maps, type trees and example files, install with the pack and are required to run the Example for France.
  - [Example files](#)  
These example files are included with the Example for France.
  - [How to run the example in Design Studio](#)  
Steps to run the Example for France.
  - [How to run the example in Design Server](#)  
Run instructions for the MINOS/CFONB SEPA example (example for France).
- 

## Directory structure

The files needed to run the Example for France are located in subdirectories under:

```
<install_dir>/packs/financial_payments_vn.n.n/n/
```

This table shows the installed location of all of the files required for the example:

Directory:	Description
./sepa/examples/france/data	Sample input test data for MINOS and CFONB conversions.
./sepa/examples/france/maps	Example converter maps for France.
./sepa/examples/france/type_trees	MINOS and CFONB type trees
./sepa/mapsandschemas	Contains all UNIFI schemas used by the maps.
./sepa/type_trees	Contains all UNIFI type trees used by the maps.

## Example for France components

Example maps, type trees and example files, install with the pack and are required to run the Example for France.

The type trees, maps, and example files for the Example for France install in these directories (respectively):

```
<install_dir>/packs/financial_payments_vn.n.n/n/sepa/examples/france/type_trees
```

```
<install_dir>/packs/financial_payments_vn.n.n/n/sepa/examples/france/maps
```

```
<install_dir>/packs/financial_payments_vn.n.n/n/sepa/examples/france/data
```

- [Type trees](#)  
These type trees install with the pack and are required to run the Example for France:
- [Maps](#)  
These maps install with the pack and are required to run the Example for France:

## Type trees

These type trees install with the pack and are required to run the Example for France:

- minos.mtt - Contains a definition for selected MINOS formats as defined in Version 5 of the MINOS Standard and validated against real life sample data.
- CFONB320.mtt - Contains a definition for the CFONB Paiement International (PI) and Virement National France (VN) as defined in Version 3 dated January 2005 and validated against real life sample data.

## Maps

These maps install with the pack and are required to run the Example for France:

- sepa\_fr.mms - Contains these executable maps:
  - sepfr3ct\_pacs\_008\_minos - Converts from \$pacs.008 UNIFI to MINOS Remise Aller Virement (Credit Transfer). The records are all given a default code operation 120.
  - sepfr5dd\_pacs\_003\_minos - Converts from \$pacs.003 UNIFI to MINOS Remise Aller Prelevement (Direct Debit). The records are all given a default code operation of 180 (Prelevement a 4 jours).
  - sepfr1ct\_pain\_001\_cfobn - Converts from pain.001 UNIFI to CFONB Virement National France (Credit Transfer)format. The CFONB records are all given a default code operation of VF.
- fr\_sepa.mms - Contains these executable maps:
  - frsep3ct\_minos\_pacs\_008 - Converts from MINOS Remise Aller Virement (Credit Transfer) to \$pacs.008 UNIFI message.
  - frsep5dd\_minos\_pacs\_003 - Converts from MINOS Remise Aller Prelevement (Direct Debit) to \$pacs.003 UNIFI message.
  - frsep1ct\_cfobn\_pain\_001 - Converts from CFONB Virement National France (Credit Transfer) format to \$pain.001 UNIFI message.

## Example files

These example files are included with the Example for France.

- sepa\_minos\_config.xml - This configuration file is to be used as input card #1 to the following executable maps:

- sepfr3ct\_pacs\_008\_minos.mmc
- sepfr5dd\_pacs\_003\_minos.mmc
- frsep3ct\_minos\_pacs\_008.mmc
- frsep5dd\_minos\_pacs\_003.mmc

This configuration file is used to populate sample valid values such as IBAN and BIC numbers used by SEPA. It can be modified as needed to add more specific values.

- sepa\_cfobn\_config.xml - This configuration file is to be used as input card #1 to the following executable maps:

- frsep1ct\_cfobn\_pain\_001.mmc
- sepfr1ct\_pain\_001\_cfobn.mmc

- bic.xml - File that contains BIC numbers used in the configuration and sample input files.

- FIToFICstmrcdtTrf\_pacs008.xml - Sample data for input card #2 of sepfr3ct\_pacs\_008\_minos.mmc

- FIToFICstmrdrcdtDbt\_pacs003.xml - Sample data for input card #2 of sepfr5dd\_pacs\_003\_minos

- CstmrcdtTrfInitn\_pain001.xml - Sample data for input card #2 of sepfr1ct\_pain\_001\_cfobn.mmc

- fr\_pain001\_cfobn.in - Sample data for input card #2 of frsep1ct\_cfobn\_pain\_001

- fr\_pacs008\_minos.in - Sample data for input card #2 of frsep3ct\_minos\_pacs\_008

- fr\_pacs003\_minos.in - Sample data for input card #2 of frsep5dd\_minos\_pacs\_003

## How to run the example in Design Studio

Steps to run the Example for France.

### About this task

Run the example map as follows:

### Procedure

1. Use the Design Studio to open the following map source files:
  - fr\_sepa.mms
  - sepa\_fr.mms
2. Verify the input and output card settings to ensure the correct files are being used.
3. Build the maps in the source files, and then run the following transformation maps:
  - frsep1ct\_cfobn\_pain\_001
  - frsep3ct\_minos\_pacs\_008
  - frsep5dd\_minos\_pacs\_003
  - sepfr1ct\_pain\_001\_cfobn
  - sepfr3ct\_pacs\_008\_minos
  - sepfr5dd\_pacs\_003\_minos

- **[Customization notes](#)**

Consider these customization points about the maps as you use the Example for France.

## Customization notes

Consider these customization points about the maps as you use the Example for France.

- It is assumed all currencies are EUR.
- In order to determine a BIC from the MINOS format, a translation table lookup is required. This translation table is not supplied with the pack, and must be sourced separately. A default BIC value is used in the configuration file and must be reviewed.
- In order to convert from MINOS Account details to IBAN a translation table lookup is required. This translation table is not supplied with the Pack, and must be sourced separately. Default IBAN values are used in the configuration file and must be reviewed.

## How to run the example in Design Server

Run instructions for the MINOS/CFONB SEPA example (example for France).

### About this task

These steps describe how to run the MINOS/CFONB SEPA example.

### Procedure

1. Import the sepaFR.zip file into the Design Server.
2. Create a package for the project and build all the maps.
3. Open the sepaFR project in the Design Server.
4. Run the following maps:
  - frsep1ct\_cfonb\_pain\_001
  - frsep3ct\_minos\_pacs\_008
  - frsep5dd\_minos\_pacs\_003
  - sepfr1ct\_pain\_001\_cfonb
  - sepfr3ct\_pacs\_008\_minos
  - sepfr5dd\_pacs\_003\_minos
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).
  - [How to download output files](#)  
Download the output files.
  - **[Customization notes](#)**  
Consider these customization points about the maps as you use the Example for France.

## How to download output files

Download the output files.

### About this task

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

### Procedure

1. Click on the output Card Settings you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:

```
data/ach_contested_dishonored_return.out
```

copy only:

```
ach_contested_dishonored_return.out
```
3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.
6. Click Ok.
7. Build and run the map.
8. Go to Files and select Download to view the data.

## Customization notes

Consider these customization points about the maps as you use the Example for France.

- It is assumed all currencies are EUR.
- In order to determine a BIC from the MINOS format, a translation table lookup is required. This translation table is not supplied with the pack, and must be sourced separately. A default BIC value is used in the configuration file and must be reviewed.
- In order to convert from MINOS Account details to IBAN a translation table lookup is required. This translation table is not supplied with the Pack, and must be sourced separately. Default IBAN values are used in the configuration file and must be reviewed.

## Example for Germany

The DTAUS data format was defined within the overall online banking standard that was announced in 1995 by the German banks represented by their associations participating in the Central Banking Committee (ZKA - Zentraler Kreditausschuss).

The full standard is the "Homebanking Computer Interface (HBCI)". This format is used for both interbank and customer-bank payments processing in Germany.

In the DTAUS format, a physical file contains:

- a single file header also called Record A
- one or more payment exchange messages called Record C
- a single file trailer called Record E

There is a single format used for both direct debit or credit transfer, identified by Record A (File Header) Field 3 (Identifier). However, a logical file must contain only credits or only direct debits (no mixed payment records). Record A contains the sender and receiver of the file, and is a fixed length of 128 bytes. Each Record C contains details of the orders to be executed (credits or debits) and contains a constant and a variable length section. Record E is used for performing checks.

- [Directory structure](#)
- [Example for Germany components](#)
  - Example maps, type trees and example files, install with the pack and are required to run the Example for Germany.
- [Maps](#)
  - These maps install with the pack and are required to run the Example for Germany:
- [Example files](#)
  - These example files are included with the Example for Germany.
- [How to run the example in Design Studio](#)
  - These steps describe how to run the Example for Germany.
- [How to run the example in Design Server](#)
  - Run instructions for the DATUS SEPA example (example for Germany).

## Directory structure

The files needed to run the Example for Germany are located in sub-directories under:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/

This table shows the installed location of all of the files required for the example:

Directory:	Description
..../sepa/examples/germany/data	sample input test data for DTAUS conversions.
..../sepa/examples/germany/maps	Example converter maps for Germany.
..../sepa/examples/germany/type_trees	Type trees for Germany.
..../sepa/mapsandschemas	Contains all UNIFI schemas used by the maps.
..../sepa/type_trees	Contains all UNIFI type trees used by the maps.

## Example for Germany components

Example maps, type trees and example files, install with the pack and are required to run the Example for Germany.

The type trees, maps, and example files for the Example for Germany install in these directories (respectively):

<install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/germany/type\_trees

<install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/germany/maps

<install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/germany/data

- [Type trees](#)
  - These type trees install with the pack and are required to run the Example for Germany:

## Type trees

These type trees install with the pack and are required to run the Example for Germany:

This subdirectory contains the following .mtt files:

- dtaus1.2.mtt
- DTAUS1.3.mtt
- sepa\_config.mtt
- bic.mtt
- SUM.mtt

The trees dtaus1.2 and dtaus1.3 contain definition for all DTAUS domestic record formats.

## Maps

These maps install with the pack and are required to run the Example for Germany:

- de\_sepa.mms - Contains one executable map:
  - desep1ct\_dtaus\_pain001 - This is a Credit Transfer Map that converts a DTAUS domestic record format to a pain.001 Customer Credit Transfer Initiation message.
- sepa\_de.mms - Contains these executable maps:
  - sepde1ct\_pain001\_dtaus - This map converts a Credit Transfer pain.001 message to the DTAUS domestic record format. The pain.001 message is validated using the pain.001.001.09 schema
  - sepde4dd\_pacs003\_dtaus - This map converts a Direct Debit pacs.003 message to DTAUS record format. The pacs.003 message is validated using the pacs.003.001.08 schema
  - sepde2dd\_pain008\_dtaus - This map converts a direct debit pain.008 message to DTAUS record format. The pain.008 message is validated using the pain.008.001.08 schema.

## Example files

These example files are included with the Example for Germany.

- dtseconf.xml - Input card to map desep1ct\_dtaus\_pain001
- CTDTAUS.txt - Input card to map desep1ct\_dtaus\_pain001
- CstmrCdtTrfInitn\_pain001.xml - Input card to map sepde1ct\_pain001\_dtaus.
- BIC.txt - Input card to map sepde1ct\_pain001\_dtaus and sepde2dd\_pain008\_dtaus.
- SEPACConfig.xml - Input card to map sepde1ct\_pain001\_dtaus and sepde2dd\_pain008\_dtaus.
- FIToFICstmrDrctDbt\_pacs003.xml - Input card to map sepde4dd\_pacs003\_dtaus.
- CstmrDrctDbtInitn\_pain008.xml - Input card to map sepde2dd\_pain008\_dtaus.

## How to run the example in Design Studio

These steps describe how to run the Example for Germany.

### About this task

- The maps included in the de\_sepa.mms, are used to convert from domestic DTAUS format to SEPA format.
- The maps included in the sepa\_de.mms, are used to convert from SEPA to domestic DTAUS format.
- It is assumed that all currencies are EUR.
- In order to convert from Domestic Sort Code to BIC a translation table lookup is required. This translation table is not supplied with the Pack for Financial Payments and must be sourced separately. A default BIC value is used in the maps which must be reviewed.

### Procedure

1. Use the Design Studio to open the following map source files:
  - de\_sepa.mms
  - sepa\_de.mms
2. Verify the input and output card settings to ensure the correct files are being used.
3. Build the maps in the source files, and then run the following transformation maps:
  - desep1ct\_dtaus\_pain001
  - sepde1ct\_pain001\_dtaus
  - sepde2dd\_pain008\_dtaus
  - sepde4dd\_pacs003\_dtaus

Note: Map desep1ct\_dtaus\_pain001 reads input file CTDTAUS.txt in the data file, or it can use the one created by map sepde1ct\_pain001\_dtaus and creates a pain.001 file. This resulting file needs to be a valid SEPA file. Ensure the SEPA validation process includes the BIC values used in the resulting pain.001 file. This map uses a config file to populate sample valid values such as IBAN numbers and SEPA. This config file can be modified as needed to add more user specific values.

## How to run the example in Design Server

Run instructions for the DATUS SEPA example (example for Germany).

### About this task

These steps describe how to run the DATUS SEPA example.

### Procedure

1. Import the sepaDE.zip file into the Design Server.
2. Create a package for the project and build all the maps.
3. Open the sepaDE project in the Design Server.
4. Run the following maps:
  - desep1ct\_dtaus\_pain001
  - sepde1ct\_pain001\_dtaus
  - sepde2dd\_pain008\_dtaus
  - sepde4dd\_pacs003\_dtaus
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).
  - [How to download output files](#)Download the output files.

## How to download output files

Download the output files.

### About this task

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

### Procedure

1. Click on the output Card Settings you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:  
  
data/ach\_contested\_dishonored\_return.out  
  
copy only:  
  
ach\_contested\_dishonored\_return.out
3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

## Example for the UK

The Example for the UK demonstrates how to use the BACS / SEPA converter maps.

Note: This format is available for purchase from APACS at [www.apacs.org.uk](http://www.apacs.org.uk), and references Standard 18 - 1 October 2002.pdf BACS Interchange Standards (v18/9 dated 1 October 2002)

The BACS standard contains two formats for data records: BACS input and BACS output. Both of these formats have the same basic field structure of 100 bytes, but the BACS output format is extended by additional fields. The BACS standard also defines Volume and File and User Header records which vary in size. The BACS input and output formats are described in as follows:

- **BACS input** - This format is used by Banks, and their customers, to send payment data to BACS by electronic transfer, or other means. After initial validation, the data is forwarded to the relevant bank(s) using BACS output format. The BACS input format can be either 100 or 106 bytes. The additional 6 bytes are used to specify individual processing dates within BACS. For full details on this process, refer to the BACS User Manual.
- **BACS output** - The BACS output is always 120 bytes. The additional 20 bytes contain fields added after validation by BACS: Error Code, BACS User Number and BACS Reference (unique reference for each payment; used by BACS for query purposes).

The SEPA type tree and converter maps are based upon the output format. If conversion to and from the input format is required, it can be easily achieved since the base 100-byte format is identical, although the extra data provided by the BACS output format is useful in providing additional unique identifiers for each transaction.

There are several types of data records in BACS format. These data records are identified by Transaction Code (TX Code) and vary depending upon whether the sender is a Bank or a Bank's Customer. The SEPA type tree contains a single file description containing all possible record types.

- [\*\*Directory structure\*\*](#)  
The following directory structure is used for the BACS / SEPA example
  - [\*\*Data directory\*\*](#)  
The BACS / SEPA example data directory contains the example files described here.
  - [\*\*Maps\*\*](#)  
The maps directory contains two source maps.
  - [\*\*Type trees\*\*](#)  
The BACS / SEPA example contains one type tree, in the type\_trees directory.
  - [\*\*How to run the example in Design Studio\*\*](#)  
These procedures describe how to run the BACS /SEPA example.
  - [\*\*How to run the example in Design Server\*\*](#)  
Run instructions for the BACS / SEPA example (example for U.K.).
- 

## Directory structure

The following directory structure is used for the BACS / SEPA example

- <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/uk/data
  - Sample input test data for BACS conversions.
- <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/uk/maps
  - Example UK converter maps.
- <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/uk/type\_trees
  - BACS type tree
- <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/mapsandschemas
  - Contains all UNIFI schemas used by the maps.
- <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/type\_trees
  - Contains all UNIFI type trees used by the maps.

## Data directory

The BACS / SEPA example data directory contains the example files described here.

The files listed here are installed in the following directory location:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/uk/data:

- bacs\_ct\_test.dat - Sample test for the uksepa1ct\_bacs\_pain\_001 and uksepa2ct\_bacs\_pacs\_008 maps. The file contains both credit transfer and direct debit data, but only the credit transfer records are processed (identified by transaction type in pos'n 17-18 of "Z4", "Z5" or "99").
- bacs\_dd\_test.dat - Sample test for the uksepa1dd\_bacs\_pain\_008 and uksepa2dd\_bacs\_pacs\_003 maps. The file contains both credit transfer and direct debit data, but only the direct debit records are processed (identified by transaction type in pos'n 17-18 of "01", "04" or "17").
- FIToFICstmrDrctDbt\_pacs003.xml- Sample test data for the sepauk2dd\_pacs\_003\_bacs map.
- FIToFICstmrCdtTrf\_pacs008.xml - Sample test data for the sepauk2ct\_pacs\_008\_bacs map.
- CstmrCdtTrfInitn\_pain001.xml - Sample test data for the sepauk1ct\_pain\_001\_bacs map.
- CstmrDrctDbtInitn\_pain008.xml - Sample test data for the sepauk1dd\_pain\_008\_bacs map.

## Maps

The maps directory contains two source maps.

- [\*\*sepa\\_uk.mms\*\*](#)  
The sepa\_uk.mms map source file contains the executable maps:
- [\*\*uk\\_sepa.mms\*\*](#)  
The uk\_sepa.mms map source file contains the executable maps:

## sepa\_uk.mms

The sepa\_uk.mms map source file contains the executable maps:

- sepauk1ct\_pain\_001\_bacs - Converts from pain.001 UNIFI to BACS credit transfer. The BACS records are all given a default transaction type of "99" (Bank Giro Credit).
- sepauk1dd\_pain\_008\_bacs - Converts from pain.008 UNIFI to BACS direct debit. The BACS records are all given a default transaction type of "17" (Direct Debit).

- `sepauk2ct_pacs_008_bacs` - Converts from pacs.008 UNIFI to BACS credit transfer. The BACS records are all given a default transaction type of "99" (Bank Giro Credit).
- `sepauk2dd_pacs_003_bacs` - Converts from pacs.003 UNIFI to BACS direct debit. The BACS records are all given a default transaction type of "17" (Direct Debit).

Note: For all of the maps, the UTL1 trailer is updated with the credit or debit totals.

---

## uk\_sepa.mms

The uk\_sepa.mms map source file contains the executable maps:

- `uksepa1ct_bacs_pain_001` - Converts from BACS Credit Transfer to pain.001 UNIFI. The UNIFI message is created as a MIXD Grouping, meaning that all unique BACS Originator IDs are mapped to the top-level PmtInf structure, and related Destination IDs are mapped to the nested CdtTrfTxInf structure.
- `uksepa1dd_bacs_pain_008` - Converts from BACS Direct Debit to pain.008 UNIFI. The UNIFI message is created as a "MIXD" Grouping, meaning that all unique BACS Originator IDs are mapped to the top-level PmtInf structure, and related Destination IDs are mapped to the nested DrctDbtTxInf structure.
- `uksepa2ct_bacs_pacs_008` - Converts from BACS Credit Transfer to pacs.008 UNIFI.
- `uksepa2dd_bacs_pacs_003` - Converts from BACS Direct Debit to pacs.003 UNIFI.

---

## Type trees

The BACS / SEPA example contains one type tree, in the type\_trees directory.

The bacs.mtt is located in:

`<install_dir>/packs/financial_payments_vn.n.n/n/sepa/examples/uk/type_trees`

Contains a definition for all BACS payment type, as defined in APACS standard 18, and validated against real-life sample data.

Note: The BACS Output record definition is used.

---

## How to run the example in Design Studio

These procedures describe how to run the BACS /SEPA example.

---

### About this task

Follow these instructions to run the example:

---

### Procedure

1. Use the Design Studio to open the following map source files:
  - `uk_sepa.mms`
  - `sepa_uk.mms`
2. Verify the input and output card settings to ensure the correct files are being used.
3. Build the maps in the source files, and then run the following transformation maps:
  - `uksepa1ct_bacs_pain_001`
  - `uksepa1dd_bacs_pain_008`
  - `uksepa2ct_bacs_pacs_008`
  - `uksepa2dd_bacs_pacs_003`
  - `sepauk1ct_pain_001_bacs`
  - `sepauk1dd_pain_008_bacs`
  - `sepauk2ct_pacs_008_bacs`
  - `sepauk2dd_pacs_003_bacs`

---

## How to run the example in Design Server

Run instructions for the BACS / SEPA example (example for U.K.).

---

### About this task

These steps describe how to run the BACS / SEPA example.

---

### Procedure

1. Import the sepaUK.zip file into the Design Server.
2. Create a package for the project and build all the maps.
3. Open the sepaUK project in the Design Server.
4. Run the following maps:
  - `uksepa1ct_bacs_pain_001`

- uksepa1dd\_bacs\_pain\_008
  - uksepa2ct\_bacs\_pacs\_008
  - uksepa2dd\_bacs\_pacs\_003
  - sepauk1ct\_pain\_001\_bacs
  - sepauk1dd\_pain\_008\_bacs
  - sepauk2ct\_pacs\_008\_bacs
  - sepauk2dd\_pacs\_003\_bacs
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).
- [How to download output files](#)  
Download the output files.
  - [Customize the maps](#)  
Points that should be noted when customizing the BACS / SEPA maps.

## How to download output files

Download the output files.

### About this task

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

### Procedure

1. Click the output Card Settings you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:  
  
data/ach\_contested\_dishonored\_return.out  
  
copy only:  
  
ach\_contested\_dishonored\_return.out
3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

## Customize the maps

Points that should be noted when customizing the BACS / SEPA maps.

- It is assumed all currencies are EUR.
- In order to convert from Domestic Sort Code to BIC a translation table lookup is required. This translation table is not supplied with the pack, and must be sourced separately. A default BIC value is used in the maps which must be reviewed.
- In order to convert from Domestic Account Code to IBAN the relevant BIC4 is required. This is not available, so all IBANs are created with the following format:  
"GB" + "00" = "XXXX" = Domestic Sort Code + Domestic Account No (where "00" is a dummy checkdigit, and "XXXX" is a placeholder for BIC4).
- It is not always obvious how to determine the field equivalences between BACS and UNIFI. The mapping rules for the following data must be reviewed and/or sourced locally at the time of implementation:
  - BACS Account Type
  - BACS Transaction Type
  - UNIFI TxId
  - UNIFI EndToEndId
  - UNIFI InstrId
  - UNIFI MsgId
  - UNIFI CrDtTm (creation date)
  - UNIFI DbtrAgt (debtor's agent)
  - UNIFI CdtrAgt (creditor's agent)UNIFI CdtrAgt (creditor's agent)
  - UNIFI Grpg (grouping)
  - UNIFI InitgPty (initiating party)
  - UNIFI ReqdExctnDt (execution date)
  - UNIFI MndtId (direct debit mandate id)
  - UNIFI DtOfSgntr (date mandate signed)

## Example for Italy

The domestic format example for Italy includes maps, type trees, and data used to convert SEPA data to SIA Rete Interbacaria (RNI) Italian domestic format, and conversion from the domestic formats to SEPA.

RNI Is a proprietary message format from SIA Interbank Company for Automation (Società Interbancaria per l'Automazione). These messages are used to carry out banking operations such as the following:

- Exchange accounting information
- Determining the balance of each participant
- Procedures for truncated cheques
- Electronic collection orders (RIBAs)
- Direct debits
- Retail credit transfers

These procedures are managed by service providers, or *centri applicativi*, which are bank-owned software companies that carry out a number of activities on the banks' behalf in connection with the exchange of accounting information on interbank payments.

- **[Example for Italy components](#)**

Example maps, type trees and example files, install with the pack and are required to run the Example for Italy.

- **[How to run the example in Design Studio](#)**

This Example for Italy demonstrates how to map a RNI message into a corresponding SEPA message.

- **[How to run the example in Design Server](#)**

Run instructions for the RNI SEPA example (example for Italy).

---

## Example for Italy components

Example maps, type trees and example files, install with the pack and are required to run the Example for Italy.

The type trees, maps, and example files for the Example for Italy install in these directories (respectively):

```
<install_dir>/packs/financial_payments_vn.n.n.n/sepa/examples/italy/type_trees
<install_dir>/packs/financial_payments_vn.n.n.n/sepa/examples/italy/maps
<install_dir>/packs/financial_payments_vn.n.n.n/sepa/examples/italy/data
```

- **[Type trees](#)**

These type trees install with the pack and are required to run the Example for Italy:

- **[Maps](#)**

These maps install with the pack and are required to run the Example for Italy.

- **[Example files](#)**

These example files are included with the Example for Italy.

---

## Type trees

These type trees install with the pack and are required to run the Example for Italy:

This subdirectory contains the following .mtt files:

- bonfici\_ordinari\_mssw.mtt - Type tree that represents the credit transfers RNI messages that make use of message switching transfer protocols.
- bonfici\_ordinari\_ft.mtt - Type tree that represents the credit transfers RNI messages that make use of file transfer protocols.
- incassi\_commerciali\_mssw.mtt - Type tree that represents the direct debit RNI messages that make use of message switching transfer protocols.
- incassi\_commerciali\_ft.mtt - type tree that represents the direct debit RNI messages that make use of file transfer protocols.

Note: The type trees are based on SIA-RI-BON 001 document Rel. 5.6 and SIA-RI-ICI 001 document Rel 5.7.

---

## Maps

These maps install with the pack and are required to run the Example for Italy.

- [it\\_sepa.mms](#) - Map source used to convert an RNI message to SEPA core message format.
- [sepa\\_it.mms](#) - Map source used to convert a SEPA core message format to an RNI message.

---

## Example files

These example files are included with the Example for Italy.

The example files are located in the ..//sepa/examples/italy/data directory, and include input files for both [it\\_sepa.mms](#) and [sepa\\_it.mms](#).

- **[Input files for it\\_sepa.mms](#)**

The following are the input files for [it\\_sepa.mms](#).

- **[Input files for sepa\\_it.mms](#)**

The following are the input files for [sepa\\_it.mms](#).

- [Other configuration files](#)

These configuration files store fields that are required in the RNI message format but are not available in the SEPA core message format.

## Input files for it\_sepa.mms

The following are the input files for it\_sepa.mms.

- m550(03)\_in.rete - An Interbank Credit Transfer instruction message.
- m401(riba).rete - An Interbank Direct Debit instruction message.
- m550(04)\_in.rete - A returned Interbank Credit Transfer instruction message.
- m405\_riba(03)\_in.rete - A returned Interbank Direct Debit instruction message.
- m550(05)\_in.rete - A rejected Interbank Credit Transfer instruction message.
- m405\_riba(01)\_in.rete - A rejected Interbank Direct Debit instruction message.
- sepa\_ct\_config.xml - A configuration file used to store fields that are required in the SEPA credit transfer messages but is not available in the RNI message format.
- sepa\_dd\_config.xml - A configuration file used to store fields that are required in the SEPA direct debit messages but is not available in the RNI message format.

## Input files for sepa\_it.mms

The following are the input files for sepa\_it.mms.

- FIToFICstmrCdtTrf\_pacs008.xml - A SEPA Financial Institution to Financial Institution Customer Credit Transfer request core message.
- FIToFICstmrDrctDbt\_pacs003.xml - A SEPA Financial Institution to Financial Institution Customer Direct Debit request core message.
- PmtRtr\_pacs004ct.xml - A SEPA Payment Return core message on a Credit Transfer request.
- PmtRtr\_pacs004dd.xml - A SEPA Payment Return core message on a Direct Debit request.
- FIToFIPmtStsRpt\_pacs002ct.xml - A SEPA Payment Status Report core message on a Credit Transfer request.
- FIToFIPmtStsRpt\_pacs002dd.xml - A SEPA Payment Status Report core message on a Direct Debit request.

## Other configuration files

These configuration files store fields that are required in the RNI message format but are not available in the SEPA core message format.

- rete\_550\_config.xml
- rete\_401\_riba\_config.xml
- rete\_405\_riba\_config.xml
- bic.xml - Contains test BIC(s) utilized in the example.

## How to run the example in Design Studio

This Example for Italy demonstrates how to map a RNI message into a corresponding SEPA message.

### About this task

The example maps allow the use of a configuration file that represents field values specific to the target format that is not readily available from the source format.

### Procedure

1. Use the Design Studio to open the following map source file:
  - it\_sepa.mms
2. Build the maps in the source file, and then run the following transformation maps:
  - itsep02c\_rete\_pacs\_008 - Converts a RNI 550 message into a SEPA pacs.008
  - itsep04d\_rete\_pacs\_003 - Converts a RNI 401 message into a SEPA pacs.003
  - itsep06c\_rete\_pacs\_004 - Converts a returned RNI 550 message into SEPA pacs.004
  - itsep08d\_rete\_pacs\_004 - Converts a returned RNI 401 message (equivalent to a RNI 405) into SEPA pacs.004
  - itsep10c\_rete\_pacs\_002 - Converts a rejected RNI 550 message into SEPA pacs.002
  - itsep12d\_rete\_pacs\_002 - Converts a rejected RNI 401 message (equivalent to a RNI 405) into SEPA pacs.002
3. The 2nd input card makes use of either sepa\_ct\_config.xml or a sepa\_dd\_config.xml. It contains data which are required in the target SEPA format but is not available in the source RNI format.  
For example:

```
constant name : settlement_method with value "CLRG".
```

You must make a business decision as to how to determine what type of settlement will be applied per RNI message that is being converted to SEPA.

During implementation, this file must be replaced with the actual source (that is,, database repository) or it must be based upon your particular situation.

4. Use the Design Studio to open the following map source file:
  - sepa\_it.mms
5. Build the maps in the source files, and then run the following transformation maps:
  - sept02c\_pacs\_008\_rete - Converts a SEPA pacs.008 to a RNI 550 message

- sepit04d\_pacs\_003\_rete - Converts a SEPA pacs.003 to a RNI 401(riba) message
  - sepit06c\_pacs\_004\_rete - Converts a SEPA pacs.004 to a "returned" RNI 550 message
  - sepit08d\_pacs\_004\_rete - Converts a SEPA pacs.004 to a "returned" RNI 401(riba) equivalent to RNI 405 message.
  - sepit10c\_pacs\_002\_rete - Converts a SEPA pacs.002 to a "rejected" RNI 550 message.
  - sepit12d\_pacs\_002\_rete - Converts a SEPA pacs.002 to a "rejected" RNI 401(riba) equivalent to RNI 405 message.
6. The 2nd input card makes use of either rete\_550\_config.xml, rete\_401\_riba\_config.xml or rete\_405\_riba\_config.xml It contains data which is required in the RNI format but is not available in the SEPA format.

For example:

constant name : mittente with value "12345".

You must determine what is the "mittente" (sender) five digit numeric id to be applied per SEPA transaction that is being converted to a RNI message.

During actual implementation, this file must be replaced with actual source (database repository) or must be based upon your unique situation.

7. Prior to executing the sepa validation map against the SEPA messages from this example, perform the following:

- Backup the bic.xml file that is located in:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/mapsandschemas

- Copy the bic.xml file from:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/italy/data

to

<install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/mapsandschemas

## How to run the example in Design Server

Run instructions for the RNI SEPA example (example for Italy).

### About this task

These steps describe how to run the RNI SEPA example.

### Procedure

1. Import the sepaIT.zip file into the Design Server.
2. Create a package for the project and build all the maps.
3. Open the sepaIT project in the Design Server.
4. Run the following maps:
  - itsep02c\_rete\_pacs\_008
  - itsep04d\_rete\_pacs\_003
  - itsep06c\_rete\_pacs\_004
  - itsep08d\_rete\_pacs\_004
  - itsep10c\_rete\_pacs\_002
  - itsep12d\_rete\_pacs\_002
  - sepit02c\_pacs\_008\_rete
  - sepit04d\_pacs\_003\_rete
  - sepit06c\_pacs\_004\_rete
  - sepit08d\_pacs\_004\_rete
  - sepit10c\_pacs\_002\_rete
  - sepit12d\_pacs\_002\_rete
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).

- [Building multiple maps using Deploy](#)

To deploy large numbers of maps (generally, when a project contains more than 10 maps), use the instructions provided here.

- [How to download output files](#)

Download the output files.

## Building multiple maps using Deploy

To deploy large numbers of maps (generally, when a project contains more than 10 maps), use the instructions provided here.

### About this task

Follow these steps to deploy large numbers of maps:

### Procedure

1. From the Design Server UI, click on the Deploy drop down, and click Packages.
2. Define a new Package, then click Add icon.
3. Define a Name field on the Edit Package dialog.
4. From the Project drop down, select the imported project.

5. Check top level box on Maps and Files drop down, this select all maps and files in the project
  6. Save the Package.
  7. Return to Design Server UI, main page, click Deploy drop down, scroll down and select Deploy from the list on the left.
  8. Select the desired server (see the Server definition on Deployment > Deployment overview) and select the package.
  9. Click Deploy.
  10. Return to the Design Server UI, main page, click Design, select imported project (one just deployed).
  11. Open the map.
- 

## How to download output files

Download the output files.

### About this task

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

### Procedure

1. Click on the output Card Settings you want to download.
  2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:
- ```
data/ach_contested_dishonored_return.out
```
- copy only:
- ```
ach_contested_dishonored_return.out
```
3. From Files, click the New icon to open the New File dialog box.
  4. Paste the file name in the Name field.
  5. Click the Folder field drop down and select data.
  6. Click Ok.
  7. Build and re-run the map.
  8. Go to Files and select Download to view the data.
- 

## PAIN / PACS example

This example shows how to use the PACS to PAIN message and the PAIN to PACS message converter maps.

- [Conversions demonstrated by the example](#)
  - [Conversions demonstrated by the example](#)  
The PAIN / PACS example shows how to convert these messages:
    - [How to run the example in Design Studio](#)
    - [How to run the example in Design Server](#)
- Run instructions for the PAIN / PACS example.
- [Customize the maps](#)  
Note these points about the PAIN /PACS example maps:

## Conversions demonstrated by the example

This example show how to convert:

- pain.001.001.09 CustomerCreditTransferInitiation to a PACS.008.001.08 FIToFICustomerCreditTransfer (CORE SEPA message type)
- pain.008.001.08 CustomerDirectDebitInitiation to a PACS.003.001.08 FIToFICustomerDirectDebit (CORE SEPA message type)
- pacs.003.001.08 FIToFICustomerDirectDebit (CORE SEPA message type) to a pain.002.001.10 PaymentStatusReport
- PACS.008.001.08 FIToFICustomerCreditTransfer (CORE SEPA message type) to a pain.002.001.10 PaymentStatusReport

The conversions are based on:

- UNIFI (ISO 20022) Message Definition Reports for Payments Standards - Initiation and Payments Standards - Clearing and Settlement
- European Payments Council RuleBook and Implementation Guidelines for Credit Transfer and Direct Debit Core

The following directory structure is used:

```
<install_dir>/packs/financial_payments_vn.n.n.n/sepa/examples/pain_pacs/data - sample input test data for conversions
<install_dir>/packs/financial_payments_vn.n.n.n/sepa/examples/pain_pacs/maps - example converter maps
<install_dir>/packs/financial_payments_vn.n.n.n/sepa/mapsandschemas - contains all UNIFI schemas used by the maps
<install_dir>/packs/financial_payments_vn.n.n.n/sepa/type_trees - contains all UNIFI type trees used by the maps
where <install_dir> is the installation location of the Pack for Financial Payments.
```

- [Example maps and example files](#)

The maps and example files used in the PAIN/PACS example are contained in the maps and data sub-directories, respectively.

---

## Example maps and example files

The maps and example files used in the PAIN/PACS example are contained in the maps and data sub-directories, respectively.

### Maps

The following PAIN/PACS maps are contained in the `<install_dir>/packs/financial_payments_vn.n.n/n/sepa/examples/pain_pacs/maps` directory:

- `pacs_pain.mms` - contains two executable maps :
  - `pacs_003_pain_002` - Converts from `pacs.003.001.08 FIToFICustomerDirectDebit` to `pain.002.001.10 PaymentStatusReport`.
  - `pacs_008_pain_002` - Converts from `pacs.008.001.08 FIToFICustomerCreditTransfer` to `pain.002.001.10 PaymentStatusReport`.
- `pain_pacs.mms` - contains two executable maps :
  - `pain_001_pacs_008` Converts from `pain.001.001.09 CustomerCreditTransferInitiation` to a `pacs.008.001.08 FIToFICustomerCreditTransfer`.
  - `pain_008_pacs_003` Converts from `pain.008.001.08 CustomerDirectDebitInitiation` to a `pacs.003.001.08 FIToFICustomerDirectDebit`

### Example files

The following PAIN/PACS example files are contained in the `<install_dir>/packs/financial_payments_vn.n.n/n/sepa/examples/pain_pacs/data` directory :

- `FIToFICstmrDrctDbt_pacs003.xml` : Sample test for the `pacs_003_pain_002` map.
- `FIToFICstmrCdtTrf_pacs008.xml` : Sample test for the `pacs_008_pain_002` map.
- `CstmrCdtTrfInitn_pain001.xml` : Sample test for the `pain_001_pacs_008` map.
- `CstmrDrctDbtInitn_pain008.xml` : Sample test for the `pain_008_pacs_003` map.

---

## Conversions demonstrated by the example

The PAIN / PACS example shows how to convert these messages:

- `pain.001.001.09 CustomerCreditTransferInitiation` to a `pacs.008.001.08 FIToFICustomerCreditTransfer` (CORE SEPA message type)
- `pain.008.001.08 CustomerDirectDebitInitiation` to a `pacs.003.001.08 FIToFICustomerDirectDebit` (CORE SEPA message type)
- `pacs.003.001.08 FIToFICustomerDirectDebit` (CORE SEPA message type) to a `pain.002.001.10 PaymentStatusReport`
- `pacs.008.001.08 FIToFICustomerCreditTransfer` (CORE SEPA message type) to a `pain.002.001.10 PaymentStatusReport`

The conversions are based on:

- UNIFI (ISO 20022) Message Definition Reports for Payments Standards - Initiation and Payments Standards - Clearing and Settlement
- European Payments Council RuleBook and Implementation Guidelines for Credit Transfer v4.0 and Direct Debit Core v4.0

---

## How to run the example in Design Studio

### About this task

Follow these steps to run the PAIN/PACS example:

### Procedure

1. Use the Design Studio to open the following map source files:
  - `pain_pacs.mms`
  - `pacs_pain.mms`
2. Verify the input and output card settings to ensure that the correct files are being used.
3. Build the maps in the source files, and then run the following transformation maps:
  - `pacs_008_pain_002`
  - `pacs_003_pain_002`
  - `pain_001_pacs_008`
  - `pain_008_pacs_003`

---

## How to run the example in Design Server

Run instructions for the PAIN / PACS example.

### About this task

These steps describe how to run the PAIN/PACS example.

## Procedure

---

1. Import the sepaPainPacs.zip file into the Design Server.
2. Create a package for the project and build all the maps.
3. Open the sepaPainPacs project in the Design Server.
4. Run the following maps:
  - pacs\_008\_pain\_002
  - pacs\_003\_pain\_002
  - pain\_001\_pacs\_008
  - pain\_008\_pacs\_003
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).
  - [How to download output files](#)  
Download the output files.

---

## How to download output files

Download the output files.

### About this task

---

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

## Procedure

---

1. Click on the output Card Settings you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:  
  
data/ach\_contested\_dishonored\_return.out  
  
copy only:  
  
ach\_contested\_dishonored\_return.out
3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

---

## Customize the maps

Note these points about the PAIN /PACS example maps:

- It is assumed all currencies are EUR.
- Any rules with the comment // NEEDS CODING will have to be modified. The fields that need more coding deal with specific account lookup information, uniqueness over time rules, and settlement dates that cannot be determined from the original data.

---

## Passthrough Example for z/OS

The Passthrough Example for z/OS, validates a message against a schema in the z/OS environment and contains a sample of the JCL required to run it.

- [Using the example files](#)

---

## Using the example files

- This map is a sample validation against a schema, in order to validate a SEPA message to be structurally correct. It is not to be confused with the full validation framework that the SEPA component offers.
- The purpose of the example map sepa\_passthrough.mms is to do a schema validation for a pacs.008 message on z/OS. The map will take a pacs.008 data file message and validate it against the pacs.008.001.08 schema. The schema used in this example is pacs.008.001.08.xsd which resides in the following installation path:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/mapsandschemas

Where <install\_dir> is the installation location of the Pack for Financial Payments.

- For validation against a schema on z/OS, the type tree that represents the schema needs to be modified in the Location for the Doc Object, so that it points to the DDNAME where the schema will be referenced. The format for this modification is //DD:PC008XSD. The type tree, pacs.008.001.08\_mvs.mtt, contains that change.
  - The map needs to be built for the z/OS platform, generating an .mvs file, which then needs to be ported in Binary mode to the z/OS platform. The schema, pacs.008.001.08.xsd, and data file, FIToFICstmrCdtTrf\_pacs008.xml also need to be ported in Binary mode to z/OS, following the convention of a unique eight character name. The map and the schema must be in the same location in the z/OS environment.
- The JCL provided in the maps subdirectory, which can also be ported to z/OS in TEXT (ASCII) mode, shows an example for the name of the data sets and file names used.
- The execution of this map produces no output, as its objective is mainly for validation purposes. In the event the validation fails, modify the JCL by adding a trace parameter, such as: PARM='MAPDDS /P256:12 -IF1 INPAC008 -TI'

## Sample JCL for the validation framework maps example

This example demonstrates how to deploy and execute the SEPA validation maps on z/OS batch.

- [Example files](#)
  - [How to run the example](#)
- Use these files to run the Sample JCL for the Validation Framework Maps.

## Example files

These files contained in the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa/examples/sample\_jcl directory are used to run the example:

- sepavalidation.jcl - One approach to run the validation framework for SEPA on z/OS.
- put\_mvs\_sample.scp - Example FTP script to transfer compiled maps, inputs, and schemas for the validation framework.
- params.parm - Example parameters file used from the sepavalidation.jcl. The file includes run time parameters for the map execution.

## How to run the example

Use these files to run the Sample JCL for the Validation Framework Maps.

## About this task

The purpose of this example is to show one approach to set up and execute the validation maps provided in the Pack for Financial Payments SEPA component. The included JCL contains comments on the various steps performed. It is assumed that the base product for z/OS batch is already installed and functional on your z/OS machine.

Because of limitations in porting files to z/OS through the Integration Flow Designer, this example includes an FTP script file that can be used to transfer all of the files needed to run the validation framework maps included in the pack.

Perform the following steps to deploy and execute the SEPA validation maps on z/OS batch:

## Procedure

- Create a copy of the <install\_dir>/packs/financial\_payments\_vn.n.n.n/sepa directory to hold the z/OS modified files.
- Open the following type trees in the new type\_trees directory and update the schema location to point to the DDNAME for the schemas as they will be defined on your z/OS system:
  - bic.mtt
  - curcode.mtt
  - camt.027.001.07.mtt
  - camt.029.001.09.mtt
  - camt.087.001.06.mtt
  - camt.056.001.08.mtt
  - pacs.002.001.10.mtt
  - pacs.003.001.08.mtt
  - pacs.004.001.09.mtt
  - pacs.007.001.09.mtt
  - pacs.008.001.08.mtt
  - pacs.028.001.03.mtt
  - pain.001.001.09.mtt
  - pain.002.001.10.mtt
  - pain.007.001.09.mtt
  - pain.008.001.08.mtt
  - pain.009.001.06.mtt
  - pain.010.001.06.mtt
  - pain.011.001.06.mtt
  - pain.012.001.06.mtt
  - sepa\_config.mtt
  - tracelog.mtt
  - xliff.mtt

3. Build all of the above maps for the z/OS platform.
  4. If multiple users will be executing the jobs, or if a non-owner of the data sets will be executing the jobs, edit the file `sepamsgs.xml` to use the ddname of this file.  
As an example: `<!DOCTYPE xliff SYSTEM "xliff.dtd">`  
changes to: `<!DOCTYPE xliff SYSTEM "//DD:XLIFF">`  
where XLIFF is replaced with the dataset name being used to represent the `sepamsgs.xml` file.
  5. Using the `put_mvs_sample.scp` file, make the appropriate modifications to refer to the specific hostname you are transferring the files to, then execute this script.
  6. Make any modifications to the JCL for anything specific to your execution environment. Make any modifications to the map run parameters you may want to change in the `params.parm` file.
  7. Execute the map with the JCL.
- 

## SWIFTNet FIN / SEPA example

This example demonstrates how to use the SWIFTNet FIN / SEPA example.

- [Example files](#)
  - [How to run the example in Design Studio](#)  
These examples demonstrate how to map a SWIFTNet FIN message to a SEPA message, as well as how to map a SEPA message to a SWIFTNet FIN message.
  - [How to run the example in Design Server](#)  
Run instructions for the SWIFTNet FIN / SEPA example.
- 

## Example files

The SWIFT FIN Example files install in the following directories:

```
<install_dir>/packs/financial_payments_vn.n.n.n/sepa/examples/swiftfin/data
<install_dir>/packs/financial_payments_vn.n.n.n/sepa/examples/swiftfin/maps
<install_dir>/packs/financial_payments_vn.n.n.n/sepa/examples/swiftfin/type_trees
```

where `install_dir` represents the installed location of the Pack for Financial Payments.

- [Data directory](#)  
This directory contains sample data for the FIN to SEPA ISO 20022 and SEPA ISO 20022 to FIN conversion examples.
  - [Maps](#)  
These maps are contained in the maps subdirectory.
  - [Type trees](#)  
The SWIFTNet FIN example contains two type trees located in the `type_trees` directory:
- 

## Data directory

This directory contains sample data for the FIN to SEPA ISO 20022 and SEPA ISO 20022 to FIN conversion examples.

The message types are described below.

- FIN to SEPA ISO 20022 (used in `fn_sepamms`)
  - MT101 - Request for Transfer
  - MT102 - Multiple Customer Credit Transfer
  - MT102 - Reject of Multiple Customer Credit Transfer
  - MT102 - Return of Multiple Customer Credit Transfer
  - MT102 - Plus STP variant of MT102
  - MT103 - Single Customer Credit Transfer
  - MT103 - Reject of Single Customer Credit Transfer
  - MT103 - Return of Single Customer Credit Transfer
  - MT103 - Plus STP variant of MT103

The conversion examples assume that MT 102 and MT 103 Reject and Return messages are defined as per the SWIFT User Handbook, Usage Guidelines, see the Payments Reject/Return Guidelines chapter. The conversion examples expect the first three mandatory lines of Tag 72 to be defined as per these guidelines, for example:

`:72:/REJT/2!n or :72:/RETN/2!n (where 2!n = tag of field in error)`

`:72:/2!c2!n/[29x] (error code plus optional text description)`

`:72:/MREF/16x (field 20 of original message)`

- SEPA ISO 20022 to FIN (used in `sepa_fn.mms`)
  - pacs.002 - PaymentStatusReport
  - pacs.004 - PaymentReturn
  - pacs.008 - FItoFICustomerCreditTransfer
  - pain.001 - CustomerCreditTransferInitiation
- Other files
  - `sepa_config.xml` - Contains configuration parameters for the examples.
  - `bic.xml` - Contains test BIC(s) used in the example.

- swift\_config.xml - Contains configuration parameters for the examples.

## Maps

These maps are contained in the maps subdirectory.

- fn\_sepamms - This map source contains these SWIFT FIN converter examples:

Map name	Input file
mt101_pain_001	mt101_seqa.inp and mt101_seqb.inp
mt102_pacs_002	mt102_rjct.inp
mt102_pacs_004	mt102_retn.inp
mt102_pacs_008	mt102.inp
mt102plus_pacs_008	mt102plus.inp
mt103_pacs_002	mt103_reject.inp
mt103_pacs_004	mt103_retrn.inp
mt103_pacs_008	mt103.inp
mt103plus_pacs_008	mt103plus.inp

There are two input files for mt101\_pain\_001:

- mt101\_seqa.inp - Caters for the situation where the Ordering Customer (50a) is present only in Sequence A, and produces a pain\_001 with a Grouping of MIXD.
- mt101\_seqb.inp - has 50a present in every Sequence B, and produces a pain\_001 with a Grouping of SNGL.  
Refer to the UNIFI documentation for pain.001 for more information about Grouping.
- [\*\*sepa\\_fn.mms\*\*](#)  
The sepa\_fn.mms map source is used to convert SEPA messages to a SWIFT FIN format

## sepa\_fn.mms

The sepa\_fn.mms map source is used to convert SEPA messages to a SWIFT FIN format

The SEPA messages are detailed in this table:

Map name	Input file
pacs_002_mt102	pacs_002_mt102.xml
pacs_002_mt103	pacs_002_mt103.xml
pacs_004_mt102	pacs_004_mt102.xml
pacs_004_mt103	pacs_004_mt103.xml
pacs_008_mt102	pacs_008_mt102.xml
pacs_008_mt102plus	pacs_008_mt102plus.xml
pacs_008_mt103	pacs_008_mt103.xml
pacs_008_mt103plus	pacs_008_mt103plus.xml
pain_001_mt101	pain_001_mt101.xml

## Type trees

The SWIFTNet FIN example contains two type trees located in the type\_trees directory:

- swift\_iso7775.mtt - This type tree represents the SWIFT FIN Payments messages (MT1nn). The type tree supports SWIFT 2007 FIN Standards.
- swiftroute.mtt - This is a utility type tree used to pass parameters to and from the RUN maps

## How to run the example in Design Studio

These examples demonstrate how to map a SWIFTNet FIN message to a SEPA message, as well as how to map a SEPA message to a SWIFTNet FIN message.

### About this task

The example maps allow the use of a configuration file that represents field values specific to the target format that is not readily available from the source format.

Follow these steps to run the example:

### Procedure

1. Use the Design Studio to open the following map source files:
  - fn\_sepamms
  - sepa\_fn.mms

2. Build the maps in the source files, and then run the following transformation maps.

- mt101\_pain\_001
- mt102\_pacs\_002
- mt102\_pacs\_004
- mt102\_pacs\_008
- mt102plus\_pacs\_008
- mt103\_pacs\_002
- mt103\_pacs\_004
- mt103\_pacs\_008
- mt103plus\_pacs\_008
- pacs\_002\_mt102
- pacs\_002\_mt103
- pacs\_004\_mt102
- pacs\_004\_mt103
- pacs\_008\_mt102
- pacs\_008\_mt102plus
- pacs\_008\_mt103
- pacs\_008\_mt103plus
- pain\_001\_mt101

3. Review the contents of sepa\_config.xml. This file contains data which are required in the SEPA format but is not available in the SWIFT format.

For example:

constant name : inout\_indicator with value **O**.

A business decision must be made as to how to determine what type of direction will be applied per SEPA transaction that is being converted to a SWIFT message.

During actual implementation, this file must be replaced with an actual source (that is, the database repository), or it must be based upon your unique situation.

A value of **O** populates an outbound specific application header block and an **I** will populate all inbound specific application header block.

- [Conversion notes](#)

---

## Conversion notes

The conversions also take into account the EPC Implementation Guidelines for SEPA. In many cases, the quality of the input data determines whether a successful conversion is possible.

In particular, the following FIN to SEPA and SEPA to FIN points should be noted:

- FIN to SEPA - MT data considerations
  - All accounts should be specified as an IBAN.
  - Use BIC/BEI when possible, as conversion of other forms (for example, name and address) is less successful.
  - When converting Name Address to ISO 20022 a country is usually mandatory, which is not available in FIN. In these cases a default of US has been provided.
  - When mapping charges to ISO 20022 a mandatory Charges Party is required, which is not available in FIN. In these cases a default BIC of "XXXXXXX" has been provided.
- SEPA to FIN - ISO 20022 data considerations  
Parties in ISO 20022 have diverse formats, many of which have no equivalent in FIN, and so conversion is not always successful. In order to maximize the chances of success ensure parties are defined as:

BIC/BEI

or

Postal Address (with at least 1 AdrLine)

---

## How to run the example in Design Server

Run instructions for the SWIFTNet FIN / SEPA example.

---

### About this task

These steps describe how to run the EPC SEPA Validation example.

---

### Procedure

1. Import the sepaSwiftFin.zip file into the Design Server UI. See the release notes for import instructions.

2. Create a package for the project and build all the maps.

3. Open the sepaSwiftFin project in the Design Server UI.

4. Run the following maps:

- mt101\_pain\_001
- mt102\_pacs\_002
- mt102\_pacs\_004
- mt102\_pacs\_008
- mt102plus\_pacs\_008
- mt103\_pacs\_002

- mt103\_pacs\_004
- mt103\_pacs\_008
- mt103plus\_pacs\_008
- pacs\_002\_mt102
- pacs\_002\_mt103
- pacs\_004\_mt102
- pacs\_004\_mt103
- pacs\_008\_mt102
- pacs\_008\_mt102plus
- pacs\_008\_mt103
- pacs\_008\_mt103plus
- pain\_001\_mt101

5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.

6. To download the output file, see [How to download output files](#).

- [Building multiple maps using Deploy](#)

To deploy large numbers of maps (generally, when a project contains more than 10 maps), use the instructions provided here.

- [How to download output files](#)

Download the output files.

## Building multiple maps using Deploy

To deploy large numbers of maps (generally, when a project contains more than 10 maps), use the instructions provided here.

### About this task

Follow these steps to deploy large numbers of maps:

### Procedure

1. From the Design Server UI, click on the Deploy drop down, and click Packages.
2. Define a new Package, then click Add icon.
3. Define a Name field on the Edit Package dialog.
4. From the Project drop down, select the imported project.
5. Check top level box on Maps and Files drop down, this select all maps and files in the project
6. Save the Package.
7. Return to Design Server UI, main page, click Deploy drop down, scroll down and select Deploy from the list on the left.
8. Select the desired server (see the Server definition on Deployment > Deployment overview) and select the package.
9. Click Deploy.
10. Return to the Design Server UI, main page, click Design, select imported project (one just deployed).
11. Open the map.

## How to download output files

Download the output files.

### About this task

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

### Procedure

1. Click on the output Card Settings you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:  
  
data/ach\_contested\_dishonored\_return.out  
  
copy only:  
  
ach\_contested\_dishonored\_return.out
3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

## Overview of the SWIFT component

The SWIFT component supports the SWIFT MT and SWIFT MX message standards. This allows for easy integration of SWIFT messages into your existing systems.

The SWIFT components can be deployed in many different ways, including through the Command Server and Launcher editions. They may also be used with IBM Transformation Extender Integration Server to utilize IBM Integration Bus, IBM Sterling B2B Integrator, or IBM Business Process Manager Advanced.

SWIFT components can also be embedded in your application through use of the APIs provided by the Transformation Extender for Application Programming edition.

Major benefits of the SWIFT component include:

- Compliance with both MT and MX SWIFT standards
  - Regular updates at the pack level that are aligned with scheduled standards changes
  - Type trees for easy integration of the SWIFT standards with your applications
  - Support for MT and MX translation
  - Comprehensive validation and error reporting
- [How to set up the Transformation Extender project](#)  
The Pack for Financial Payments directory structure must be configured within an IBM Transformation Extender project.
- [SWIFT common components](#)  
The Pack for Financial Payments includes components that are used in MT and MX transformations and validations.
- [SWIFT MT components](#)  
These major components support the SWIFT MT standard:
- [SWIFT MX components](#)  
The following are major components of the SWIFT MX standard.
- [Folder structure](#)  
The SWIFT component folders in the Transformation Extender Pack for Financial Payments are located under  
`<install_dir>/packs/financial_payments_vn.n.n.n/swift/`.

---

## How to set up the Transformation Extender project

The Pack for Financial Payments directory structure must be configured within an IBM Transformation Extender project.

### About this task

---

These steps describe how to define the pack directory structure within an Transformation Extender project.

### Procedure

---

1. Open Design Studio.
2. Select **File > New > Extender Project**.
3. Decide on a unique Project name, for example `financial_payments_vn.n.n.n/swift`, where `n.n.n.n` is the version of the Pack for Financial Payments.
4. Clear the Use default location and click on Browse.
5. Locate and choose the default installation directory for the packs. For example, on Windows: `C:/<install_dir>/packs/financial_payments_vn.n.n.n/swift` where `<install_dir>` indicates the installation location of the Pack for Financial Payments, and `n.n.n.n` indicates the version of the Pack for Financial Payments.
6. Click Ok.
7. Click Finish.

---

## SWIFT common components

The Pack for Financial Payments includes components that are used in MT and MX transformations and validations.

These common components consist of sample data, maps, type trees, and schemas. These components are located in the common directory at  
`<install_dir>/packs/financial_payments_vn.n.n.n/swift/common`.

Throughout this documentation, `<install_dir>` is the installation location of the Pack for Financial Payments, and `n.n.n.n` is the current version of the Pack for Financial Payments.

For more information, see [Common SWIFT components](#).

---

## SWIFT MT components

These major components support the SWIFT MT standard:

- SWIFT MT type tree.
- Java™ Validation Component (JVC) to ensure strict compliance with the SWIFT MT standard.
- Logical Message Format (LMF) type tree and maps.
- Examples

The SWIFT MT components are installed in the following location:

`<install_dir>/packs/financial_payments_vn.n.n.n/swift/mt`

Throughout this documentation, `<install_dir>` is the installation location of the Pack for Financial Payments, and `n.n.n.n` is the current version of the Pack for Financial Payments.

For further information, see [SWIFT MT Components](#).

## SWIFT MX components

The following are major components of the SWIFT MX standard.

- A full set of SWIFT MX schemas and type tree.
- A framework for validating SWIFT MX messages.
- Examples that include SWIFT MT and MX translation maps

The SWIFT MX components are installed in the following location: <install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mx

In the above location, <install\_dir> is the installation location of the Pack for Financial Payments, and n.n.n.n is the current version of the Pack for Financial Payments.

## Folder structure

The SWIFT component folders in the Transformation Extender Pack for Financial Payments are located under <install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/.

Folder	Description
common/data	Sample BIC and currency code and country code lookup files, and a sample jar file to upload schemas to IBM Sterling B2B Integrator.
common/maps	Maps to create lookup files from the SWIFT bank and currency files.
common/schemas	Schemas used to describe the BIC and currency lookup files.
common/type_trees	Type trees for the BIC and currency lookup files
mt/examples	Examples for statement splitting, batch validation and JVC validation using the Launcher. Also includes IBM Sterling B2B Integrator Generic Deenvelope and Generic Envelope examples.
mt/jvc/maps	Map to invoke the JVC. Placeholder for the JVC configuration file.
mt/jvc/metadata	Files used by the JVC for syntax validation.
mt/lmf/from_lmf	Maps for converting LMF format to MT format.
mt/lmf/mapping_tables	Documentation for the mappings from SWIFT to LMF in spreadsheet format.
mt/lmf/to_lmf	Maps for converting MT into LMF.
mt/type_trees	Core SWIFT type trees, JVC and LMF type trees, and general purpose MT type trees.
mx/data	Sample data.
mx/examples	<ul style="list-style-type: none"><li>• Bundling and unbundling MX with the Business Application Header.</li><li>• MT and MX Translation maps.</li><li>• IBM Sterling B2B Integrator Generic Deenvelope service and Generic Envelope service maps.</li></ul>
mx/maps	MX validation framework maps.
mx/msd	Deployment script for the MT and MX translation maps and MX framework validation.
mx/schemas	Latest versions of the SWIFT MX schemas as of the time of this pack release.
mx/type_trees	Full set of SWIFT MX type trees, and type trees used by the MT and MX translation maps.

In addition, two jar files for the JVC are placed in the IBM Transformation Extender installation directory:

- jvcwrap.jar - This file is the version independent wrapper class for simple invocation of the JVC.
- jvalccyy.jar - This file is the core JVC jar file (where ccyy indicates the release version of the pack, for example 432).
- [Additional Configuration for MT JVC validation](#)

## Additional Configuration for MT JVC validation

The swiftMTjvcConfig.tar.gz file is contained within UIProjectImports directory.

The UIProjectImports directory is located in the following location:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/UIProjectImports

Where, <install\_dir> is the installation location of the Pack for Financial Payments, and n.n.n.n is the current version of the Pack for Financial Payments.

Extract the following from swiftMTjvcConfig.tar.gz file.

- jvcwrap.jar
- jvalccyy.jar

Copy jars to <brand\_install\_dir>/extjar

## Common SWIFT components

There are artifacts in the SWIFT component of the Pack for Financial Payments that are used in both the MT and MX processing maps. These artifacts are included in the common directory, which is located at the same level as the mt and mx directories.

The common directory contains the following components:

- Common data components
- Common map components
- Common schema components
- Common type tree components

These components are described in detail in this documentation.

- **[Common data components](#)**

Common data components consist of the bic.xml file; currencycodedecimals.xml file; and the swiftnnnnxsd4si.jar file.

- **[Common map components](#)**

The bictoxml and currencytoxml executable maps are under common/maps/bankfiletoxml.

- **[Common schema components](#)**

The bic.xsd and the ccy.xsd schemas are common schema components.

- **[Common type tree components](#)**

Common type tree components consist of: bankfiletoxml.mtt, bic.mtt, and ccy.mtt

---

## Common data components

Common data components consist of the bic.xml file; currencycodedecimals.xml file; and the swiftnnnnxsd4si.jar file.

The common data components are described here:

- data/bic.xml - This file is used for validating BIC values in the transaction data. The bic.xml file provided by the pack is a sample file that provides a starting point for using BIC validation.
- data/currencycodedecimals.xml - This file is used for validating currency code and country code values in the transaction data.
- data/swiftnnnnxsd4si.jar - This file is used for uploading the XML schemas from the Pack to the IBM Sterling B2B Integrator repository. See [Deploying the XML schemas to IBM Sterling B2B Integrator \(Deprecated\)](#).

---

## Common map components

The bictoxml and currencytoxml executable maps are under common/maps/bankfiletoxml.

- bictoxml map - This map creates the bic.xml file based on the FI file in the BIC directory. This file is included in the BIC directory and can be downloaded from SWIFT.

Input Card 1: BIC

Output Card 1: BICxml - The output generates name-value pairs of the FI file.

An example of the output is shown here:

```
<BIC
id="_home_markdown_jenkins_workspace_Transform_in_SSVD8_11.0.1_com.ibm.help.spe_fsp_pk.doc_Swift_901_concepts_c_pack_swif
t_common_map_components_TESTCC37XXX" subtype="BEID">Test Bank</BIC>
```

- BIC id - Represents the actual 8-character, or 11-character formatted BIC.

- subtype - Represents the precise type of financial institution, for example, a bank, or a broker.

- element value - This is the description of the institution.

- currencytoxml map - This map creates the currencycodedecimals.xml file, based on the CU file in the BIC directory. This file is included in the BIC directory that can be downloaded from SWIFT.

Input Card 1: Currency

Output Card 1: Currencyxml. The output generates name-value pairs of the CU file.

An example of the output is shown here:

```
<currencycode
id="_home_markdown_jenkins_workspace_Transform_in_SSVD8_11.0.1_com.ibm.help.spe_fsp_pk.doc_Swift_901_concepts_c_pack_swif
t_common_map_components_EUR" countrycode="DE">2</currencycode>
```

- currencycode id - Represents the currency corresponding to the countrycode.

- country code - Two character country representation.

- element value - Number of fractional decimal places allowed for the currency and country code combination

---

## Common schema components

The bic.xsd and the ccy.xsd schemas are common schema components.

The common schema components are described here:

- schemas/bic.xsd - This schema is used by the bic.mtt type tree, and provides the formatting rules for the bic.xml data file.

- schemas/ccy.xsd - This schema is used by the ccy.mtt type tree, and provides the formatting rules for the currencycodedecimals.xml data file. There are two groups in this schema. The default group uses both the currency and country codes, and there is an additional definition that uses the country code and currency codes independently.

---

## Common type tree components

Common type tree components consist of: bankfiletoxml.mtt, bic.mtt, and ccy.mtt

Common type tree components consist of the following:

- type\_trees/bankfiletoxml.mtt - This type tree is used with the bankfiletoxml to convert SWIFT provided BIC provider list data to the bic.xml file used by many of the maps for BIC validation.
- type\_trees/bic.mtt - This type tree is used with the bic.xml data file and contains the structures defined in the bic.xsd.
- type\_trees/ccy.mtt - This type tree is used with the currencycodedecimals.xml data file and contains the structures defined in the ccy.xsd.

---

## SWIFT MT Components

For a description of the supported SWIFT standards, see the release notes.

- **[SWIFT MT core type trees](#)**

The following type trees are provided to describe the SWIFT MT standard:

- **[Other SWIFT MT trees](#)**

Other trees that are supplied with the MT components are described in the table provided here.

- **[Java Validation Component](#)**

The Java Validation Component (JVC) provides a framework for validating SWIFT messages.

- **[Logical Message Format](#)**

The Logical Message Format (LMF) provides an independent representation of SWIFT messages, which are based on business elements and classes.

- **[Universal Confirmation Components](#)**

The Universal Confirmation (UC) validation component provides a framework to generate and validate the Universal Confirmation messages.

---

## SWIFT MT core type trees

The following type trees are provided to describe the SWIFT MT standard:

- swift\_iso7775\_ccyy
- swift\_iso15022\_ccyy

The primary purpose of the type trees listed above is to provide a full syntactic definition of the SWIFT MT user-to-user messages, thereby allowing the maps to be created to use these type trees for easy integration and exchange of SWIFT MT messages with other applications.

The SWIFT type trees contain all of the user-to-user messages (Categories 1 through 9), plus the Service and System Message definitions (Category 0).

The SWIFT MT type trees are installed in the following location:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mt/type\_trees

Throughout this documentation, <install\_dir> indicates the installation location of the Pack for Financial Payments, and n.n.n.n represents the current version of the Pack for Financial Payments .

- **[Syntax validation in SWIFT MT type trees](#)**
- **[Supported message types in SWIFT MT type trees](#)**

---

## Syntax validation in SWIFT MT type trees

The syntactic definition covers the following elements:

- Blocks 1, 2, 3, and 5 - envelope validation:
  - Check the block structure.
  - Ensure that only permitted fields are present, and in the correct order.
- Block 4 - message body validation:
  - Make certain that only permitted sequences and fields are present.
  - Check the sequence structure and the order of sequences.
  - Check the order of fields within the message or within the sequence.
  - Check for the allowed format options of a field (for example, 98A and 98C).
  - Check the structure of sub-fields with a field.
  - Check for valid qualifiers of a field.
  - Check the cardinality of qualifiers, fields, and sequences (that is, optional, mandatory, repeating).
- Data size
  - For each field, or subfield, check the minimum and maximum size restrictions.
- Data type
  - For each field, or subfield, check data type (date, integer, decimal, text). For text fields, character set validation is not performed.
- Code words

- For each field, or subfield, check for a valid code word. Code words are only validated when an error code is quoted in the SWIFT User Handbook.

## Supported message types in SWIFT MT type trees

There are two type trees that contain the standards information for the MT message types, and the type tree name contains the year of support for the version of the MT messages:

- [swift\\_iso7775\\_ccyy](#)
- [swift\\_iso15022\\_ccyy](#)

See the tables provided here for a list of the MT messages supported in each of the type trees.

Note: The SWIFT type trees do not recognize the message separators used with any of the various SWIFTNet Interface products (for example, the S-Block used by SWIFT Alliance Access). See the SWIFT MT Other type trees documentation for details on parsing messages containing message separators.

- [\*\*swift\\_iso7775\\_ccyy\*\*](#)

These SWIFT MT messages are supported in the swift\_iso7775\_ccyy type tree.

- [\*\*swift\\_iso15022\\_ccyy\*\*](#)

These SWIFT MT message types are supported in the swift\_iso15022\_ccyy type tree.

## swift\_iso7775\_ccyy

These SWIFT MT messages are supported in the swift\_iso7775\_ccyy type tree.

MT670, MT671

## Other SWIFT MT trees

Other trees that are supplied with the MT components are described in the table provided here.

genericfin	General-purpose trees for processing batches of SWIFT messages.
ir_fin_15022_ccyy	Used by the LMF maps for creating ISO 15022 messages.
lmf_ccyy	Main LMF trees.
swiftroute	General-purpose trees for general processing.
validator	Used by the JVC maps for starting the JVC.

The other SWIFT trees provide support for various activities within the pack. These trees can be used as templates and examples if it is required.

Note: These trees are tested for the various activities for which they are used within the pack, but they are not tested for all possible uses. Test trees thoroughly if you use them for your own purposes. Testing is necessary to ensure that the type tree meets your requirements.

The purpose of the type tree is described as follows:

- genericfin - This type tree processes batches of SWIFT MT Messages. Each message is separated by various delimiters typically found in various SWIFTNet interface products.  
The batch of messages is defined within the Generic\ Batch group, which contains a repeating Message element. Message is partitioned into four types: AckNack, System Message, FINPay (MT121) and UserMessage (for MT Categories 1 - 9). Each message can be delimited by various delimiters: S-Block, SOH, space and \$.  
The type tree cannot process the detailed content of SWIFT MT messages, as Block 4 is defined as a 'Blob'. It instead provides a high-level overview of a batch of SWIFT MT messages.  
Note: A 'blob' is a type tree item that is typically used in representing any text strings that are interpreted as characters with any syntax, and no length restrictions.
- swiftroute - The type tree has various purposes. It is associated with control-logic and map-routing activities and for use as a 'scratchpad' to store and format text strings.
- lmf\_ccyy - This type tree is the main LMF type tree. See the Logical Message Format documentation for details on the LMF type tree. All elements in the type tree are text defined fields.
- ir\_fin\_15022\_ccyy- The type tree contains a generic representation of the messages from the iso\_15022 type tree for those MT messages that have LMF maps. The messages and the elements they contain are represented as generic business elements (for example, Party and Narrative) in order to simplify the output mapping of these message types.  
The type tree does not contain any syntax parsing capability. Do not use the type tree to parse SWIFT messages. This type tree is designed for use as output. All elements in the type tree are text defined fields.
- validator - The type tree is a simple type tree. It is used by the validate messages map to start the JVC. See the JVC documentation for details about validate\_messages.

## Java Validation Component

The Java Validation Component (JVC) provides a framework for validating SWIFT messages.

The JVC can be used to check messages before they are transmitted to the SWIFT network to ensure compliance. It provides a configurable validation framework, with error reporting functionality, that allows the source of the error to be quickly located.

- [Overview of the JVC](#)  
The Java Validation Component (JVC) validates the following items in accord with the latest SWIFT standards.
- [How to configure the JVC](#)  
The JVC is controlled by the jvalccyy.prop file.
- [JVC installation](#)  
When JVC is installed on Windows, the jvalccyy.jar and jvcwrap.jar files are placed in the ITX installation directory.

## Overview of the JVC

The Java Validation Component (JVC) validates the following items in accord with the latest SWIFT standards.

- Message syntax - presence and order of fields and sequences.
- Field syntax - size and data type.
- Field and sequence cardinality - optional, mandatory, repeating.
- Codewords
- Network validated rules at both message and field level
- Message envelope syntax - SWIFT header and trailer.
- Market practice rules.

The JVC validates all user-to-user messages, that is, all of Category 1 (MT1nn), through Category 9 (MT9nn). Category 0 (MT0nn) Service and System Messages are not validated by the JVC.

## How to configure the JVC

The JVC is controlled by the jvalccyy.prop file.

In addition, certain properties can be overridden during map execution by the supplied map validate\_messages .

- [\*\*jvalccyy.prop\*\*](#)  
The jvalccyy.prop file contains a number of configurable parameters for controlling the behavior of the JVC.
- [\*\*How to specify a jvalccyy.prop file location\*\*](#)  
The location for the jvalccyy.prop file can be specified in a number of ways. The following options are available, and are shown in the sequence which the JVC will use to locate jvalccyy.prop.
- [\*\*message\\_definitions.directory\*\*](#)  
The message\_definitions.directory identifies the location of the metadata files used by the JVC for syntactic validation, and for enabling and disabling message-specific field level and Network Rule validation.
- [\*\*validate\\_messages\*\*](#)  
The validate messages map can be used to start the JVC. It can be found in  
`<install_dir>/packs/financial_payments_vn.n.n.n/swift/mt/jvc/maps/validate_messages`

## jvalccyy.prop

The jvalccyy.prop file contains a number of configurable parameters for controlling the behavior of the JVC.

These parameters tell the JVC where to find other files that it uses, as well as specifying certain validation options.

When running a map that calls the JVC, the jvalccyy.prop file can be located in a directory of your choosing. Refer to the section *How to specify jvalccyy.prop location* for more details. If the jvalccyy.prop file is not found on start up, the JVC terminates with an error message.

Note that the recommended best practice is to use a single jvalccyy.prop file for each version of the pack. This is due to several factors, including performance considerations and the fact that jvalccyy.prop contains locations of various other components, such as BIC files, currency files, and XML metadata files. If there is a requirement to use different maps with different validation settings, then the JVC Validator override flags can be used to achieve this. Refer to the validate\_messages section for details.

The parameters set by the jvalccyy.prop file include swift.pack.version=srgccy

This is the current version of the Pack for Financial Payments and is not to be changed. It is used to validate that the correct version of jvalccyy.jar is used.

If this value does not match the version number contained in the jvalccyy.jar, the JVC terminates with an error message.

message.definition.directory

This parameter identifies the location of the metadata files used by the JVC for syntactic validation, and for enabling and disabling message-specific field level and Network Rule validation.

If the metadata files are not found in the specified location, the JVC will terminate with an error message.

rules.networkvalidation.enabled = true|false

- true - The default value, and the recommended setting. It performs all syntax and semantic validation, including validation defined by the “special functions” in the SWIFT manuals (for example “Party Field Option J”, “Payments Reject/Return” and so forth).
- false - Performs only basic syntax validation.

bic.file.enabled=true|false

- true - Indicates that the BIC/BEI validation is required.
- false - Default value. Indicates that BIC/BEI validation is not required

Note: If bic.file.enabled=false, then the following Network Rules are also disabled:

- C05
- E57
- T27

bic.definition.file

This parameter identifies the location of the bic.xml lookup file used by the JVC for BIC/BEI validation. .

If bic.file.enabled=true and the bic.xml file is not found, the JVC terminates with an error message.

If bic.file.enabled=false, the JVC does not attempt to open the bic.xml file

`countrycurrencycodes.definition.file`

This parameter identifies the location of the `currencycodedecimals.xml` lookup file used by the JVC for Currency Code and Country Code validation.

`ReportingMode=verbose|terse`

- `verbose` - This is the default value. Validation results and error messages are returned in a multi-line, XML-like syntax.
- `terse` - Validation results and error messages are usually returned as a single line of plain text. Some messages may contain multiple lines, if they include data from a multi-line field that was in error.

`validateCopyofFields=true|false`

- `true` - Causes validation to be performed on the `CopyOfFields` elements in message types MTn92, MTn95, and MTn96.
- `false` - This is the default value. Causes `CopyOfFields` validation not to be performed.

`FileActMode.enabled=true|false`

Controls the validation for Tag 51A in MTs 101, 102, 103, 103\_REMIT, 104, 107, and 416. No other MTs, Tags, or validation rules are affected.

- `true` - Enable FileAct mode, and allow Tag 51A to be present.
- `false` - Disable FileAct mode, and return error code D63 if Tag 51A is present.

Note: If `FileActMode.enabled` is not present in `jvalccyy.prop`, or is present but contains any other value, validation checking defaults to `FileActMode.enabled=false`.  
`MessageLength.enabled=true|false`

Controls the validation for message length for all MT messages.

- `true` – Enable message length validation and return error code M50 if the message exceeds the permitted length.
- `false` – Disable message length checking.

Note: If `MessageLength.enabled` is not present in `jvalccyy.prop`, or is present but contains any other value, validation checking will default to `MessageLength.enabled=true`.

`checkE76.CCY=ccyymmdd`

where CCY is a former European currency used in E76 error validation, and `ccyymmdd` is the value date after which this currency must not be used. These parameters should not be changed in normal operation.

`rules.marketpractice.enabled=true|false`

- `true` - Market Practice validation is performed based upon the SWIFT document V1.1 published August 26, 2002.
- `false` - This is the default value. Market Practice validation is not performed.

SWIFT has discontinued this document, therefore, this feature is no longer maintained.

`rules.marketpractice.baseclass`

Indicates the base class name used for Market Practice validation. The default value shown here should not be changed:

`com.ibm.websphere.dtx.ip.swift.srgccyy.validation`

`rules.marketpractice.MTnnn`

Indicates the rules that are to be validated for a particular message. The rule name (for example S101) is appended to the `BaseClass` to obtain the class to use. For example:

`com.ibm.websphere.dtx.ip.swift.srgccyy.validation.S101`

These features are used for enabling and configuring basic Java logging capabilities:

- `log.enable=true|false` - Default is false.
- `log.filename=` Default value for `swiftlog.txt`
- `log.append=true|flase` - Default is false.
- `log.filesize=1000000` - Maximum log file size in bytes before file is recycled.
- `log.level=ALL` - Allowable values are OFF, ALL (default), SEVERE, WARNING, INFO, FINE

Editing will be required to change `PACK_INSTALL_DIR` with actual location where the pack zip distro was extracted.

## How to specify a `jvalccyy.prop` file location

The location for the `jvalccyy.prop` file can be specified in a number of ways. The following options are available, and are shown in the sequence which the JVC will use to locate `jvalccyy.prop`.

Note: To set up the `jvalccyy.prop` file for the ITX Design Server, see the instructions for the `swiftMTjvcConfig.tar.gz` file that are contained in the release notes.

### 1. Use a JVM system property

Specify the location by using a JVM system property called "`DTX_SWIFT_CONFIG_DIR`" that contains the fully qualified path of the directory containing the `jvalccyy.prop` file.

JVM system properties are set by using the `-D` option. This can be specified in a number of ways:

- Update the `config.yaml` file with this command:

```
[JVM Options]optionN=<install_dir>/packs/financial_payments_vn.n.n.n/swift/mt/jvc/maps
```

where N is the next available option number.

Example:

```
[JVM Options]option1=<install_dir>/packs/financial_payments_v9.0.1.0/swift/mt/jvc/maps
```

- When using IBM Integration Bus, you can use the following command to add the JVM System Property DTX\_SWIFT\_CONFIG\_DIR to the IBM Integration Bus Execution Group:

```
mqsiclchangeproperties < BrokerName > -e < ExecutionGroupName > -o ComIbmJVMManager -n jvmSystemProperty -v"-DDTX_SWIFT_CONFIG_DIR=<absolute_directory>"
```

To check the jvmSystemProperty value of the JVM Option that is defined for the IBM Integration Bus Execution Group, use the following IBM Integration Bus command:

```
mqsiereportproperties < BrokerName > -e < ExecutionGroupName > -o ComIbmJVMManager -n jvmSystemProperty
```

## 2. Use the Global System environment variable

---

To use this method, specify the location using a global environment variable called DTX\_SWIFT\_CONFIG\_DIR that contains the fully-qualified path of the directory containing jvalccyy.prop. For example, when using the Command Server, set DTX\_SWIFT\_CONFIG\_DIR by using the Windows **SET** command or the UNIX **EXPORT** command.

## 3. Use the validate\_messages map

---

To use this method, set the rule for element JvalPropPath in Output Card 1 to the directory containing jvalccyy.prop. For example, ="c:/jvc/jvalccyy.prop"

## 4. Use the default location

---

To specify use of the default location, set the map rule for item "JvalPropPath" in "validate\_messages" to =NONE.

jvalccyy.prop is installed in <install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mt/jvc/maps for all versions of ITX.

For Transformation Extender V8.n, the jvalccyy.prop file can be located in any directory, but the map calling the JVC must be located in the same directory as jvalccyy.prop.

For ITX V9.5 jvalccyy.prop must be moved to the following location:

- Windows - <install\_dir>
- Linux® - <install\_dir>/bin

## How to choose the best method

---

The choice of method to use to define the location of the jvalccyy.prop is entirely dependent on individual circumstances, and no one method is better than another. Choose the method that is best suited to your environment.

As a guide, here is a brief summary of the advantages and disadvantages of the different methods:

- JVM System Property - The advantages and disadvantages are similar to those of using a Global Environment Variable, but apply only when ITX has to initiate a Java™ Virtual Machine (JVM) to run the JVC. For example, this option will not work with ITX Design Server.
- Global System Environment Variable - An advantage with this method is flexibility. The location can be changed without any need to recompile ITX maps or redeploy ITX components. You would, however, need to restart any running process, such as Launcher, after any changes are made to the variable. A disadvantage is that this is not an ITX component but a system-wide variable, and internal security policies may prevent access to these settings.
- "validate\_messages" map - The main advantage with this method is that all configuration is contained within ITX components, so it might be simpler to manage. The main disadvantage is that the map must be recompiled and redeployed, but this may not be an issue if the location rarely changes.
- Use the default location - This is the simplest method, and might be the preferred option for backwards compatibility with existing configurations. The main disadvantage is that you need to be aware of the default location, which varies between ITX versions.

## messagedefinitions.directory

---

The messagedefinitions.directory identifies the location of the metadata files used by the JVC for syntactic validation, and for enabling and disabling message-specific field level and Network Rule validation.

If the metadata files are not found in the specified location, the JVC will terminate with an error message.

rules.networkvalidation.enabled

Whether all syntax and semantic validation, including the validation defined by the "special functions" in the SWIFT manuals (for example "Party Field Option J", "Payments Reject/Return," and so forth), are performed. Valid values: true, false

true

Default value and recommended setting. All validation is performed.

false

Only basic syntax validation is performed.

bic.file.enabled

Whether BIC/BEI validation is required. Valid values: true, false

true

BIC/BEI validation is required.

false

Default value. BIC/BEI validation is not required.

If bic.file.enabled=true and the bic.xml file is not found, the JVC terminates with an error message.

#### bic.definition.file

Location of the bic.xml lookup file used by the JVC for BIC/BEI validation. The default location on ITX is

<install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/common/data/bic.xml

If bic.file.enabled=true and the bic.xml file is not found, the JVC terminates with an error message.

#### countrycurrencycodes.definition.file

Location of the currencycodedecimals.xml lookup file used by the JVC for Currency Code and Country Code validation. The default location on ITX is

<install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/common/data/currencycodedecimals.xml

The currencycodedecimals.xml file that is included with the product is an example only. You are responsible for providing your own currencycodedecimals.xml file, which is generated from data that you download from SWIFT or ISO. See the [Common map components](#) topic for details.

#### ReportingMode

Valid values: verbose, terse

##### verbose

Default. Validation results and error messages are returned in a multi-line, XML-like syntax.

##### terse

Validation results and error messages are usually returned as a single line of plain text. Some messages may contain multiple lines, if they include data from a multi-line field that was in error.

#### validateCopyofFields

Whether validation is performed on the CopyOfFields elements in message types MTn92, MTn95, and MTn96. Valid values: true, false

##### true

CopyOfFields validation is performed.

##### false

Default. CopyOfFields validation is not performed.

#### checkE76.CCY=ccyymmdd

where CCY is a former European currency used in E76 error validation. Valid value: ccyymmdd

##### ccyymmdd

The value date after which this currency must not be used. These parameters should not be changed in normal operation.

#### rules.marketpractice.enabled

This feature is no longer maintained. Indicates whether Market Practice validation is performed based upon the SWIFT document V1.1 published August 26, 2002.

Valid values: true, false

##### true

Market Practice validation is performed.

##### false

Default. Market Practice validation is not performed.

#### rules.marketpractice.baseclass

Indicates the Base Class name used for Market Practice validation. Do not change the default value shown.

##### com.ibm.websphere.dtx.ip.swift.srgccyy

Default value, where ccyy indicates the SRG version supported by the Pack for Financial Payments.

#### rules.marketpractice.MTnnn

The rules that are to be validated for a particular message. The rule name (for example, S101) is appended to the BaseClass to obtain the class to use.

##### com.ibm.websphere.dtx.ip.swift.srgccyy.validation.S101

Example value.

These features are used for enabling and configuring basic Java logging capabilities:

- log.enable=true|false - Default is false.
- log.filename= Default value for ITX: <install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/swiftlog.txt
- log.append=true|false - Default is false.
- log.filesize=1000000 - Maximum log file size in bytes before file is recycled.
- log.level=ALL - Allowable values are OFF, ALL (default), SEVERE, WARNING, INFO, FINE

The following features in jvalccyy.prop are not currently in use:

- codelist.grammar.file - Not currently in use.
- 110n.locale=es - Not currently in use and commented out.
- 110n.country=ES - Not currently in use and commented out.

---

## validate\_messages

The validate messages map can be used to start the JVC. It can be found in <install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mt/jvc/maps/validate\_messages

This map can be incorporated directly into your workflow, or adapted to meet your needs. It can also be called from another map by using the RUN command. The map has one input and two output cards:

- Input Card 1 - SWIFT message, which is defined as a blob item type tree.
- Output Card 1 - Validator settings for defining pack version number (do not change in normal operation), validator flags, and jvalccyy.prop location.

- Output Card 2: ValidatorResults. This card is used to call the JVC by use of the JVCWrapper validate method. It uses parameters from Output Card 1 to collect the validation results.

Validator flags can be used to modify the behavior of the JVC. They are specified as a single eight-character string, and the position within the string determines which flag is being set. The meaning and usage of each flag is shown in the table.

Position	Name	Allowable Values	Description
1	Preload Definitions	0	Load message definitions as needed (recommended).
		1	Preload all message definitions
2	Map Server Mode	0	Enforce normal CRLF checking (recommended)
		1	Use <NL> as a line delimiter instead of <CR><LF>
3	Network Rules	0	Do not enforce network rules
		1	Enforce network rules
		2	Check jvalccyy.prop to determine if network rules enforced
4	Check Methods	0	Do not enforce field-level rules
		1	Enforce field-level rules
		2	Check metadata file to determine if field-level rules enforced
5	BIC Validation	0	Do not enforce BIC validation
		1	Enforce BIC validation
		2	Check jvalccyy.prop to determine if BIC validation enforced
6	Market Practice	0	Enforce market practice rules
		1	Do not enforce market practice rules
		2	Check jvalccyy.prop to determine if market practice rules enforced
7	FileActMode	0	FileActMode is disabled
		1	FileActMode is enabled
		2	Check jvalccyy.prop to determine FileActMode
8	MessageLength	0	MessageLength check is disabled
		1	MessageLength check is enabled
		2	Check jvalccyy.prop to determine MessageLength

Use a value of 0 or 1, for example, for the Network Rules, BIC Validation, or Market Practice flags in order to override the settings that are specified in the jvalccyy.prop file. This lets different maps, or map instances, that are in the same directory to use different validation criteria. For example, one map or map instance can enforce BIC validation, while another has BIC validation disabled.

Note that the flags are positional, and that the character position determines which parameter is being acted on. For example, to override the value for Flag position 8 (Message Length), all 7 previous Flags must also be supplied.

For backward compatibility with earlier pack versions, only the first six Flags are mandatory for Flag overrides. If only six flags are supplied, the remaining two flags default to the behavior that existed before the two parameter overrides were introduced, as follows:

- Flag 7 FileActMode=false
- Flag 8 MessageLength=true

## JVC installation

When JVC is installed on Windows, the jvalccyy.jar and jvcwrap.jar files are placed in the ITX installation directory.

For the TX version prior to 10.2.1, when JVC is installed on Windows, the jvalccyy.jar and jvcwrap.jar files are placed in the ITX installation directory.

For TX version 10.2.1 and up, the jvalccyy.jar and jvcwrap.jar will be included in swiftMTjvcConfig.tar.gz under the UIProjectImports folder. You must modify the CLASSPATH environment variable to include jvalccyy.jar and jvcwrap.jar.

On the Design Server, extract jvcwrap.jar and jvalccyy.jar files from swiftJVConfigIBM.tar.gz.

Copy jars to the location set on the Design Server config.yaml, under property server.persistence.libs (previously TX\_ADDITIONAL\_LIBS), for example: /opt/tlxlibs.

Restart the Design Server: ./ITX stop, and then ./ITX start

- [Installing JVC on non-Windows environments](#)

## Installing JVC on non-Windows environments

Copy all of the .jar files from your <itx\_runtime\_install\_dir>/extjar directory to the <itx\_runtime\_install\_dir>/libs directory on your non-Windows system.

## Logical Message Format

The Logical Message Format (LMF) provides an independent representation of SWIFT messages, which are based on business elements and classes.

To see the detailed mapping tables, go to <install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mt/lmf/mapping\_tables.

To see the detailed mapping tables see the swiftLMFmappingDoc.zip file.

- [LMF overview](#)  
The LMF provides a set of business messages that are independent of network message format or structure.
  - [LMF structure](#)  
The entities within the LMF, as defined in lmf\_ccyy, consist of Messages, Sequences, and Classes.
  - [LMF supported message types](#)  
The LMF components consists of two sets of type tree (lmf\_ccyy and ir\_fin\_15022\_ccyy), and a set of to\_lmf and from\_lmf maps for translating MT messages to LMF format, and LMF format to MT respectively.
  - [LMF message mapping](#)
- 

## LMF overview

The LMF provides a set of business messages that are independent of network message format or structure.

This allows different message formats to be mapped to each other through the LMF. When changes in the elements in those messages occur (for example, at SWIFT standards releases), changing the LMF reflects those changes and minimizes the impact on the integration maps with your host application.

The LMF is implemented as ITX type tree. The LMF is based on the ISO 15022 format, and was originally conceived as a way of assisting migration from SWIFT ISO7775 Payments, Statements and Securities messages to their ISO 15022 equivalents. For this reason, the internal structure of the LMF is similar to ISO 15022 business elements, and is described in this documentation.

Note: The LMF uses an XML-like syntax. There is no schema for the LMF, therefore, LMF instance data cannot be used in situations where the presence of a schema is required for correct operation.

---

## LMF structure

The entities within the LMF, as defined in lmf\_ccyy, consist of Messages, Sequences, and Classes.

- **Messages** - Business messages are the highest level concept in the LMF. These messages might correspond directly to an equivalent network message, or more often cover a number of different network messages. For instance, the LMF "Transfers" instruction message covers SWIFT MT 202 and MT 210.
  - **Sequences** - Each LMF message is constructed from a series of sequences, like the ones that are used in SWIFT messages. Each sequence might contain a number of other entities, either classes, or other sequences called subsequences.
  - **Classes** - Within each sequence, the individual business elements are called classes. Classes represent each actual business data element, such as a reference. Whereas network message formats contain fields, these are not present in the LMF. Instead, the classes represent types of data (for example, flags, indicators, and dates), and the specific data elements are instances of those classes.
- Each class consists of a set of attributes and subfields. The attributes describe how the class is being used. The subfields contain the actual data that is in use (for example, the date value, or the reference value). The attributes consist of:
- s - Not used.
  - f - Format value. The format value varies from class to class. It is enforced by a restriction list in the type tree. It describes the format of the data that is held in the class, for example DateOnly to represent the SWIFT 98A date format
  - q - Qualifier value. Varies from class to class. Enforced by a restriction list. It contains the qualifier that describes the business meaning of the class.
  - dss - Contains the data source scheme, if used. The data source scheme is a field that is used in SWIFT ISO 15022 messages.

## LMF supported message types

The LMF components consists of two sets of type tree (lmf\_ccyy and ir\_fin\_15022\_ccyy), and a set of to\_lmf and from\_lmf maps for translating MT messages to LMF format, and LMF format to MT respectively.

Each **to\_lmf** map uses one input card, and one output card:

Input Card 1: MT message in the current swift\_iso7775\_ccyy or swift\_iso15022\_ccyy type tree.

Output Card 1: LMF message corresponding to the MT message in the lmf type tree

Each **from\_lmf** map uses one input card, and one output card:

Input Card 1: LMF message corresponding to the MT message in the lmf type tree.

Output Card 1: MT message in either iso7775\_ccyy or ir\_fin\_15022\_ccyy type tree. For further information on this type tree see [Other SWIFT MT trees](#).

Supported MT Message(s)	To_lmf map name	From_lmf map name
MT101	swift_mt101_tolmf	swift_mt101_fromlmlf
MT102	swift_mt102_tolmf	swift_mt102_fromlmlf
MT103	swift_mt103_tolmf	swift_mt103_fromlmlf
MT103+	swift_mt103_tolmf	swift_mt103_fromlmlf
MT190	swift_mtn90_tolmf	swift_mtn90_fromlmlf
MT191	swift_mtn91_tolmf	swift_mtn91_fromlmlf
MT192	swift_mtn92_tolmf	swift_mtn92_fromlmlf
MT195	swift_mtn95_tolmf	swift_mtn95_fromlmlf
MT196	swift_mtn96_tolmf	swift_mtn96_fromlmlf
MT202	swift_mt202_tolmf	swift_mt202_fromlmlf
MT202 COV	swift_mt202_COV_tolmf	swift_mt202_COV_fromlmlf

Supported MT Message(s)	To_Lmf map name	From_Lmf map name
MT205	swift_mt205_tolmf	swift_mt205_fromlmf

## LMF message mapping

Logical Message Format (LMF) transformation maps are available for the following message types: Payments, Transfers, Treasury Markets, Trading, Statements, Settlement, Corporate Actions, Cash Management, and Common Group Messages.

- [LMF Header](#)  
Specific information and usage requirements (for example, mandatory, optional, not used, etc.) specific to mapping SWIFTNet messages into the LMF are given for each header attribute.
- [Payments](#)  
The following tables provide LMF Transformation Maps for payments messages.
- [Alternative LMF mapping for Tag 35B](#)  
The documentation provided here presents an alternative LMF mapping of Tag 35B, using the format given by the Usage Rules.

## LMF Header

Specific information and usage requirements (for example, mandatory, optional, not used, etc.) specific to mapping SWIFTNet messages into the LMF are given for each header attribute.

The attributes are shown in the order in which they appear in the LMF header.

Attribute	Description
LMFType	This specifies the LMF message type for the SWIFTNet message being mapped in. A restriction list of valid values is provided in the LMF; the valid values are listed in the LMFType attributes table. See <a href="#">LMFType attributes</a>
version	Set to =NONE. A valid version must be specified for this attribute to indicate the LMF version of the message. However, for ease of maintaining backward compatibility of LMF versions, a type tree syntax object is used to generate/validate this attribute. By default, the value for the current LMF version will be generated when mapping to LMF.
direction	Mandatory for SWIFT. Specifies the processing direction for the logical message. Therefore, the value must be O to signify an outbound message (from internal applications to be sent outside the organization). This will actually create a SWIFT inbound message. For messages received from the SWIFT network, this value will be I.
sndaddr	Mandatory for SWIFT. Specifies the LT address for the sender of the message. For messages received from SWIFT this will be populated by the Sender's LT.
rcvaddr	Mandatory for SWIFT. Specifies the address/identifier (typically a BIC) for the receiver of the message. This may be an 8, 11 or 12 character BIC. For messages received from SWIFTNet this will contain the LT of the receiver.
function	Optional for SWIFT. Specifies the function/reason for the logical message. A restriction list with valid values is provided in the LMF type tree. The value must be equal to the datafield function in the Msgfunct class if it is mapped to the LMF (for example, 22A in MT 300). If a Msgfunct class is not mapped to the LMF (e.g. MT 103), the value is normally set to NEWM, but you are free to choose any other value so long as it is in the restriction list.
Subfunction	Optional for SWIFT. Specifies the subfunction for the logical message. A restriction list with valid values is provided in the LMF type tree. The value must be equal to the datafield subfunction in the Msgfunct class if it is mapped to the LMF (e.g. 94A in MT300).
msgtype	Mandatory for SWIFT. The value varies according to the SWIFT message type. See <a href="#">LMFType attributes</a>
userref	Optional for SWIFT. Specifies any user reference material in the SWIFT User Header Block 3. Contains tags 103, 113, 108, 119, 115, 423, 106, 424, 111, 165 and 433, in that order, delimited by ^. See the SWIFT User Handbook for full definitions of these tags.
headertext	Optional for SWIFT. Specifies other header information. For messages sent to SWIFT (Input Messages), the value is set to: [[Priority Block]^*[Delivery Monitoring Code]^*[Obsolescence Period Code]^^*[Session Number]^*[Sequence Number]]  For messages received from SWIFT (Output Messages), the value is set to: [Input Time]^*[MIR]^*[Output Date]^*[Output Time]^*[Priority Block]^*[Session Number]^*[Sequence Number]
priority	Mandatory for SWIFT. Specifies the priority of the SWIFT message. Valid values are "N" (Normal) or "U" (Urgent).
Deliverymonitoring	Mandatory for SWIFT. Specifies the priority of the SWIFT message. Valid values are "N" (Normal) or "U" (Urgent).

- [LMFType attributes](#)  
The LMFType attribute specifies the LMF message type for the SWIFT message being mapped.
- [msgtype attributes](#)  
The LMF msgtype value varies according to SWIFT message type.

## LMFType attributes

The LMFType attribute specifies the LMF message type for the SWIFT message being mapped.

A restriction list of valid values is provided in the LMF. Valid values are:

<b>SWIFT message</b>	<b>LMF message</b>
MT101, MT102, MT103, MT103+	PAYMENT
MT202, MT210	TRANSFER
MT300, MT304, MT305,	FX
MT320	LOANDEPOSIT
MT502, MT509	TRADEORDER
MT515	TRADECONF
MT564, MT565, MT566, MT567, MT568	CORPEVENT
MT540, MT541, MT542, MT543, MT578	SETTINST
MT564, MT565, MT566, MT567, MT568	SETTCOMP
MT900, MT910	CONFIRMATION
MT940, MT942, MT950	STATEMENT
MTn90, MTn91, MTn92, MTn95, MTn96	COMMON

## msgtype attributes

The LMF msgtype value varies according to SWIFT message type.

These are the LMF msgtype values for the following SWIFT message types.

<b>SWIFT message</b>	<b>LMF msgtype</b>
MT101	101
MT102	102
MT103	103
MT103+	103+
MT202	202
MT210	210
MT300	300
MT304	304
MT305	305
MT320	320
MT502	502
MT509	537
MT515	515
MT535	535
MT536	536
MT537	537
MT540	540
MT541	541
MT542	542
MT543	543
MT544	544
MT545	545
MT546	546
MT547	547
MT548	548
MT564	564
MT565	565
MT566	566
MT567	567
MT568	568
MT578	578
MT900	900
MT910	910
MT940	940
MT950	950
MTn90	one of: 190, 290, 390, 490, 590, 690, 790, 890 or 990
MTn91	one of: 191, 291, 391, 491, 591, 691, 791, 891 or 991
MTn92	one of: 192, 292, 393, 492, 592, 692, 792, 892 or 992
MTn95	one of: 195, 295, 395, 495, 595, 695, 795, 895 or 995
MTn96	one of: 196, 296, 396, 496, 596, 696, 796, 896 or 996

## Payments

The following tables provide LMF Transformation Maps for payments messages.

- MT 101 request for transfer**

This table shows the mappings that are needed to map an MT 101 into the LMF.

## MT 101 request for transfer

This table shows the mappings that are needed to map an MT 101 into the LMF.

Note: In the table below, when a Party field, consisting of only an Account, or NCS code, is mapped to the LMF in one of the "C" tag fields (for example 57C), an additional Party structure is mapped to the LMF. This additional Party structure consists of only the Qualifier attribute, and no other fields are mapped. This additional "Empty" Party structure is there to signify that the MT field does not contain any Party data, but only Account data.

SWIFT: MT 101					LMF: payment_M

## Alternative LMF mapping for Tag 35B

The documentation provided here presents an alternative LMF mapping of Tag 35B, using the format given by the Usage Rules.

In the SWIFT User Handbook, the Usage Rules for 35B state the following:

When an ISIN identifier is not used, one of the following codes must be used as the first characters of the Description of Security (Subfield 2):

- [/2!a/] The ISO two-digit country code, followed by the national scheme number.
- [/TS/] Followed by the ticker symbol.
- [/XX/] Bilaterally agreed, or proprietary scheme which can be further identified by a code, or short description identifying the scheme used.
- [/4!c/] Code identifying the type of security identifier used. This code must be one published by ISO 20022 (ExternalFinancialInstrumentIdentificationTypeCode).

Since Usage Rules are not enforced on the SWIFT Network, the SWIFT component does not enforce these rules either. Although SWIFT has suggested an alternative format for 35B, it is not validated. It is therefore up to you, as a user of this format, to ensure that it conforms to the format expected by the recipient of the message.

In the LMF maps, Tag 35B is treated as a simple text field, either with, or without an ISIN.

It is possible, however, to amend the LMF maps to separate these fields and map them individually to and from the LMF, if that is a requirement of your system.

Note: This alternative LMF mapping has not been incorporated into the LMF maps in the pack, and so any implementation of these rules must be reapplied to subsequent releases of the pack.

See the example for details.

- [ToLMF map](#)  
This example is based on MT540, but it is valid for any occurrence of 35B.
- [FromLMF map](#)  
A similar method can be applied to the FromLMF map to extract data from these sub-fields and map to the output MT message.

## ToLMF map

This example is based on MT540, but it is valid for any occurrence of 35B.

There will be a rule such as the following:

```
ToLMF_FinInstID (EITHER (ISIN# General Line SubField:ISIN<>IDOffI #35B NonISO15022 General Field:54x_BSequence , "N/A") ,
 EITHER (Narrative_35x General Line SubField[1] IN IDOffI #35B NonISO15022 General
Field:54x_BSequence , "N/A") ,
 EITHER (Narrative_35x General Line SubField[2] IN IDOffI #35B NonISO15022 General
```

```

Field:54x_BSequence , "N/A") ,
 EITHER (Narrative_35x General Line SubField[3] IN IDOffI #35B NonISO15022 General
Field:54x_BSequence , "N/A") ,
 EITHER (Narrative_35x General Line SubField[4] IN IDOffI #35B NonISO15022 General
Field:54x_BSequence , "N/A"))

```

This rule can be amended to look for the alternative format given in the Usage Rules, and call another functional map:

```

= IF (LEFT (Narrative_35x General Line SubField[1]:Narrative<>IDOffI #35B NonISO15022 General Field:54x_BSequence, 1) =
"/" &
(MID (Narrative_35x General Line SubField[1]:Narrative<>IDOffI #35B NonISO15022 General Field:54x_BSequence, 4, 1) ="/" |
MID (Narrative_35x General Line SubField[1]:Narrative<>IDOffI #35B NonISO15022 General Field:54x_BSequence, 6, 1) ="/")
&
SIZE (WORD (Narrative_35x General Line SubField[1]:Narrative<>IDOffI #35B NonISO15022 General Field:54x_BSequence, "/", 3
)) > 0,
ToLMF_FinInstID_AltrntId (Narrative<>IDOffI #35B NonISO15022 General Field:54x_BSequence),
ToLMF_FinInstID (EITHER (ISIN# General Line SubField:ISIN<>IDOffI #35B NonISO15022 General Field:54x_BSequence , "N/A") ,
EITHER (Narrative_35x General Line SubField[1] IN IDOffI #35B NonISO15022 General
Field:54x_BSequence , "N/A") ,
EITHER (Narrative_35x General Line SubField[2] IN IDOffI #35B NonISO15022 General
Field:54x_BSequence , "N/A") ,
EITHER (Narrative_35x General Line SubField[3] IN IDOffI #35B NonISO15022 General
Field:54x_BSequence , "N/A") ,
EITHER (Narrative_35x General Line SubField[4] IN IDOffI #35B NonISO15022 General
Field:54x_BSequence , "N/A"))

```

The rules for the ToLMF\_FinInstID\_AltrntId map are as follows, assuming an input card name of 35B\_Desc):

LMF Sub-field	Mapping rule
f	= "FinInstIDVar"
TickerSymbol_S	= WORD ( Narrative_35x General Line SubField[1]:35B_Desc, "/", 2 )
LocalID_S	= WORD ( Narrative_35x General Line SubField[1]:35B_Desc, "/", 3 )
NarrativeVal_S[1]	= Narrative_35x General Line SubField[2]:35B_Desc
NarrativeVal_S[2]	= Narrative_35x General Line SubField[3]:35B_Desc
NarrativeVal[3]	= Narrative_35x General Line SubField[4]:35B_Desc

All other fields can be set to NONE.

Using these rules, an input of the following:

```
:35B:/TS/IBM Ord
SCTY DESC EXTRA 1
SCTY DESC EXTRA 2
```

Gives the following LMF element:

```
<FinInstID s="" f="FinInstIDVar" q="">
 <TickerSymbol>TS</TickerSymbol>
 <LocalId>IBM Ord</LocalId>
 <NarrativeVal>SCTY DESC EXTRA 1</NarrativeVal>
</FinInstID>
```

## FromLMF map

A similar method can be applied to the FromLMF map to extract data from these sub-fields and map to the output MT message.

The following simple rule can be changed to look for the presence of LocalID and map accordingly:

Rule:

```
FromLMF_FinInstID_35B (FinInstID_C Class:TRADDET_LMF_In)
```

Changed rule:

```
= IF (PRESENT (LocalId_S SubField:FinInstID_C Class:TRADDET_LMF_In) ,
FromLMF_FinInstID_AltrntId (FinInstID_C Class:TRADDET_LMF_In) ,
FromLMF_FinInstID_35B (FinInstID_C Class:TRADDET_LMF_In))
```

The mapping rules for FromLMF\_FinInstID\_Altrntid are as follows, assuming an input card name of FinInstid\_IR:

FinInstID_C Field	Mapping rule
FieldTag	="35"
GeneralFormatOption	="B"
NarrativeVal_S[1]	="/" + TickerSymbol_S SubField:FinInstId_IR + "/" + LocalId_S SubField:FinInstId_IR
NarrativeVal_S[s]	=NarrativeVal_S SubField:FinInstId_IR

## Universal Confirmation Components

The Universal Confirmation (UC) validation component provides a framework to generate and validate the Universal Confirmation messages.

It is used to generate confirmations based from different channels:

- FIN MT103
- CSV file structure
- SWIFT gpi Tracker PaymentStatusRequest API

You can perform the checks on messages before transmission to ensure compliance. It provides a configurable transformation and validation framework with the error reporting functionality that helps to locate the source of the error.

- [Overview of the Universal Confirmation Components](#)  
The Universal Confirmation translation component supports the following:
- [Configuration Files](#)  
The Universal Confirmation validation and translation controlled by configuration files.

---

## Overview of the Universal Confirmation Components

The Universal Confirmation translation component supports the following:

- MT103 to MT199.
- MT103(s) to CSV file structure for payment confirmation.
- CSV file structure for payment confirmation of MT103 to MT199.
- MT103 to PaymentStatusRequest gpi API Tracker version 3.0.
- PaymentStatusRequest gpi API to MT199.

The Universal Confirmation validation component validates api, csv and fin messages.

MT103, MT199 messages in accordance with the latest SWIFT standard.

- Message syntax: Presence and order of fields and sequences.
- Field syntax: Size and data type.
- Field and sequence cardinality: Optional, mandatory, repeating.
- Codewords and constraints.
- Network validated rules at both message and field level.
- Market practice rules.

The CSV file structure for payment confirmation of MT103, FIN Universal Confirmations CSV file structure for payment confirmation of MT 103. standard.

The API messages are based from SWIFT gpi API Tracker version 3.0.

---

## Configuration Files

The Universal Confirmation validation and translation controlled by configuration files.

There are two types of configuration files:

- Validation Configuration Files.
- Translation Configuration Files.
- [Validation Configuration Files](#)  
The validation configuration files contain several configurable parameters to control the behavior of the Universal Confirmation validation example.
- [Translation Configuration File](#)
- [Configuration file location](#)  
The configuration files are required for the validation and translation maps to run successfully. If these files are absent, the map terminates.

---

## Validation Configuration Files

The validation configuration files contain several configurable parameters to control the behavior of the Universal Confirmation validation example.

These files are shipped with api and csv validation examples. These files are in the config folder and identified by the trailing codeword `_cfg` in the filename.

The configuration file contains the configurable parameters for each field to control the behavior of the Universal Confirmation validation. These parameters specify certain validation options.

When you run the api or csv validation maps, the configuration files must be present. See "Configuration file location" topic for more details.

If the configuration and translation files are not found, the map execution terminates.

---

### debug=true|false

Controls the content of validation results.

- true: This is a default value and the recommended setting. Validation results contain all field name, value, offset, data type, and error description (if there are any validation failures).
- false: When you set the value to false, it shows only the field that has an error with the field name, value, offset, data type, and error description.

---

### validate=true|false

This flag appears for each field or group and controls the validation of the respective field or group.

- true: This is a default value. It requires the field or group validation.

- false: When you set the value to false, it does not require the field or group validation.

## min=0|1

---

Identifies the field or group being optional or mandatory.

- 0: Indicates that the field or group is optional.
- 1: Indicates that the field or group is mandatory.

## Max=n

---

Identifies the number of occurrences of respected the field or group.

- n: Indicates the maximum number of times a field or group can be repeated.
- \*: Indicates that the field or group can be repeated infinite time.

## type

---

Identifies the type of field or group.

## constraints

---

Identifies the validation to be applied on the respected field or group.

## codelist

---

Contains the list of valid codewords for the respected field or group.

- **Validation Configuration File scenarios**

For example, camt.a01.001.04\_cfg.json file in universal\_confirmation/api/data/config has below configuration for field update\_payment\_scenario:

## Validation Configuration File scenarios

For example, camt.a01.001.04\_cfg.json file in universal\_confirmation/api/data/config has below configuration for field update\_payment\_scenario:

```
"update_payment_scenario": {
 "validate": true,
 "min": 1,
 "max": 1,
 "type": "PaymentScenario1Code",
 "codelist": [
 "COVE",
 "CCTR"
]
}
```

### "validate":

- If the Validate property is set to true, the field will be validated for configurations provided.
- If the Validate property is set to false, the field will not be validated for configurations provided.

"max": 1: Indicates only 1 maximum allowed occurrence for the field.

"codelist": Indicates the codewords "COVE" and "CCTR" being valid codewords for the field.

Constraints: Indicates the validation rules to be enforced.

## Translation Configuration File

---

The translation file uc\_translation\_cfg.json contains a few system generated parameters for creation of UC Message MT199, which are not present in input message api, csv or fin.

- **Translation Configuration File scenarios**

The translation file serves a purpose of holding system generated fields. Fields from the translation file are used to generate the output only, if they are not available in the input file.

## Translation Configuration File scenarios

The translation file serves a purpose of holding system generated fields. Fields from the translation file are used to generate the output only, if they are not available in the input file.

## General Information

---

The following fields can be set in the translation configuration file.

## MT header fields

---

session\_number: Mapped to field Session Number of block 1 of MT199.  
sequence\_number: Mapped to field Sequence Number of block 1 of MT199.  
logical\_terminal: Mapped to field DestinationAddress of block 2 of MT199.  
branch\_code: Mapped to field DestinationAddress of block 2 of MT199.  
priority\_block: Mapped to field PriorityBlock of block 2 of MT199.  
delivery\_monitoring\_code: Mapped to field DeliveryMonitoringCd of block 2 of MT199.  
obsolescence\_period\_code: Mapped to field ObsolescencePeriodCd of block 2 of MT199.  
business\_service: Mapped to field ServiceTypeID Tag111 of block 3 of MT199.  
update\_payment\_scenario: Mapped to field update\_payment\_scenario of api.

## PaymentStatusRequest

---

status: Mapped to field StatusCode of Tag79 Line2 of block 4 of MT199.  
reason: Mapped to field ReasonCode of Tag79 Line2 of block 4 of MT199.  
return: Mapped to field return of api.

## Additional information

---

forwarded\_to\_agent: Mapped to field ForwardedTo BIC of Tag79 Line3 of block 4 of MT199.  
settlement\_method: Mapped to field Settlmnt\_Method of Tag79 Line3 of block 4 of MT199.  
clearing\_system: Mapped to field Clearing\_System of Tag79 Line3 of block 4 of MT199.

## foreign\_exchange\_details

---

target\_currency: Mapped to field TargetCCY CUR of Tag79 Line5 of block 4 of MT199.  
exchange\_rate: Mapped to field ExchangeRate of Tag79 Line5 of block 4 of MT199.

## MT103 to CSV

---

In addition to above generic details, following functionality is specially for MT103 to csv translation.

In MT103 to csv, multiple occurrences of MT103 can be provided in the input file. A csv record (basic or advance) is generated for each MT103 instance.

The translation file for MT103 to csv can be provided with multiple occurrences.

In case of multiple occurrences of data provided in a translation file, reference of MT103 (Tag20) is matched with field instruction\_reference of translation configuration file in order to identify which occurrence of the translation file should be used for the current instance of MT103 to generate the csv record.

If the reference of MT103 (Tag20) is not found in the translation configuration file, an error is reported in the MT103\_config\_mismatch.out file stating reference to MT103 file.

If a single occurrence of data is provided in the translation file, the same instance is used to generate a csv record.

## CSV to MT199

---

Following functionality is specially for CSV to MT199 translation.

In csv to MT199, multiple occurrences of csv record (basic or advance) can be provided in the input file. MT199 instance are generated for each csv record.

The translation file for csv to MT199 can be provided with multiple occurrences.

In case, multiple occurrences of data is provided in uc\_translation\_cfg.json translation configuration file, Related\_Reference field of each CSV record is matched with field instruction\_reference of translation configuration file in order to identify which occurrence of translation configuration file should be used for current csv record to generate the MT199 instances.

If the field Related\_Reference of csv record is not found in the translation configuration file, an error is reported in the csv\_config\_mismatch.out file stating reference to that csv record.

If a single occurrence of data is provided in the translation file, the same instance is used to generate all MT199 instances.

## Configuration file location

---

The configuration files are required for the validation and translation maps to run successfully. If these files are absent, the map terminates.

The files are in <install\_dir>/packs/financial\_payments\_vn.n.n/n/swift/mt/examples/universal\_confirmation/\*/data/config directory.

Where, \* = api, csv, fin.

The configuration files are identified by the trailing codeword `_cfg` in the filename. All translation files named uc\_translation\_cfg.json are located at the above mentioned directory.

---

## SWIFT MX components

This documentation describes the SWIFT MX components.

For a description of specific versions of the SWIFT standards that are supported, see the release notes. The versions of the ITX base product that are required for this pack are described in the system requirements.

- [SWIFT MX components overview](#)

The schema versions that are included in the release are determined by publication date.

- [SWIFT MX schemas and type tree](#)

The SWIFT component of the Pack for Financial Payments includes all of the published SWIFT schemas, and also includes the type tree representation of these schemas.

- [MX validation](#)

This documentation describes MX validation.

---

## SWIFT MX components overview

The schema versions that are included in the release are determined by publication date.

The following are the main components of the SWIFT component MX:

- MX schemas and type tree
- MX validation framework
- MX schema validation maps
- MX extended validation maps
- Examples

## Terminology

---

The following terms are used throughout this documentation:

- **Extended validation** - In the MX Validation Framework, these rules are applied to the following generic MX fields:
  - XML elements of type BIC, or BICorBEI are checked for valid BIC or BEI.
  - XML elements that contain a currency code are checked for a valid code.
  - XML elements that contain a country code are checked for a valid code.
  - XML elements that contain an Amount and a Currency. These elements are checked for a valid currency and a valid number of decimal places as specified for that currency.
  - XML elements that contain an IBAN Identifier are checked for structure (country code, check digit, and bank account number)

## SWIFT MX schemas and type tree

---

The SWIFT component of the Pack for Financial Payments includes all of the published SWIFT schemas, and also includes the type tree representation of these schemas.

## MX validation

---

This documentation describes MX validation.

- [MX validation overview](#)

MX validation in the Pack for Financial Payments uses the following maps:

- [MX validation framework map](#)

The individual MX validation maps are controlled by this single executable map. The map source file is mx\_validation\_framework. The executable map name is swiftval.

- [MX configuration file](#)

The settings for MX validation are controlled by the mxconfig.xml file in the mx/maps directory.

- [Individual MX validation maps](#)

The MX validation maps validate for schema, BIC, IBAN, currency code, decimal places, and country codes for supported message types.

- [List of supported messages](#)

The supported MX messages are listed in the tables that are provided here.

- [Error reporting in the MX validation framework](#)

If errors are detected in the MX message, an error report is generated.

- [Adding maps to the MX validation framework](#)  
Additional XML messages can be added to the framework to perform XML schema validation and optionally your own extended validation rules.
- [How to use different levels of validation in the MX validation framework](#)  
You can perform different levels of validation for different message types.
- [Debugging the MX validation framework](#)  
The MX framework map is designed to record the steps it performs in parsing the data to determine the correct **RUN** map to use.

## MX validation overview

MX validation in the Pack for Financial Payments uses the following maps:

- Individual MX validation maps for each supported message type.
- A framework map that can be used to execute the maps, or as an example to build your own execution framework.
- [Framework map](#)  
The framework map works by attempting to identify the message type from the input data, by looking for the schema name in the schema name space.
- [MX validation maps](#)  
The individual MX validation maps are organized into map source files according to their business function.
- [MX schema validation maps](#)  
A separate map source file contains maps that only perform schema validation. The map source file is called `mx_schema_validation`, and contains a map for each supported MX message.

## Framework map

The framework map works by attempting to identify the message type from the input data, by looking for the schema name in the schema name space.

For example:

```
<Document xmlns="urn:iso:std:iso:20022:tech:xsd:colr.003.001.02"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
```

This information is used to determine the correct validation map name, and when it is identified, the relevant map is then run. An error report is produced if a validation failure is detected, and is also produced if it is not possible to identify the message type from the input data. See [Error reporting in the MX validation framework](#).

Configuration file, `mxconfig.xml`, is used to control the level of validation that is performed by each of the individual MX validation maps. See [MX configuration file](#).

If the message type cannot be identified from the input data, then, it is possible to provide the message type in the `mxconfig` file so that the framework map can identify the correct map to run. See [MX configuration file](#).

You can customize the framework to add your own validation maps, if required. But the relationship between schema name and map name must be maintained in order for the framework map to identify the correct validation map to run. See [Adding maps to the MX validation framework](#).

You can use different levels of validation for different message types, if required, by using separate configuration files for different message types. See [How to use different levels of validation in the MX validation framework](#).

The framework map can be run in debug mode to help with problem diagnosis. See [Debugging the MX validation framework](#). The framework map is called `swiftval`, and can be found in `validation_framework`. See [Framework map](#).

## MX validation maps

The individual MX validation maps are organized into map source files according to their business function.

For example, the `mx_acmt_validation` map source file contains the validation maps for all of the acmt messages. See [List of supported messages](#).

Each map is named according to a convention based on the MX schema name. For example:

Schema name	Validation map name
<code>pacs.008.001.04</code>	<code>ps008104_pacs_008_001_04</code>

The validation map name is derived from the schema name as follows:

Character 1 of the validation map name	represents character 1 of the schema name
Character 2 of the validation map name	represents character 4 of the schema name
Characters 3 - 5 of the validation map name	represents characters 6 - 8 of the schema name
Character 6 of the validation map name	represents character 12 of the schema name
Characters 7 and 8 of the validation map name	represents characters 14 and 15 of the schema name
Character 9 of the validation map name	represents the underscore character
Characters 10 - 24 of the validation map name	represents the full schema name, but with periods replaced with underscores

Note: There are exceptions to this naming scheme for the Application Header schema (`$ahV10.xsd`) and the E&I schemas that are named `swift.eni$xxxx.nnn.nnn.nn.xsd`. See [List of supported messages](#).

Each validation map performs a range of validation tasks. These following tasks are performed:

- Schema validation to check the MX instance conforms to the schema definition.
- BIC validation to ensure that only valid BICs are used.
- Country validation to ensure that only valid country codes are used.

- Currency validation to ensure that only valid currency codes are used.
- Decimal place validation to ensure the correct number of decimals per currency is used.
- IBAN validation to ensure that the IBAN contains a valid currency code and valid check digits as stated in the guidelines in the Swift MT User Handbook for IBANs (see Message Format Validation Rules, Part II Components, Chapter 4 Special Functions, topic IBAN).

Schema validation is always performed in the validation maps, but each of the other validation tasks can be turned off or on as required by using the supplied configuration file. See [MX configuration file](#).

The validation maps use the bic.xml and currencycodedecimals.xml files to verify BICs, Currency Codes, Country Codes, and Decimal Places information.

The bic.xml file contains a list of BICs created from the SWIFT published BIC address list.

The currencycodedecimals.xml file contains a list of countries, their country codes, and the number of decimal places their currency allows. This data is obtained from the SWIFT published list.

The SWIFT component of the Pack for Financial Payments includes a utility for creating both of these files. See [Common SWIFT components](#).

The individual MX validation maps can be run from the framework map, or they can be called individually as an independent executable map.

If you execute these maps outside of the framework map, then you must build your own error handling and error reporting routines. If so, the framework map can be used as an example in building your own routines See [Individual MX validation maps](#).

## MX schema validation maps

A separate map source file contains maps that only perform schema validation. The map source file is called mx\_schema\_validation , and contains a map for each supported MX message.

Use the MX schema validation maps only if you want to perform schema validation, and you do not want to perform extended validation. Be aware of the following points regarding these maps.

- The map names are the same as for the extended validation maps, as shown in the [List of supported messages](#).
- The maps use the same number of input and output cards as the extended validation maps.
- The maps are not compiled in the deploy script.
- If you want to use the maps instead of the extended validation maps, you must compile and deploy them manually. Compiling the maps overwrites the extended validation executable maps as the maps are named the same.

## MX validation framework map

The individual MX validation maps are controlled by this single executable map. The map source file is mx\_validation\_framework. The executable map name is swiftval.

The map has the following five inputs and three outputs:

Input or Output	Description
Input 1 (mx)	The MX data file. This file can be of any message type that is supported by the pack, or can be of a type that you add.
Input 2 (mxconfig)	The MX map configuration data. See“ <a href="#">MX configuration file</a> .
Input 3 (bicDirectory)	The BIC information file.
Input 4 (ccyCtryCodeList)	The Currency Code, Country Code, and Decimal Places information file.
Input 5 (errorMsgList)	The source file for all of the error messages.
Output 1 (Framework)	This card performs the main processing in the map, and it creates an audit log of the results. It determines the schema name from the input MX instance in input 1 (mx). If this is unsuccessful, it then tries to obtain the schema name from the mxconfig.xml file in input 2 (mxconfig). Having obtained the schema name, it then performs a <b>RUN</b> command to invoke the relevant validation map for this schema. If the map is unable to obtain the schema name from either of these two methods, the map will not perform any validation.
Output 2 (GatherResults)	This card analyzes the results of the <b>RUN</b> command. If the <b>RUN</b> command completed successfully, this card stores the result of the <b>RUN</b> command of the validation map. If the <b>RUN</b> command did not complete successfully, this card performs a <b>LOOKUP</b> on file errcodes.txt in input 5 (errorMsgList), to obtain the relevant error message.
Output 3 (FinalOutput)	This card determines whether Trace is turned on in mxconfig in input 2 (mxconfig). If Trace is turned on, this card returns a concatenation of Output 1 (Framework) plus Output 2 (GatherResults). If Trace is not turned on, it returns Output 2 (GatherResults).

Prior to running the MX validation framework, build the maps for Windows using the build\_deploy\_mx\_validation.bat file. The build\_deploy\_mx\_validation.bat file creates the deployment\_mx\_validation directory under the mx/maps directory.

Prior to running the MX validation frame, build the maps as described in [Building multiple maps using Deploy](#).

To run the MX Validation Framework, execute the swiftval map, overriding the first input with the MX data to validate.

Input Card 2 may be overridden with different mxconfig files in order to use different levels of validation for different message types (See [How to use different levels of validation in the MX validation framework](#)).

For most cases the other inputs should remain static for optimal performance.

## MX configuration file

The settings for MX validation are controlled by the mxconfig.xml file in the mx/maps directory.

The default content of the mxconfig.xml file is shown here:

```
<?xml version="1.0" encoding="UTF-8"?>
<Configuration>
 <XMLSchemaName></XMLSchemaName>
 <MapTrace>F</MapTrace>
 <ExtendedValidation>
 <BICValidation>T</BICValidation>
 <IBANValidation>T</IBANValidation>
 <CountryCodeValidation>T</CountryCodeValidation>
 <CurrencyCodeValidation>T</CurrencyCodeValidation>
 <DecimalPlacesValidation>T</DecimalPlacesValidation>
 </ExtendedValidation>
</Configuration>
```

- **Schema name**

The XMLSchemaName element can be used to provide the namespace information if the message data does not contain the schema namespace information.

- **Map trace**

This setting controls the optional debug log of the control map.

- **Extended validation settings**

Extended validation settings have a Boolean T/F value. The value T represents enabled, and the value F represents disabled.

## Schema name

The XMLSchemaName element can be used to provide the namespace information if the message data does not contain the schema namespace information.

An XMLSchemaName element is shown here:

```
<XMLSchemaName>acmt.008.001.01</XMLSchemaName>
```

This feature is not supported in IBM Sterling B2B Integrator

## Map trace

This setting controls the optional debug log of the control map.

Setting this element to T produces an audit log of all of the steps that the framework map records, and the values that the steps produce. Here is an example of the output from the trace:

```
<MapVersion>SWIFT MX Validation vn.n.n.n release</MapVersion>
<MapRunDate>20120531</MapRunDate>
<MapStartTime>15:05:59296</MapStartTime>
<config_SchemaName>ABSENT</config_SchemaName>
<xmllns_SchemaName>colr.003.001.02</xmllns_SchemaName>
<SchemaName> colr.003.001.02</SchemaName>
<MapName>ai004101_admi_004_001_01
<Command>-A -OBI -IH1 - 4.0.477</Command>
<Run>Error(-1), "XMLParser: Input XML data is invalid."
SAXParseException, Error [line: 10 column: 41] Datatype error:
Type:NumberFormatException, Message:Invalid chars encountered.
</Run>
<MapEndTime>15:05:59421</MapEndTime>
</Framework>Error(-1), "XMLParser: Input XML data is invalid."
SAXParseException, Error [line: 10 column: 41] Datatype
error:NumberFormatException, Message:Invalid Chars encountered
```

## Extended validation settings

Extended validation settings have a Boolean T/F value. The value T represents enabled, and the value F represents disabled.

The extended validation settings are listed here:

- The BICValidation setting validates the BIC against the list of BICs in the bic.xml file.
- The IBANValidation setting validates the IBAN for country code values that are found in the currencycode.xml file, and validates the check digit.
- The CountryCodeValidation setting validates all country codes that are found in the document against the currencycode.xml file.
- The CurrencyCodeValidation setting validates all currency codes that are found in the document against the currencycode.xml file.
- The DecimalPlacesValidation setting validates all of the currency amounts for the number of decimal places that are allowed for the specified currency. The currencycode.xml file is used for the validation of places. This validation is disabled if CountryCodeValidation is set to false.

## Individual MX validation maps

The MX validation maps validate for schema, BIC, IBAN, currency code, decimal places, and country codes for supported message types.

The map source for these maps is organized into map source files named according to their business function. For example, mx\_acmt\_validation is for all of the acmt messages. See [List of supported messages](#) for a full list of supported MX messages.

These maps all have the same five inputs and four outputs:

Input/output	Description
Input 1 (mx)	The MX data file compatible with the map input card definition. This card is overridden when this map is called from the swiftval framework map.
Input 2 (mxconfig)	The MX map configuration data. See <a href="#">MX configuration file</a> .
Input 3 (bicDirectory)	The BIC information file.
Input 4 (ccyCtryCodeList)	The currency code and decimal places information file.
Input 5 (errorMsgList)	The source file for all of the error messages.
Output 1 (SchemaValidation)	This card uses the GETXMLERRORMSG function to retrieve all of the XML schema errors in the XML document. This card uses the Sink adapter.
Output 2 (CurrencyAndAmountsList)	This card collects all of the elements from the data that needs to be validated. This card uses the Sink adapter.
Output 3 (validate)	This card uses the output from the CurrencyAndAmountsList output card to validate the data. It captures the errors through a series of rule checks to validate BIC, IBAN, country code, currency code, and decimal place values.
Output 4 (ErrorCollector)	This card collects all of the error information that is generated by the map. The SchemaValidation and the validate card outputs are captured in this card, and then sent as output from the map through the file adapter by default. When used as a <b>RUN</b> map, this output is passed back to the framework by use of the <b>ECHOIN</b> function.

You can run the individual MX validation maps using the framework map, or you can run the validation map that is in the relevant map source file to override the first input with MX data to validate. The other inputs remain static for optimal performance. The first four inputs for these maps are overridden when using the framework map in calling these extended validation maps.

Note: For the MX Header schema \$ahV10 only schema validation is possible, since it does not contain any elements that require extended validation

## List of supported messages

The supported MX messages are listed in the tables that are provided here.

- [Account Management list of supported messages](#)  
The table shows the supported MX messages for Account Management in the mx\_acmt\_validation executable map.
- [Cash Management list of supported messages](#)  
The table shows the supported MX messages for Cash Management in the mx\_camt\_validation executable map.
- [Collateral Management list of supported messages](#)  
The table shows the supported MX messages for Collateral Management in the mx\_colr\_validation executable map.
- [MX Application Headers list of supported messages](#)  
The table shows the supported MX messages for MX Application Headers in the mx\_head\_validation executable map.
- [Payments, Clearing and Settlement list of supported messages](#)  
The table shows the supported MX messages for Payments, Clearing and Settlement in the mx\_pacs\_validation executable map.
- [Payments Initiation list of supported messages](#)  
The table shows the supported MX messages for Payments Initiation in the mx\_pain\_validation executable map.
- [Reference Data list of supported messages](#)  
The table shows the supported MX messages for Reference Data in the mx\_reda\_validation executable map.
- [Securities Clearing list of supported messages](#)  
The table shows the MX messages for Securities Clearing in the mx\_secl\_validation executable map.
- [Securities Events list of supported messages](#)  
The table shows the supported MX messages for Securities Events in the mx\_seev\_validation executable map.
- [Securities Management list of supported messages](#)  
The table shows the supported MX messages for Securities Management in the mx\_semt\_validation executable map.
- [Securities Settlement list of supported messages](#)  
The table shows the MX messages for Securities Settlement in the mx\_sese\_validation executable map.
- [Securities Trading list of supported messages](#)  
The table shows the supported MX messages for Securities Trading in the mx\_setr\_validation executable map.
- [Trade Services Management list of supported messages](#)  
The table shows the supported MX messages for Trade Services Management in the mx\_tsmt\_validation executable map.

## Account Management list of supported messages

The table shows the supported MX messages for Account Management in the mx\_acmt\_validation executable map.

Type trees	Schema name	Validation map name
acmt_001_001_08	acmt.001.001.08.xsd	at001108_acmt_001_001_08
acmt_002_001_08	acmt.002.001.08.xsd	at002108_acmt_002_001_08

## MX Application Headers list of supported messages

The table shows the supported MX messages for MX Application Headers in the mx\_head\_validation executable map.

Type trees	Schema name	Validation map name
\$ahV10	\$ahV10.xsd	\$V0_\$ahV10
head_001_001_02	head_001_001_02.xsd	hd001102_head_001_001_02

## Payments, Clearing and Settlement list of supported messages

The table shows the supported MX messages for Payments, Clearing and Settlement in the mx\_pacs\_validation executable map.

Type trees	Schema name	Validation map name
pacs_002_001_14	pacs.002.001.14.xsd	ps002114_pacs_002_001_14
pacs_003_001_11	pacs.003.001.11.xsd	ps003111_pacs_003_001_11
pacs_004_001_13	pacs.004.001.13.xsd	ps004113_pacs_004_001_13
pacs_007_001_13	pacs.007.001.13.xsd	ps007113_pacs_007_001_13
pacs_008_001_10	pacs.008.001.10.xsd	ps008110_pacs_008_001_10
pacs_008_001_12	pacs.008.001.12.xsd	ps008112_pacs_008_001_12
pacs_009_001_11	pacs.009.001.11.xsd	ps009111_pacs_009_001_11
pacs_010_001_06	pacs.010.001.06.xsd	ps010106_pacs_010_001_06
pacs_028_001_06	pacs.028.001.06.xsd	ps028106_pacs_028_001_06

## Payments Initiation list of supported messages

The table shows the supported MX messages for Payments Initiation in the mx\_pain\_validation executable map.

Type trees	Schema name	Validation map name
pain_001_001_12	pain.001.001.12.xsd	pn001112_pain_001_001_12
pain_002_001_14	pain.002.001.14.xsd	pn002114_pain_002_001_14
pain_007_001_12	pain.007.001.12.xsd	pn007112_pain_007_001_12
pain_008_001_11	pain.008.001.11.xsd	pn008111_pain_008_001_11
pain_009_001_08	pain.009.001.08.xsd	pn009108_pain_009_001_08
pain_010_001_08	pain.010.001.08.xsd	pn010108_pain_010_001_08
pain_011_001_08	pain.011.001.08.xsd	pn011108_pain_011_001_08
pain_012_001_08	pain.012.001.08.xsd	pn012108_pain_012_001_08
pain_017_001_04	pain.017.001.04.xsd	pn017104_pain_017_001_04
pain_018_001_04	pain.018.001.04.xsd	pn018104_pain_018_001_04

## Reference Data list of supported messages

The table shows the supported MX messages for Reference Data the mx\_reda\_validation executable map.

Type trees	Schema name	Validation map name
reda_001_001_04	reda.001.001.04.xsd	ra001104_reda_001_001_04
reda_002_001_04	reda.002.001.04.xsd	ra002104_reda_002_001_04
reda_004_001_07	reda.004.001.07.xsd	ra004107_reda_004_001_07
reda_005_001_03	reda.005.001.03.xsd	ra005103_reda_005_001_03
reda_074_001_01	reda.074.001.01.xsd	ra074101_reda_074_001_01

## Securities Clearing list of supported messages

The table shows the MX messages for Securities Clearing in the mx\_secl\_validation executable map.

Type trees	Schema name	Validation map name
secl_001_001_03	secl.001.001.03.xsd	sl001103_secl_001_001_03
secl_002_001_03	secl.002.001.03.xsd	sl002103_secl_002_001_03

## Error reporting in the MX validation framework

If errors are detected in the MX message, an error report is generated.

Two types of error messages are generated from the MX validation framework map, a schema validation error, and an extended validation error.

- A schema validation error indicates that the MX instance data does not match the schema.
- An extended validation error indicates that the MX instance data contains an invalid BIC, Country, Currency, IBAN, or incorrect decimal places.

## Schema validation error message

The error report contains the SAX parsing error message, or messages. An example of a schema validation error message is shown here:

```
Error (-1), "XMLParser: Input XML data is invalid." SAXParseException, Error [line: 24 column: 23] Datatype error: Type:InvalidDatatypeValueException, Message:Value
```

```
'99BADBIC' does not match regular expression facet '[A-Z]{6,6}[A-Z2-9][A-NP-ZO-9]([A-Z0-9]{3,3}){0,1}'.
```

## Extended validation error message

---

The extended validation error report contains an extended error message with the error code, text that explains the error, and an offset location of the error.

An example of an extended error message is shown here:

```
E80001 - UX - Invalid country code found at position 7362
```

This error shows that the value UX is not a valid country code, and the position of UX can be found on the 7,362nd position from the beginning of the file.

The resource map that is used for the extended error messages is called errorcodes.txt, and can be found in the mx/maps directory. These error codes are externalized so that you can easily update them for translation, or for wording changes. Translate only the text of the message and not the error code. Additional error messages can be added, if they follow the error code format and they are listed in ascending order by error message number.

---

## Adding maps to the MX validation framework

---

Additional XML messages can be added to the framework to perform XML schema validation and optionally your own extended validation rules.

Maps added to the framework must be consistent with existing validation maps in that they must have the same input and output cards, and map naming conventions, as described in [Individual MX validation maps](#). Perform these steps to add more messages:

1. Create additional validation maps. Copy an existing validation map and edit it according to your needs. Rename the map to specify the message type, bearing in mind the rules governing validation map names. See [Individual MX validation maps](#).
  2. Modify the input card in this map to use either the native XML schema, or create a Xerces type tree from the schema using the Transformation Extender Map Designer schema importer utility. The resulting type tree can be used as the input card source.
  3. Add the **RESTART** attribute to the Document Element, which is at the top level of the schema or the type tree. This ensures that all of the errors are captured.
  4. Use the existing map rules as a template to update the rules in Output Card 2, to collect all the elements that you want to validate, such as BICs and IBANs.
- 

## How to use different levels of validation in the MX validation framework

---

You can perform different levels of validation for different message types.

For example, you might not want to perform BIC validation for the camt messages, but you do want to perform this for the pacs messages. In this situation, you would use two separate mxconfig.xml files:

mxconfig_camt.xml	BIC validation=F
mxconfig_pacs.xml	BIC validation=T

How you use these files depends on whether you are using the framework map, or are running the individual MX validation maps independently of the framework. The examples here use the Command Server as the ITX map execution platform.

This example shows how to use the files when you use the framework map:

```
dtxcmdsv swiftval -IF1 camt.053.001.04.xml IF2 mxconfig_camt.xml
```

```
dtxcmdsv swiftval -IF1 pacs.008.001.04.xml IF2 mxconfig_pacs.xml
```

This example shows how to use the files when you use the individual MX validation maps:

```
dtxcmdsv ct053104_camt_053_001_04 -IF1 camt.053.001.04.xml IF2 mxconfig_camt.xml
```

```
dtxcmdsv ps008104_pacs_008_001_04 -IF1 pacs.008.001.04.xml IF2 mxconfig_pacs.xml
```

## Debugging the MX validation framework

---

The MX framework map is designed to record the steps it performs in parsing the data to determine the correct **RUN** map to use.

It captures the metadata information obtained from the configuration input and the message data. The map can, optionally, output all of this information for debugging purposes. To enable this feature see the [MX configuration file](#).

Error messages alert you that something went wrong in the process:

## E09005 - Input validation failure from map ct052102\_camt\_052\_001\_02

---

The E09005 message alerts you that the RUN map being called was unsuccessful in parsing the data and so did not produce any output. In order to determine what is wrong in this case, run the data directly through the map ct052102\_camt\_052\_001\_02 with the Transformation Extender Trace setting enabled.

## E09003 The WTX map failed due to invalid input card

---

The E09003 message usually occurs if the schema for the message data is not in the correct location, or if the message data is missing. Ensure that the schemas are deployed to the correct location. The default location the maps use is ..schemas.

## E09006 The XML schema name: badname.001.001.01 used as input to the map in the configuration file was not able to be identified.

The map as shipped supports a set of messages and specific versions. If data is passed to the framework, and this data is missing the schema name, or if the validation map name cannot be determined, then this message will be triggered. Ensure that the data being checked has the schema name, and that the schema is in place for the data to use. If the schema is not included, it can be added. See [Adding maps to the MX validation framework](#).

## Building and deploying SWIFT map systems

Batch scripts are included in the installation for the build and deployment of the SWIFT component MT and MX systems.

Additionally, ITX based systems (msd files) are also included for MX systems. These scripts make it simple to build all of the required maps, copy support files, and optionally FTP all of the files to their runtime destination directories.

- [Build Script Files](#)  
The location of the build script files, as well as a description of each, are included here.
- [Script Process Description](#)  
The documentation provided here describes script parameters, as well as the activities that the scripts perform.
- [Running the build and deployment scripts](#)  
Four individual systems can be built and deployed through use of the batch scripts.
- [How to enable SFTP to deploy the pack](#)  
By default, FTP is used to deploy the files to the target system.

## Build Script Files

The location of the build script files, as well as a description of each, are included here.

Script file name	Directory	Description
build_deploy_jvc.bat	../mt/jvc/maps	This script builds the SWIFT Java validation utility maps. Optionally, by use of FTP or SFTP, the script can deploy the maps, metadata, and the Java jar files to the target system.
build_deploy_lmf.bat	../mt/lmf	This script builds the LMF transformation maps. Optionally, by use of either FTP or SFTP, the script can deploy the maps.
build_deploy_mx_validation.bat	../mx/maps	This script builds the SWIFT MX validation maps, and copies all of the necessary support files. Optionally, by use of either FTP or SFTP, the script can deploy all of the maps and support files to the target system.

## Script Process Description

The documentation provided here describes script parameters, as well as the activities that the scripts perform.

- [Script parameters](#)  
The parameters that are listed here are used for all of the build and deploy scripts in the IBM Transformation Extender Pack for Financial Payments.
- [Actions performed by the build and deploy scripts](#)  
The build and deployment scripts perform the following actions, which are based on the parameters that are passed when they are invoked.

## Script parameters

The parameters that are listed here are used for all of the build and deploy scripts in the IBM Transformation Extender Pack for Financial Payments.

1. Mandatory - Operating system for map compile. This first parameter is always required. The parameter sets the operating system that the map step uses during compile.
2. TX installation directory.
3. FTP username - If no username is given, it is assumed that the deployment step is not required, and parameters 3 - 5 are not needed.
4. FTP user's password.
5. FTP server location - The FTP server location can be either a DHCP name, or the physical IP address.
6. Top-level target directory - The top-level target directory to deploy map files, schemas, and supporting files. This file must not contain spaces and must be the Transformation Extender home directory that contains the libs directory.

## Actions performed by the build and deploy scripts

The build and deployment scripts perform the following actions, which are based on the parameters that are passed when they are invoked.

1. The first parameter identifies the map compiler platform that the script is to use.
2. TX installation directory identifies which TX version will be used to compile the maps.
3. If the FTP username parameter is passed to the script, then the remaining parameters must also be passed (FTP password, FTP server, and the Transformation Extender target directory on the remote server).

4. A local deploy directory structure is created after parameter validation, if the directory structure does not already exist. This directory is created so that all of the files that need to be deployed are in a single directory.

The structure of this directory resembles the pack directory structure. The directory is created under the directory from which the batch file is running.

These corresponding directories are created:

- The build\_deploy\_jvc.bat file creates the directory deployment\_jvc under the mt/jvc/maps directory.
- The build\_deploy\_lmf.bat file creates the directory deployment\_lmf under the mt/lmf/maps directory.
- The build\_deploy\_mx\_validation.bat file creates the directory deployment\_mx\_validation under the mx/maps directory.

5. All maps for the system are compiled into the deploy directory for the operating system and are then passed to the script as the first parameter.

6. Any supporting files are then copied to the deploy directory.

7. FTP and SFTP deployment scripts are created from a template file (a file with an .scp extension). This file is in the same directory as the batch script at execution time. For security purposes, these scripts are deleted after the deployment completes.

Note: If you must keep these FTP scripts for debugging purposes, comment out the line 'del deploy.scp' in the batch script.

8. All of the files in the local deployment directory are transferred through use of FTP by default. They can, however, be modified by using SFTP.

9. When script execution is complete, a log file named *build script name.log* is available in the same directory as the script. The log file lists all of the actions that are performed by the script, and whether the action was successful

---

## Running the build and deployment scripts

Four individual systems can be built and deployed through use of the batch scripts.

See [Build Script Files](#) for details about these scripts.

To run the script, follow these steps:

1. Open a command prompt, and go to the directory that contains the script.

2. Call the script by passing in command-line parameters. The following are the available options: All supported OS by TX version

3. TX installation directory.

4. If the files must be copied to a remote system, add these parameters:

- a. FTP username - If a username is not given, it is assumed that the deployment step is not required. Parameters b - d are not needed.
- b. FTP user's password.
- c. FTP server location. This location can be identified as either a DHCP name or the physical IP address.
- d. Top-level target directory to which map files, schemas, and supporting files are deployed.

Note: The script is designed to use paths without spaces for parameter **d**. Ensure that your destination path does not contain spaces.

Note: For parameter **d**, under the top-level directory that is specified, the files are deployed to a subfolder called mt, or mx, depending on the deployment type, and distributed to other folders under this folder.

As an example, a call to a script in which all parameters pass is indicated by the following message:

```
<build script name>.bat AIX <TX install dir> user password UNIXMACHINE
/usr/apps/websphere_transformation_extender
```

---

## How to enable SFTP to deploy the pack

By default, FTP is used to deploy the files to the target system.

If your system uses SFTP, then the commented line in the following script can be edited:

```
REM psftp %USER%@%FTP_SERVER% -pw %PASSWORD% -bc -be -b deploy.scp >> %LOG%
```

The following is the default FTP line after it is commented to enable SFTP deployment:

```
psftp %USER%@%FTP_SERVER% -pw %PASSWORD% -bc -be -b deploy.scp >> %LOG% REM ftp -s:deploy.scp >> %LOG%
```

The default SFTP process uses the command from PuTTY. Modify the psftp line if you use other SFTP software.

---

## Implementing SWIFT component in IBM Sterling B2B Integrator (Deprecated)

The following are required in order to use the Pack for Financial Payments, SWIFT component with IBM Sterling B2B Integrator:

- IBm Transformation Extender Integration Server
- Transformation Extender Pack for Financial Payments
- IBM Sterling B2B Integrator

This documentation assumes familiarity with IBM Sterling B2B Integrator concepts and terminology.

IBM Sterling B2B Integrator is a transaction engine that runs business processes that you define, and manages them according to your business requirements. It supports high-volume electronic message exchange, complex routing, translation, and flexible interaction with multiple internal systems and external business partners. Using the IBm Transformation Extender Integration Server with IBM Sterling B2B Integrator, business process can derive benefit from the Transformation Extender transformation capabilities.

The following IBM Sterling B2B Integrator services are examples of services that provide Transformation Extender integration capabilities:

- Generic Enveloping Service
- Generic Deenveloping Service

Both of the services can be configured to allow you to choose:

- SWIFT component, JVC compliance checking for business process handling
- SWIFT component, MX validation for business process handling MX messages

Transformation Extender maps can run within the IBM Sterling B2B Integrator services on some, but not all, versions of the base product. See the system requirements for those versions of the base product that support IBM Sterling B2B Integrator.

- [Deploying the XML schemas to IBM Sterling B2B Integrator \(Deprecated\)](#)

The SWIFT component of the Pack for Financial Payments contains SWIFT MX schemas and other pack-specific XML schemas that are used for configuration, transformation, and validation.

- [Using JVC compliance checking on IBM Sterling B2B Integrator \(Deprecated\)](#)

The documentation provided here describes how to enable and deploy the SWIFT component of the Pack for Financial Payments compliance checking to IBM Sterling B2B Integrator.

- [Using MX validation for MX compliance checking on IBM Sterling B2B Integrator \(Deprecated\)](#)

The following procedures describe how to enable the Pack for Financial Payments compliance checking for SWIFT MX messages, and how to deploy its SWIFT MX compliance component to the IBM Sterling B2B Integrator server.

---

## Deploying the XML schemas to IBM Sterling B2B Integrator (Deprecated)

The SWIFT component of the Pack for Financial Payments contains SWIFT MX schemas and other pack-specific XML schemas that are used for configuration, transformation, and validation.

For these XML schemas to be used within the IBM Sterling B2B Integrator, they must be uploaded to the IBM Sterling B2B Integrator schema repository. The steps provided here describe how to check-in (upload) the XML schemas that come with the pack to the IBM Sterling B2B Integrator schema repository.

The Transformation Extender base product resolves the location of the XML schemas used within an Transformation Extender map that is executing within the IBM Sterling B2B Integrator in the following order:

1. The XML schema is resolved by searching the SI schema repository.
2. If the schema is not found in the SI repository, the Transformation Extender locates the schema based on any file path references associated with it.

To deploy XML schemas to the IBM Sterling B2B Integrator server:

1. Stop IBM Sterling B2B Integrator.
2. Navigate to `<si_install_dir>/bin`.
3. Load the XML schemas to the IBM Sterling B2B Integrator directory.

a. For Windows, enter the following at the command prompt or in the Run dialog box:

```
InstallService.cmd product short name/common/data/swiftnnnnxs4si.jar
```

Note: To obtain the product short name, open a command prompt, change the directory to C:/IBM, then enter dir /x. The product short name is displayed. For example, the product short name for IBM Transformation Extender version 8.4.1 is WEBSPH~1.1.

b. For Linux® and UNIX platforms, enter:

```
installService.sh <pack_install_dir>/common/data/swiftnnnnxs4si.jar
```

4. Restart IBM Sterling B2B Integrator.

In the directory locations, *product short name* indicates the short name of the installation directory; *<install\_dir>* indicates the installation location of the Pack for Financial Payments, and *n.n.n.n* indicates the version number of the Pack for Financial Payments.

---

## Using JVC compliance checking on IBM Sterling B2B Integrator (Deprecated)

The documentation provided here describes how to enable and deploy the SWIFT component of the Pack for Financial Payments compliance checking to IBM Sterling B2B Integrator.

- [Enabling JVC compliance checking on IBM Sterling B2B Integrator](#)

These are the steps required to enable the JVC compliance checking for the Generic Envelope and Generic Deenvelope services, using the IBM Sterling B2B Integrator Dashboard.

- [Deploying JVC compliance checking on IBM Sterling B2B Integrator](#)

You can deploy JVC compliance checking on IBM Sterling B2B Integrator.

---

## Enabling JVC compliance checking on IBM Sterling B2B Integrator

These are the steps required to enable the JVC compliance checking for the Generic Envelope and Generic Deenvelope services, using the IBM Sterling B2B Integrator Dashboard.

### About this task

If a Transformation Extender map is specified in the SWIFT envelope, the specified map is used only for translation, and compliance checking is handled separately.

### Procedure

1. Open the IBM Sterling B2B Integrator Dashboard.
2. On the SWIFT envelope, set the attribute Compliance Check message to **Yes**.
3. Set the attribute Use Transformation Extender compliance checking to **Yes**.
4. Set the WebSphere Transformation Extender Compliance Checking Options based upon your preferences.

- Validate BIC addresses.

Note: Validation for BIC, currency, and country codes is made against the IBM Sterling B2B Integrator SWIFT code lists. If the default SWIFT code lists versions have zero entries, the validation defaults against the following repository files that come with the SWIFT component: bic.xml and currencycode.xml

## Deploying JVC compliance checking on IBM Sterling B2B Integrator

You can deploy JVC compliance checking on IBM Sterling B2B Integrator.

### About this task

If the SWIFT component of the Transformation Extender Pack for Financial Payments is installed on the IBM Sterling B2B Integrator server, skip step 1.

If the Transformation Extender Pack for Financial Payments is not installed on the IBM Sterling B2B Integrator server, then you must deploy the components to the IBM Sterling B2B Integrator server using the procedures provided here.

In the following procedures, *<si\_install\_dir>* is the location where the IBM Sterling B2B Integrator server is installed.

In the following procedures, make certain that the permissions are set properly on the pack directory.

### Procedure

1. Deploy the pack to the IBM Sterling B2B Integrator server. See the pack release notes for deployment instructions.
2. After installing the Transformation Extender Pack for Financial Payments on Windows, copy jvalccyy.jar from the following location:  
`<install_dir>/packs/financial_payments_vn.n.n.n/UIProjectImports/swiftMTjvcConfig.tar.gz`  
to the following directory on the IBM Sterling B2B Integrator server:  
`<si_install_dir>/jar/SterlingTX/n_n_n`  
where *n\_n\_n* indicates the IBM Transformation Extender base product version.  
Note: The JVC must be set to verbose mode.
3. Install the jvalccyy.jar file by using the IBM Sterling B2B Integrator third party installer utility called install3rdParty under *<si\_install\_dir>/bin*  
For example:  
`<si_install_dir>/bin/install3rdParty.cmd<SP>SterlingTX<SP>n_n_n<SP>-j<SP><install_dir>/extjar/jvalccyy.jar -nodeploy`  
Where, <SP> is Space.  
Note: Make sure to depict appropriate spacing in the command.  
The above command is contained in one line.
4. Define customer\_overrides.properties under the following directory:  
`<si_install_dir>/properties`  
Include the following entry:  
`translator.SWIFTValidation=com.ibm.websphere.dtx.ip.swift.srgccyy.Validator`  
`translator.DTX_SWIFT_CONFIG_DIR=<install_dir>/packs/financial_payments_vn.n.n.n/swift/mt/jvc/maps`
5. Restart IBM Sterling B2B Integrator. This is required after changes are made to the customer\_overrides.properties file.
6. Verify the configuration by executing the MT Generic Envelope and Deenvelope example maps. The result should be consistent with the expected results as defined in [Expected results](#).

## Using MX validation for MX compliance checking on IBM Sterling B2B Integrator (Deprecated)

The following procedures describe how to enable the Pack for Financial Payments compliance checking for SWIFT MX messages, and how to deploy its SWIFT MX compliance component to the IBM Sterling B2B Integrator server.

- [Enabling MX compliance checking on IBM Sterling B2B Integrator](#)  
This documentation describes how to enable MX validation for the Generic Enveloping and Generic Deenveloping services.
- [Deploying MX compliance checking components](#)

## Enabling MX compliance checking on IBM Sterling B2B Integrator

This documentation describes how to enable MX validation for the Generic Enveloping and Generic Deenveloping services.

### About this task

If a Transformation Extender map is specified in the SWIFT envelope, the specified map is used only for translation. Compliance checking is handled separately.

### Procedure

1. On the SWIFT envelope, set the attribute Compliance Check message to Yes.
2. Set the attribute Use Transformation Extender compliance checking to Yes.
3. Set the Transformation Extender compliance checking options based upon your preferences:
  - Validate BIC addresses
  - Validate IBAN data

- Validate currency codes
- Validate amount and the number of decimal digits
- Validate country codes

Note: Validation for BIC, currency, and country codes are made against the Sterling SWIFT code lists. If the default SWIFT code list versions have zero entries, the validation defaults against the following repository files that come with the SWIFT component of the Pack for Financial Payments: bic.xml and currencycodedecimals.xml.

## Deploying MX compliance checking components

### About this task

If the SWIFT component of the Pack for Financial Payments is installed on the IBM Sterling B2B Integrator server, then you can skip step 1 in the following procedure, and you can continue with step 2.

If the SWIFT component of the Pack for Financial Payments is not installed on the IBM Sterling B2B Integrator server, then you must deploy the components to the IBM Sterling B2B Integrator server, using the following procedures:

In the following procedures, and throughout this documentation, `<si_install_dir>`, is the location where the IBM Sterling B2B Integrator is installed.

Note: Make certain that the permissions are set properly on the pack directory structure and subsequent sub-directories, including all of the compiled maps.

### Procedure

1. Deploy the Pack for Financial Payments to the IBM Sterling B2B Integrator server.
2. After installing the SWIFT component of the Pack for Financial Payments on Windows, define the `customer_overrides.properties` under the following directory:  
`<si_install_dir>/properties`  
Include the following entry:  
  
`translator.framework_driver_map_location=<install_dir>/financial_payments_vn.n.n.n/swift/mx/maps/swiftval.mmc`
3. Restart IBM Sterling B2B Integrator. This is required after changes are made to the `customer_overrides.properties` file.
4. Verify the configuration by executing the MX Generic Envelope and Deenvelope example maps. The result should be consistent with the expected results as defined in [Expected results](#).

## SWIFT component examples

- [Bank to XML example](#)
- [SWIFT to LMF example](#)
- [SWIFT from LMF example](#)
- [SWIFT MT Compliance example](#)
- [MT JVC Report example](#)  
This example takes a file in SWIFT Alliance Access (SAA) format containing a batch of SWIFT messages and uses the JVC to create a validation report.
- [MT950 Splitter Map example](#)  
The MT950 Splitter Map example contains 2 maps that demonstrate techniques for splitting a 5k MT950 Statement message into smaller MT950 messages.
- [MT Launcher Validation framework](#)  
This sample validation framework uses the Transformation Extender Launcher and the JVC to perform trigger-based MT validation.
- [MT - MX translation maps example \(Deprecated\)](#)  
The MT - MX translation maps example shows how the SWIFT component can be used to translate between MT and MX messages.
- [SWIFT MX Message Bundle and Unbundle map example using Design Server](#)  
This example demonstrates the use of a map that splits the MX message Business Application Header (BAH) from the MX message data, and also packages the BAH with the message data.
- [SWIFT MX validation example](#)  
This example demonstrates SWIFT MX validation.
- [IBM Sterling B2B Integrator examples \(Deprecated\)](#)  
The documentation provided here describes how to use the IBM Sterling B2B Integrator examples.
- [Universal Confirmation examples](#)

## Bank to XML example

- [How to run the example in Design Studio](#)  
Run instructions for the Bank to XML example.
- [How to run the example in Design Server](#)  
Run instructions for the Bank to XML example.

## How to run the example in Design Studio

Run instructions for the Bank to XML example.

## About this task

---

These steps describe how to run the Bank to XML example in Design Studio.

## Procedure

---

1. Use the Design Studio to open the following map source file: bankfiletoxml.mms.
2. Build all the maps in the source file, and then run the following transformation maps:
  - bictoxml
  - currencytoxml

## How to run the example in Design Server

---

Run instructions for the Bank to XML example.

## About this task

---

These steps describe how to run the Bank to XML example in Design Server.

## Procedure

---

1. Import the swiftBankFileXML.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the swiftBankFileXML project in the Design Server UI.
4. Run the following maps:
  - currencytoxml (maps/bankfiletoxml)
  - bictoxml (maps/bankfiletoxml)
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, refer to [How to download output files](#).
  - [How to download output files](#)  
After you build/run maps, download the output files.

## How to download output files

---

After you build/run maps, download the output files.

## About this task

---

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

## Procedure

---

1. Click the output Card Settings that you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:  
  
`data/ach_contested_dishonored_return.out`  
copy only:  
  
`ach_contested_dishonored_return.out`
3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

## SWIFT to LMF example

---

- [How to run the example in Design Studio](#)  
Run instructions for the SWIFT to LMF example.
- [How to run the example in Design Server](#)  
Run instructions for the SWIFT to LMF example.

# How to run the example in Design Studio

Run instructions for the SWIFT to LMF example.

## About this task

These steps describe how to run the SWIFT to LMF example in Design Studio.

## Procedure

1. Use the Design Studio to open the following map source files:

- swift\_mt101\_tolmf.mms
- swift\_mt102\_tolmf.mms
- swift\_mt103\_tolmf.mms
- swift\_mt202\_COV\_tolmf.mms
- swift\_mt202\_tolmf.mms
- swift\_mt205\_COV\_tolmf.mms
- swift\_mt205\_tolmf.mms
- swift\_mt210\_tolmf.mms
- swift\_mt300\_tolmf.mms
- swift\_mt304\_tolmf.mms
- swift\_mt305\_tolmf.mms
- swift\_mt320\_tolmf.mms
- swift\_mt502\_tolmf.mms
- swift\_mt509\_tolmf.mms
- swift\_mt515\_tolmf.mms
- swift\_mt535\_tolmf.mms
- swift\_mt536\_tolmf.mms
- swift\_mt537\_tolmf.mms
- swift\_mt548\_tolmf.mms
- swift\_mt549\_tolmf.mms
- swift\_mt564\_tolmf.mms
- swift\_mt565\_tolmf.mms
- swift\_mt566\_tolmf.mms
- swift\_mt567\_tolmf.mms
- swift\_mt568\_tolmf.mms
- swift\_mt578\_tolmf.mms
- swift\_mt900\_tolmf.mms
- swift\_mt910\_tolmf.mms
- swift\_mt940\_tolmf.mms
- swift\_mt942\_tolmf.mms
- swift\_mt950\_tolmf.mms
- swift\_mtn90\_tolmf.mms
- swift\_mtn91\_tolmf.mms
- swift\_mtn92\_tolmf.mms
- swift\_mtn95\_tolmf.mms
- swift\_mtn96\_tolmf.mms
- swift\_settconf\_mt54x\_tolmf.mms
- swift\_settinst\_mt54x\_tolmf.mms

2. Build all the maps in the source files, and then run the maps. See [SWIFT To LMF maps](#).

# How to run the example in Design Server

Run instructions for the SWIFT to LMF example.

## About this task

These steps describe how to run the SWIFT to LMF example in Design Server.

## Procedure

1. Import the swiftToLMF.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the swiftToLMF project in the Design Server UI.
4. Run the maps, see [SWIFT To LMF maps](#).
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).

- [SWIFT To LMF maps](#)

The maps to be run are listed below:

- [How to download output files](#)

After you build/run maps, download the output files.

## SWIFT To LMF maps

The maps to be run are listed below:

- swift\_mt537\_tolmf (maps/swift\_mt537\_tolmf)
- swift\_settconf\_mt54x\_tolmf (maps/swift\_settconf\_mt54x\_tolmf)
- swift\_mt568\_tolmf (maps/swift\_mt568\_tolmf)
- tolmf\_packet\_payment\_101 (maps/swift\_mt101\_tolmf)
- tolmf\_packet\_tradeorder\_509 (maps/swift\_mt509\_tolmf)
- tolmf\_packet\_transfer\_mt210 (maps/swift\_mt210\_tolmf)
- swift\_mt548\_tolmf (maps/swift\_mt548\_tolmf)
- tolmf\_swift\_mt515 (maps/swift\_mt515\_tolmf)
- swift\_mt535\_tolmf (maps/swift\_mt535\_tolmf)
- tolmf\_packet\_common\_mtn91 (maps/swift\_mtn91\_tolmf)
- tolmf\_packet\_confirmation\_mt910 (maps/swift\_mt910\_tolmf)
- tolmf\_packet\_payment\_102 (maps/swift\_mt102\_tolmf)
- swift\_settinst\_mt54x\_tolmf (maps/swift\_settinst\_mt54x\_tolmf)
- tolmf\_packet\_confirmation\_mt900 (maps/swift\_mt900\_tolmf)
- tolmf\_packet\_transfer\_mt202 (maps/swift\_mt202\_tolmf)
- tolmf\_packet\_transfer\_mt202\_COV (maps/swift\_mt202\_COV\_tolmf)
- tolmf\_packet\_statement\_mt942 (maps/swift\_mt942\_tolmf)
- tolmf\_packet\_fx\_304 (maps/swift\_mt304\_tolmf)
- swift\_mt565\_tolmf (maps/swift\_mt565\_tolmf)
- tolmf\_packet\_fx\_305 (maps/swift\_mt305\_tolmf)
- swift\_mt564\_tolmf (maps/swift\_mt564\_tolmf)
- tolmf\_packet\_payment\_103 (maps/swift\_mt103\_tolmf)
- tolmf\_packet\_common\_mtn95 (maps/swift\_mtn95\_tolmf)
- tolmf\_packet\_320 (maps/swift\_mt320\_tolmf)
- tolmf\_packet\_transfer\_mt205 (maps/swift\_mt205\_tolmf)
- tolmf\_packet\_fx\_300 (maps/swift\_mt300\_tolmf)
- tolmf\_packet\_statement\_mt950 (maps/swift\_mt950\_tolmf)
- tolmf\_packet\_common\_mtn90 (maps/swift\_mtn90\_tolmf)
- swift\_mt536\_tolmf (maps/swift\_mt536\_tolmf)
- swift\_mt549\_tolmf (maps/swift\_mt549\_tolmf)
- tolmf\_packet\_common\_mtn96 (maps/swift\_mtn96\_tolmf)
- swift\_mt567\_tolmf (maps/swift\_mt567\_tolmf)
- swift\_mt566\_tolmf (maps/swift\_mt566\_tolmf)
- tolmf\_swift\_mt578 (maps/swift\_mt578\_tolmf)
- tolmf\_packet\_common\_mtn92 (maps/swift\_mtn92\_tolmf)
- tolmf\_packet\_transfer\_mt205\_COV (maps/swift\_mt205\_COV\_tolmf)
- tolmf\_packet\_order\_502 (maps/swift\_mt502\_tolmf)
- tolmf\_packet\_statement\_mt940 (maps/swift\_mt940\_tolmf)

## How to download output files

After you build/run maps, download the output files.

### About this task

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

### Procedure

1. Click the output Card Settings that you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:  

```
data/ach_contested_dishonored_return.out
```

copy only:  

```
ach_contested_dishonored_return.out
```
3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

## SWIFT from LMF example

Run instructions for the SWIFT from LMF example.

## How to run the example in Design Studio

Run instructions for the SWIFT from LMF example.

### About this task

These instructions describe how to run the SWIFT from LMF example in Design Studio.

### Procedure

1. Use the Design Studio to open the following map source files:
  - swift\_ca\_event\_fromlmf.mms
  - swift\_mt101\_fromlmf.mms
  - swift\_mt102\_fromlmf.mms
  - swift\_mt103\_fromlmf.mms
  - swift\_mt202\_COV\_fromlmf.mms
  - swift\_mt202\_fromlmf.mms
  - swift\_mt205\_COV\_fromlmf.mms
  - swift\_mt205\_fromlmf.mms
  - swift\_mt210\_fromlmf.mms
  - swift\_mt300\_fromlmf.mms
  - swift\_mt304\_fromlmf.mms
  - swift\_mt305\_fromlmf.mms
  - swift\_mt320\_fromlmf.mms
  - swift\_mt502\_fromlmf.mms
  - swift\_mt509\_fromlmf.mms
  - swift\_mt515\_fromlmf.mms
  - swift\_mt535\_fromlmf.mms
  - swift\_mt536\_fromlmf.mms
  - swift\_mt537\_fromlmf.mms
  - swift\_mt548\_fromlmf.mms
  - swift\_mt549\_fromlmf.mms
  - swift\_mt578\_fromlmf.mms
  - swift\_mt900\_fromlmf.mms
  - swift\_mt910\_fromlmf.mms
  - swift\_mt940\_fromlmf.mms
  - swift\_mt942\_fromlmf.mms
  - swift\_mt950\_fromlmf.mms
  - swift\_mtn90\_fromlmf.mms
  - swift\_mtn91\_fromlmf.mms
  - swift\_mtn92\_fromlmf.mms
  - swift\_mtn95\_fromlmf.mms
  - swift\_mtn96\_fromlmf.mms
  - swift\_settconf\_mt54x\_fromlmf.mms
  - swift\_settinst\_mt54x\_fromlmf.mms
2. Build all the maps in the source files, and then run the maps. See [SWIFT from LMF maps](#).

## How to run the example in Design Server

Run instructions for the SWIFT from LMF example.

### About this task

These instructions describe how to run the SWIFT from LMF example in Design Server.

### Procedure

1. Import the swiftFromLMF.zip file into the Design Server UI. See the release notes for import instructions.
  2. Create a package for the project and build all the maps.
  3. Open the swiftFromLMF project in the Design Server UI.
  4. Run the maps, see [SWIFT from LMF maps](#).
  5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
  6. To download the output file, see [How to download output files](#).

## How to download output files

After you build/run maps, download the output files.

### About this task

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

### Procedure

1. Click the output Card Settings that you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:  

```
data/ach_contested_dishonored_return.out
```

  
copy only:  

```
ach_contested_dishonored_return.out
```
3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

## How to download output files

After you build/run maps, download the output files.

### About this task

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

### Procedure

1. Click the output Card Settings that you want to download.
  2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:

```
data/ach_contested_dishonored_return.out
```

copy only:

```
ach_contested_dishonored_return.out
```
  3. From Files, click the New icon to open the New File dialog box.
  4. Paste the file name in the Name field.
  5. Click the Folder field drop down and select data.
  6. Click Ok.
  7. Build and re-run the map.
  8. Go to Files and select Download to view the data.
- 

## MT JVC Report example

This example takes a file in SWIFT Alliance Access (SAA) format containing a batch of SWIFT messages and uses the JVC to create a validation report.

The report shows the validation status of each message. The example data file contains both valid and invalid messages, so that both validation passes and failures are demonstrated.

- [Configuration of SWIFT MT JVC Report example in Design Studio](#)  
This topic documents how to configure the MT JVC Report example in Design Studio.
- [Configuration of SWIFT MT JVC Report example in Design Server](#)

---

## Configuration of SWIFT MT JVC Report example in Design Studio

This topic documents how to configure the MT JVC Report example in Design Studio.

### Before you begin

The jvalccyy.prop is installed in `<install_dir>/packs/financial_payments_vn.n.n.n/swift/mt/jvc/maps` for all versions of ITX.

For Transformation Extender V8.n, the jvalccyy.prop file can be in any directory, however the map calling the JVC must be in the same directory as jvalccyy.prop.

### Procedure

Move the jvalccyy.prop in the following location for ITX V.9.n and higher versions:

- Windows: `<tx_install_dir>`
- Linux: `<tx_install_dir>/bin`
- [Additional configuration for MT JVC validation](#)
- [How to run the example in Design Studio](#)  
The MT JVC Report example map creates a JVC validation report from a batch of SWIFT messages.

---

## Additional configuration for MT JVC validation

### Pre-requisites

The swiftMTjvcConfig.tar.gz file is contained within UIProjectImports directory.

The UIProjectImports directory is located in the following location:

`<install_dir>/packs/financial_payments_vn.n.n.n/UIProjectImports`

Where, `<install_dir>` is the location where the pack zip distro was extracted and n.n.n.n is the current version of the pack.

Extract the following from swiftMTjvcConfig.tar.gz file:

- jvcwrap.jar
- jvalccyy.jar

---

## How to run the example in Design Studio

The MT JVC Report example map creates a JVC validation report from a batch of SWIFT messages.

### Before you begin

Refer to [Additional configuration for MT JVC validation](#).

For Design Studio, will require administrative rights:

Copy jars to `<TX_install_dir>/extjar`.

For Design Server installation:

See [Configuration files for Design Server](#) for the steps to perform before you import `<project>.zip` file.

where `<project>.zip` can be any of the following:

- swiftJVCReport.zip

### About this task

These steps describe how to run the MT JVC Report example in Design Studio:

### Procedure

1. Copy the following file into <install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mt/examples/jvc\_report:
  - For versions of the base product, prior to version 9.0.0, copy file:  
<install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mt/jvc/maps/jvalccyy.prop
  - For versions of the base product, version 9.0.0 and later:  
Copy <install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mt/jvc/maps/jvalccyy.prop to the base product installation directory.
2. Edit the copied jvalccyy.prop file ensure that the Network Rule validation is ON, BIC validation is OFF and terse mode is ON:
  - rules.networkvalidation.enabled=true
  - bic.file.enabled=false
  - ReportingMode=terse
3. Use the Design Studio to open the following map source file <install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mt/jvc/maps/validate\_messages.
  - a. Compile the executable map "validate\_messages".
  - b. Copy the resultant validate\_messages.mmc file to the jvc\_report example folder.
4. Use the Design Studio to open the following map source file <install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mt/examples/jvc\_report/jvc\_report and compile the executable map jvc\_report.
5. Run the jvc\_report. The JVC validation results for each MT message in the input file are reported in the output file, jvc\_report.txt, located in the same folder as the example.

## Configuration of SWIFT MT JVC Report example in Design Server

### Configuration files for Design Server

The swiftMTjvcConfig.tar.gz file is contained within UIPackageImports directory.

The UIPackageImports directory is located in the following location:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/UIPackageImports

Where, <install\_dir> is the location where the pack zip distro was extracted and n.n.n.n is the current version of the pack.

Use these steps to run this file:

Extract the swiftMTjvcConfig.tar.gz file.

Follow the below steps, before you import <project>.zip file.

Perform the steps in the same directory location as the Design Server is installed:

1. Create a temp directory called packs.  
Example: /home/user/packs
2. For UNIX environment, FTP (in binary mode) the swiftMTjvcConfig.tar.gz to the pack's directory defined in Step 1.
3. Untar the swiftMTjvcConfig.tar.gz file.  
Example: \$ tar -zxf swiftMTjvcConfig.tar.gz
4. For Container based Design Server installation:
  - a. Run the **jvcsetup.sh** script.  
Example: \$ ./jvcsetup.sh
  - b. The script copies the following to the ITX server:
    - jvcwrap.jar
    - jvalccyy.jar
 packs/swift folder and sub-folders includes the jvalccyy.prop and XML metadata.

#### Optional:

- a. Run the **cleanjvc.sh** script.  
Example: \$ ./cleanjvc.sh
  - b. The script removes the following to the ITX server:
    - jvcwrap.jar
    - jvalccyy.jar
 packs/swift folder and sub-folders includes the jvalccyy.prop and XML metadata.
5. For Native based installation:
    - a. Copy the jvalccyy.jar and jvcwrap.jar into the directory defined in config.yaml server.persistence.files, by default, this is set to /opt/tlxlibs.
    - b. Restart the application running ./ITX stop and then ./ITX start.
  6. After importing <project>.zip project:
    - a. Copy the jvalccyy.prop file to the workdir directory under directory set in the config.yaml server.persistence.files, the default settings is /opt/tlxfiles/workdir.
    - b. On the project, update the map rule on the validate\_message map, on output card #1 item JvalPropPath. Change the map rule from =NONE to the location of the jvalccyy.prop.

Example:

    - On UNIX  
="DS\_DATA\_DIR/workdir"
    - On WINDOWS  
="DS\_DATA\_DIR\\workdir"

where DS\_DATA\_DIR refers to the Design Server data directory, set in the config.yamlserver.persistence.files previously TX\_FILE\_DIR

7. Restart the Design Server: ./ITX stop and ./ITX start.

Note: To reflect any jvalccyy.prop updates, repeat step 7.

- [How to run the example in Design Server](#)

Run instructions for the SWIFT MT JVC Report example.

## How to run the example in Design Server

Run instructions for the SWIFT MT JVC Report example.

### About this task

Follow these steps to run the SWIFT MT JVC Report example in Design Server.

### Procedure

1. Import the swiftJVCReport.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the swiftJVCReport project in the Design Server UI.
4. Run the maps:
  - jvc\_report (maps/jvc\_report)
  - validate\_messages (maps/validate\_messages)
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).
  - [How to download output files](#)  
After you build/run maps, download the output files.

## How to download output files

After you build/run maps, download the output files.

### About this task

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

### Procedure

1. Click the output Card Settings you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:  
  
data/ach\_contested\_dishonored\_return.out  
  
copy only:  
  
ach\_contested\_dishonored\_return.out
3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

## MT950 Splitter Map example

The MT950 Splitter Map example contains 2 maps that demonstrate techniques for splitting a 5k MT950 Statement message into smaller MT950 messages.

These are the maps and the technique used by each:

### mt950\_split

This map uses recursion (that is, the map calls itself recursively) to perform the split. This method requires only one data pass to split the MT950 into smaller messages and to recalculate opening and closing balances on each split message. However, this method does not scale well due to the resources consumed during recursion, and can exceed the thread stack size limit.

### mt950\_split\_v2

This map uses the CLONE function to perform the split. This method scales better than the recursive map. The disadvantage is that two data passes are required to split the MT950 into smaller messages and to recalculate opening and closing balances on each split message.

- [MT 950 Splitter Map example overview](#)

The example maps split a large MT950 Statement message and generate multiple, smaller MT950 files.

## MT 950 Splitter Map example overview

The example maps split a large MT950 Statement message and generate multiple, smaller MT950 files.

For each of the smaller files the example maps recalculate running balances, and maintain the message sequence number within the overall statement number. Both example maps work on the following algorithm:

Variables names match the map input card names:

- n - Indicates the number of statement lines in each target message. The default is 30, but this parameter can be adjusted as necessary, based on the average expected size of a statement line.
- t - Indicates the number of lines in the source message. This value is calculated by the map using COUNT.
- T - Indicates total number of target messages. Calculated as INT(t/n)+1
- x - Indicates current target message number iteration (incremented by the map).

As an example: n=30, t=70, then T=INT(70/30)+1=3

therefore, three target messages are needed

The Target lines are built for each iteration using EXTRACT on the source message statement line's INDEX:

```
=EXTRACT (StatementLine #61 General Field WHERE
INDEX (StatementLine #61 General Field) >= (n*(x-1)+1 &
INDEX (StatementLine #61 General Field) <= x*n)
mt950_split is executed as a recursive map until x > T
mt950_split_v2 is executed T times using CLONE to control the iteration.
```

- [How to run the example in Design Studio](#)  
Run instructions for the MT950 Splitter Map example.
- [How to run the example in Design Server](#)  
Run instructions for the MT950 Splitter Map example.

## How to run the example in Design Studio

Run instructions for the MT950 Splitter Map example.

### About this task

These steps describe how to run the MT950 Splitter Map example in Design Studio.

### Procedure

1. Use the Design Studio to open the following map source files:
  - mt950\_split.mms
  - mt950\_split\_v2.mms
2. Build the maps in the source files, and then run the following maps:
  - mt950\_control (maps/mt950\_split)
  - v2\_mt950\_recalc (maps/mt950\_split\_v2)
  - v2\_mt950\_control (maps/mt950\_split\_v2)

## How to run the example in Design Server

Run instructions for the MT950 Splitter Map example.

### About this task

These steps describe how to run the MT950 Splitter Map example in Design Server.

### Procedure

1. Import the swiftMT950Split.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the swiftMT950Split project in the Design Server UI.
4. Run the maps.
  - mt950\_control (maps/mt950\_split)
  - v2\_mt950\_recalc (maps/mt950\_split\_v2)
  - v2\_mt950\_control (maps/mt950\_split\_v2)
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.

6. To download the output file, see [How to download output files](#).

- [How to download output files](#)

After you build/run maps, download the output files.

---

## How to download output files

After you build/run maps, download the output files.

### About this task

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

### Procedure

1. Click the output Card Settings that you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.

For example, if the Command text box displays:

```
data/ach_contested_dishonored_return.out
```

copy only:

```
ach_contested_dishonored_return.out
```

3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

---

## How to run mt950\_split\_v2

### About this task

These steps describe how to run the mt950\_split\_v2 map.

### Procedure

1. Use the Map Designer to open mt950\_split\_v2 . It contains these executable maps: v2\_mt950\_control, v2\_mt950\_runmap\_split, v2\_mt950\_recalc and v2\_mt950\_runmap\_balance.
  - a. v2\_mt950\_control counts the number of statement lines (t), supplies the default value for n (30), calculates T and calls v2\_mt950\_runmap\_split.
  - b. v2\_mt950\_runmap\_split generates smaller messages based on the parameters supplied by the calling map. The split messages are all contained in a single file called mt950\_split.txt. This is an intermediate file, where the opening and closing balances have not been recalculated
  - c. v2\_mt950\_recalc calls v2\_mt950\_runmap\_balance for each split message in mt950\_split.txt
  - d. v2\_mt950\_runmap\_balance recalculates the opening and closing balance for each split message. The closing balance from one message is carried over into the following message using a work file called ClosingBal.dat.
2. Build all four maps.
3. Run the v2\_mt950\_control map. This will create the intermediate file, mt950\_split.txt.
4. Run the v2\_mt950\_recalc map. This will recalculate balances and create a separate file for each split MT950 using the following naming convention:  
mt950\_recalc\_StatementNo(from Tag 28C)\_SequenceNo\_TimeStamp.txt

These files are located in the same folder as this example.

---

## MT Launcher Validation framework

This sample validation framework uses the Transformation Extender Launcher and the JVC to perform trigger-based MT validation.

The Transformation Extender Launcher Edition is required to run this example.

The framework for this sample is triggered by placing a file containing a single MT message into a folder, which causes the framework to be invoked to validate the message. Depending on the results of the validation, the framework either creates an error report file, or passes the message through unchanged. After being processed, the file is deleted from the input folder. Using this method it is possible to validate numerous separate files by placing them into the input folder. The framework, therefore, consists of a folder structure for processing the data, a map source file for performing the validation, and a Launcher System Definition file for deploying to the Launcher. The framework is installed into this directory location: <install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mt/examples/validation

Where *install\_dir* is the installed location of the installation location of the Pack for Financial Payments and *n.n.n.n* is the version number of the Pack for Financial Payments.

The structure of this top-level folder is as follows:

```

data/input
Placeholder for files to be validated
data/output/error/
Placeholder for error reports.
data/output/passed/
Placeholder for files that pass validation.

maps/execution/
Executable maps are deployed here.
maps/source/validate_mt
Where validate_mt is the source map file for deployment.
msds/validate_mt.msd
Where validate_mt.msd is the system definition file for deployment.

```

The following instructions are for deploying and running the framework on a Windows platform. Refer to the Transformation Extender documentation for instructions on running the Launcher on other platforms.

- [\*\*Deploying the Launcher Validation Framework\*\*](#)  
These procedures describe how to deploy the Launcher Validation Framework.
- [\*\*Running the Launcher Validation Framework\*\*](#)  
Perform the following procedure to run the Launcher Validation Framework:

## Deploying the Launcher Validation Framework

These procedures describe how to deploy the Launcher Validation Framework.

### Procedure

1. Open validate\_mt.msd using the Integration Flow Designer. The Integration Flow Designer is part of the IBM Transformation Extender Design Studio.
2. Right-click on validate\_mt system, and select Deploy/Local. The maps are then compiled, and a pop-up box will state "The Deploy operation has completed successfully. Would you like to see the results?"
3. Click Yes, and view the MSEDploy.TXT file. There should be no errors, and a message should state "Deploy has completed successfully". If the deploy has failed the most likely explanation is an error with the installation.
4. Review the MSEDploy.TXT to locate the source of the error. If successful, the Launcher execution file validate\_mt.msl is placed in the <tx\_install\_dir>/systems folder.

### Results

If successful, the jvalccyy.prop file is copied to the maps/execution folder. Review this file to ensure it has the required parameter settings. See the JVC documentation for details on configuring the JVC.

## Running the Launcher Validation Framework

Perform the following procedure to run the Launcher Validation Framework:

1. Using the Launcher Administration tool Administration tool, create a Launcher System.  
Note: The Launcher Administration tool installs with the Transformation Extender Launcher Edition
2. Start the Launcher processes.
3. Start the Management Console, and connect it to your Launcher System. The system is now ready to process files.  
Note: Refer to the Transformation Extender Launcher documentation for details about how to set up and run a Launcher System.
4. Place a file containing a single MT message in the data/input folder.
  - If it passes validation, it is copied to the data/output/passed folder, and deleted from the data/input folder.
  - If it fails validation, an error report is placed in the data/output/error folder, and the file is deleted from the data/input folder. To ensure uniqueness, each filename is appended with a date-time stamp when placed in the passed folder.

Error files are in a simple XML format (there is schema for this), and are also appended with a date-time stamp. The actual format of the error report depends upon the following factors:

- Whether the JVC is run in verbose mode, or in terse mode.
- The type of error - for example, a low-level syntax error versus a conditional rule error.
- Whether the data in error was multi-line or single line.

## MT - MX translation maps example (Deprecated)

The MT - MX translation maps example shows how the SWIFT component can be used to translate between MT and MX messages.

The MT - MX translation maps example provides examples for the Payments, Funds, and Corporate Actions business areas.

The example can be found in the following location:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mx/examples/mt\_mx\_translation

- [How to run the example in Design Studio](#)

This example describes how to run the MT / MX Translation Maps example.

- [How to run the example in Design Server](#)

---

## How to run the example in Design Studio

This example describes how to run the MT / MX Translation Maps example.

### About this task

---

Follow these steps to run the example.

### Procedure

---

1. Run the build script build\_mt\_mx\_translation.bat.
2. This script can be found in the maps sub-directory. This will compile all of the maps in the example.
3. Check the log produced by the script to check there are no compilation errors. The log is called build\_deploy\_mt\_mx\_translation.log. The log is located in the maps sub-folder.
4. Use the Design Studio to open the following map source files:
  - mt101\_mx\_pain\_001.mms
  - mt103\_mx\_pacs\_008.mms
  - mt202\_COV\_mx\_pacs\_009.mms
  - mt202\_mx\_pacs\_009.mms
  - mt502\_mx\_setr\_004.mms
  - mt502\_mx\_setr\_010.mms
  - mt509\_mx\_setr\_016.mms
  - mt515\_mx\_setr\_006.mms
  - mt515\_mx\_setr\_012.mms
  - mt564\_mx\_seev\_031.mms
  - mt565\_mx\_seev\_033.mms
  - mt566\_mx\_seev\_036.mms
  - mt900\_mx\_camt\_054.mms
  - mt910\_mx\_camt\_054.mms
  - mt940\_mx\_camt\_053.mms
  - mt941\_mx\_camt\_052.mms
  - mt942\_mx\_camt\_052.mms

## How to run the example in Design Server

### How to run the MT to MX Translation maps example in Design Server:

1. Import the swiftMTmxTranslation.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the swiftMTmxTranslation project in the Design Server UI.
4. Run the following maps:
  - cor15001\_mt564\_seev\_031 (maps/mt564\_mx\_seev\_031)
  - cor15004\_mt565\_seev\_033 (maps/mt565\_mx\_seev\_033)
  - cor15007\_mt566\_seev\_036 (maps/mt566\_mx\_seev\_036)
  - pym11001\_mt101\_pain1 (maps/mt101\_mx\_pain\_001)
  - pym51001\_mt103core\_pacs8 (maps/mt103\_mx\_pacs\_008)
  - pym51002\_mt103plus\_pacs8 (maps/mt103\_mx\_pacs\_008)
  - pym51003\_mt202\_pacs9 (maps/mt202\_mx\_pacs\_009)
  - pym51004\_mt202\_cov\_pacs9 (maps/mt202\_COV\_mx\_pacs\_009)
  - pym91001\_mt900\_camt54 (maps/mt900\_mx\_camt\_054)
  - pym91002\_mt910\_camt54 (maps/mt910\_mx\_camt\_054)
  - pym91003\_mt940\_camt53 (maps/mt940\_mx\_camt\_053)
  - pym91004\_mt941\_camt52 (maps/mt941\_mx\_camt\_052)
  - pym91005\_mt942\_camt52 (maps/mt942\_mx\_camt\_052)
  - pym91006\_mt950\_camt53 (maps/mt950\_mx\_camt\_053)
  - snf51003\_mt502\_setr\_004 (maps/mt502\_mx\_setr\_004)
  - snf51007\_mt502\_setr\_010 (maps/mt502\_mx\_setr\_010)
  - snf51011\_mt509\_setr\_016 (maps/mt509\_mx\_setr\_016)
  - snf51015\_mt515\_setr\_006 (maps/mt515\_mx\_setr\_006)
  - snf51016\_mt515\_setr\_012 (maps/mt515\_mx\_setr\_012)
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).

### How to run the MX to MT Translation maps example in Design Server:

1. Import the swiftMXmtTranslation.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the swiftMTmxTranslation project in the Design Server UI.
4. Run the following maps:
  - cor25001\_seev\_031\_002\_08\_mt564 (maps/mx\_seev\_031\_mt564)
  - cor25004\_seev\_033\_mt565 (maps/mx\_seev\_033\_mt565)
  - cor25007\_seev\_036\_mt566 (maps/mx\_seev\_036\_mt566)
  - pym11002\_pain1\_mt101 (maps/mx\_pain\_001\_mt101)
  - pym61001\_pacs8\_mt103core (maps/mx\_pacs\_008\_mt\_103core)
  - pym61002\_pacs9\_mt202 (maps/mx\_pacs\_009\_mt202)
  - pym61003\_pacs9\_mt202\_cov (maps/mx\_pacs\_009\_mt202\_cov)
  - snf61003\_setr\_004\_mt502 (maps/mx\_setr\_004\_mt502)
  - snf61007\_setr\_010\_mt502 (maps/mx\_setr\_010\_mt502)
  - snf61011\_setr\_016\_mt509 (maps/mx\_setr\_016\_mt509)
  - snf61015\_setr\_006\_mt515 (maps/mx\_setr\_006\_mt515)
  - snf61016\_setr\_012\_mt515 (maps/mx\_setr\_012\_mt515)
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).
- **Building multiple maps using Deploy**  
To deploy large numbers of maps (generally, when a project contains more than 10 maps), use the instructions provided here.

---

## Building multiple maps using Deploy

To deploy large numbers of maps (generally, when a project contains more than 10 maps), use the instructions provided here.

### About this task

Follow these steps to deploy large numbers of maps:

### Procedure

1. From the Design Server UI, click on the Deploy drop down, and click Packages.
2. Define a new Package, then click Add icon.
3. Define a Name field on the Edit Package dialog.
4. From the Project drop down, select the imported project.
5. Check top level box on Maps and Files drop down, this select all maps and files in the project
6. Save the Package.
7. Return to Design Server UI, main page, click Deploy drop down, scroll down and select Deploy from the list on the left.
8. Select the desired server (see the Server definition on Deployment > Deployment overview) and select the package.
9. Click Deploy.
10. Return to the Design Server UI, main page, click Design, select imported project (one just deployed).
11. Open the map, see [How to run the example in Design Server](#).

---

## SWIFT MX Message Bundle and Unbundle map example using Design Server

This example demonstrates the use of a map that splits the MX message Business Application Header (BAH) from the MX message data, and also packages the BAH with the message data.

Any MX message type requiring packaging with a BAH can be used with this map.

- [How to run the example in Design Studio](#)  
Run instructions for the Swift MX Message Bundle example.
- [How to run the example in Design Server](#)  
Run instructions for the SWIFT MX Message Bundle and Unbundle map example.

---

## How to run the example in Design Studio

Run instructions for the Swift MX Message Bundle example.

### About this task

These steps describe how to run the Swift MX Message Bundle example in Design Studio.

### Procedure

1. Use the Design Studio to open the following map source file: mxmessage.mms
2. Build all the maps in the source file, and then run the following transformation maps:
  - mxpack
  - mxunpack

---

## How to run the example in Design Server

Run instructions for the SWIFT MX Message Bundle and Unbundle map example.

### About this task

Follow these steps to run the SWIFT MX Message Bundle and Unbundle map example in Design Server.

### Procedure

1. Import the swiftMXmsgPackage.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open the **swiftMXmsgPackage** project in the Design Server UI.
4. Run the following maps:
  - mxpack
  - mxunpack
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
6. To download the output file, see [How to download output files](#).
  - [How to download output files](#)  
After you build/run maps, download the output files.
  - [Example executable maps](#)  
There are two example executable maps in the MX Message Bundle and Unbundle example:

---

## How to download output files

After you build/run maps, download the output files.

## About this task

---

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

## Procedure

---

1. Click the output Card Settings you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.

For example, if the Command text box displays:

data/ach\_contested\_dishonored\_return.out

copy only:

ach\_contested\_dishonored\_return.out

3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Click the Folder field drop down and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

---

## Example executable maps

There are two example executable maps in the MX Message Bundle and Unbundle example:

- mxpack - Executable map that bundles the SWIFT message data with the required Business Application Header (BAH). This map takes the BAH and the message data and packages them into a single output with a wrapper around the existing pieces of data. The map uses the mxpackage type tree, with the BAH and the MX data being treated as blob item text elements. The BAH input data is separated from the namespace information, and the rest of the message is treated as a text blob and packaged with the message document data which is treated the same as the BAH data.
- mxunpack - Executable map that unbundles the SWIFT message data and the BAH, creating two output files. The input uses the mxpackage type tree to determine the BAH group and the MX message group. The first output file contains the BAH data mapped directly from the input. The second output file contains the MX message.

---

## SWIFT MX validation example

This example demonstrates SWIFT MX validation.

- [How to run the example in Design Studio](#)  
Run instructions for the Swift MX Validation example.
- [How to run the example in Design Server](#)  
Run instructions for the SWIFT MX Validation example.

---

## How to run the example in Design Studio

Run instructions for the Swift MX Validation example.

## About this task

---

These steps describe how to run the Swift MX Validation example in Design Studio.

## Procedure

---

1. Use the Design Studio to open the following map source file: swiftval.mms.
2. Build the map in the source file, and then run the map:
  - swiftval

---

## How to run the example in Design Server

Run instructions for the SWIFT MX Validation example.

## About this task

---

Follow these steps to run the SWIFT MX Validation example in Design Server.

## Procedure

---

1. Import the swiftMXCompliance.zip file into the Design Server UI. See the release notes for import instructions.
  2. Create a package for the project and build all the maps.
  3. Open the swiftMXCompliance project in the Design Server UI.
  4. Run the swiftval map.
  5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
  6. To download the output file, see [How to download output files](#).
- [How to download output files](#)  
After you build/run maps, download the output files.
- 

## How to download output files

After you build/run maps, download the output files.

## About this task

---

To download the output file, go to **Files** in the Design Server UI and download the desired file using these steps:

## Procedure

---

1. Click the output Card Settings you want to download.
  2. From the Command text box, copy the name of the file that you want to download. Make certain that you copy only the file name.  
For example, if the Command text box displays:  
  
data/ach\_contested\_dishonored\_return.out  
  
copy only:  
  
ach\_contested\_dishonored\_return.out
  3. From File, click the New icon to open the New File dialog box.
  4. Paste the file name in the Name field.
  5. Click the Folder field drop down and select data.
  6. Click Ok.
  7. Build and re-run the map.
  8. Go to File and select Download to view the data.

## IBM Sterling B2B Integrator examples overview

In IBM Sterling B2B Integrator, a *service* is a resource that you can configure to carry out an activity.

A typical activity scenario is one where SWIFT data must be sent to a trading partner. In preparation for this, the data must be enveloped in order to provide identifying batch and interchange data. The SWIFT Envelope business process calls Generic Envelope to provide these enveloping services, while the SWIFT Deenvelope business process calls Generic Deenvelope to provide de-enveloping services.

A document envelope consists of control information that enables organizations to effectively exchange documents. The document envelope takes the original document, assigns a control number, and packages header and trailer information with it, prior to submitting it to a trading partner. Creating document envelopes is necessary if you wish to do electronic exchange of data with your trading partners.

The SWIFT envelopes can be configured to specify Transformation Extender maps for any data transformation requirements. These maps are invoked by the Generic Envelope and Deenvelope services.

The pack examples for IBM Sterling B2B Integrator demonstrate, on both SWIFT MT and MX formats, the following:

- Creation of fully enveloped SWIFT outbound messages.
- Successfully process inbound SWIFT messages.
- Use of Transformation Extender maps for data transformation.
- Use of SWIFT compliance checking that is provided by the Pack for Financial Payments.

Transformation Extender maps can run within the IBM Sterling B2B Integrator services on some, but not all, versions of the Transformation Extender base product. See the product release notes for those versions of the base product that support IBM Sterling B2B Integrator.

## Directory structure of the IBM Sterling B2B Integrator examples

The SWIFT component examples for IBM Sterling B2B Integrator include transformation maps, corresponding type trees, test data, and exported IBM Sterling B2B Integrator artifacts.

The IBM Sterling B2B Integrator artifacts include trading partner envelopes, and business processes, which are relevant when executing the Transformation Extender map within IBM Sterling B2B Integrator.

The table shows the directory structure used for processing SWIFT MT data, using both IBM Sterling B2B Integrator Generic Envelope and Generic Deenvelope services.

Header	Header
mt/examples/sterling	
mt/examples/sterling/services	
mt/examples/sterling/services/generic_deenvelope	
mt/examples/sterling/services/generic_deenvelope/data	Placeholder for input test data for the Generic De-envelope service
mt/examples/sterling/services/generic_deenvelope/maps	Placeholder for the SWIFT MT transformation map invoked by SI's Generic De-envelope service
mt/examples/sterling/services/generic_deenvelope/platform_support	Placeholder for IBM Sterling B2B Integrator export (.xml) files
mt/examples/sterling/services/generic_envelope	Placeholder for the SWIFT MT transformation scenario using SI's Generic Envelope service

## IBM Sterling B2B Integrator Generic Envelope service MT example

The Generic Envelope example demonstrates how to transform a proprietary single credit transfer positional (flat) file into MT103 STP messages.

The positional file has a 'one line' per record format and terminates with a newLine. Each record consists of data elements which are delimited by horizontal tabs HEX"09". The first record in the file is reserved as the header record, and each record is separated by a 45 character broken line. Each data element within a record was designed to match corresponding SWIFT FIN MT tag fields that makes up a MT103 STP message body.

The example file consists of three single credit transfer records.

The Generic Envelope service MT example files install into the following directory:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mt/examples/sterling/services/generic\_envelope

The source for this type of map is the credit\_transfer\_to\_mt103+, and the map is called crdt\_xfer\_to\_mt103\_plus.

- Input 1 (single\_credit\_transfer\_flat) – This card is used to represent the credit transfer positional data file.
- Output 1 (mt103\_plus\_block4) – This card retrieves all data elements that match corresponding SWIFT FIN MT tag fields that make up a MT103 STP message body.

The resulting MT103 STP message from the translation map is limited to the block 4 message body and does not include envelopes. The envelopes, for example, block 1, block 2 and block 3, are populated as part of the Generic Envelope service.

## IBM Sterling B2B Integrator Generic Deenvelope service MT example

The Generic Deenvelope example demonstrates how to transform a MT103 STP message into a single credit transfer positional (flat) file.

The positional file has a 'one line' per record format and terminates with a newLine. Each record consists of data elements which are delimited by horizontal tabs HEX"09". The first record in the file is reserved as the header record, and each record is separated by a 45 character broken line. Each data element within a record was designed to match corresponding SWIFT FIN MT tag fields that make up a MT103 STP message body.

The Generic Deenvelope service MT example files install into the following directory:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mt/examples/sterling/services/generic\_deenvelope.

The source for this type of map is the mt103+\_to\_credit\_transfer, and the map is called mt103\_plus\_to\_crdt\_xfer\_flat.

- Input 1 (mt103\_plus) – This card is used to represent the SWIFT MT103 STP data file.
- Output 1 (single\_credit\_transfer\_flat) – This card retrieves all data elements that match corresponding positional credit transfer element fields.

## IBM Sterling B2B Integrator Generic Envelope service MX example

The Generic Envelope service MX example demonstrates how to transform a proprietary customer credit transfer positional (flat) file into an XML SWIFT MX pacs.008.nnn.nn document.

The positional file follows a 'tag value' format, and terminates with a newLine. Each tag and value is separated by a colon ':', example MsgId:XXXX123456789. Each record starts with a tag MsgId and ends with a tag CdtrTwnNm. Each data element within a record was designed to match corresponding SWIFT MX pacs.008.nnn.nn element fields.

The example file consists of three customer credit transfer records. The Generic Envelope service MX example files install into the following directory:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mx/examples/sterling/services/generic\_envelope. The source for this type of map is the credit\_transfer\_to\_mx\_pacs8 , and the map is called cstmr\_cdtrrf\_to\_pacs812.

- Input 1 (cstmrCrdtTrfFlat) – This card is used to represent the credit transfer positional data file.
- Output 1 (pacs\_008\_nnn\_nn) – This card retrieves all data elements that match corresponding SWIFT MX tag fields that make up a pacs.008.nnn.nn document.

The resulting message from the translation map is limited to the SWIFT MX pacs.008.nnn.nn document payload and does not include envelopes. The envelopes, for example, SWIFT Alliance Access Protocol Data Units (PDUs) and DataPDUs are populated as part of the Generic Envelope service.

## IBM Sterling B2B Integrator Generic Deenvelope MX example

The Generic Deenvelope service MX example demonstrates how to transform an XML SWIFT MX pacs.008.nnn.nn document to a proprietary customer credit transfer positional (flat) file.

The positional file follows a 'tag value' format, and terminates with a newLine. Each tag and value is separated by a colon ':', example MsgId:XXXX123456789. Each record starts with a tag MsgId and ends with a tag CdtrTwnNm. Each data element within a record was designed to match corresponding SWIFT MX pacs.008.nnn.nn element fields.

The Generic Deenvelope service MX example files install into the following directory:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/swift/mx/examples/sterling/services/generic\_deenvelope.

The source for this type of map is the mx\_pacs8\_to\_credit\_transfer , and the map is called pacs812\_to\_cstmr\_cdtrrf

- Input 1 (pacs\_008\_nnn\_nn) – This card is used to represent the SWIFT MX pacs.008.nnn.nn data file.
- Output 1 (cstmrCrdtTrfFlat) – This card retrieves all data elements that match corresponding positional credit transfer element fields.

Note: This example IBM Transformation Extender map expects a fully enveloped MX pacs.008.nnn.nn message as input when executed within the IBM Sterling B2B Integrator Generic Deenvelope service. The IBM Sterling B2B Integrator Generic Deenvelope service only passes the actual MX instance document without the SWIFT Alliance Access (SAA) envelopes. For example, the SAA PDU and DataPDU information are stripped off by the Generic Deenvelope service, and only the MX payload pacs.008.nnn.nn instance document is passed to the example IBM Transformation Extender map.

## Design considerations for the MT and MX Generic Envelope and Deenvelope examples

This documentation describes design features and concepts that were used in building the example transformation maps invoked by the Generic Deenvelope and Generic Envelope services.

- **IBM Sterling B2B Integrator data harness**

In some cases, IBM Transformation Extender maps must share information with the IBM Sterling B2B Integrator services and other IBM Sterling B2B Integrator processes.

- **Thread safety**

The Generic Deenvelope service and the Generic Envelope service example maps are 'thread-safe' when they are deployed in the IBM Sterling B2B Integrator environment.

- **Specific map and type tree settings**

Important map and type tree settings that are used in the examples are of particular importance for running with the MT and MX Generic Envelope service.

---

## IBM Sterling B2B Integrator data harness

In some cases, IBM Transformation Extender maps must share information with the IBM Sterling B2B Integrator services and other IBM Sterling B2B Integrator processes.

IBM Sterling B2B Integrator

For example, the maps can perform one of the following activities:

- Store information about the data, for example, a document ID or other key field that can be used by Sterling B2B Integrator to track the data.
- Get information from Sterling B2B Integrator tables, such as trading partner information, or code list table data. The maps read and write this information to Sterling B2B Integrator database tables using the Sterling B2B Integrator adapter. This is referred to as the Sterling B2B Integrator Data Harness which provides access to these tables.

The Sterling B2B Integrator adapter is used to get and to set certain values that are maintained in the Sterling B2B Integrator adapter database tables.

- The **setProcessData** call is used to set values such as reference ids in the **processData** table. This value can be used by other services in the Business Process flow.
- The **setCorrelation** call is used to set the values such as reference ids in the correlation data table. This value can be used to help search for documents processed by the map.

The Generic Deenvelope service and Generic Envelope service example maps use PUT calls to the Sterling B2B Integrator adapter in order to set the transaction reference number for MT scenarios, and instruction id, for MX scenarios in the Sterling B2B Integrator database called **ProcessData** and **Correlation** tables.

---

## Thread safety

The Generic Deenvelope service and the Generic Envelope service example maps are 'thread-safe' when they are deployed in the IBM Sterling B2B Integrator environment.

A thread-safe map can run in a multi-threaded environment. One of the attributes a map needs in order to run in a multi-threaded environment is that when multiple occurrences of the map are instantiated, none of the resources used by an individual instance of the map are used by another instance of the map.

For example, the map work files, audit logs, backup files, and trace logs are individually named; that is, they are unique within each instance of the map.

For more information about thread safety, including how you can verify that the map meets at least the basic thread-safe checks, see the Transformation Extender Map Designer documentation.

---

## Specific map and type tree settings

Important map and type tree settings that are used in the examples are of particular importance for running with the MT and MX Generic Envelope service.

- **Burst**

The *burst* concept deals with the scope of the data that is processed in one run of the map. Generic Envelope service example maps are set to execute in burst mode.

- **Audit settings**

Audit settings enable a map to generate data audit information that can be used by the Generic service in business process reports.

- **Restart**

The use of a restart flag allows a IBM Transformation Extender map to continue to attempt to process remaining transactions after an invalid transaction is found in the input file.

- **Custom MT type tree**

On the Generic Envelope service MT example, the Generic Envelope service expects that the resulting file of the transformation map contains only SWIFT MT block 4 content, without any header or trailer information.

---

## Burst

The *burst* concept deals with the scope of the data that is processed in one run of the map. Generic Envelope service example maps are set to execute in burst mode.

The Generic Envelope service runs a portion of the input with each iteration of the map. This is expected behavior in several IBM Sterling B2B Integrator services.

In the Generic Envelope service example, in the map input card, the FetchAs property is set to Burst with a FetchUnit of 1. This allows the IBM Transformation Extender map to process a single transaction at a time, as expected by the Generic Envelope service.

---

## Audit settings

Audit settings enable a map to generate data audit information that can be used by the Generic service in business process reports.

In the map settings, the MapAudit switch is set to ON, the BurstAudit and SummaryAudit settings are set to Always, and the AuditLocation is set to Memory.

In the Generic Deenvelope MT example, the Data Audit Settings for the map are set as follows:

Audit	Message MT103_Plus Category 1 Text Block:mt103_plus
Track	Occurrence
Details	Occurrence
Item Data	Occurrence

In the Generic Envelope service MT example, the Data Audit Settings for the map are set as follows:

Audit	Record:single_credit_transfer_flat
Track	Occurrence
Details	Occurrence
Item Data	Occurrence

In the Generic Deenvelope MX example, the Data Audit Settings for the map are set as follows:

Audit	FIToFICstmrCdtTrfsequence:packs_008_001_02
Track	Occurrence
Details	Occurrence
Item Data	Occurrence

In the Generic Envelope service MX example, the Data Audit Settings for the map are set as follows:

Audit	Record:cstrmCrdtTrfFlat
Track	Occurrence
Details	Occurrence
Item Data	Occurrence

## Restart

The use of a restart flag allows a IBM Transformation Extender map to continue to attempt to process remaining transactions after an invalid transaction is found in the input file.

### Generic Deenvelope service MT example

In the Generic Deenvelope service MT example, the swift\_mt103\_plus\_nohdrs.mtt type tree File group specifies the Restart flag on the following component:

- Message MT103\_Plus Category 1 TextBlock:mt103\_plus

### Generic Envelope service MT example

In the Generic Envelope service MT example, the single\_credit\_transfer\_flat.mtt type tree in the File group specifies the Restart flag on the following component:

- Record:single\_credit\_transfer\_flat

### Generic Deenvelope service MX example

In the Generic Deenvelope MX service example, the pacs.008.nnn.nn.xsd schema File group specifies the Restart flag on the following components:

- FIToFICstmrCdtTrf:sequence:pacs\_008\_nnn\_nn

### Generic Envelope service MX example

In the generic envelope service MX example, the cstmr\_cdttrf\_flat.mtt type tree in the File group specifies the Restart flag on the following component:

- Record:cstmrCrdtTrfFlat

## Custom MT type tree

On the Generic Envelope service MT example, the Generic Envelope service expects that the resulting file of the transformation map contains only SWIFT MT block 4 content, without any header or trailer information.

For example, blocks 1, 2, and ,3 are not populated by the map. This information is provided by the Generic Envelope service. The Transformation Extender Pack for Financial Payments ships type trees that represent SWIFT MT message syntax. That includes SWIFT MT headers and trailers, such as block 1, 2, 3, 4 and 5. This documentation provides the steps needed to build a custom type tree based from the provided type trees without any header or trailer information.

The type tree used in the examples, swift\_mt103\_plus\_nohdrs.mtt, is a subset of the swift\_iso7775\_ccyy.mtt type tree that is included with the SWIFT component of the Transformation Extender Pack for Financial Payments . This type tree is shared between the Generic Deenvelope service and the Generic Envelope service examples.

In the above file name, ccyy indicates a four-digit year value; for example, 2012.

- [Building a custom MT type tree](#)

This procedure describes how to create a custom MT103 STP type tree.

## Building a custom MT type tree

This procedure describes how to create a custom MT103 STP type tree.

### About this task

Perform the following steps to create a custom MT103 STP type tree:

### Procedure

1. Open the **swift\_iso7775\_ccyy.mtt** type tree that installs with the SWIFT component of the IBM Transformation Extender Pack for Financial Payments.
2. Select **Save As** and define a new type tree named **swift\_mt103\_plus\_nohdrs.mtt**.
3. Under SWIFT > Batch, remove all groups except **Category1**.
4. Under SWIFT > Batch > Category1 group, remove all groups except for MT 103.
5. Under the SWIFT > Block > Text, remove all categories except for **Category1**.
6. Under the SWIFT > Block > Text > Category1 category, remove all category groups except for MT103\_Plus.
7. Under the SWIFT > Block > Text > Category1 > MT103\_Plus category, create a copy of the **Message** group called **MessageContentOnly** in the same **MT103\_Plus** category
8. On the SWIFT > Block > Text > Category1 > MT103\_Plus > MessageContentOnly group, update the following **Type Syntax** properties to **None**:
  - a. Initiator
  - b. Terminator
9. Under the SWIFT > Block > Text > Category1 > MT103\_Plus category, create a new **block4ContentOnly** group with the following properties:
  - a. Set the **Class** to **Group**.
  - b. Set **Group Subclass** to **Sequence**
  - c. Set Group Subclass > Format to **Implicit**.
  - d. Include the **MessageContentOnly** group as a component of **block4ContentOnly** with a range of (1:s).
10. Under the SWIFT > Message category, remove all **Category** groups except for **Category1**.
11. Under the SWIFT > Message > Category1 group, remove the all groups except for **MT103**.
12. Under the SWIFT > Message > Category1 > MT103 group, remove **Core** group.
13. Under the SWIFT > Message > Input category, remove all groups except for **Category1**.
14. Under the SWIFT > Message > Input > Category1 group, remove all groups except for **MT103**.
15. Under SWIFT > Message > Input > Category1 > MT103 group, remove the **Core** group.
16. Under SWIFT > Message > Output category, remove all groups except for **Category1**.
17. Under the SWIFT > Message > Output > Category1 group, remove all groups except for **MT103**.
18. Under the SWIFT > Message > Output > Category1 > MT103 group, remove the **Core** group.
19. Under the SWIFT > Message > LiveMsgs group remove all components except for **MT103 Category1**.
20. Under the SWIFT > Subfield > Block category, remove the **Tag 270** and **Tag 280** groups.
21. Analyze and save the type tree. Warnings will occur. Errors will not exist.

## Deploying and executing the MT and MX Generic Envelope and Deenvelope examples

These procedures describe how to run the Generic Deenvelope and Generic Envelope services examples from the IBM Transformation Extender and from the IBM Sterling B2B Integrator.

The example maps call the IBM Sterling B2B Integrator adapter to write values to IBM Sterling B2B Integrator tables. Because of this, the map fails if you attempt to run the map outside of IBM Sterling B2B Integrator.

The map can also be tested by using the Run on Sterling B2B Integrator option in the Design Studio. Test the map to make certain that the map is built to run properly on IBM Sterling B2B Integrator even though the Generic Envelope and Deenvelope services are not invoked. The Design Studio preferences must be configured to connect to the IBM Sterling B2B Integrator. See the Design Studio documentation for more information.

- [Deploying the example maps to IBM Sterling B2B Integrator](#)  
The map is deployed using either IBM Transformation Extender Design Studio or the IBM Sterling B2B Integrator dashboard.
- [Running the MT examples](#)  
This documentation describes how to configure and run the Generic Deenvelope service and Generic Envelope service examples on MT.
- [Running the MX examples](#)  
The documentation provided here describes how to configure and run the Generic Deenvelope service and Generic Envelope service examples on MX.
- [Expected results](#)

## Deploying the example maps to IBM Sterling B2B Integrator

The map is deployed using either IBM Transformation Extender Design Studio or the IBM Sterling B2B Integrator dashboard.

- [Deploying the map using Transformation Extender](#)  
The documentation provided here describes how to deploy the map to IBM Sterling B2B Integrator using IBM Transformation Extender Design Studio.
- [Deploying the map using IBM Sterling B2B Integrator](#)  
The following procedures describe an alternate method of checking in the map by using the IBM Sterling B2B Integrator dashboard.

## Deploying the map using Transformation Extender

The documentation provided here describes how to deploy the map to IBM Sterling B2B Integrator using IBM Transformation Extender Design Studio.

## Procedure

---

1. Configure IBM Transformation Extender Design Studio preferences before you attempt to connect to the IBM Sterling B2B Integrator server. See the IBM Transformation Extender Design Studio documentation for more information.
  2. Open the source map in IBM Transformation Extender Design Studio.
  3. Right click on the map, then choose Deploy to Sterling B2B Integrator. Enter your ID and password if you are prompted.
- 

## Deploying the map using IBM Sterling B2B Integrator

The following procedures describe an alternate method of checking in the map by using the IBM Sterling B2B Integrator dashboard.

## Procedure

---

1. Compile the source maps for the correct platform on which the IBM Sterling B2B Integrator is installed.
  2. From the IBM Sterling B2B Integrator dashboard, go to Deployment > Maps, then select the **Check in new Map from Map Editor** option.  
If the map has already been deployed to the IBM Sterling B2B Integrator, you can update it by first searching for the map, and then using the Map Source Manager to check out the map and then check in the new version.
- 

## Running the MT examples

This documentation describes how to configure and run the Generic Deenvelope service and Generic Envelope service examples on MT.

1. Set the SYSTEM environment variables to contain the installation directory.
  2. Configure the jvalccyy.prop file. See the documentation that is titled [How to configure the JVC](#)
  3. Copy and install the SWIFT JAR files from IBM Transformation Extender to IBM Sterling B2B Integrator. See [Deploying JVC compliance checking on IBM Sterling B2B Integrator](#). Follow the instructions for the install3rdParty.cmd file.
  4. Create a customer\_overrides\_properties.cmd file to include translator statements for IBM Sterling B2B Integrator. Follow the steps in [Deploying JVC compliance checking on IBM Sterling B2B Integrator](#).
  5. Build the maps for Windows by using the build\_deploy\_jvc.bat file. The build\_deploy\_jvc.bat file creates the directory, deployment\_jvc, under the mt/jvc/maps directory. Copy the files to the correct Windows folders.
  6. Import IBM Sterling B2B Integrator artifacts. From the IBM Sterling B2B Integrator dashboard, import one of the following files from the platform\_support directory of the example: ExportSWIFTmtDeenvSIOBJECTS.xml or ExportSWIFTmtEnvSIOBJECTS.xml, then proceed as described here:
    - a. Log in to the IBM Sterling B2B Integrator dashboard.
    - b. From the Administration menu, expand the Deployment and Resource Manager sections, and then select the Import/Export option.
    - c. Choose the Import Resources option.
    - d. Select a file name:
      - For the Generic Deenvelope services example for MT, select the ExportSWIFTmtDeenvSIOBJECTS.xml file name.
      - For the Generic Envelope services example for MT, select the ExportSWIFTmtEnvSIOBJECTS.xml file name.
    - e. Enter the default SI B2Bi account passphrase and then check the Import All Resources check box.
- [Deploying the example maps to IBM Sterling B2B Integrator](#)  
The example maps are deployed using either IBM Transformation Extender Design Studio, or through use of the IBM Sterling B2B Integrator dashboard.
  - [Deploying maps from within IBM Transformation Extender](#)  
This documentation describes how to deploy the example maps to IBM Sterling B2B Integrator using Design Studio.
  - [Deploying maps using IBM Sterling B2B Integrator](#)
  - [How to run MT examples from IBM Sterling B2B Integrator](#)  
The SWIFT MT examples can be run from the Generic Deenvelope service and the Generic Envelope service.
- 

## Deploying the example maps to IBM Sterling B2B Integrator

The example maps are deployed using either IBM Transformation Extender Design Studio, or through use of the IBM Sterling B2B Integrator dashboard.

## Deploying maps from within IBM Transformation ExtenderIBM®

This documentation describes how to deploy the example maps to IBM Sterling B2B Integrator using Design Studio.

## Procedure

---

1. Configure Design Studio preferences before you attempt to connect to the IBM Sterling B2B Integrator server.
  2. Open the source map in Design Studio.
    - a. If you are running the Generic Deenvelope service example, open the mt103\_plus\_to\_crdt\_xfer\_flat file from source map, mt103+\_to\_credit\_transfer .
    - b. If you are running the Generic Envelope service example, open the crdt\_xfer\_to\_mt103\_plus file from source map credit\_transfer\_to\_mt103+ .
  3. Right click on the map, then choose Deploy to Sterling B2B Integrator. Enter your ID and your password if you are prompted.
-

# Deploying maps using IBM Sterling B2B Integrator

## About this task

These procedures describe how to use the IBM Sterling B2B Integrator dashboard to check in the map.

## Procedure

1. Use IBM Transformation Extender to compile the source maps for the correct platform on which IBM Sterling B2B Integrator is installed.
  - a. Open the source map in the IBM Transformation Extender Design Studio.
    - If you are running the Generic Deenvelope service example, open the mt103\_plus\_to\_crdt\_xfer\_flat file from the mt103+\_to\_credit\_transfer source map.
    - If you are running the Generic Envelope service example, open the crdt\_xfer\_to\_mt103\_plus file from the credit\_transfer\_to\_mt103+ source map.
2. From the IBM Sterling B2B Integrator dashboard, go to Deployment > Maps, then select the Check in a new Map from the Map Editor option.  
Note: If the map has already been deployed to the IBM Sterling B2B Integrator you can update it by first searching for the map, and then using the Map Source Manager to check out the map. Then check in the new version.

# How to run MT examples from IBM Sterling B2B Integrator

The SWIFT MT examples can be run from the Generic Deenvelope service and the Generic Envelope service.

## About this task

These procedures describe how to run the deenvelope and envelope example maps from the IBM Sterling B2B Integrator dashboard.

## Procedure

1. From the Administration menu, go to the Business Process manager page.
2. Search for a Business Process:
  - If you are running the IBM Sterling B2B Integrator Generic Deenvelope service example, search for the EDIDeenvelope Business Process.
  - If you are running the IBM Sterling B2B Integrator Generic Envelope service example, search for the SWIFT\_MT\_103STP\_EnvelopeUsingWTX Business Process.
3. Select the execution manager for the Business Process.

# Running the MX examples

The documentation provided here describes how to configure and run the Generic Deenvelope service and Generic Envelope service examples on MX.

To run the examples, you must first perform the steps listed here.

1. Set the SYSTEM environment variables to contain the IBM Transformation Extender installation directory.
  2. Deploy the XML schemas by using the InstallService.cmd file. See the procedures in [Deploying the XML schemas to IBM Sterling B2B Integrator \(Deprecated\)](#) to accomplish this activity.
  3. Create a customer\_overrides\_properties.cmd file to include translator statements for IBM Sterling B2B Integrator. Follow the procedures provided in [Deploying MX compliance checking components](#).
  4. Build the maps for Windows using the build\_deploy\_mx\_validation.bat file. The build\_deploy\_mx\_validation.bat file creates the deployment\_mx\_validation directory under the mx/maps directory. Copy the files to the proper Windows folders.  
Note: The swiftval map must be deployed to IBM Sterling B2B Integrator along with the example maps.
  5. Import Sterling B2B Integrator artifacts (for MX). From the Sterling B2B Integrator dashboard, import one of the following files from the platform\_support directory of the example: ExportSWIFTmxDeenvSIOBJECTS.xml and ExportSWIFTmxEnvSIOBJECTS.xml.
    - a. Login to the Sterling B2B Integrator dashboard.
    - b. From the Administration menu, expand the Deployment and Resource Manager sections, then select the Import/Export option.
    - c. Choose the Import Resources option.
      - For the Generic Deenvelope services example for MX, select the file name: ExportSWIFTmxDeenvSIOBJECTS.xml
      - For the Generic Envelope services example for MX, select the file name: ExportSWIFTmxEnvSIOBJECTS.xml
  6. Enter the default SI B2Bi account passphrase and then check the Import All Resources check box.
- [Importing IBM Sterling B2B Integrator](#)  
The map is deployed by using either IBM Transformation Extender Design Studio or the IBM Sterling B2B Integrator dashboard.
  - [Deploying the map from within IBM Transformation Extender](#)  
These steps describe how to deploy the map to IBM Sterling B2B Integrator using IBM Transformation Extender Design Studio.
  - [Deploying the maps using IBM Sterling B2B Integrator](#)  
The following procedures describe the method of checking in the map by using the IBM Sterling B2B Integrator dashboard.
  - [How to run the MX examples from IBM Sterling B2B Integrator](#)  
These procedures describe how to run the Generic Deenvelope service and the Generic Envelope service example maps from the IBM Sterling B2B Integrator dashboard:

# Importing IBM Sterling B2B Integrator

The map is deployed by using either IBM Transformation Extender Design Studio or the IBM Sterling B2B Integrator dashboard.

## Deploying the map from within IBM Transformation Extender

These steps describe how to deploy the map to IBM Sterling B2B Integrator using IBM Transformation Extender Design Studio.

### Procedure

1. Configure Design Studio preferences before you attempt to connect to the IBM Sterling B2B Integratorserver. See the Design Studio documentation for more information.
2. Open the source map in Design Studio.
  - If you are running the Generic Deenvelope service example, open the pacs812\_to\_cstmr\_cdtrrf to pacs8nn\_to\_cstmr\_cdtrrf file from source map: mx\_pacs8\_to\_credit\_transfer .
  - If you are running the Generic Envelope service example, open the cstmr\_cdtrrf\_to\_pacs812 to cstmr\_cdtrrf\_to\_pacs8nn file from source map: credit\_transfer\_to\_mx\_pacs8
3. Right click on the map, then choose Deploy to Sterling B2B Integrator. Enter your id and your password if you are prompted.
4. Repeat steps 2 and 3 to deploy the map for MX validation, swiftval file from source map: mx\_validation\_framework .

## Deploying the maps using IBM Sterling B2B Integrator

The following procedures describe the method of checking in the map by using the IBM Sterling B2B Integrator dashboard.

### Procedure

1. Use the IBM Transformation Extender Design Studio to compile the source maps for the correct platform on which IBM Sterling B2B Integrator is installed.
2. Open the source map in IBM Transformation Extender Design Studio.
  - If you are running the Generic Deenvelope service example, open the pacs812\_to\_cstmr\_cdtrrf to pacs8nn\_to\_cstmr\_cdtrrf file from source map: mx\_pacs8\_to\_credit\_transfer
  - If you are running the Generic Envelope service example, open the cstmr\_cdtrrf\_to\_pacs812 to cstmr\_cdtrrf\_to\_pacs8nn file from source map: credit\_transfer\_to\_mx\_pacs8
3. From the IBM Sterling B2B Integrator dashboard, go to Deployment > Maps, then select the Check in new Map from Map Editor option. Compiled maps will include: pacs812\_to\_cstmr\_cdtrrf to pacs8nn\_to\_cstmr\_cdtrrf, cstmr\_cdtrrf\_to\_pacs812 to cstmr\_cdtrrf\_to\_pacs8nn and swiftval (compiled from running the build\_deploy\_mx\_validation.bat) If the map has already been deployed to the IBM Sterling B2B Integrator, you can update it by first searching for the map, and then using the Map Source Manager to check out the map and then check in the new version.

## How to run the MX examples from IBM Sterling B2B Integrator

These procedures describe how to run the Generic Deenvelope service and the Generic Envelope service example maps from the IBM Sterling B2B Integrator dashboard:

### Procedure

1. Import IBM Sterling B2B Integrator artifacts. See [Importing IBM Sterling B2B Integrator](#) for instructions.
2. Deploy the example maps. See [Deploying the example maps to IBM Sterling B2B Integrator](#) for instructions.
3. From the Administration menu, go to the Business Process Manager page.
4. Search for a business process:
  - If you are running the IBM Sterling B2B Integrator Generic Deenvelope service example, search for the EDIDeenvlope Business Process.
  - If you are running the IBM Sterling B2B Integrator Generic Envelope service example, search for the SWIFT\_MX\_PACS8\_EnvelopeUsingWTX Business Process.
5. Select the execution manager for the Business Process, then select the Execute option.
6. On the Local Desktop file name, browse, and then select, the appropriate input file from the data folder.
  - If you are running the Generic Service Deenvelope example, select the pacs\_008\_nnn\_nn\_pdu.in input file.
  - If you are running the Generic Service Envelope example, select the cstmr\_cdtrrf\_flat.dat input file.Note: If the Sterling server is running on UNIX, use cstmr\_cdtrrf\_flat\_LNX.dat as the input file.
7. Select the Go option.
8. The Execute Business Process results show a status of Success for all of the steps in the business process.

You can view more details, such as Status Report, document, and Instance Data by going to this location:

Business Process > Monitor > Current Process

The translated output of the examples can be viewed by going to this location:

Business > Monitor > Current Documents

The document information shows the translated output of the Generic Deenvelope service and the Generic Envelope service. The Document Instance Data shows the Process data values that are set by the service, including the instrID values set by the map.

## Expected results

The expected results vary, depending upon which example is run. Results for the MT generic services de-envelope and envelope services, as well as for the MX generic services de-envelope and envelope service are described in the following documentation.

- [\*\*Generic Deenvelope service MT example: expected results\*\*](#)  
Expect these results from the Generic Deenvelope service MT example:
  - [\*\*Generic Envelope service MT example: expected results\*\*](#)  
Expect the following results from the Generic Envelope service MT example:
  - [\*\*Generic Deenvelope service MX example, expected results\*\*](#)  
Expect the following results from the Generic Deenvelope service MX example.
  - [\*\*Generic Envelope service MX example: expected results\*\*](#)  
Expect the following results from the Generic Envelope service MX example:
- 

## Generic Deenvelope service MT example: expected results

Expect these results from the Generic Deenvelope service MT example:

- When analyzing the swift\_mt103\_plus\_nohdrs.mtt type tree, warnings are expected. Errors are not expected.
  - The translation map generates one credit transfer transaction.
  - The result of the translation map is the same format as the creditTransfer\_flat.dat input file used for the sample IBM Transformation Extender map for the IBM Sterling B2B Integrator Generic Envelope service for MT.
  - The entry for the transaction reference number, transRef, exists in both the ProcessData and correlation tables.
- 

## Generic Envelope service MT example: expected results

Expect the following results from the Generic Envelope service MT example:

- When analyzing the single\_credit\_transfer\_flat.mtt type tree, no error or warning is expected.
  - The translation map generates three MT103+ SWIFT FIN messages.
  - When a compliance check is run against the result of the translation map, two valid, and one invalid (first of the three transactions), MT103+ SWIFT FIN messages are generated.
  - The failure is due to the absence of required tag 121 (UETR) on block 3.
  - The entry for transaction reference number, transRef, exists in both the ProcessData and Correlation tables.
- 

## Generic Deenvelope service MX example, expected results

Expect the following results from the Generic Deenvelope service MX example.

- The translation map generates three customer credit transfer transactions.
  - The result of the translation map is the same format as the cstmr\_cdttrf\_flat.dat input file used for the sample Transformation Extender map for the IBM Sterling B2B Integrator Generic Envelope service for MX.
  - Compliance check performed against the MX document prior to execution of the translation map indicates two valid and one invalid (first of the three transactions), within the SWIFT MX message.
  - The failure is due to an invalid currency code on element IntrBkSttlmAmt currency attribute.
  - The entry for transaction instruction identification, instrID, exists in both the ProcessData and Correlation tables.
- 

## Generic Envelope service MX example: expected results

Expect the following results from the Generic Envelope service MX example:

- The entry for the transaction instruction identification (instrID) exists in both the ProcessData and Correlation tables.
  - When analyzing the cstmr\_cdttrf\_flat.mtt type tree, no error or warning is expected.
  - The translation map generates three FIToFICstmrCdtTrf (pacs.008.nnn.nn) SWIFT MX documents.
- 

## Universal Confirmation examples

Examples in Universal Confirmation component:

- Universal Confirmation API Example
  - Universal Confirmation CSV Example
  - Universal Confirmation FIN Example
  - [\*\*Configuration of SWIFT Universal Confirmation examples in Design Studio\*\*](#)  
This topic documents how to configure the Universal Confirmation examples in Design Studio.
  - [\*\*Configuration of SWIFT Universal Confirmation examples in Design Server\*\*](#)
- 

## Configuration of SWIFT Universal Confirmation examples in Design Studio

This topic documents how to configure the Universal Confirmation examples in Design Studio.

## Before you begin

---

The jvalccyy.prop is installed in <install\_dir>/packs/financial\_payments\_yn.n.n.n/swift/mt/jvc/maps for all versions of ITX.

## Procedure

---

Move the jvalccyy.prop in the following location for ITX V.9.n and higher versions:

- Windows: <tx\_install\_dir>
- Linux: <tx\_install\_dir>/bin
- [How to run the Universal Confirmation API example in Design Studio](#)
- [How to run the Universal Confirmation CSV example in Design Studio](#)
- [How to run the Universal Confirmation FIN example in Design Studio](#)

## How to run the Universal Confirmation API example in Design Studio

---

### About this task

---

This topic describes how to run the Universal Confirmation API example in Design Studio.

## Procedure

---

1. Use the Design Studio to open and build all maps in uc\_api\_validation.mms, uc\_translation.mms, and validate\_messages.mms maps.
2. Run the map uctrxapi in uc\_translation.mms for MT103 to api translation.
3. Run the map uctrx199 in uc\_translation.mms for api to MT199 translation.

Expected results:

- a. Valid Scenarios:  
In case of successful pre-validation, translation, and post validation, following files appear in the data folder:
  - api.json: For MT103 to api translation.
  - MT199.out: For api to MT199 translation.
- b. Invalid Scenarios:  
An error file prevalidation\_failed.json file appears in the data folder in following scenarios, but not limited to:
  - Any of the pre-validation executable map \*.mmc is not found .
  - Input source file is invalid and not compliant with pre-validation rules.
  - The translation executable map is not found, or translation is failed.
  - Unsupported input provided for translation.An error file postvalidation\_failed.json file appears in the data folder in following scenarios:
  - Any of the post validation executable map \*.mmc is not found.
  - The outputfile is invalid and not compliant with post validation rules.

## How to run the Universal Confirmation CSV example in Design Studio

---

### About this task

---

This topic describes how to run the Universal Confirmation CSV example in Design Studio.

## Procedure

---

1. Use the Design Studio to open and build all maps in uc\_csv\_validation.mms, uc\_translation.mms, and validate\_messages.mms maps.
2. Run the map ucrtcsv in uc\_translation.mms for MT103 to csv translation.
3. Run the map uctrx199 in uc\_translation.mms for csv to MT199 translation.

Expected results:

- a. Valid Scenarios:  
In case of successful pre-validation, translation, and post validation, following files appear in the data folder:
  - CSV.csv: For MT103 to csv translation.
  - MT199.out: For csv to MT199 translation.
- b. Invalid Scenarios:  
An error file prevalidation\_failed.json file appears in the data folder in following scenarios, but not limited to:
  - Any of the pre-validation executable map \*.mmc is not found .
  - Input source file is invalid and not compliant with pre-validation rules.
  - The translation executable map is not found, or translation is failed.
  - Unsupported input provided for translation.An error file postvalidation\_failed.json file appears in the data folder in following scenarios:
  - Any of the post validation executable map \*.mmc is not found.
  - The outputfile is invalid and not compliant with post validation rules.

If the reference of MT103 does not match with the instruction\_reference in the translation configuration file, an error file MT103\_config\_mismatch.out appears in the data folder.

# How to run the Universal Confirmation FIN example in Design Studio

## Before you begin

Refer to [Additional configuration for MT JVC validation](#).

For Design Studio, will require administrative rights:

Copy jars to <TX\_install\_dir>/extjar.

For Design Server installation:

See [Configuration files for Design Server](#) for the steps to perform before you import <project>.zip file.

where <project>.zip can be any of the following:

- swiftUCapi.zip
- swiftUCcsv.zip
- swiftUCfin.zip

## About this task

This topic describes how to run the Universal Confirmation FIN example in Design Studio.

## Procedure

1. Use the Design Studio to open and build all maps in uc\_translation.mms, and validate\_messages.mms maps.
2. Run the map uctrx199 in uc\_translation.mms for fin to MT199 translation.
3. Check for the output file prevalidation\_failed.json, postvalidation\_failed.json, or MT199.out in the data folder.

Note: Any one of the three files will appear in the data folder.

Expected results:

- a. Valid Scenarios:  
In case of successful pre-validation, translation, and post validation, the MT199.out (For fin to MT199 translation) file appears in the data folder.

- b. Invalid Scenarios:

An error file prevalidation\_failed.json file appears in the data folder in following scenarios, but not limited to:

- Any of the pre-validation executable map \*.mmc is not found.
- Input source file is invalid and not compliant with prevalidation rules.
- The translation executable map is not found, or translation is failed.
- Unsupported input provided for translation.

An error file postvalidation\_failed.json file appears in the data folder in following scenarios:

- Any of the post validation executable map \*.mmc is not found.
- The output file is invalid and not compliant with post validation rules.

# Configuration of SWIFT Universal Confirmation examples in Design Server

## Configuration files for Design Server

The swiftMTjvcConfig.tar.gz file is contained within UIPackageImports directory.

The UIPackageImports directory is located in the following location:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/UIProjectImports

Where, <install\_dir> is the location where the pack zip distro was extracted and n.n.n.n is the current version of the pack..

Use these steps to run this file:

Extract the swiftMTjvcConfig.tar.gz file.

Follow the below steps, before you import <project>.zip file.

Perform the steps in the same directory location as the Design Server is installed:

1. Create a temp directory called packs.  
Example: /home/user/packs
2. For UNIX environment, FTP (in binary mode) the swiftMTjvcConfig.tar.gz to the pack's directory defined in Step 1.
3. Untar the swiftMTjvcConfig.tar.gz file.  
Example: \$ tar -zxf swiftMTjvcConfig.tar.gz
4. For Container based Design Server installation:
  - a. Run the **jvcsetup.sh** script.  
Example: \$ ./jvcsetup.sh
  - b. The script copies the following to the ITX server:
    - jcwrap.jar

- jvalccyy.jar
- packs/swift folder and sub-folders includes the jvalccyy.prop and XML metadata.

**Optional:**

- a. Run the `cleanjvc.sh` script.  
Example: `$ ./cleanjvc.sh`

- b. The script removes the following to the ITX server:

- jcwrap.jar
- jvalccyy.jar

packs/swift folder and sub-folders includes the jvalccyy.prop and XML metadata.

5. For Native based installation:

- a. Copy the jvalccyy.jar and jcwrap.jar into the directory defined in config.yaml server.persistence.files, by default, this is set to /opt/txlibs.
- b. Restart the application running `./ITX stop` and then `./ITX start`.

6. After importing `<project>.zip` project:

- a. Copy the jvalccyy.prop file to the workdir directory under directory set in the config.yaml server.persistence.files, the default settings is /opt/txfiles/workdir.
- b. On the project, update the map rule on the validate\_message map, on output card #1 item JvalPropPath. Change the map rule from =NONE to the location of the jvalccyy.prop.

Example:

- On UNIX  
= "DS\_DATA\_DIR/workdir"
- On WINDOWS  
= "DS\_DATA\_DIR\\workdir"

where DS\_DATA\_DIR refers to the Design Server data directory, set in the config.yamlserver.persistence.files previously TX\_FILE\_DIR

7. Restart the Design Server: `./ITX stop` and `./ITX start`.

Note: To reflect any jvalccyy.prop updates, repeat step 7.

- [How to run the Universal Confirmation API example in Design Server](#)
- [How to run the Universal Confirmation CSV example in Design Server](#)
- [How to run the Universal Confirmation FIN example in Design Server](#)

## How to run the Universal Confirmation API example in Design Server

### About this task

This topic describes how to run the Universal Confirmation API in Design Server.

To configure the Design Server, see [Configuration of SWIFT Universal Confirmation examples in Design Server](#).

### Procedure

1. Import the swiftUCApi.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open swiftUCApi project in the Design Server UI.  
Note:  
For version 10.0.0.0, do the following steps.
  - Update the Input Card #2 Config file path.
    - For all run map using the input card #2 Config, update the path references on the input card #2 from data/..config to data/config.
4. Run any of the two router maps in the uc\_translation.mms:
  - ucrtxapi: Router map for MT103 to api translation.
  - ucrtx199: Router map for api to MT199 translation.
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, select View Data.
6. To download the output file, see [How to download output files of Universal Confirmation API example](#).
  - [How to download output files of Universal Confirmation API example](#)

## How to download output files of Universal Confirmation API example

### Before you begin

Maps are built/run.

### About this task

To download the output file, go to Files in the Design Server UI and download the desired file as follows.

## Procedure

---

1. Click the output Card Settings that you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make sure that you copy only the file name.  
Example 1:

For MT103 to api translation, the Command text box displays: data/api.json.

copy only: api.json.

Example 2:

For api to MT199 translation, the Command text box displays: data/MT199.out.

copy only: MT199.out.

3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Drop down the Folder field and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

---

## How to run the Universal Confirmation CSV example in Design Server

### About this task

---

This topic describes how to run the Universal Confirmation CSV in Design Server.

## Procedure

---

1. Import the swiftUCcsv.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open swiftUCcsv project in the Design Server UI.  
Note:  
For version 10.0.0.0, do the following steps.
  - Update the Input Card #2 Config file path.
    - For all run map using the input card #2 Config, update the path references on the input card #2 from data/..config to data/config.
4. Run any of the two router maps in the uc\_translation.mms:
  - uc csvfile: Router map for MT103 to csv translation.
  - uc trx199: Router map for csv to MT199 translation.
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, select View Data.
6. To download the output file, see [How to download output files of Universal Confirmation CSV example](#).
  - [How to download output files of Universal Confirmation CSV example](#)

---

## How to download output files of Universal Confirmation CSV example

### Before you begin

---

Maps are built/run.

### About this task

---

To download the output file, go to Files in the Design Server UI and download the desired file as follows.

## Procedure

---

1. Click the output Card Settings that you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make sure that you copy only the file name.  
Example 1:

For csv to MT199 translation, the Command text box displays: data/MT199.out.

copy only: MT199.out.

Example 2:

For MT103 to csv translation, the Command text box displays: data/CSV.csv.

copy only: CSV.csv.

3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Drop down the Folder field and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

---

## How to run the Universal Confirmation FIN example in Design Server

### About this task

This topic describes how to run the Universal Confirmation FIN in Design Server.

### Procedure

1. Import the swiftUCfin.zip file into the Design Server UI. See the release notes for import instructions.
2. Create a package for the project and build all the maps.
3. Open swiftUCfin project in the Design Server UI.  
Note:  
For version 10.0.0.0, do the following steps.
  - Update the Input Card #2 Config file path.
    - For all run map using the input card #2 Config, update the path references on the input card #2 from data/..config to data/config.
4. Run the main router map in the uc\_translation.mms:
  - uctrx199: Router map for MT103 to MT199 translation.
5. View the output. Go to the map Diagram-Result, and hover the cursor over Target, select View Data.
6. To download the output file, see [How to download output files of Universal Confirmation FIN example](#).
  - [How to download output files of Universal Confirmation FIN example](#)

---

## How to download output files of Universal Confirmation FIN example

### Before you begin

Maps are built/run.

### About this task

To download the output file, go to Files in the Design Server UI and download the desired file as follows.

### Procedure

1. Click the outputCard Settings that you want to download.
2. From the Command text box, copy the name of the file that you want to download. Make sure that you copy only the file name.  
Example:  
For fin to MT199 translation, the Command text box displays: data/MT199.out.  
copy only: MT199.out.
3. From Files, click the New icon to open the New File dialog box.
4. Paste the file name in the Name field.
5. Drop down the Folder field and select data.
6. Click Ok.
7. Build and re-run the map.
8. Go to Files and select Download to view the data.

---

## Financial Payments Plus standards

The IBM Transformation Extender Pack for Financial Payments Plus, uses the strength of the data definitions and transformation capabilities from various key financial services standards.

The following industry standards are supported:

- CBPR+
- EBA EURO1/STEP1
- NBOR ReGIS
- TARGET2 RTGS/CLM/CoCo/Securities
- CHAPS L4L/ENH
- SWIFT GPI/UC

- SIC RTGS
- [Overview](#)  
IBM Transformation Extender Pack for Financial Payments Plus provides support for clients that need to create, validate, or transform ISO 20022 messages based on various financial market infrastructure standards.
- [Glossary](#)  
The **Cross-Border Payments and Reporting Plus (CBPR+)** working group formulates and refines the market practice guidelines. They develop ISO20022 usage guidelines that cover migration of MT categories 1, 2 and 9 to lessen the impact to correspondent banks as well as other users of these messages, including security players.

## Overview

IBM Transformation Extender Pack for Financial Payments Plus provides support for clients that need to create, validate, or transform ISO 20022 messages based on various financial market infrastructure standards.

The pack provides different levels of validation:

- XML schema only
- Enhanced extended validation
  - Extended validation
    - BIC lookup
    - Ccy lookup
    - Ctry lookup
    - IBAN format check
    - Maximum allowed decimal places
  - Market Infrastructure usage guidelines rules
    - CBPR+
    - CHAPS L4L/ENH
    - EBA Clearing EURO1/STEP1
    - NBOR ReGIS
    - TARGET2 CLM/RTGS/CoCo/Securities
    - SWIFT GPI/UC
    - SIC RTGS

It also supports MX translation based on CBPR+ translation guides.

This Pack can be configured to leverage the MT validation component of the Pack for Financial Payments.

## Glossary

The **Cross-Border Payments and Reporting Plus (CBPR+)** working group formulates and refines the market practice guidelines. They develop ISO20022 usage guidelines that cover migration of MT categories 1, 2 and 9 to lessen the impact to correspondent banks as well as other users of these messages, including security players.

The **European Banking Association Clearing (EBA) EURO1/STEP1 (E1S1)** system processes transactions of high priority and urgency, and primarily of large amount, both at a domestic and at a cross-border level. EURO1 is the only private sector large-value payment system for single same-day euro transactions at a pan-European level. STEP1 is a same-day single payment service and processes retail payment orders and bank-to-bank transfers related to such commercial transactions.

The **National Bank of Romania (NBOR) ReGIS** is the national funds transfer system with real-time gross settlement (RTGS) for payments in LEI currency owned and operated by the National Bank of Romania, used for the settlement of central bank's monetary policy operations, interbank transfers, operations of other financial market infrastructures that operate at the national level, as well as payments initiated by participants on behalf of their customers, regardless of value.

The **TARGET2 (T2)** is the **Real-Time Gross Settlement (RTGS)** system owned and operated by the Eurosystem. Central banks and commercial banks can submit payment orders in euro to TARGET2, where they are processed and settled in central bank money, i.e., money held in an account with a central bank.

The **TARGET2 (T2) Central Liquidity Management (CLM)** component enables its participants to optimize their liquidity management, to group their accounts and to pool the available intraday liquidity for the benefit of all members of the group. It allows participants to control their liquidity outflow by setting limits, actively managing payment queues or prioritizing certain payments.

The **TARGET2 (T2) Common Components (CoCo)** are a set of extracted Common Reference Data Management (CRDM) messages related to common components. CRDM provides common reference data management features that allows participants to create and maintain common reference data for configuration of data related parties, cash accounts, rules and parameters.

The **TARGET2 Securities (T2S)** is a European platform designed to centralize and harmonize the settlement of securities transactions. Managed by the European Central Bank (ECB), T2S enables the seamless settlement of securities transactions in central bank money across various European markets.

The **Bank of England Clearing House Automated Payment System (CHAPS)** is a sterling same-day system that is used to settle the high-value wholesale payments as well as time-critical lower-value payments, like buying or paying a deposit on a property. **CHAPS** migration to ISO20022 will be done in:

- Phase 1 all DP or direct participants will use like-for-like (L4L) ISO20022 messaging, easy to translate back to existing MT messaging, since there will be no additional data requirements.
- Phase 2 all DP or direct participants will use enhanced (ENH) ISO20022 messaging, with data that is above that is required or supported in existing MT message formats where possible. Includes fields which will support transmission of more information about the identities of those involved in the payments and the purpose of the payment.

The **SWIFT Universal Confirmation (UC)** provides an ISO 20022-compliant XML message that can be used to confirm both MT103 or pacs.008 by providing confirmations to the SWIFT GPI Tracker. The Tracker enables participants to track payments status in real time via end-to-end tracking database that is hosted by SWIFT.

The **SWIFT Global Payment Innovation (GPI)** tracker messages enables member banks to track payment statuses in real time through an end-to-end tracking database, incorporated by SWIFT. Includes ISO 20022 XML compliant messages used for payment status updates, reporting, trace and alert notifications.

- SWIFT gpi Customer Credit Transfer (**gCCT**), first service implemented as part of the gpi initiative. Offers enhanced payment services thru faster, same day use of funds, (within the time zone of the receiving gpi customer), transparency of deducts, end-to-end payments tracking, remittance information transferred unaltered.
- SWIFT gpi Instant Payments (**gCCT Inst**) is a gCCT transaction used for cross-border real-time payments.
- SWIFT gpi for Corporates (**g4C**) service allow g4C corporates receive standardized and consistent payment statuses from their g4C banks that can easily be centralized and integrated into their Treasury Management Systems (TMS) or Enterprise Resource Planning (ERP) applications.
- SWIFT gpi Cover Payments (**gCOV**) which is part of the gCCT service. The gCOV service is designed to further increase the timely processing of gCCT transactions by expediting credit to the beneficiary of the cover and facilitating its reconciliation with the underlying credit transfer.
- SWIFT gpi Financial Institution Transfer (**gFIT**) service focuses on financial institution transfers and was designed to support financial institutions with monitoring of their settlement risk and counterparty exposure, intraday liquidity management and forecasting an improved operational efficiency.

The **SWIFT Go** is a service dedicated to low-value, cross-border transactions.

The **SIC (SIX Interbank Clearing) RTGS** is the **Real-Time Gross Settlement (RTGS)** system for clearing and settlement of interbank payments in Swiss francs (CHF). It is operated by SIX Interbank Clearing under the oversight of Swiss National Bank (SNB). SIC processes both large-value and retail payments, ensuring safe and efficient transactions in central bank money. There are two main RTGS services within the SIC framework: SIC for Swiss franc payments and euroSIC for euro payments as well as SIC IP for instant payments.

## Components

The following lists the components of the Pack for Financial Payment Plus:

- Below is a list of translation scenarios supported:

MT - MX translation

Based on CBPR+ Translation guidelines

MT -> MX

- MT103 COR/STP/SWIFTGo/RETN -> pacs.008.001.08 or pacs.004.001.09
- MT196/MT296 -> camt.029.001.09
- MT192/MT292 -> camt.056.001.08
- MT202 COR/COV/RETN -> pacs.009.001.08 ADV/COR/COV or pacs.004.001.09
- MT205 COR/COV/RETN -> pacs.009.001.08 COR/COV or pacs.004.001.09
- MT900/MT910 -> camt.054.001.08

MX -> MT

- pacs.002.001.10 -> MT199/MT299
- pacs.004.001.09 -> MT103 RETN/MT202 RETN/MT205 RETN
- pacs.008.001.08 COR/STP/SWIFTGo -> MT103 COR/SWIFTGo
- pacs.009.001.08 ADV/COR/COV -> MT202 COR/COV
- pacs.009.001.08 COR/COV -> MT205 COR/COV
- camt.029.001.09 -> MT196/MT296
- camt.052.001.08 -> MT942
- camt.053.001.08 -> MT940
- camt.054.001.08 -> MT900/MT910
- camt.056.001.08 -> MT192/MT292
- camt.057.001.06 -> MT210
- camt.058.001.08 -> MT292
- camt.107.001.01 -> MT110
- camt.108.001.01 -> MT111
- camt.109.001.01 -> MT112

- MX validation

## Examples

This documentation lists and describes the examples of Financial Payments Plus.

- [CBPR+ Examples:](#)
  - [CHAPS L4L/ENH Examples:](#)
  - [EBA EURO1/STEP1 Examples:](#)
  - [NBOR ReGIS Examples:](#)
  - [TARGET2 CLM/RTGS/CoCo/Securities Examples:](#)
  - [SWIFT GPI/UC Examples:](#)
  - [SIC \(SIX Interbank Clearing\) Validation Examples:](#)
- 

## CBPR+ Examples:

- [CBPR+ Validation Examples:](#)
  - [CBPR+ Translation Examples:](#)
- 

## CBPR+ Validation Examples:

- [CBPR+ enhanced MX validation \(using flows\) Example](#)  
This example demonstrates the CBPR+ enhanced MX validation for CBPR+ messages using flow server.
  - [CBPR+ enhanced MX validation \(using maps\) Example](#)  
This example demonstrates the CBPR+ enhanced MX validation for CBPR+ messages using maps only.
  - [CBPR+ schema validation \(using maps\) Example](#)  
This example demonstrates the CBPR+ schema validation for CBPR+ messages using maps only.
- 

## CBPR+ enhanced MX validation (using flows) Example

This example demonstrates the CBPR+ enhanced MX validation for CBPR+ messages using flow server.

The flow can perform following level of validation:

- MX extended validation includes following checks:
    - BIC lookup
    - Country code lookup
    - Currency code lookup
    - IBAN format
    - Allowed maximum fractional digits per currency
    - Usage guideline rules, see mxconfig.xml for list of rules
  - Schema validation
  - [What the example contains](#)  
Files included in this example are as follows:
  - [How to run the example](#)  
This CBPR+ MX Validation will use the sample files to demonstrate the generation of validation reports as output from a CBPR+ XML message.
  - [How to customize the mxconfig.xml file](#)  
Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.
- 

## What the example contains

Files included in this example are as follows:

- cbpr\_validation.zip
  - Test Data Files:
    - cbpr\_pacs\_009\_adv.xml
    - cbpr\_pacs\_009\_adv\_bad\_rule.xml
    - cbpr\_pacs\_009\_adv\_bad\_schema.xml
  - Validation Files:
    - mxconfig.xml
    - bic.xml
    - currencycodedecimals.xml
  - Schemas:
    - bic.xsd  
Metadata that represents the bic.xml repository file structure.
    - ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
    - mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.
    - cbprErrorReport.mtt  
Metadata that represent the xml based structure of the validation report.

- swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.

- Common:
    - mxut1001\_bizsvc\_cbpr
  - Flows:
    - cbpr\_validation

## How to run the example

This CBPR+ MX Validation will use the sample files to demonstrate the generation of validation reports as output from a CBPR+ XML message.

The stopValidation.json file will report the validation failure due to the pre-conversion checks:

**If input file is other than any of the supported CBPR+ messages as per schema list indicated above.**

1. Import the cbpr\_validation.zip project into the Design Server.

2. Open the cbpr\_validation\_flow project in Design Server and view the cbpr\_validation flow.

a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:

b. It utilizes the following nodes:

i. Source Nodes:

- mx\_input

This node identifies the input data to be validated in the flow. It uses the INPUT\_FILE variable to set the location of the data.

ii. Map Nodes:

- MX pre-check

Runs map mxut1001\_bizsvc\_cbpr which sets flow variables, checks pre-validation conditions and creates infoset.json for validation.

- EXT\_VAL

Runs map cbpr6200\_val which calls the appropriate map to perform extended validation of a CBPR+ message.

- XSD\_VAL

Runs map cbpr6100\_val which calls the appropriate map to perform schema validation of a CBPR+ message.

Note: The maps cbpr6200\_val and cbpr6100\_val internally call all the other maps identified in the above Flow Description step.

- iii. Decision Nodes:
    - pre-valid chk  
This node checks the flow variable stopValidation to decide if further validation/processing is not required.
    - EXT\_RESULT\_FORMAT  
This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for extended validation should be generated in XML (default) or JSON.
    - XSD\_RESULT\_FORMAT  
This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for schema-only validation should be generated in XML (default) or JSON.
  - iv. Route Nodes:
    - VAL\_TYPE  
This node checks the variable VALIDATION\_TYPE to determine if the process will do extended validation or schema-only validation on the data.
  - v. Log Nodes:
    - FAILURE  
In case of no validation due to precondition check failures, this node creates a log file specified by the flow variable FAILURE\_LOG.
  - vi. Fail Node:
    - STOP  
It generates error message setup in the node in case of no validation performed.
  - vii. Passthrough Nodes:
    - EXT\_XML\_CONVERT  
This node receives an extended validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.
    - XSD\_XML\_CONVERT  
This node receives a schema-only validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.
  - viii. Format Converter Nodes:
    - EXT\_JSON\_CONVERT  
This node receives an extended validation report in XML format and converts it to JSON before passing it to the appropriate target node.
    - XSD\_JSON\_CONVERT  
This node receives a schema-only validation report in XML format and converts it to JSON before passing it to the appropriate target node.
  - ix. Target Nodes:
    - ext\_xml  
This node contains the resulting extended validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.
    - ext\_json  
This node contains the resulting extended validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.
    - xsd\_xml  
This node contains the resulting schema-only validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.
    - xsd\_json  
This node contains the resulting schema-only validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.
  - c. It utilizes the following variables:
- Flow variables:
- VALIDATION\_TYPE  
The default value is extended.
- For schema-only validation, it can be changed to schema. This is used in Route node VAL\_TYPE.
- REPORT\_FORMAT  
The default value is xml.
- It can be changed to json. This is used in Decision nodes EXT\_RESULT\_FORMAT and XSD\_RESULT\_FORMAT.
- INPUT\_FILE  
The default value is ..../tools/mxservice/data/cbpr\_pacs\_009\_adv.xml.
- This is the data file to be used for validation and can be customized. This is used in Source node mx\_input.
- BIC\_FILE  
The default value is ..../data/bic.xml.
- This is the location of the bic cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.
- CCY\_FILE  
The default value is ..../data/currencycodedecimals.xml.
- This is the location of the country code cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.
- MXCONFIG\_FILE  
The default value is ..../data/mxconfig.xml.

This is the location of the file containing the rule validation settings that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.

- OUTPUT\_RESULT\_XML

The default value is validation\_result.xml.

This is the location of the validation report file in xml format. It is used in Target nodes ext\_xml and xsd\_xml. It can be customized.

- OUTPUT\_RESULT\_JSON

The default value is validation\_result.json.

This is the location of the validation report file in json format. It is used in Target nodes ext\_json and xsd\_json. It can be customized.

- FAILURE\_LOG

The default value is stopMXValidation.json.

This is the location of the failure log. It is used in Log node FAILURE. It can be customized.

- bizSvc

For internal use in the Map node MX pre-check to determine the type of data being read in the input file.

- stopValidation

For internal use in the Map node MX pre-check and is checked in Decision node pre-valid chk to cause a Failure log in case a data file was not recognized as a valid CBPR+ message.

3. Open the main flow cbpr\_validation in the Design Server. It utilizes above one source node, three map nodes, one route nodes, three decision nodes, one log node, one fail node, two passthrough nodes, two format converter nodes and four target nodes.

4. In Design Server, create a package cbpr\_mx\_validation that contains the input files and one flow cbpr\_validation. The maps will automatically be included during deployment of the package onto the runtime server.

Note: Not required for running flows on Design Server user interface directly.

- [\*\*Run the example using three different methods\*\*](#)

You can run the example using three different methods:

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.

2. Deploying the example to tx-rest and running it using the Swagger interface.

3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- [\*\*Run the example from the Design Server user interface\*\*](#)

Use the following steps to run the example from the Design Server user interface:

• [\*\*Run the example using the Swagger interface\*\*](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

- [\*\*Run the example using the flow command server process \(flowcmdserver\)\*\*](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_validation flow and click on Run button.

2. Set toggle switch Run On Design Server and select flow input file. Example is cbpr\_pacs\_009\_adv.xml.

Note: If a default path is assigned to variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.

Flow will run and report with the green check box. The report lists the execution of all nodes.

3. To examine the data passed on each link, right click on each link and select View Link Data.

4. To view the target node, right click on the node input icon and select View Data.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed if you do not have a server definition to deploy in Design Server.

2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.

3. Deploy the created package to the server definition in Design Server.

4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.

5. In the Swagger Explore window, enter /v2/docs and click on the Explore button to view the deployed package.

You should see a Miscellaneous section having two actions: A **PUT** /v2/run/cbpr\_validation and a **POST** /v2/run/cbpr\_validation.

6. In the **PUT** action:

a. Expand the **PUT** action and select the Try it out button.

b. Leave the input and output sections empty.

c. Under flow\_vars section, delete the entire content and replace it with the commands to run the flow. For example:

```

 {
 "INPUT_FILE": "C:/mydir/data/cbpr_pacs_009_adv.xml",
 "OUTPUT_RESULT_JSON": "C:/mydir/data/validation_result.json",
 "REPORT_FORMAT": "json",
 "VALIDATION_TYPE": "extended"
 }

```

or

```

 {
 "INPUT_FILE": "C:/mydir/data/cbpr_pacs_009_adv.xml",
 "OUTPUT_RESULT_XML": "C:/mydir/data/validation_result.xml",
 "REPORT_FORMAT": "xml",
 "VALIDATION_TYPE": "extended"
 }

```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. This run should generate the output same as above.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json. There will be a DELETE /v2/packages/{name} action.
  8. Expand the DELETE /v2/packages/{name} action and select Try it out.
  9. In the Name field, enter the name you gave to the created package.
  10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. The below command is for CBPR+ cbpr\_pacs\_009\_adv.xml message.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_validation.json
--var "INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\cbpr_pacs_009_adv.xml"
--audit "C:\ftpserver\deployment\tools\mx_service\data\cbpr_pacs_009_adv_adt.json" -ad
```

- The results will be in C:\ftpserver\deployment\flows as validation\_result.xml or validation\_result.json depending on the value of the REPORT\_FORMAT variable.
4. Use the following command to execute with the variable VALIDATION\_TYPE value defined in the Flow settings in Design Server (extended or schema).

```
--flow cbpr_validation.json
--var "INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\cbpr_pacs_009_adv.xml"
--var "VALIDATION_TYPE=extended"
--audit "C:\ftpserver\deployment\tools\mx_service\data\cbpr_pacs_009_adv_adt.json" -ad
```

5. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\ftpserver\\\\deployment\\\\tools\\\\mx_service\\\\data\\\\cbpr_pacs_009_adv_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

6. Examine the flow output result file validation\_results.xml and the audit file cbpr\_pacs\_009\_adv\_adt.json.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

### Example

To disable the BIC lookup validation feature.

### About this task

Change sub-element ExtendedValidation/BICValidation value from T to F.

### Procedure

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the flow.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

## CBPR+ enhanced MX validation (using maps) Example

This example demonstrates the CBPR+ enhanced MX validation for CBPR+ messages using maps only.

The maps can perform following level of validation:

- MX enhanced validation includes following checks:
  - BIC lookup
  - Country code lookup
  - Currency code lookup
  - IBAN format
  - Allowed maximum fractional digits per currency
  - Usage guideline rules, see mxconfig.xml for list of rules
- Schema validation:
  - Enforces validation based on XSD.

- **What the example contains**

Files and directories included in this example are as follows:

- **Run the example in Design Studio**
- **Run the example in Design Server User Interface**
- **How to customize the mxconfig.xml file**

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

## What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources to use when running under Design Studio.

- cbpr\_mx\_camt\_validation\_enh.mms  
Utility map called by main map for all the camt CBPR xml message MX validation.
- cbpr\_mx\_pacs\_validation\_enh.mms  
Utility map called by main map for all the pacs CBPR xml message MX validation.
- cbpr\_mx\_pain\_validation\_enh.mms  
Utility map called by main map for all the pain CBPR xml message MX validation.
- cbpr\_mx\_validation\_frmwrk\_map\_enh.mms  
The Main map used to apply MX validation to CBPR xml messages.

Note: When running under Design Server, the main framework map is cbpr\_mx\_validation\_frmwrk\_map\_flw\_enh.mms.

- Schemas:  
The schemas directory contains the following files:

- bic.xsd  
Metadata that represents the bic.xml repository file structure.
- ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
- mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.

- Trees:

The trees directory contains the following files:

- swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
- cbprErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.

- Data:

The data directory contains the following files:

- bic.xml  
Repository file listing all BICs which are used during validation.
- currencycodedecimals.xml  
Repository file listing country codes, currency codes and corresponding maximum fractionally digits, used as reference for validation.
- mxconfig.xml  
Contains the MX configuration information on how to process the message.

- Sample CBPR+ valid files for test purpose with header envelope:

- bah\_pacs\_002\_001\_10\_valid.xml

- bah\_pain\_001\_001\_09\_valid.xml
- bah\_pain\_002\_001\_10\_valid.xml
- bah\_pain\_008\_001\_08\_valid.xml

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, cbpr6000\_val (under cbpr\_mx\_validation\_frmwrk\_map\_enh.mms file or cbpr\_mx\_validation\_frmwrk\_map\_flw\_enh.mms file if running under Design Server) with desired input file.
3. Run the main router map, cbpr6000\_val.  
You will see the output file in the data folder called cbpr\_error\_report.xml.

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter the user and password credentials.
3. If the project does not exist, import cbpr\_validation\_map.zip.
4. If absent, create a package containing all the Maps, Files and Flows.
5. Build the package in the desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map cbpr6000\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map cbpr6000\_val.
10. Right click on the output card on canvas and select View data.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

### Example

To disable the BIC lookup validation feature.

### About this task

Change sub-element ExtendedValidation/BICValidation value from T to F.

### Procedure

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the map.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

## CBPR+ schema validation (using maps) Example

This example demonstrates the CBPR+ schema validation for CBPR+ messages using maps only.

The maps can perform following level of validation:

- Schema validation
- [What the example contains](#)  
Files and directories included in this example are as follows:
- [Run the example in Design Studio](#)

- [Run the example in Design Server User Interface](#)
- 

## What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources to use when running under Design Studio.
  - cbpr\_mx\_schema\_validation\_xsd.mms  
Contains maps for Schema validation of any CBPR message.
  - cbpr\_mx\_schema\_validation\_frmwrk\_map\_xsd.mms  
The Main map used to apply schema validation to CBPR xml messages.
- Schemas:  
The schemas directory contains the following files:  
(Based from SWIFT MyStandards Readiness CBPR+ portal)
  - camt.029.001.09.xsd
  - camt.052.001.08.xsd
  - camt.053.001.08.xsd
  - camt.054.001.08.xsd

- Trees:

The trees directory contains the following files:

- swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
- cbprErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.

- Data:

The data directory contains the following files:

- mxconfig.xml  
Contains the MX configuration information on how to process the message.

Note: The mxconfig.xml file is not used in schema validation and can be ignored.

- Sample CBPR+ valid files for test purpose with header envelope:

---

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.

2. Replace the input card 1 in router map, cbpr6100\_val (under cbpr\_schema\_only\_frmwrk\_map\_xsd.mms file) with desired input file.

3. Run the main router map, cbpr6100\_val.

You will see the output file in the data folder called cbpr\_error\_report.xml.

---

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.

2. Enter the user and password credentials.

3. If the project does not exist, import cbpr\_validation\_map.zip.

4. If absent, create a package containing all the Maps, Files and Flows.

5. Build the package in the desired server (to build all maps).

6. Open the project.

7. In the Maps tab, open the map cbpr6100\_val.

8. Modify the settings for input card 1 on design canvas to point to the desired test file.

9. Save, build, and run the map cbpr6100\_val.

10. Right click on the output card on canvas and select View data.

---

## CBPR+ Translation Examples:

This example demonstrates the CBPR MX to MT (camt.108.001.01 to MT111) message translation using flow server.
- [\*\*CBPR+ MX to MT \(camt.109.001.01 to MT112\) Translation Example\*\*](#)  
This example demonstrates the CBPR MX to MT (camt.109.001.01 to MT112) message translation using flow server.
- [\*\*CBPR+ MX to MT \(pacs.002.001.10 to MT199/MT299\) Translation Example\*\*](#)  
This example demonstrates the CBPR+ MX to MT (pacs.002.001.10 to MT199/MT299) message translation using flow server.
- [\*\*CBPR+ MX to MT \(pacs.004.001.09 to MTnnnRETN\) Translation Example\*\*](#)  
This example demonstrates the CBPR MX to MT (pacs.004.001.09 to MTnnnRETN) message translation using flow server.
- [\*\*CBPR+ MX to MT \(pacs.008.001.08 to MT103\) Translation Example\*\*](#)  
This example demonstrates the CBPR+ MX to MT (pacs.008.001.08 to MT103) message translation using flow server.
- [\*\*CBPR+ MX to MT \(pacs.009.001.08 to MT202\) Translation Example\*\*](#)  
This example demonstrates the CBPR+ MX to MT (pacs.009.001.08 to MT202) message translation using flow server.
- [\*\*CBPR+ MX to MT \(pacs.009.001.08 to MT205\) Translation Example\*\*](#)  
This example demonstrates the CBPR+ MX to MT (pacs.009.001.08 to MT205) message translation using flow server.
- [\*\*CBPR+ MT to MX \(MT900/MT910 to camt.054.001.08\) Translation Example\*\*](#)  
This example demonstrates the CBPR+ MT to MX (MT900/MT910 to camt.054.001.08) message translation using flow server.
- [\*\*CBPR+ MT to MX \(MT192/MT292 to camt.056.001.08\) Translation Example\*\*](#)  
This example demonstrates the CBPR+ MT to MX (MT192/MT292 to camt.056.001.08) message translation using flow server.
- [\*\*CBPR+ MT to MX \(MT196/MT296 to camt.029.001.09\) Translation Example\*\*](#)  
This example demonstrates the CBPR+ MT to MX (MT196/MT296 to camt.029.001.09) message translation using flow server.
- [\*\*CBPR+ MT to MX \(MT103 to pacs.008.001.08 OR MT103 RETN to pacs.004.001.09\) Translation Example\*\*](#)  
This example demonstrates the CBPR+ MT to MX (MT103 to pacs.008.001.08 OR MT103 RETN to pacs.004.001.09) message translation using flow server.
- [\*\*CBPR+ MT to MX \(MT103 SWIFTGo to pacs.008.001.08\) Translation Example\*\*](#)  
This example demonstrates the CBPR+ MT to MX (MT103 SWIFTGo to pacs.008.001.08) message translation using flow server.
- [\*\*CBPR+ MT to MX \(MT202 ADV/COR/COV to pacs.009.001.08 OR MT202 RETN to pacs.004.001.09\) Translation Example\*\*](#)  
This example demonstrates the CBPR+ MT to MX (MT202 ADV/COR/COV to pacs.009.001.08 OR MT202 RETN to pacs.004.001.09) message translation using flow server.
- [\*\*CBPR+ MT to MX \(MT205 COR/COV to pacs.009.001.08 OR MT205 RETN to pacs.004.001.09\) Translation Example\*\*](#)  
This example demonstrates the CBPR+ MT to MX (MT205 COR/COV to pacs.009.001.08 OR MT205 RETN to pacs.004.001.09) message translation using flow server.
- [\*\*CBPR+ MT message validation Example\*\*](#)  
This example shows how flow server can be used for validating any Swift MT message.

## CBPR+ MX to MT (camt.029.001.09 to MT196/MT296) Translation Example

This example demonstrates the CBPR MX to MT (camt.029.001.09 to MT196/MT296) message translation using flow server.

- [\*\*What the example contains\*\*](#)  
Files included in this example are as follows:
- [\*\*How to run the example\*\*](#)  
This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT196 or MT296 message output from a CBPR+ camt.029.001.09 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_029\_mt196\_valid.xml
    - env\_camt\_029\_mt296\_valid.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_029.xsd

- camt.029.001.09.xsd
  - trx\_config.xsd
  - infoset.mtt
  - swift\_iso7775\_ccyy.mtt
  - swiftroute\_funds.mtt
  - Maps:
    - cbpr2520\_camt029\_framework
    - cbpr2522\_camt029\_translate
    - cbpr2523\_camt029\_mtn96
    - cbpr2501\_mxmt\_setvarlog
  - Flows:
    - cbpr\_camt029\_mtn96
  - cbprJnodesConfigIBM.tar.gz
- 

## How to run the example

This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT196 or MT296 message output from a CBPR+ camt.029.001.09 XML message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar tx-server:/opt/ibm/wsdtx/libs/
- Restart the design server, i.e., **docker restart** tx-server.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, i.e., **podman restart**<brand>-server.

This example generates MT196 or MT296 based on the <OrgnlMsgNmId>.

Also, may generate audit.log.json log file to report the translation failure due to the pre-conversion checks.

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_camt029\_mtn96.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
    - @packagemap=cbpr\_plus/translation/mx-xt/maps/cbpr\_t9n\_mx\_camt029\_translate/cbpr2522\_camt029\_translate
    - @packagemap=cbpr\_plus/translation/mx-xt/maps/cbpr\_t9n\_mx\_camt029\_mtn96/cbpr2523\_camt029\_mtn96
    - @packagemap=cbpr\_plus/translation/mx-xt/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog
  - b. It utilizes the following nodes:
    - i. Source Node
      - camt\_029
 

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
    - ii. Map Node
      - mx\_translate
 

Runs framework map cbpr2520\_camt029\_framework, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).
    - iii. Target Node
      - mtn96
 

This node contains the resulting translation in MT (MT196/MT296) format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.

iv. Log Node

- audit\_log

This node creates a log file specified by the flow variable AUDIT\_LOG.

c. It utilizes the following flow variables:

- INPUT\_FILE

Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mx-  
mt/data/env\_camt\_029\_mt196\_valid.xml. This is the data file to be used for translation and can be customized. It is used in the Source node camt\_029

- OUTPUT\_RESULT\_MT

Default value for the flow variable OUTPUT\_RESULT\_MT is mtn96.out. This is the location of the output file in mt format. It is used in the Target node mtn96. It can be customized.

- AUDIT\_LOG

Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.

- CONFIG\_FILE

Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mx-  
mt/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_camt029\_mtn96 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.

4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.

- [Run the example using three different methods](#)

You can run the example using three different methods:

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.

2. Deploying the example to tx-rest and running it using the Swagger interface.

3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- [Run the example from the Design Server user interface](#)

Use the following steps to run the example from the Design Server user interface.

- [Run the example using the Swagger interface](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

- [Run the example using the flow command server process \(flowcmdserver\)](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface.

1. In the Design Server, open cbpr\_camt029\_mtn96 flow and click on Run button.

2. Set toggle switch Run On Design Server and select flow input file env\_camt\_029\_mt196\_valid.xml.

Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.

Flow will run and report with the green check box. The report lists execution of all nodes.

3. Right click and select View Data on each link to examine the data.

4. Right click on the node and select View Log to see the logs.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.

2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.

3. Deploy the created package to the server definition in Design Server.

4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.

5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.

You can see the cbpr\_camt029\_mtn96 section having two actions: A PUT /v2/run/cbpr\_camt029\_mtn96 and a POST /v2/run/cbpr\_camt029\_mtn96.

6. In the PUT action:

a. Expand the PUT action and select the Try it out button.

b. Leave the input and output sections empty.

c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_camt_029_mt196_valid.xml",
 "OUTPUT_RESULT_MT": "C:/tests_dir/data/mtn96.txt",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_camt029_mt96.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_029_mt196_valid.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\mt96.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_029_mt196_valid_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_029_mt196_valid_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\ftpserver\deployment\cbpr_plus\translation\mx-
mt\data\env_camt_029_mt196_valid_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file mt96.out and the audit file env\_camt\_029\_mt196\_valid\_adt.json.

## CBPR+ MX to MT (camt.052.001.08 to MT942) Translation Example

This example demonstrates the CBPR MX to MT (camt.052.001.08 to MT942) message translation using flow server.

- What the example contains**  
Files included in this example are as follows:
- How to run the example**  
This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT942 message output from a CBPR+ camt.052.001.08 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_052\_mt942\_valid.xml
    - env\_camt\_052\_mt942\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_052.xsd
    - camt.052.001.08.xsd
    - trx\_config.xsd
    - infoset.mtt

    - cbpr2547\_camt052\_translate
    - cbpr2548\_camt052\_mt942
    - cbpr2501\_mxmt\_setvarlog
  - Flows:
    - cbpr\_camt052\_mt942
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT942 message output from a CBPR+ camt.052.001.08 XML message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txls:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart** <brand>-server.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart** <brand>-server.

This example may generate failure in the audit.log.json log file to report the translation failure due to the pre-conversion checks:

<ElctrncSeqNb> must be present in <BkToCstmrAcctRpt><Rpt><ElctrncSeqNb> and its length must be less than or equal to 5.

OR

<LgISeqNb> must be present in <BkToCstmrAcctRpt><Rpt><LgISeqNb> and its length must be less than or equal to 5.

There must be a maximum 190 occurrence of <Ntry> in <BkToCstmrAcctRpt><Rpt><Ntry>.

There must be present any ONE of the following:

- <BkToCstmrAcctRpt><Rpt><Ntry>
- <BkToCstmrAcctRpt><Rpt><TxSummry><TtlCdtNtries><NbOfNtries> AND <BkToCstmrAcctRpt><Rpt><TxSummry><TtlCdtNtries><Sum>
- <BkToCstmrAcctRpt><Rpt><TxSummry><TtlDbtNtries><NbOfNtries> AND <BkToCstmrAcctRpt><Rpt><TxSummry><TtlDbtNtries><Sum>

For all occurrence of <BkToCstmrAcctRpt><Rpt><Ntry>, value of <Ccy> in <BkToCstmrAcctRpt><Rpt><Ntry><Amt><Ccy> must be equal to value of <Ccy> in <BkToCstmrAcctRpt><Rpt><Acct><Ccy>, TotalNumberOfDigits <BkToCstmrAcctRpt><Rpt><Ntry><Amt> must be less than or equal to 14.

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_camt052\_mt942.

a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:

- @packagemap=cbpr\_plus/translation/mx-ml/maps/cbpr\_t9n\_mx\_camt052\_translate/cbpr2547\_camt052\_translate
- @packagemap=cbpr\_plus/translation/mx-ml/maps/cbpr\_t9n\_mx\_camt052\_mt942/cbpr2548\_camt052\_mt942
- @packagemap=cbpr\_plus/translation/mx-ml/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog

b. It utilizes the following nodes:

i. Source Node

- camt\_052

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.

ii. Map Node

- mx\_translate

Runs framework map cbpr2546\_camt052\_framework, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).

iii. Target Node

- mt942

This node contains the resulting translation in MT format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.

iv. Log Node

- audit\_log

This node creates a log file specified by the flow variable AUDIT\_LOG.

c. It utilizes the following flow variables:

- INPUT\_FILE

Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mx-ml/data/env\_camt\_052\_mt942\_valid.xml. This is the data file to be used for translation and can be customized. It is used in the Source node camt\_052.

- **OUTPUT\_RESULT\_MT**  
Default value for the flow variable OUTPUT\_RESULT\_MT is mt942.out. This is the location of the output file in mt format. It is used in the Target node mt942. It can be customized.
- **AUDIT\_LOG**  
Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
- **CONFIG\_FILE**  
Default value for the flow variable CONFIG\_FILE is ..\cbpr\_plus\translation\mx-mt\data\trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_camt052\_mt942 in the Design Server, It utilizes one source node, one map node, one log node, and one target node.
4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.

- **[Run the example using three different methods](#)**

You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- **[Run the example from the Design Server user interface](#)**

Use the following steps to run the example from the Design Server user interface.

- **[Run the example using the Swagger interface](#)**

To run the example, deploy to tx-rest and run it using the Swagger interface.

- **[Run the example using the flow command server process \(flowcmdserver\)](#)**

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface.

1. In the Design Server, open cbpr\_camt052\_mt942 flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_camt\_052\_mt942\_valid.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see the cbpr\_camt052\_mt942 section having two actions: A PUT /v2/run/cbpr\_camt052\_mt942 and a POST /v2/run/cbpr\_camt052\_mt942.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_camt_052_mt942_valid.xml",
 "OUTPUT_RESULT_MT": "C:/tests_dir/data/mt942.txt",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_camt052_mt942.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_052_mt942_valid.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\mt942.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_052_mt942_valid_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_052_mt942_valid_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\cbpr_plus\\\\translation\\\\mx-
mt\\\\data\\\\env_camt_052_mt942_valid_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file mt942.out and the audit file env\_camt\_052\_mt942\_valid\_adt.json.

## CBPR+ MX to MT (camt.053.001.08 to MT940) Translation Example

This example demonstrates the CBPR+ MX to MT (camt.053.001.08 to MT940) message translation using maps.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT940 message output from a CBPR+ camt.053.001.08 XML message.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT940 message output from a CBPR+ camt.053.001.08 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_053\_mt940\_valid.xml
    - env\_camt\_053\_mt940\_bad.xml
    - trx\_config.xml
  - Schemas:

You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
  2. Deploying the example to tx-rest and running it using the Swagger interface.
  3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).
- **[Run the example from the Design Server user interface](#)**  
Use the following steps to run the example from the Design Server user interface.
  - **[Run the example using the Swagger interface](#)**  
To run the example, deploy to tx-rest and run it using the Swagger interface.
  - **[Run the example using the flow command server process \(flowcmdserver\)](#)**  
To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface.

1. In the Design Server, open cbpr\_camt053\_mt940 flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_camt\_053\_mt940\_valid.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable. Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see the cbpr\_camt053\_mt940 section having two actions: A PUT /v2/run/cbpr\_camt053\_mt940 and a POST /v2/run/cbpr\_camt053\_mt940.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_camt_053_mt940_valid.xml",
 "OUTPUT_RESULT_MT": "C:/tests_dir/data/mt940.txt",
```

```
"AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

---

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_camt053_mt940.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_053_mt940_valid.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\mt940.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_053_mt940_valid_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_053_mt940_valid_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\ftpserver\\deployment\\cbpr_plus\\translation\\mx-
mt\\data\\env_camt_053_mt940_valid_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file mt940.out and the audit file env\_camt\_053\_mt940\_valid\_adt.json.

---

## CBPR+ MX to MT (camt.054.001.08 to MT900/MT910) Translation Example

This example demonstrates the CBPR MX to MT (camt.054.001.08 to MT900/MT910) message translation using flow server.

- [What the example contains](#)  
Files included in this example are as follows:
- [How to run the example](#)  
This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT900 or MT910 message output from a CBPR+ camt.054.001.08 XML message.

---

## How to run the example

This mx-*mt* translation will use the sample files to demonstrate the generation of SWIFT MT900 or MT910 message output from a CBPR+ camt.054.001.08 XML message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart** <brand>-server.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart** <brand>-server.

This example generates MT900 or MT910 based on the <CdtDbtInd> which could be CRDT (will generate MT910) or DBIT (will generate MT900).

Also, may generate failure in the audit.log.json log file to report the translation failure due to the pre-conversion checks:

```
Either <CdtDbtInd> is not one of these (CRDT, DBIT) or <Sts><Cd> is not BOOK.
TotalNumberOfDigits <Ntry><Amt> less than or equal to 14.
Only one occurrence is allowed for <Ntfctn>, <Ntry>, <NtryDtls> and <TxDtls>.
Either one must exist <Ntfctn><Ntry><ValDt> or <Ntfctn><Ntry><NtryDtls><TxDtls><RltdDts><IntrBkSttlmDt>.
```

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_camt054\_mt9n0.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
    - @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_camt054\_translate/cbpr2512\_camt054\_translate
    - @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_camt054\_mt900/cbpr2513\_camt054\_mt900
    - @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_camt054\_mt910/cbpr2514\_camt054\_mt910
    - @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog
  - b. It utilizes the following nodes:
    - i. Source Node
      - camt\_054  
This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
    - ii. Map Node
      - mx\_translate  
Runs framework map cbpr2510\_camt054\_framework, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).
    - iii. Target Node
      - mt9n0  
This node contains the resulting translation in MT format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.
    - iv. Log Node
      - audit\_log  
This node creates a log file specified by the flow variable AUDIT\_LOG.
  - c. It utilizes the following flow variables:
    - INPUT\_FILE  
Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mx-*mt*/data/env\_camt\_054\_crdt.xml. This is the data file to be used for translation and can be customized. It is used in the Source node camt\_054.
    - OUTPUT\_RESULT\_MT

Default value for the flow variable OUTPUT\_RESULT\_MT is mt9n0.out. This is the location of the output file in mt format. It is used in Target node mt900 or mt910 . It can be customized.

- AUDIT\_LOG  
Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
- CONFIG\_FILE  
Default value for the flow variable CONFIG\_FILE is ../cbpr\_plus/translation/mx-mt/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_camt054\_mt9n0 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.
4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.

- **[Run the example using three different methods](#)**

You can run the example using three different methods:

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
  2. Deploying the example to tx-rest and running it using the Swagger interface.
  3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).
- **[Run the example from the Design Server user interface](#)**  
Use the following steps to run the example from the Design Server user interface.
  - **[Run the example using the Swagger interface](#)**  
To run the example, deploy to tx-rest and run it using the Swagger interface.
  - **[Run the example using the flow command server process \(flowcmdserver\)](#)**  
To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface.

1. In the Design Server, open cbpr\_camt054\_mt9n0 flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_camt\_054\_dbit.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see the cbpr\_camt054\_mt9n0 section having two actions: A PUT /v2/run/cbpr\_camt054\_mt9n0 and a POST /v2/run/cbpr\_camt054\_mt9n0.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_camt_054_dbit.xml",
 "OUTPUT_RESULT_MT": "C:/tests_dir/data/mt900.txt",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_camt054_mt9n0.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_054_dbit.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\mt9n0.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_054_dbit_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_054_dbit_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\cbpr_plus\\\\translation\\\\mx-
mt\\\\data\\\\env_camt_054_dbit_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file mt900.out and the audit file env\_camt\_054\_dbit\_adt.json.

## CBPR+ MX to MT (camt.056.001.08 to MT192/MT292) Translation Example

This example demonstrates the CBPR MX to MT (camt.056.001.08 to MT192/MT292) message translation using flow server.

- [What the example contains](#)

Files included in this example are as follows:

- [How to run the example](#)

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT192 or MT292 message output from a CBPR+ camt.056.001.08 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_056\_mt192\_valid.xml
    - env\_camt\_056\_mt292\_valid.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_056.xsd
    - camt.056.001.08.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2540\_camt056\_framework
    - cbpr2542\_camt056\_translate
    - cbpr2543\_camt056\_mtn92
    - cbpr2501\_mxmt\_setvarlog
  - Flows:
    - cbpr\_camt056\_mtn92
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT192 or MT292 message output from a CBPR+ camt.056.001.08 XML message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar

- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart** <brand>-server.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart** <brand>-server.

This example generates MT192 or MT292 based on the <Orgn1MsgNmId>.

Also, may generate failure in the audit.log.json log file to report the translation failure due to the pre-conversion checks.

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_camt056\_mtn92.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
    - @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_camt056\_translate/cbpr2542\_camt056\_translate
    - @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_camt056\_mtn92/cbpr2543\_camt056\_mtn92
    - @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog
  - b. It utilizes the following nodes:
    - i. Source Node
      - camt\_056
 

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
    - ii. Map Node
      - mx\_translate
 

Runs framework map cbpr2540\_camt056\_framework, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).
    - iii. Target Node
      - mtn92
 

This node contains the resulting translation in MT format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.
    - iv. Log Node
      - audit\_log
 

This node creates a log file specified by the flow variable AUDIT\_LOG.
- c. It utilizes the following flow variables:
  - INPUT\_FILE
 

Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mx-mt/data/env\_camt\_056\_mt192\_valid.xml. This is the data file to be used for translation and can be customized. It is used in the Source node camt\_056.
  - OUTPUT\_RESULT\_MT
 

Default value for the flow variable OUTPUT\_RESULT\_MT is mtn92.out. This is the location of the output file in mt format. It is used in the Target node mt192 or mt292. It can be customized.
  - AUDIT\_LOG
 

Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
  - CONFIG\_FILE
 

Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mx-mt/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.
3. Open the flow cbpr\_camt056\_mtn92 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.
4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.
- **Run the example using three different methods**  
 You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- [\*\*Run the example from the Design Server user interface\*\*](#)

Use the following steps to run the example from the Design Server user interface.

- [\*\*Run the example using the Swagger interface\*\*](#)  
To run the example, deploy to tx-rest and run it using the Swagger interface.
- [\*\*Run the example using the flow command server process \(flowcmdserver\)\*\*](#)  
To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface.

1. In the Design Server, open cbpr\_camt056\_mtn92 flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_camt\_056\_mt192\_valid.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.

You can see the cbpr\_camt056\_mtn92 section having two actions: A PUT /v2/run/cbpr\_camt056\_mtn92 and a POST /v2/run/cbpr\_camt056\_mtn92.

6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_camt_056_mt192_valid.xml",
 "OUTPUT_RESULT_MT": "C:/tests_dir/data/mtn92.txt",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

7. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
8. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json. There will be a DELETE /v2/packages/{name} action.
9. Expand the DELETE /v2/packages/{name} action and select the Try it out.
10. In the Name field, enter the name you gave it to the created package.

You can see a response of 204 with a timestamp, if it is successful.

---

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_camt056_mtn92.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_056_mt192_valid.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\mtn92.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_056_mt192_valid_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_056_mt192_valid_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\ftpserver\\deployment\\cbpr_plus\\translation\\mx-
mt\\data\\env_camt_056_mt192_valid_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file `mtn92.out` and the audit file `env_camt_056_mt192_valid_adt.json`.

---

## CBPR+ MX to MT (camt.057.001.06 to MT210) Translation Example

This example demonstrates the CBPR MX to MT (camt.057.001.06 to MT210) message translation using flow server.

- **What the example contains**

Files included in this example are as follows:

- `cbpr_translation.zip`
  - Files:
    - `env_camt_057_bad.xml`
    - `env_camt_057_valid.xml`
    - `trx_config.xml`
  - Schemas:
    - `head.001.001.02_camt_057.xsd`
    - `camt.057.001.06.xsd`
    - `trx_config.xsd`
    - `infoset.mtt`
    - `swift_iso7775_ccyy.mtt`
    - `swiftroute_funds.mtt`
  - Maps:
    - `cbpr2600_camt057_framework`
    - `cbpr2601_camt057_translate`
    - `cbpr2605_camt057_mt210`
    - `cbpr2501_mxmt_setvarlog`
  - Flows:
    - `cbpr_camt057_mt210`
- `cbprJnodesConfigIBM.tar.gz`

---

## How to run the example

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT210 message output from a CBPR+ camt.057.001.06 XML message.

The `cbprJnodesConfigIBM.tar.gz` file is available either in `IBM_financialpaymentsplus_vn.n.n.n.zip` or in `UIProjectImports` directory.

Extract from `cbprJnodesConfigIBM.tar.gz` file.

- `jnodes0.jar`

The following jars needs to be copied from `<TX_install_dir>/jars`:

- `jackson-core-n.n.n.jar`
- `jackson-annotations-n.n.n.jar`
- `jackson-databind-n.n.n.jar`

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to `<TX_install_dir>/extjar`.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml `server.persistence.libs`, by default, this is set to `/opt/txlabs`:

- `jvcwrap.jar`
- `jvalccyy.jar`

Restart the running application `./ITX stop` and then `./ITX start`.

For the Docker environments,

- `docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/`.
- Restart the design server, i.e., `docker restart <brand>-server`.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- `podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/`.

- Restart the design server, i.e., **podman restart <brand>-server**.

This example may generate failure in the audit.log.json log file to report the translation failure due to the pre-conversion checks:

```
NumberOfOccurrences <Ntfctn><Itm> should not be greater than 1.
Currency should not be any of these: {"XAU", "XAG", "XPD", "XPT"} for <Ntfctn><Itm><Amt><Ccy>
TotalNumberOfDigits <Ntry><Amt> less than or equal to 14.
```

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_camt057\_mt210.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
    - @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_camt057\_translate/cbpr2601\_camt057\_translate
    - @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_camt057\_mt210/cbpr2605\_camt057\_mt210
    - @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog
  - b. It utilizes the following nodes:
    - i. Source Node
      - camt\_057
 This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
    - ii. Map Node
      - mx\_translate
 Runs framework map cbpr2600\_camt057\_framework, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).
    - iii. Target Node
      - mt210
 This node contains the resulting translation in MT format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.
    - iv. Log Node
      - audit\_log
 This node creates a log file specified by the flow variable AUDIT\_LOG.
  - c. It uses the following flow variables:
    - INPUT\_FILE
 Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mx-mt/data/env\_camt\_057\_valid.xml. This is the data file to be used for translation and can be customized. It is used in the Source node camt\_057
    - OUTPUT\_RESULT\_MT
 Default value for the flow variable OUTPUT\_RESULT\_MT is mt210.out. This is the location of the output file in mt format. It is used in the Target node mt210. It can be customized.
    - AUDIT\_LOG
 Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
    - CONFIG\_FILE
 Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mx-mt/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.
3. Open the flow cbpr\_camt057\_mt210 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.
4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.

- **Run the example using three different methods**

You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- **Run the example from the Design Server user interface**

Use the following steps to run the example from the Design Server user interface:

- **Run the example using the Swagger interface**

To run the example, deploy to tx-rest and run it using the Swagger interface.

- **Run the example using the flow command server process (flowcmdserver)**

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_camt057\_mt210 flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_camt\_057\_valid.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.

- Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
  4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see the cbpr\_camt057\_mt210 section having two actions: A PUT /v2/run/cbpr\_camt057\_mt210 and a POST /v2/run/cbpr\_camt057\_mt210.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_camt_057_valid.xml",
 "OUTPUT_RESULT_MT": "C:/tests_dir/data/mt210.txt",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

  - d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_camt057_mt210.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_057_valid.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\mt210.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_057_valid_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_057_valid_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

 Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
 The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\cbpr_plus\\\\translation\\\\mx-
 mt\\\\data\\\\env_camt_057_valid_adt.json"
 Flow completed successfully
 Elapsed time: 3048ms
```

5. Examine the flow output result file mt210.out and the audit file env\_camt\_057\_valid\_adt.json.

## CBPR+ MX to MT (camt.058.001.08 to MT292) Translation Example

This example demonstrates the CBPR MX to MT (camt.058.001.08 to MT292) message translation using flow server.

- [What the example contains](#)  
Files included in this example are as follows:
- [How to run the example](#)  
This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT292 message output from a CBPR+ camt.058.001.08 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip

- Files:
  - env\_camt\_058\_bad.xml
  - env\_camt\_058\_valid.xml
  - trx\_config.xml
- Schemas:
  - head.001.001.02\_camt\_058.xsd
  - camt.058.001.08.xsd
  - trx\_config.xsd
  - infoSet.mtt
  - swift\_iso7775\_ccyy.mtt
  - swiftRoute\_funds.mtt
- Maps:
  - cbpr2610\_camt058\_framework
  - cbpr2611\_camt058\_translate
  - cbpr2612\_camt058\_mt292
  - cbpr2501\_mxmt\_setvarlog
- Flows:
  - cbpr\_camt058\_mt292
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-*mt* translation will use the sample files to demonstrate the generation of SWIFT MT292 message output from a CBPR+ camt.058.001.08 XML message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart** <brand>-server.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart** <brand>-server.

This example may generate failure in the audit.log.json log file to report the translation failure due to the pre-conversion checks:

**NumberOfOccurrences <OrgnlItm><OrgnlNtfctnRef>** should not be greater than 1.

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_camt058\_mt292.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
    - @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_camt058\_translate/cbpr2611\_camt058\_translate
    - @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_camt058\_mt292/cbpr2612\_camt058\_mt292
    - @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog
  - b. It utilizes the following nodes:
    - i. Source Node
      - camt\_058
 

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
    - ii. Map Node
      - mx\_translate
 

Runs framework map cbpr2610\_camt058\_framework, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).

- iii. Target Node
  - mt292
 

This node contains the resulting translation in MT format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.
- iv. Log Node
  - audit\_log
 

This node creates a log file specified by the flow variable AUDIT\_LOG.
- c. It utilizes the following flow variables:
  - INPUT\_FILE
 

Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mx-mt/data/env\_camt\_058\_valid.xml. This is the data file to be used for translation and can be customized. It is used in the Source node camt\_058
  - OUTPUT\_RESULT\_MT
 

Default value for the flow variable OUTPUT\_RESULT\_MT is mt292.out. This is the location of the output file in mt format. It is used in the Target node mt292. It can be customized.
  - AUDIT\_LOG
 

Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
  - CONFIG\_FILE
 

Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mx-mt/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_camt058\_mt292 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.
  4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.
- [Run the example using three different methods](#)  
You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
  2. Deploying the example to tx-rest and running it using the Swagger interface.
  3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).
- [Run the example from the Design Server user interface](#)  
Use the following steps to run the example from the Design Server user interface.
  - [Run the example using the Swagger interface](#)  
To run the example, deploy to tx-rest and run it using the Swagger interface.
  - [Run the example using the flow command server process \(flowcmdserver\)](#)  
To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface.

1. In the Design Server, open cbpr\_camt058\_mt292 flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_camt\_058\_valid.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see the cbpr\_camt058\_mt292 section having two actions: A PUT /v2/run/cbpr\_camt058\_mt292 and a POST /v2/run/cbpr\_camt058\_mt292.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_camt_058_valid.xml",
```

```

"OUTPUT_RESULT_MT": "C:/tests_dir/data/mt292.txt",
"AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}

```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```

flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_camt058_mt292.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_058_valid.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\mt292.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_058_valid_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_058_valid_adt.json" -ad

```

4. The flow will report status similar to:

```

***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\ftpserver\\deployment\\cbpr_plus\\translation\\mx-
mt\\data\\env_camt_058_valid_adt.json"
Flow completed successfully
Elapsed time: 3048ms

```

5. Examine the flow output result file mt292.out and the audit file env\_camt\_058\_valid\_adt.json.

## CBPR+ MX to MT (camt.107.001.01 to MT110) Translation Example

This example demonstrates the CBPR MX to MT (camt.107.001.01 to MT110) message translation using flow server.

- [What the example contains](#)  
Files included in this example are as follows:
- [How to run the example](#)  
This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT110 message output from a CBPR+ camt.107.001.01 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_107\_valid.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_107.xsd
    - camt.107.001.01.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2620\_camt107\_framework
    - cbpr2621\_camt107\_translate
    - cbpr2622\_camt107\_mt110
    - cbpr2501\_mxmt\_setvarlog
  - Flows:
    - cbpr\_camt107\_mt110
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-*mt* translation will use the sample files to demonstrate the generation of SWIFT MT110 message output from a CBPR+ camt.107.001.01 XML message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlxlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart <brand>-server**.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart <brand>-server**.

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_camt107\_mt110.

a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:

- @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_camt107\_translate/cbpr2621\_camt107\_translate
- @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_camt107\_mt110/cbpr2622\_camt107\_mt110
- @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog

b. It utilizes the following nodes:

i. Source Node

- camt\_107  
This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.

ii. Map Node

- mx\_translate  
Runs framework map cbpr2620\_camt107\_framework, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).

iii. Target Node

- mt110  
This node contains the resulting translation in MT format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.

iv. Log Node

- audit\_log  
This node creates a log file specified by the flow variable AUDIT\_LOG.

c. It utilizes the following flow variables:

- INPUT\_FILE

Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mx-*mt*/data/env\_camt\_107\_valid.xml. This is the data file to be used for translation and can be customized. It is used in the Source node camt\_107

- OUTPUT\_RESULT\_MT

Default value for the flow variable OUTPUT\_RESULT\_MT is mt110.out. This is the location of the output file in mt format. It is used in the Target node mt110. It can be customized.

- AUDIT\_LOG

Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.

- CONFIG\_FILE

Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mx-*mt*/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_camt107\_mt110 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.

4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.

- [Run the example using three different methods](#)

You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- [Run the example from the Design Server user interface](#)

Use the following steps to run the example from the Design Server user interface.

- [Run the example using the Swagger interface](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

- [Run the example using the flow command server process \(flowcmdserver\)](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface.

1. In the Design Server, open cbpr\_camt107\_mt110 flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_camt\_107\_valid.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see the cbpr\_camt107\_mt110 section having two actions: A PUT /v2/run/cbpr\_camt107\_mt110 and a POST /v2/run/cbpr\_camt107\_mt110.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_camt_107_valid.xml",
 "OUTPUT_RESULT_MT": "C:/tests_dir/data/mt110.txt",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_camt107_mt110.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_107_valid.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\mt110.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_107_valid_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_107_valid_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server
Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\ftpserver\\deployment\\cbpr_plus\\translation\\mx-
mt\\data\\env_camt_107_valid_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file `mt110.out` and the audit file `env_camt_107_valid_adt.json`.

## CBPR+ MX to MT (camt.108.001.01 to MT111) Translation Example

This example demonstrates the CBPR MX to MT (camt.108.001.01 to MT111) message translation using flow server.

- **What the example contains**

Files included in this example are as follows:

- `cbpr_translation.zip`
  - Files:
    - `env_camt_108_valid.xml`
    - `trx_config.xml`
  - Schemas:
    - `head.001.001.02_camt_108.xsd`
    - `camt.108.001.01.xsd`
    - `trx_config.xsd`
    - `infoset.mtt`
    - `swift_iso7775_ccyy.mtt`
    - `swiftroute_funds.mtt`
  - Maps:
    - `cbpr2630_camt108_framework`
    - `cbpr2631_camt108_translate`
    - `cbpr2632_camt108_mt111`
    - `cbpr2501_mxmt_setvarlog`
  - Flows:
    - `cbpr_camt108_mt111`
- `cbprJnodesConfigIBM.tar.gz`

## What the example contains

Files included in this example are as follows:

- `cbpr_translation.zip`
  - Files:
    - `env_camt_108_valid.xml`
    - `trx_config.xml`
  - Schemas:
    - `head.001.001.02_camt_108.xsd`
    - `camt.108.001.01.xsd`
    - `trx_config.xsd`
    - `infoset.mtt`
    - `swift_iso7775_ccyy.mtt`
    - `swiftroute_funds.mtt`
  - Maps:
    - `cbpr2630_camt108_framework`
    - `cbpr2631_camt108_translate`
    - `cbpr2632_camt108_mt111`
    - `cbpr2501_mxmt_setvarlog`
  - Flows:
    - `cbpr_camt108_mt111`
- `cbprJnodesConfigIBM.tar.gz`

## How to run the example

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT111 message output from a CBPR camt.108.001.01 XML message.

The `cbprJnodesConfigIBM.tar.gz` file is available either in `IBM_financialpaymentsplus_vn.n.n.n.zip` or in `UIProjectImports` directory.

Extract from `cbprJnodesConfigIBM.tar.gz` file.

- `jnodes0.jar`

The following jars needs to be copied from `<TX_install_dir>/jars`:

- `jackson-core-n.n.n.jar`
- `jackson-annotations-n.n.n.jar`
- `jackson-databind-n.n.n.jar`

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to `<TX_install_dir>/extjar`.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in `config.yaml` `server.persistence.libs`, by default, this is set to `/opt/txlabs`:

- `jvcwrap.jar`
- `jvalccyy.jar`

Restart the running application `./ITX stop` and then `./ITX start`.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart** <brand>-server.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart** <brand>-server.

This example may generate failure in the audit.log.json log file to report the translation failure, if the input message is not camt.108.001.01.

1. Import the cbpr\_translation.zip project into the Design Server.
  2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_camt108\_mt111.
    - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
      - @packagemap=cbpr\_plus/translation/mx-ml/maps/cbpr\_t9n\_mx\_camt108\_translate/cbpr2631\_camt108\_translate
      - @packagemap=cbpr\_plus/translation/mx-ml/maps/cbpr\_t9n\_mx\_camt108\_mt111/cbpr2632\_camt108\_mt111
      - @packagemap=cbpr\_plus/translation/mx-ml/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog
    - b. It utilizes the following nodes:
      - i. Source Node
        - camt\_108
 

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
      - ii. Map Node
        - mx\_translate
 

Runs framework map cbpr2630\_camt108\_framework, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).
      - iii. Target Node
        - mt111
 

This node contains the resulting translation in MT format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.
      - iv. Log Node
        - audit\_log
 

This node creates a log file specified by the flow variable AUDIT\_LOG.
    - c. It utilizes the following flow variables:
      - INPUT\_FILE
 

Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mx-ml/data/env\_camt\_108\_valid.xml. This is the data file to be used for translation and can be customized. It is used in the Source node camt\_108
      - OUTPUT\_RESULT\_MT
 

Default value for the flow variable OUTPUT\_RESULT\_MT is mt111.out. This is the location of the output file in mt format. It is used in the Target node mt111. It can be customized.
      - AUDIT\_LOG
 

Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
      - CONFIG\_FILE
 

Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mx-ml/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.
  3. Open the flow cbpr\_camt108\_mt111 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.
  4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.
- [\*\*Run the example using three different methods\*\*](#)  
You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
  2. Deploying the example to tx-rest and running it using the Swagger interface.
  3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).
- [\*\*Run the example from the Design Server user interface\*\*](#)  
Use the following steps to run the example from the Design Server user interface.
  - [\*\*Run the example using the Swagger interface\*\*](#)  
To run the example, deploy to tx-rest and run it using the Swagger interface.
  - [\*\*Run the example using the flow command server process \(flowcmdserver\)\*\*](#)  
To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface.

1. In the Design Server, open cbpr\_camt108\_mt111 flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_camt\_108\_valid.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.

You can see the cbpr\_camt108\_mt111 section having two actions: A PUT /v2/run/cbpr\_camt108\_mt111 and a POST /v2/run/cbpr\_camt108\_mt111.

6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_camt_108_valid.xml",
 "OUTPUT_RESULT_MT": "C:/tests_dir/data/mt111.txt",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.

You can see a response of 204 with a timestamp, if it is successful.

---

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_camt108_mt111.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_108_valid.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_108_111.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_108_111_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_108_111_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\cbpr_plus\\\\translation\\\\mx-
mt\\\\data\\\\env_camt_108_111_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file env\_camt\_108\_111.out and the audit file env\_camt\_108\_111\_adt.json.

---

## CBPR+ MX to MT (camt.109.001.01 to MT112) Translation Example

This example demonstrates the CBPR MX to MT (camt.109.001.01 to MT112) message translation using flow server.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT112 message output from a CBPR+ camt.109.001.01 XML message.

---

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_109\_valid.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_109.xsd
    - camt.109.001.01.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2640\_camt109\_framework
    - cbpr2641\_camt109\_translate
    - cbpr2642\_camt109\_mt112
    - cbpr2501\_mxmt\_setvarlog
  - Flows:
    - cbpr\_camt109\_mt112
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-*mt* translation will use the sample files to demonstrate the generation of SWIFT MT112 message output from a CBPR+ camt.109.001.01 XML message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlxlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart** <brand>-server.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart** <brand>-server.

This example may generate failure in the audit.log.json log file to report the translation failure, if input message is not camt.109.001.01

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_camt109\_mt112.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
    - @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_camt109\_translate/cbpr2641\_camt109\_translate
    - @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_camt109\_mt112/cbpr2642\_camt109\_mt112
    - @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog
  - b. It utilizes the following nodes:
    - i. Source Node
      - camt\_109

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
    - ii. Map Node
      - mx\_translate

Runs framework map cbpr2640\_camt109\_framework, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).

iii. Target Node

- mt112  
This node contains the resulting translation in MT format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.

iv. Log Node

- audit\_log  
This node creates a log file specified by the flow variable AUDIT\_LOG.

c. It utilizes the following flow variables:

- INPUT\_FILE  
Default value for the flow variable INPUT\_FILE is ..../cbpr\_plus/translation/mx-mt/data/env\_camt\_109\_valid.xml. This is the data file to be used for translation and can be customized. It is used in the Source node camt\_109.
- OUTPUT\_RESULT\_MT  
Default value for the flow variable OUTPUT\_RESULT\_MT is mt112.out. This is the location of the output file in mt format. It is used in the Target node mt112. It can be customized.
- AUDIT\_LOG  
Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
- CONFIG\_FILE  
Default value for the flow variable CONFIG\_FILE is ..../cbpr\_plus/translation/mx-mt/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_camt109\_mt112 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.

4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.

- [\*\*Run the example using three different methods\*\*](#)

You can run the example using three different methods:

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- [\*\*Run the example from the Design Server user interface\*\*](#)

Use the following steps to run the example from the Design Server user interface.

- [\*\*Run the example using the Swagger interface\*\*](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

- [\*\*Run the example using the flow command server process \(flowcmdserver\)\*\*](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface.

1. In the Design Server, open cbpr\_camt109\_mt112 flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_camt\_109\_valid.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see the cbpr\_camt109\_mt112 section having two actions: A PUT /v2/run/cbpr\_camt109\_mt112 and a POST /v2/run/cbpr\_camt109\_mt112.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_camt_109_valid.xml",
 "OUTPUT_RESULT_MT": "C:/tests_dir/data/mt112.txt",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json. There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_camt109_mt112.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_109_valid.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_109_112.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_109_112_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_camt_109_112_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

 Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
 The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\cbpr_plus\\\\translation\\\\mx-
mt\\\\data\\\\env_camt_109_112_adt.json"
 Flow completed successfully
 Elapsed time: 3048ms
```

5. Examine the flow output result file env\_camt\_109\_112.out and the audit file env\_camt\_109\_112\_adt.json.

## CBPR+ MX to MT (pacs.002.001.10 to MT199/MT299) Translation Example

This example demonstrates the CBPR+ MX to MT (pacs.002.001.10 to MT199/MT299) message translation using flow server.

- [What the example contains](#)  
Files included in this example are as follows:
- [How to run the example](#)  
This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT199 or MT299 message output from a CBPR pacs.002.001.10 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translator.zip
  - Files:
    - env\_pacs\_002\_199.xml
    - env\_pacs\_002\_299.xml
    - env\_pacs\_002\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_002.xsd
    - pacs.002.001.10.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2500\_pacs002\_framework
    - cbpr2502\_pacs002\_translate
    - cbpr2503\_pacs\_002\_mtn99
    - cbpr2501\_mxmt\_setvarlog
  - Flow:
    - cbpr\_pacs002\_mtn99
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-*mt* translation will use the sample files to demonstrate the generation of SWIFT MT199 or MT299 message output from a CBPR pacs.002.001.10 XML message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart** <brand>-server.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart** <brand>-server.

This example generates MT199 or MT299 based on the <OrgnlMsgNmId> which could be pacs.008 or MT103 (will generate MT199) or pacs.009 or MT202 or MT205 (will generate MT299).

Also, may generate failure in the audit.log.json log file to report the translation failure due to the pre-conversion checks:

**Either <OrgnlMsgNmId> is not one of these ("pacs.008", "MT103", "pacs.009", "MT202", "MT205") or <TxSts> "transaction status" is not "RJCT".**

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_pacs002\_mtn99.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
    - @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_pacs002\_translate/cbpr2502\_pacs002\_translate
    - @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_pacs002\_mtn99/cbpr2503\_pacs\_002\_mtn99
    - @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog
  - b. It utilizes the following nodes:
    - i. Source Node
      - pacs\_002

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
    - ii. Map Node
      - mx\_translate

Runs framework map cbpr2500\_pacs002\_framework, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).
    - iii. Target Node
      - mtn99

This node contains the resulting translation in MT format (mt199.out or mt299.out) and creates the output as defined by the variable OUTPUT\_RESULT\_MT.
    - iv. Log Node
      - audit\_log

This node creates a log file specified by the flow variable AUDIT\_LOG.
  - c. It utilizes the following flow variables:
    - INPUT\_FILE

Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mx-*mt*/data/env\_pacs\_002\_199.xml. This is the data file to be used for translation and can be customized. It is used in the Source node pacs\_002

    - OUTPUT\_RESULT\_MT

Default value for the flow variable OUTPUT\_RESULT\_MT is mtn99.out. This is the location of the output file in mt format. It is used in the Target nodes mt199 or mt299 . It can be customized.

- AUDIT\_LOG  
Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
- CONFIG\_FILE  
Default value for the flow variable CONFIG\_FILE is ../cbpr\_plus/translation/mx-mlt/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_pacs002\_mtn99 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.
4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.

- **[Run the example using three different methods](#)**

You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- **[Run the example from the Design Server user interface](#)**

Use the following steps to run the example from the Design Server user interface:

- **[Run the example using the Swagger interface](#)**

To run the example, deploy to tx-rest and run it using the Swagger interface.

- **[Run the example using the flow command server process \(flowcmdserver\)](#)**

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_pacs002\_mtn99 flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_pacs\_002\_199.xml or env\_pacs\_002\_299.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see the cbpr\_pacs002\_mtn99 section having two actions: A PUT /v2/run/cbpr\_pacs002\_mtn99 and a POST /v2/run/cbpr\_pacs002\_mtn99.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_pacs_002_199.xml",
 "OUTPUT_RESULT_MTL": "C:/tests_dir/data/mtl99.out",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.

7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_pacs002_mt99.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_002_199.xml"
--var "OUTPUT_RESULT_MF=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_002_n99.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_002_n99_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_002_n99_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\ftpserver\\deployment\\cbpr_plus\\translation\\mx-
mt\\data\\env_pacs_002_n99_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file env\_pacs\_002\_199.out and the audit file env\_pacs\_002\_n99\_adt.json.

## CBPR+ MX to MT (pacs.004.001.09 to MTnnnRETN) Translation Example

This example demonstrates the CBPR MX to MT (pacs.004.001.09 to MTnnnRETN) message translation using flow server.

- [What the example contains](#)  
Files included in this example are as follows:
- [How to run the example](#)  
This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MTnnn RETN message output from a CBPR pacs.004.001.09 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_pacs\_004\_mt202rtn\_valid.xml
    - env\_pacs\_004\_mt205rtn\_valid.xml
    - env\_pacs\_004\_mt103rtn\_valid.xml
    - env\_pacs\_004\_mt202rtn\_bad.xml
    - env\_pacs\_004\_mt205rtn\_bad.xml
    - env\_pacs\_004\_mt103rtn\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_004.xsd
    - pacs.004.001.09.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2850\_pacs004\_mtnnn\_RTN\_frw
    - cbpr2851\_pacs004RTN\_trx
    - cbpr2852\_pacs004\_mt202RTN
    - cbpr2853\_pacs004\_mt205RTN
    - cbpr2857\_pacs004\_mt103RTN
    - cbpr2501\_mxmt\_setvarlog
  - Flow:
    - cbpr\_pacs004\_mtnnnRTN
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MTnnn RETN message output from a CBPR pacs.004.001.09 XML message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart <brand>-server**.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart <brand>-server**.

This example generates failure in the audit.log.json log file to report the translation failure due to the pre-conversion checks:

```
<IntrBkSttlmAmt>Commodities currencies {XAU, XAG, XPD, XPT} Not allowed in Field 32A and 32B.
Count of <TxInf> is greater than one.
<RtrChain><Dbtr><Pty> is present
<RtrChain><Cdtr><Pty> is present
```

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_pacs004\_mtnnnRTN flow.

a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:

- @packagemap=cbpr\_plus/translation/mx-ml/maps/cbpr\_t9n\_mx\_pacs004\_translate/cbpr2851\_pacs004RTN\_trx
- @packagemap=cbpr\_plus/translation/mx-ml/maps/cbpr\_t9n\_mx\_pacs004\_mt20nRTN/cbpr2852\_pacs004\_mt202RTN
- @packagemap=cbpr\_plus/translation/mx-ml/maps/cbpr\_t9n\_mx\_pacs004\_mt20nRTN/cbpr2853\_pacs004\_mt205RTN
- @packagemap=cbpr\_plus/translation/mx-ml/maps/cbpr\_t9n\_mx\_pacs004\_mt103RTN/cbpr2857\_pacs004\_mt103RTN
- @packagemap=cbpr\_plus/translation/mx-ml/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog

b. It utilizes the following nodes:

i. Source Node

- pacs\_004  
This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.

ii. Map Node

- mx\_translate  
Runs framework map ccbpr2850\_pacs004\_mtnnnRTN\_frw, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).

iii. Target Node

- mtnnnRTN  
This node contains the resulting translation in MT format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.

iv. Log Node

- audit\_log  
This node creates a log file specified by the flow variable AUDIT\_LOG.

c. It utilizes the following flow variables:

- INPUT\_FILE

Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mx-ml/data/env\_pacs\_004\_mt202rtn\_valid.xml. This is the data file to be used for translation and can be customized. It is used in the Source node pacs\_004.

- OUTPUT\_RESULT\_MT

Default value for the flow variable OUTPUT\_RESULT\_MT is mt20nRTN.out. This is the location of the output file in mt format. It can be customized.

- AUDIT\_LOG

Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.

- CONFIG\_FILE

Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mx-ml/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_pacs004\_mtnnnRTN in the Design Server. It utilizes one source node, one map node, one log node, and one target node.

4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.

- **[Run the example using three different methods](#)**

You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- **[Run the example from the Design Server user interface](#)**

Use the following steps to run the example from the Design Server user interface:

- **[Run the example using the Swagger interface](#)**

To run the example, deploy to tx-rest and run it using the Swagger interface.

- **[Run the example using the flow command server process \(flowcmdserver\)](#)**

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_pacs004\_mtnnnRTN flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_pacs\_004\_mt202rtn\_valid.xml or env\_pacs\_004\_mt202rtn\_bad.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.

2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.

3. Deploy the created package to the server definition in Design Server.

4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.

5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.

You can see the cbpr\_pacs004\_mtnnnRTN section having two actions: A PUT /v2/run/cbpr\_pacs004\_mtnnnRTN and a POST /v2/run/cbpr\_pacs004\_mtnnnRTN.

6. In the PUT action:

a. Expand the PUT action and select the Try it out button.

b. Leave the input and output sections empty.

c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_pacs_004_mt202rtn_valid.xml",
 "OUTPUT_RESULT_MT": "C:/tests_dir/data/mt202RTN.out",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.

7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.

There will be a DELETE /v2/packages/{name} action.

8. Expand the DELETE /v2/packages/{name} action and select the Try it out.

9. In the Name field, enter the name you gave it to the created package.

10. Select the true option from the stop query drop down, select the blue Execute bar.

You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition.

3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_pacs004_mtnnnRTN.json
-var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_004_mt202rtn_valid.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_004_mt202rtn_valid.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_004_mt202rtn_valid_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_004_mt202rtn_valid_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server
```

```

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\cbpr_plus\\\\translation\\\\mx-
mt\\\\data\\\\env_pacs_004_mt202rtn_valid_adt.json"
Flow completed successfully
Elapsed time: 3048ms

```

5. Examine the flow output result file env\_pacs\_004\_mt202rtn\_valid.out and the audit file env\_pacs\_004\_mt202rtn\_valid\_adt.json.

## CBPR+ MX to MT (pacs.008.001.08 to MT103) Translation Example

This example demonstrates the CBPR+ MX to MT (pacs.008.001.08 to MT103) message translation using flow server.

- [What the example contains](#)**

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_pacs\_008\_103.xml
    - env\_pacs\_008\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_008.xsd
    - pacs.008.001.08.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2700\_pacs008\_framework
    - cbpr2701\_pacs008\_translate
    - cbpr2709\_pacs008\_stp\_translate
    - cbpr2703\_pacs008\_mt103
    - cbpr2704\_pacs008\_mt103\_sgo
    - cbpr2501\_mxmt\_setvarlog
  - Flow:
    - cbpr\_pacs008\_mt103
- cbprJnodesConfigIBM.tar.gz

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_pacs\_008\_103.xml
    - env\_pacs\_008\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_008.xsd
    - pacs.008.001.08.xsd
    - trx\_config.xsd
    - infoset.mtt

    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2700\_pacs008\_framework
    - cbpr2701\_pacs008\_translate
    - cbpr2709\_pacs008\_stp\_translate
    - cbpr2703\_pacs008\_mt103
    - cbpr2704\_pacs008\_mt103\_sgo
    - cbpr2501\_mxmt\_setvarlog
  - Flow:
    - cbpr\_pacs008\_mt103
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-translation will use the sample files to demonstrate the generation of SWIFT MT103 message output from a CBPR pacs.008.001.08 XML message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart** <brand>-server.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart** <brand>-server.

This example may generate failure in the audit.log.json log file to report the translation failure due to the pre-conversion checks:

```
<IntrBkSttlmAmt> Commodities currencies {XAU, XAG, XPD, XPT} Not allowed in Field 32A and 32B.
```

1. Import the cbpr\_translation.zip project into the Design Server.
  2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_pacs008\_mt103.
    - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
      - @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_pacs008\_translate/cbpr2701\_pacs008\_translate
      - @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_pacs008\_stp\_translate/cbpr2709\_pacs008\_stp\_translate
      - @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_pacs008\_mt103/cbpr2703\_pacs008\_mt103
      - @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_pacs008\_mt103\_sgo/cbpr2704\_pacs008\_mt103\_sgo
      - @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog
    - b. It utilizes the following nodes:
      - i. Source Node
        - pacs\_008
 

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
      - ii. Map Node
        - mx\_translate
 

Runs framework map cbpr2700\_pacs008\_framework, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).
      - iii. Target Node
        - mt103
 

This node contains the resulting translation in MT format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.
      - iv. Log Node
        - audit\_log
 

This node creates a log file specified by the flow variable AUDIT\_LOG.
  - c. It utilizes the following flow variables:
    - INPUT\_FILE
 

Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mx-mt/data/env\_pacs\_008\_103.xml. This is the data file to be used for translation and can be customized. It is used in the Source node pacs\_008.
    - OUTPUT\_RESULT\_MT
 

Default value for the flow variable OUTPUT\_RESULT\_MT is mt103.out. This is the location of the output file in mt format. It is used in the Target node mt103. It can be customized.
    - AUDIT\_LOG
 

Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
    - CONFIG\_FILE
 

Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mx-mt/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.
  3. Open the flow cbpr\_pacs008\_mt103 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.
  4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.
- **[Run the example using three different methods](#)**

You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- **[Run the example from the Design Server user interface](#)**

Use the following steps to run the example from the Design Server user interface:

- **[Run the example using the Swagger interface](#)**

To run the example, deploy to tx-rest and run it using the Swagger interface.

- **[Run the example using the flow command server process \(flowcmdserver\)](#)**

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_pacs008\_mt103 flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_pacs\_008\_103.xml or env\_pacs\_008\_bad.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable. Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see the cbpr\_pacs008\_mt103 section having two actions: A PUT /v2/run/cbpr\_pacs008\_mt103 and a POST /v2/run/cbpr\_pacs008\_mt103.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_pacs_008_103.xml",
 "OUTPUT_RESULT_MT": "C:/tests_dir/data/mt103.out",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```
- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_pacs008_mt103.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_008_103.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_008_103.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_008_103_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_008_103_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\cbpr_plus\\\\translation\\\\mx-
mt\\\\data\\\\env_pacs_008_103_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file env\_pacs\_008\_103.out and the audit file env\_pacs\_008\_103\_adt.json.

## CBPR+ MX to MT (pacs.009.001.08 to MT202) Translation Example

This example demonstrates the CBPR+ MX to MT (pacs.009.001.08 to MT202) message translation using flow server.

- [What the example contains](#)

Files included in this example are as follows:

- [How to run the example](#)

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT202 message output from a CBPR pacs.009.001.08 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_pacs\_009\_mt202cor\_valid.xml
    - env\_pacs\_009\_cor\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_009.xsd
    - pacs.009.001.08.xsd
    - trx\_config.xsd
    - infoSet.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2710\_pacs009\_mt202\_framework
    - cbpr2713\_pacs009\_mt202adv\_trx
    - cbpr2714\_pacs009\_mt202cov\_trx
    - cbpr2712\_pacs009\_mt202\_trx
    - cbpr2715\_pacs009\_mt202
    - cbpr2501\_mxmt\_setvarlog
  - Flow:
    - cbpr\_pacs009\_mt202
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT202 message output from a CBPR pacs.009.001.08 XML message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txls:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart <brand>-server**.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart <brand>-server**.

This example may generate failure in the audit.log.json log file to report the translation failure due to the pre-conversion checks:

```
<IntrBkSttlmAmt> Commodities currencies {XAU, XAG, XPD, XPT} Not allowed in Field 32A and 32B.
Count of <CdtTrfTxInf> is greater than one
```

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_pacs009\_mt202.

a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:

- @packagemap=cbpr\_plus/translation/mx-xt/translation/mx-xt/maps/cbpr\_t9n\_mx\_pacs009\_adv\_translate/cbpr2713\_pacs009\_mt202adv\_trx
- @packagemap=cbpr\_plus/translation/mx-xt/translation/mx-xt/maps/cbpr\_t9n\_mx\_pacs009\_cov\_translate/cbpr2714\_pacs009\_mt202cov\_trx

- @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_pacs009\_translate/cbpr2712\_pacs009\_mt202\_trx
  - @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_pacs009\_mt20n/cbpr2715\_pacs009\_mt202
  - @packagemap=cbpr\_plus/translation/mx-mt/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog
- b. It utilizes the following nodes:
- i. Source Node
    - pacs\_009
 

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
  - ii. Map Node
    - mx\_translate
 

Runs framework map cbpr2710\_pacs009\_mt202\_framework, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).
  - iii. Target Node
    - mt202
 

This node contains the resulting translation in MT format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.
  - iv. Log Node
    - audit\_log
 

This node creates a log file specified by the flow variable AUDIT\_LOG.
- c. It uses the following flow variables:
- INPUT\_FILE
 

Default value for the flow variable INPUT\_FILE is ..../cbpr\_plus/translation/mx-mt/data/env\_pacs\_009\_mt202cor\_valid.xml. This is the data file to be used for translation and can be customized. It is used in the Source node pacs\_009.
  - OUTPUT\_RESULT\_MT
 

Default value for the flow variable OUTPUT\_RESULT\_MT is mt202.out. This is the location of the output file in mt format. It is used in the Target node mt202. It can be customized.
  - AUDIT\_LOG
 

Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
  - CONFIG\_FILE
 

Default value for the flow variable CONFIG\_FILE is ..../cbpr\_plus/translation/mx-mt/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_pacs009\_mt202 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.
  4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.
- [\*\*Run the example using three different methods\*\*](#)  
You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
  2. Deploying the example to tx-rest and running it using the Swagger interface.
  3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).
- [\*\*Run the example from the Design Server user interface\*\*](#)  
Use the following steps to run the example from the Design Server user interface:
  - [\*\*Run the example using the Swagger interface\*\*](#)  
To run the example, deploy to tx-rest and run it using the Swagger interface.
  - [\*\*Run the example using the flow command server process \(flowcmdserver\)\*\*](#)  
To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_pacs009\_mt202 flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_pacs\_009\_mt202cor\_valid.xml or env\_pacs\_009\_cor\_bad.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see the cbpr\_pacs009\_mt202 section having two actions: A PUT /v2/run/cbpr\_pacs009\_mt202 and a POST /v2/run/cbpr\_pacs009\_mt202.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_pacs_009_mt202cor_valid.xml",
 "OUTPUT_RESULT_MT": "C:/tests_dir/data/mt202.out",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```
- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_pacs009_mt202.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_009_mt202cor_valid.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_009_mt202cor_valid.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_009_mt202cor_valid_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_009_mt202cor_valid_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\ftpserver\\deployment\\\\cbpr_plus\\\\translation\\\\mx-
mt\\\\data\\\\env_pacs_009_mt202cor_valid_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file env\_pacs\_009\_cor\_valid.out and the audit file env\_pacs\_009\_mt202cor\_valid\_adt.json.

## CBPR+ MX to MT (pacs.009.001.08 to MT205) Translation Example

This example demonstrates the CBPR+ MX to MT (pacs.009.001.08 to MT205) message translation using flow server.

- **What the example contains**  
Files included in this example are as follows:
- **How to run the example**  
This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT205 message output from a CBPR pacs.009.001.08 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_pacs\_009\_mt205cor\_valid.xml
    - env\_pacs\_009\_cor\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_009.xsd
    - pacs.009.001.08.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt

- Maps:
    - cbpr2724\_pacs009\_mt205\_framework
    - cbpr2725\_pacs009\_mt205\_trx
    - cbpr2726\_pacs009\_mt205cov\_trx
    - cbpr2727\_pacs009\_mt205
    - cbpr2501\_mxmt\_setvarlog
  - Flow:
    - cbpr\_pacs009\_mt205
  - cbprJnodesConfigIBM.tar.gz
- 

## How to run the example

This mx-*mt* translation will use the sample files to demonstrate the generation of SWIFT MT205 message output from a CBPR pacs.009.001.08 XML message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlxlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart <brand>-server**.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart <brand>-server**.

This example may generate failure in the audit.log.json log file to report the translation failure due to the pre-conversion checks:

```
<IntrBkSttlMntAmt>Commodities currencies {XAU, XAG, XPD, XPT} Not allowed in Field 32A and 32B.
Count of <CdtTrfTxInf> is greater than one.
```

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_pacs009\_mt205.

a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:

- @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_pacs009\_translate/cbpr2725\_pacs009\_mt205\_trx
- @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_pacs009\_cov\_translate/cbpr2726\_pacs009\_mt205cov\_trx
- @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_pacs009\_mt20n/cbpr2727\_pacs009\_mt205
- @packagemap=cbpr\_plus/translation/mx-*mt*/maps/cbpr\_t9n\_mx\_setvarlog/cbpr2501\_mxmt\_setvarlog

b. It utilizes the following nodes:

i. Source Node

- pacs\_009

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.

ii. Map Node

- mx\_translate

Runs framework map cbpr2724\_pacs009\_mt205\_framework, checks pre-translation conditions and translates the input file (mx or xml) into required output (mt).

iii. Target Node

- mt205

This node contains the resulting translation in MT format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.

iv. Log Node

- audit\_log

This node creates a log file specified by the flow variable AUDIT\_LOG.

c. It utilizes the following flow variables:

- INPUT\_FILE  
Default value for flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mx-mlt/data/env\_pacs\_009\_mt205cor\_valid.xml. This is the data file to be used for translation and can be customized. It is used in the Source node pacs\_009.
- OUTPUT\_RESULT\_MTLT  
Default value for the flow variable OUTPUT\_RESULT\_MTLT is mt205.out. This is the location of the output file in mt format. It is used in the Target node mt205. It can be customized.
- AUDIT\_LOG  
Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
- CONFIG\_FILE  
Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mx-mlt/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_pacs009\_mt205 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.

4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.

- [Run the example using three different methods](#)

You can run the example using three different methods:

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- [Run the example from the Design Server user interface](#)

Use the following steps to run the example from the Design Server user interface:

- [Run the example using the Swagger interface](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

- [Run the example using the flow command server process \(flowcmdserver\)](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_pacs009\_205 flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file env\_pacs\_009\_mt205cor\_valid.xml or env\_pacs\_009\_cor\_bad.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see the cbpr\_pacs009\_mt205 section having two actions: A PUT /v2/run/cbpr\_pacs009\_mt205 and a POST /v2/run/cbpr\_pacs009\_mt205.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/env_pacs_009_mt205cor_valid.xml",
 "OUTPUT_RESULT_MTLT": "C:/tests_dir/data/mt205.out",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.

8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_pacs009_mt205.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_009_mt205cor_valid.xml"
--var "OUTPUT_RESULT_MT=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_009_mt205cor_valid.out"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_009_mt205cor_valid_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mx-mt\data\env_pacs_009_mt205cor_valid_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server
Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\cbpr_plus\\\\translation\\\\mx-
mt\\\\data\\\\env_pacs_009_mt205cor_valid_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file env\_pacs\_009\_205cor\_valid.out and the audit file env\_pacs\_009\_mt205cor\_valid\_adt.json.

## CBPR+ MT to MX (MT900/MT910 to camt.054.001.08) Translation Example

This example demonstrates the CBPR+ MT to MX (MT900/MT910 to camt.054.001.08) message translation using flow server.

- **[What the example contains](#)**

Files included in this example are as follows:

- **[How to run the example](#)**

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ camt.054.001.08 XML message output from a SWIFT MT900 or MT910 message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - MT900.inp
    - MT910.inp
  - Schemas:
    - head.001.001.02\_camt\_054.xsd
    - camt.054.001.08.xsd
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
    - infoset.mtt
  - Maps:
    - cbpr1500\_mt9n0\_framework
    - cbpr1501\_mt9n0\_camt\_054
    - cbpr1502\_mtmx\_setvarlog
  - Flow:
    - cbpr\_mt9n0\_camt054
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ camt.054.001.08 XML message output from a SWIFT MT900 or MT910 message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart <brand>-server**.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart <brand>-server**.

This example may generate failure in the audit.log.json log file to report the translation failure due to the pre-conversion checks:

**If input file is SWIFT message other than MT900 or MT910 or not a SWIFT message.**

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_mt9n0\_camt054.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
    - @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt9n0\_camt054/cbpr1501\_mt9n0\_camt\_054
    - @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt\_setvarlog/cbpr1502\_mtmx\_setvarlog
  - b. It utilizes the following nodes:
    - i. Source Node
      - mt\_9n0
 

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
    - ii. Map Node
      - mt\_translate
 

Runs map cbpr1500\_mt9n0\_framework which set flow variables, checks pre-translation conditions and translates the input file (mt) into required output (XML).
    - iii. Target Node
      - camt.054
 

This node contains the resulting translation in XML format and creates the output as defined by the variable OUTPUT\_DOC\_RESULT\_XML.
    - iv. Log Node
      - audit\_log
 

This node creates a log file specified by the flow variable AUDIT\_LOG.
  - c. It utilizes the following flow variables:
    - INPUT\_FILE
 

Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mt-mx/data/MT900.inp. This is the data file to be used for translation and can be customized. It is used in the Source node mt\_9n0.
    - OUTPUT\_DOC\_RESULT\_XML
 

Default value for the flow variable OUTPUT\_DOC\_RESULT\_XML is env\_camt\_054\_out.xml. This is the location of the output file in mt format. It is used in the Target node camt.054. It can be customized.
    - AUDIT\_LOG
 

Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
    - CONFIG\_FILE
 

Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mt-mx/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.
3. Open the flow cbpr\_mt9n0\_camt054 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.
4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.
- **Run the example using three different methods**  
You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- [\*\*Run the example from the Design Server user interface\*\*](#)

Use the following steps to run the example from the Design Server user interface:

- [\*\*Run the example using the Swagger interface\*\*](#)
- [\*\*Run the example using the flow command server process \(flowcmdserver\)\*\*](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_mt9n0\_camt054 flow and click on Run button.

2. Set toggle switch Run On Design Server and select SWIFT MT message input file MT900.inp/MT910.inp .

Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.

Flow will run and report with the green check box. The report lists execution of all nodes.

3. Right click and select View Data on each link to examine the data.

4. Right click on the node and select View Log to see the logs.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.

2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.

3. Deploy the created package to the server definition in Design Server.

4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.

5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.

You should see a cbpr\_mt9n0\_camt054 section having two actions: A PUT /v2/run/cbpr\_mt9n0\_camt054 and a POST /v2/run/cbpr\_mt9n0\_camt054.

6. In the PUT action:

- a. Expand the PUT action and select the Try it out button.

- b. Leave the input and output sections empty.

- c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/MT900.inp",
 "OUTPUT_DOC_RESULT_XML": "C:/tests_dir/data/env_camt_054_out.xml",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.

7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.

There will be a DELETE /v2/packages/{name} action.

8. Expand the DELETE /v2/packages/{name} action and select the Try it out.

9. In the Name field, enter the name you gave it to the created package.

10. Select the true option from the stop query drop down, select the blue Execute bar.

You can see a response of 204 with a timestamp, if it is successful.

---

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.

2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.

3. Execute the flow using the flow command server. In below example, command is for SWIFT message MT900.inp.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_mt9n0_camt054.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\MT900.inp"
--var "OUTPUT_DOC_RESULT_XML=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\camt_054_001_08.xml"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\camt_054_001_08_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\cbpr_mt9n0_camt054_adt.json"
-ad
```

4. The flow will report status similar to:

```
***Starting flow command server
Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\ftpserver\\\\deployment\\\\cbpr_plus\\\\translation\\\\mt-
mx\\\\data\\\\cbpr_mt9n0_camt054_adt.json"
```

```
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file cbpr\_mt9n0\_camt054\_adt.out and the audit file cbpr\_mt9n0\_camt054\_adt.json.

## CBPR+ MT to MX (MT192/MT292 to camt.056.001.08) Translation Example

This example demonstrates the CBPR+ MT to MX (MT192/MT292 to camt.056.001.08) message translation using flow server.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ camt.056.001.08 XML message output from a SWIFT MT192 or MT292 message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - MT192.inp
    - MT292.inp
  - Schemas:
    - head.001.001.02\_camt\_056.xsd
    - camt.056.001.08.xsd
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
    - infoset.mtt
  - Maps:
    - cbpr2840\_mtn92\_framework
    - cbpr2841\_mtn92\_camt056
    - cbpr1502\_mtmx\_setvarlog
  - Flow:
    - cbpr\_mtn92\_camt056
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ camt.056.001.08 XML message output from a SWIFT MT192 or MT292 message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlbs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart <brand>-server**.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart** <brand>-server.

This example may generate failure in the audit.log.json log file to report the translation failure due to the pre-conversion checks:

**If input file is SWIFT message other than MT192 or MT292 or not a SWIFT message.**

1. Import the cbpr\_translation.zip project into the Design Server.
  2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_mtn92\_camt056.
    - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
      - @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mtn92\_camt056/cbpr2841\_mtn92\_camt056
      - @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt\_setvarlog/cbpr1502\_mtmx\_setvarlog
    - b. It utilizes the following nodes:
      - i. Source Node
        - mt\_n92

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
      - ii. Map Node
        - mt\_translate

Runs map cbpr2840\_mtn92\_framework which sets flow variables, checks pre-translation conditions and translates the input file (mt) into required output (XML).
      - iii. Target Node
        - camt.056

This node contains the resulting translation in XML format and creates the output as defined by the variable OUTPUT\_DOC\_RESULT\_XML.
      - iv. Log Node
        - audit\_log

This node creates a log file specified by the flow variable AUDIT\_LOG.
  - c. It uses the following flow variables:
    - INPUT\_FILE  
Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mt-mx/data/MT192.inp. This is the data file to be used for translation and can be customized. It is used in the Source node mt\_n92.
    - OUTPUT\_DOC\_RESULT\_XML  
Default value for the flow variable OUTPUT\_DOC\_RESULT\_XML is camt\_056\_out.xml. This is the location of the output file in mt format. It is used in the Target node camt.056. It can be customized.
    - AUDIT\_LOG  
Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
    - CONFIG\_FILE  
Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mt-mx/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.
  3. Open the flow cbpr\_mtn92\_camt056 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.
  4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.
- **[Run the example using three different methods](#)**  
You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
  2. Deploying the example to tx-rest and running it using the Swagger interface.
  3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).
- **[Run the example from the Design Server user interface](#)**  
Use the following steps to run the example from the Design Server user interface:
  - **[Run the example using the Swagger interface](#)**  
To run the example, deploy to tx-rest and run it using the Swagger interface.
  - **[Run the example using the flow command server process \(flowcmdserver\)](#)**  
To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_mtn92\_camt056 flow and click on Run button.
2. Set toggle switch Run On Design Server and select SWIFT MT message input file MT192.inp/MT292.inp .  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.

3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You should see a cbpr\_mtn92\_camt056 section having two actions: A PUT /v2/run/cbpr\_mtn92\_camt056 and a POST /v2/run/cbpr\_mtn92\_camt056.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/MT192.inp",
 "OUTPUT_DOC_RESULT_XML": "C:/tests_dir/data/camt_056_001_08.xml",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```
- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json. There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. In below example, command is for SWIFT message MT192.inp.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_mtn92_camt056.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\MT192.inp"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\camt_056_001_08_log.json"
--var "OUTPUT_DOC_RESULT_XML=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\camt_056_001_08.xml"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\cbpr_mtn92_camt056_adt.json"
-ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\ftpserver\\deployment\\cbpr_plus\\\\translation\\\\mt-
mx\\\\data\\\\cbpr_mtn92_camt056_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file cbpr\_mt192\_camt056.out and the audit file cbpr\_mtn92\_camt056\_adt.json.

## CBPR+ MT to MX (MT196/MT296 to camt.029.001.09) Translation Example

This example demonstrates the CBPR+ MT to MX (MT196/MT296 to camt.029.001.09) message translation using flow server.

- [What the example contains](#)  
Files included in this example are as follows:
- [How to run the example](#)  
This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ camt.029.001.09 XML message output from a SWIFT MT196 or MT296 message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - MT196.inp
    - MT296.inp
    - MT196\_bad.inp
  - Schemas:
    - head.001.001.02\_camt\_029.xsd
    - camt.029.001.09.xsd
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
    - infoset.mtt
  - Maps:
    - cbpr2820\_mtn96\_framework
    - cbpr2821\_mtn96\_camt029
    - cbpr1502\_mttx\_setvarlog
  - Flow:
    - cbpr\_mtn96\_camt029
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ camt.029.001.09 XML message output from a SWIFT MT196 or MT296 message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart** <brand>-server.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart** <brand>-server.

This example may generate failure in the audit.log.json file to report the translation failure due to the pre-conversion checks:

**If input file is SWIFT message other than MT196 or MT296 or not a SWIFT message.**

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_mtn96\_camt029.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
    - @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mtn96\_camt029/cbpr2821\_mtn96\_camt029
    - @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt\_setvarlog/cbpr1502\_mttx\_setvarlog
  - b. It utilizes the following nodes:
    - i. Source Node
      - mt\_n96
 

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
    - ii. Map Node
      - mt\_translate
 

Runs framework map cbpr2820\_mtn96\_framework, checks pre-translation conditions and translates the input file (mt) into required output (XML).
    - iii. Target Node

- camt.029  
This node contains the resulting translation in XML format and creates the output as defined by the variable OUTPUT\_DOC\_RESULT\_XML.

iv. Log Node

- audit\_log  
This node creates a log file specified by the flow variable AUDIT\_LOG.

c. It utilizes the following flow variables:

- INPUT\_FILE  
Default value for the flow variable INPUT\_FILE is ..\cbpr\_plus\translation\mt-mx\data\MT196.inp. This is the data file to be used for translation and can be customized. It is used in the Source node mt\_n96.
- OUTPUT\_DOC\_RESULT\_XML  
Default value for the flow variable OUTPUT\_DOC\_RESULT\_XML is camt\_029\_out.xml. This is the location of the output file in mt format. It is used in the Target node camt.029. It can be customized.
- AUDIT\_LOG  
Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
- CONFIG\_FILE  
Default value for the flow variable CONFIG\_FILE is ..\cbpr\_plus\translation\mx-mt\data\trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_mtn96\_camt029 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.

4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.

**• [Run the example using three different methods](#)**

You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

**• [Run the example from the Design Server user interface](#)**

Use the following steps to run the example from the Design Server user interface:

**• [Run the example using the Swagger interface](#)**

To run the example, deploy to tx-rest and run it using the Swagger interface.

**• [Run the example using the flow command server process \(flowcmdserver\)](#)**

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_mtn96\_camt029 flow and click on Run button.
2. Set toggle switch Run On Design Server and select SWIFT MT message input file MT196.inp/MT296.inp .  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You should see a cbpr\_mtn96\_camt029 section having two actions: A PUT /v2/run/cbpr\_mtn96\_camt029 and a POST /v2/run/cbpr\_mtn96\_camt029.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/MT196.inp",
 "OUTPUT_DOC_RESULT_XML": "C:/tests_dir/data/camt_029_001_09.xml",
```

```
"AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

---

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. In below example, command is for SWIFT message MT196.inp.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_mtn96_camt029.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\MT196.inp"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\camt_029_001_09_log.json"
--var "OUTPUT_DOC_RESULT_XML=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\camt_029_001_09.xml"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\cbpr_mtn96_camt029_adt.json"
-ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\cbpr_plus\\\\translation\\\\mt-
mx\\\\data\\\\cbpr_mtn96_camt029_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file cbpr\_mt196\_camt029.out and the audit file cbpr\_mtn96\_camt029\_adt.json.

---

## CBPR+ MT to MX (MT103 to pacs.008.001.08 or MT103 RETN to pacs.004.001.09) Translation Example

This example demonstrates the CBPR+ MT to MX (MT103 to pacs.008.001.08 or MT103 RETN to pacs.004.001.09) message translation using flow server.

- [What the example contains](#)  
Files included in this example are as follows:
- [How to run the example](#)  
This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ pacs.008.001.08 / pacs.004.001.09 XML message output from a SWIFT MT103 / MT103 RETN message.

---

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - MT103.inp
    - MT103\_RETN.inp
  - Schemas:
    - head.001.001.02\_pacs\_008.xsd
    - pacs.008.001.08.xsd
    - head.001.001.02\_pacs\_004.xsd
    - pacs.004.001.09.xsd
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
    - infoset.mtt
  - Maps:
    - cbpr2800\_mt103\_framework
    - cbpr2801\_mt103\_pacs008
    - cbpr2799\_mt103\_pacs004
    - cbpr2805\_mt103\_pacs008\_sgo
    - cbpr1502\_mt103\_setvarlog
  - Flow:
    - cbpr\_mt103\_pacs008
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ pacs.008.001.08 / pacs.004.001.09 XML message output from a SWIFT MT103 / MT103 RETN message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlxlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart <brand>-server**.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart <brand>-server**.

This example may generate failure in the audit.log.json log file to report the translation failure if the input file is a SWIFT message other than MT103 or not a SWIFT message.

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_mt103\_pacs00n.

a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:

- @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt103\_pacs008/cbpr2801\_mt103\_pacs008
- @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt103\_pacs004/cbpr2799\_mt103\_pacs004
- @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt103\_pacs008\_sgo/cbpr2805\_mt103\_pacs008\_sgo
- @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt\_setvarlog/cbpr1502\_mttx\_setvarlog

b. It utilizes the following nodes:

i. Source Node

- mt\_103

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.

ii. Map Node

- mt\_translate

Runs map cbpr2800\_mt103\_framework which sets flow variables, checks pre-translation conditions and translates the input file (mt) into required output (XML).

iii. Target Node

- pacs.00n

This node contains the resulting translation in XML format and creates the pacs.008 or pacs.004 output as defined by variable OUTPUT\_DOC\_RESULT\_XML.

iv. Log Node

- audit\_log

This node creates a log file specified by the flow variable AUDIT\_LOG.

c. It utilizes the following flow variables:

- INPUT\_FILE

Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mt-mx/data/MT103\_RETN.inp. This is the data file to be used for translation and can be customized. It is used in the Source node mt\_103.

- OUTPUT\_DOC\_RESULT\_XML

Default value for the flow variable OUTPUT\_DOC\_RESULT\_XML is pacs.00n.xml. This is the location of the output file in mt format. It is used in the Target node pacs.008 or pacs.004. It can be customized.

- AUDIT\_LOG

Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.

- **CONFIG\_FILE**

Default value for the flow variable CONFIG\_FILE is ..\cbpr\_plus\translation\mt-mx\data\trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_mt103\_pacs00n in the Design Server. It utilizes one source node, one map node, one log node, and one target node.
4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.

- **Run the example using three different methods**

You can run the example using three different methods:

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- **Run the example from the Design Server user interface**

Use the following steps to run the example from the Design Server user interface:

- **Run the example using the Swagger interface**

To run the example, deploy to tx-rest and run it using the Swagger interface.

- **Run the example using the flow command server process (flowcmdserver)**

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_mt103\_pacs00n flow and click on Run button.
2. Set toggle switch Run On Design Server and select SWIFT MT message input file MT103.inp.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You should see cbpr\_mt103\_pacs00n section having two actions: A PUT /v2/run/cbpr\_mt103\_pacs00n and a POST /v2/run/cbpr\_mt103\_pacs00n.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/MT103.inp",
 "OUTPUT_DOC_RESULT_XML": "C:/tests_dir/data/pacs_008_001_08.xml",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. In below example, command is for SWIFT message MT103.inp.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_mt103_pacs008.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\MT103.inp"
--var "OUTPUT_DOC_RESULT_XML=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\pacs_008_001_08.xml"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\pacs_008_001_08_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\cbpr_mt103_pacs008_adt.json"
-ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\cbpr_plus\\\\translation\\\\mt-
mx\\\\data\\\\cbpr_mt103_pacs008_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file cbpr\_mt103\_pacs008\_adt.out and the audit file cbpr\_mt103\_pacs008\_adt.json.

## CBPR+ MT to MX (MT103 SWIFTGo to pacs.008.001.08) Translation Example

This example demonstrates the CBPR+ MT to MX (MT103 SWIFTGo to pacs.008.001.08) message translation using flow server.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ pacs.008.001.08 XML message output from a MT103 SWIFTGo message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - MT103\_SGO.inp
  - Schemas:
    - head.001.001.02\_pacs\_008.xsd
    - pacs.008.001.08.xsd
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
    - infoset.mtt
  - Maps:
    - cbpr2808\_mt103sgo\_framework
    - cbpr2801\_mt103\_pacs008
    - cbpr2799\_mt103\_pacs004
    - cbpr2805\_mt103\_pacs008\_sgo
    - cbpr1502\_mtnx\_setvarlog
  - Flow:
    - cbpr\_mt103sgo\_pacs008
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ pacs.008.001.08 XML message output from a MT103 SWIFTGo message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart** <brand>-server.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart**<brand>-server.

This example may generate failure in the audit.log.json log file to report the translation failure if the input file is a SWIFT message other than MT103 or not a SWIFT message or Field 72, Line 1 starts with "/REJT/" OR "/RETN/".

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_mt103sgo\_pacs008.

a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:

- @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt103\_pacs008/cbpr2801\_mt103\_pacs008
- @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt103\_pacs004/cbpr2799\_mt103\_pacs004
- @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt103\_pacs008\_sgo/cbpr2805\_mt103\_pacs008\_sgo
- @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt\_setvarlog/cbpr1502\_mtmx\_setvarlog

b. It utilizes the following nodes:

i. Source Node

- mt\_103sgo

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.

ii. Map Node

- mt\_translate

Runs map cbpr2808\_mt103sgo\_framework which sets flow variables, checks pre-translation conditions and translates the input file (mt) into required output (XML).

iii. Target Node

- pacs.008

This node contains the resulting translation in XML format and creates the output as defined by the variable OUTPUT\_DOC\_RESULT\_XML.

iv. Log Node

- audit\_log

This node creates a log file specified by the flow variable AUDIT\_LOG.

c. It utilizes the following flow variables:

- INPUT\_FILE

Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mt-mx/data/MT103\_SGO.inp. This is the data file to be used for translation and can be customized. It is used in the Source node mt\_103sgo.

- OUTPUT\_DOC\_RESULT\_XML

Default value for the flow variable OUTPUT\_DOC\_RESULT\_XML is pacs\_008\_sgo.xml. This is the location of the output file in mt format. It is used in the Target node pacs.008. It can be customized.

- AUDIT\_LOG

Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.

- CONFIG\_FILE

Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mt-mx/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_mt103sgo\_pacs008 in the Design Server. It utilizes one source node, one map node, one log node, and one target node.

4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.

- **[Run the example using three different methods](#)**

You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- [Run the example from the Design Server user interface](#)

Use the following steps to run the example from the Design Server user interface:

- [Run the example using the Swagger interface](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

- [Run the example using the flow command server process \(flowcmdserver\)](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_mt103sgo\_pacs008 flow and click on Run button.
2. Set toggle switch Run On Design Server and select SWIFT MT message input file MT103\_SGO.inp.

Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.

Flow will run and report with the green check box. The report lists execution of all nodes.

3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.

3. Deploy the created package to the server definition in Design Server.

4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.

5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.

You should see a cbpr\_mt103sgo\_pacs008 section having two actions: A PUT /v2/run/cbpr\_mt103sgo\_pacs008 and a POST /v2/run/cbpr\_mt103sgo\_pacs008.

6. In the PUT action:

- a. Expand the PUT action and select the Try it out button.

- b. Leave the input and output sections empty.

- c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/MT103_SGO.inp",
 "OUTPUT_DOC_RESULT_XML": "C:/tests_dir/data/pacs_008_001_08.xml",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.

7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.

There will be a DELETE /v2/packages/{name} action.

8. Expand the DELETE /v2/packages/{name} action and select the Try it out.

9. In the Name field, enter the name you gave it to the created package.

10. Select the true option from the stop query drop down, select the blue Execute bar.

You can see a response of 204 with a timestamp, if it is successful.

---

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.

2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.

3. Execute the flow using the flow command server. In below example, command is for SWIFT message MT103\_SGO.inp.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_mt103sgo_pacs008.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\MT103_SGO.inp"
--var "OUTPUT_DOC_RESULT_XML=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\pacs_008_001_08.xml"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\pacs_008_001_08_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\cbpr_mt103sgo_pacs008_adt.json"
-ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabec2-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\cbpr_mt103sgo_pacs008_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file cbpr\_mt103sgo\_pacs008\_adt.out and the audit file cbpr\_mt103sgo\_pacs008\_adt.json.

---

## CBPR+ MT to MX (MT202 ADV/COR/COV to pacs.009.001.08 OR MT202 RETN to pacs.004.001.09) Translation Example

This example demonstrates the CBPR+ MT to MX (MT202 ADV/COR/COV to pacs.009.001.08 OR MT202 RETN to pacs.004.001.09) message translation using flow server.

- [What the example contains](#)

Files included in this example are as follows:

- [How to run the example](#)
- This mt-mx translation will use the sample files to demonstrate the generation of SWIFT CBPR+ pacs.009.001.08 output from a MT202 message or OR CBPR+ pacs.004.001.09 output from a MT202 RETN message.

---

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - MT202\_COR.inp
    - MT202\_COR\_bad.inp
    - MT202\_RTN.inp
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_004.xsd
    - head.001.001.02\_pacs\_009.xsd
    - pacs.004.001.09.xsd
    - pacs.009.001.08.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
    - trx\_config.xsd
  - Maps:
    - cbpr2810\_mt202\_framework
    - cbpr2814\_mt202\_pacs009\_adv
    - cbpr2815\_mt202\_pacs009\_cov
    - cbpr2813\_mt202\_pacs009
    - cbpr2824\_mt202RTN\_pacs004
    - cbpr1502\_mtmx\_setvarlog
  - Flow:
    - cbpr\_mt202\_pacs00n
- cbprJnodesConfigIBM.tar.gz

---

## How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of SWIFT CBPR+ pacs.009.001.08 output from a MT202 message or OR CBPR+ pacs.004.001.09 output from a MT202 RETN message.

The cbprJnodesConfigIBM.tar.gz file is available either in IBM\_financialpaymentsplus\_vn.n.n.n.zip or in UIProjectImports directory.

Extract from cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non Docker environments,

- Copy jars to <TX\_install\_dir>/extjar.

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlxlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **docker restart** <brand>-server.

Note: For RHEL, Docker is not supported, Podman can be used as a substitute since it provides a command line interface similar to Docker. Below is an example of using podman:

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/.
- Restart the design server, i.e., **podman restart** <brand>-server.

This example may generate failure in the audit.log.json log file to report the translation failure due to the pre-conversion checks:

```
Field 72, Line[1] should not start with "/REJT/".
If Field 72, Line[1] starts with "/RETN/", <Tag121><EndToEndTxnRef> should not be absent.
```

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and view the flow cbpr\_mt202\_pacs00n.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
    - @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt202\_pacs009\_adv/cbpr2814\_mt202\_pacs009\_adv
    - @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt20n\_pacs009\_cov/cbpr2815\_mt202\_pacs009\_cov
    - @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt20nRTN\_pacs004/cbpr2824\_mt202RTN\_pacs004
    - @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt20n\_pacs009/cbpr2813\_mt202\_pacs009
    - @packagemap=cbpr\_plus/translation/mt-mx/maps/cbpr\_t9n\_mt\_setvarlog/cbpr1502\_mtmx\_setvarlog
  - b. It utilizes the following nodes:
    - i. Source Node
      - mt\_202
 This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
    - ii. Map Node
      - mt\_translate
 Runs map cbpr2810\_mt202\_framework which set flow variables, checks pre-translation conditions and translates the input file (mt) into required output (XML).
    - iii. Target Node
      - pacs.00n
 This node contains the resulting translation in XML format and creates the pacs.004 or pacs.009 output as defined by variable OUTPUT\_DOC\_RESULT\_XML.
    - iv. Log Node
      - audit\_log
 This node creates a log file specified by the flow variable AUDIT\_LOG.
- c. It uses the following flow variables:
  - INPUT\_FILE
 Default value for the flow variable INPUT\_FILE is ..//cbpr\_plus/translation/mt-mx/data/MT202\_COR.inp. This is the data file to be used for translation and can be customized. It is used in the Source node mt\_202.
  - OUTPUT\_DOC\_RESULT\_XML
 Default value for the flow variable OUTPUT\_DOC\_RESULT\_XML is pacs.00n.xml. This is the location of the output file in mt format. It is used in the Target node pacs.00n. It can be customized.
  - AUDIT\_LOG
 Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
  - CONFIG\_FILE
 Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mt-mx/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.
3. Open the flow cbpr\_mt202\_pacs00n in the Design Server. It utilizes one source node, one map node, one log node, and one target node.
4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.
  - [\*\*Run the example using three different methods\*\*](#)

You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
  2. Deploying the example to tx-rest and running it using the swagger interface.
  3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).
- [\*\*Run the example from the Design Server user interface\*\*](#)

Use the following steps to run the example from the Design Server user interface:
  - [\*\*Run the example using the Swagger interface\*\*](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.
  - [\*\*Run the example using the flow command server process \(flowcmdserver\)\*\*](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_mt202\_pacs00n flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file MT202\_COR.inp or MT202\_COR\_bad.inp.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see the cbpr\_mt202\_pacs00n section having two actions: A PUT /v2/run/cbpr\_mt202\_pacs00n and a POST /v2/run/cbpr\_mt202\_pacs00n.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/MT202_COR.inp",
 "OUTPUT_DOC_RESULT_XML": "C:/tests_dir/data/pacs.009.001.08.xml",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```
- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_mt202_pacs00n.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\MT202_COR_pacs_009_valid.inp"
--var "OUTPUT_DOC_RESULT_XML=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\pacs.009.001.08.xml"
--var "OUTPUT_DOC_RESULT_XML=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\pacs.009.001.08_ADV.xml"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\MT202_pacs_009_valid_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\MT202_COR_pacs_009_valid_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\MT202_COR_pacs_009_valid_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file MT202\_COR\_pacs\_009\_valid.out and the audit file MT202\_COR\_pacs\_009\_valid\_adt.json.

## CBPR+ MT to MX (MT205 COR/COV to pacs.009.001.08 OR MT205 RETN to pacs.004.001.09) Translation Example

This example demonstrates the CBPR+ MT to MX (MT205 COR/COV to pacs.009.001.08 OR MT205 RETN to pacs.004.001.09) message translation using flow server.

- [What the example contains](#)

Files included in this example are as follows:

- [How to run the example](#)

This mt-mx translation will use the sample files to demonstrate the generation of SWIFT CBPR+ pacs.009.001.08 output from a MT205 message or CBPR+ pacs.004.001.09 output from a MT205 RETN message.

---

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - MT205\_COR.inp
    - MT205\_COR\_bad.inp

    - OUTPUT\_DOC\_RESULT\_XML
    - Default value for the flow variable OUTPUT\_DOC\_RESULT\_XML is pacs.00n.xml. This is the location of the output file in mt format. It is used in the Target node pacs.00n. It can be customized.
    - AUDIT\_LOG
    - Default value for the flow variable AUDIT\_LOG is audit.log.json. This is the location of the audit log. It is used in the Log node audit\_log. It can be customized.
    - CONFIG\_FILE
    - Default value for the flow variable CONFIG\_FILE is ..//cbpr\_plus/translation/mt-mx/data/trx\_config.xml. This is the location of the file containing the configuration settings. It can be customized.

3. Open the flow cbpr\_mt205\_pacs00n in the Design Server. It utilizes one source node, one map node, one log node, and one target node.

4. In Design Server, create a package that contains the input files and one flow. The maps will automatically be included during deployment of the package onto the runtime server.

  - [\*\*Run the example using three different methods\*\*](#)  
You can run the example using three different methods:

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
  2. Deploying the example to tx-rest and running it using the Swagger interface.
  3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).
- [\*\*Run the example from the Design Server user interface\*\*](#)  
Use the following steps to run the example from the Design Server user interface:
    - [\*\*Run the example using the Swagger interface\*\*](#)  
To run the example, deploy to tx-rest and run it using the Swagger interface.
    - [\*\*Run the example using the flow command server process \(flowcmdserver\)\*\*](#)  
To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open cbpr\_mt205\_pacs00n flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file MT205\_COR.inp or MT205\_COR\_bad.inp.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The reports list execution of all nodes.
3. Right click and select View Data on each link to examine the data.

4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You should see an cbpr\_mt205\_pacs00n section having two actions: A PUT /v2/run/cbpr\_mt205\_pacs00n and a POST /v2/run/cbpr\_mt205\_pacs00n.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/MT205_COR.inp",
 "OUTPUT_DOC_RESULT_XML": "C:/tests_dir/data/pacs.009.001.08.xml",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow cbpr_mt205_pacs00n.json
--var "INPUT_FILE=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\MT205_COR_pacs_009_valid.inp"
--var "OUTPUT_DOC_RESULT_XML=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\pacs.009.001.08.xml"
--var "AUDIT_LOG=C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\MT205_COR_pacs_009_valid_log.json"
--audit "C:\ftpserver\deployment\cbpr_plus\translation\mt-mx\data\MT205_COR_pacs_009_valid_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\cbpr_plus\\\\translation\\\\mt-
mx\\\\data\\\\MT205_COR_pacs_009_valid_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file MT205\_COR\_pacs\_009\_valid.out and the audit file MT205\_COR\_pacs\_009\_valid\_adt.json.

## CBPR+ MT message validation Example

This example shows how flow server can be used for validating any Swift MT message.

- [What the example contains](#)  
Files included in this example are as follows:
- [How to run the example](#)  
This MT validation will use the sample file to demonstrate the validation of SWIFT MT messages.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - mtxxxx.inp

- trx\_config.xml
  - Schemas:
    - validator.mtt
  - Maps:
    - validate\_messages\_enh
  - Flow:
    - mt\_validation
  - cbprJnodesConfigIBM.tar.gz
- 

## How to run the example

This MT validation will use the sample file to demonstrate the validation of SWIFT MT messages.

For the non Docker environments:

- Install the latest version of the Pack for Financial Payments.

For the Docker environments

- Extract the swiftMTjvcConfig.tar.gz file available from the Pack for Financial Payments.

This MT validation will use the sample file to demonstrate the validation of SWIFT MT messages.

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and view the flow mt\_validation. It utilizes the following nodes:
  - a. It utilizes the following nodes:
    - i. Source Node
      - mt\_input

This node identifies the input data to be translated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
    - ii. Map Node
      - validate\_messages\_enh

Runs framework map validate\_messages\_enh which validates the input SWIFT MT message and produces validation results.
    - iii. Decision Nodes
      - RESULT\_FORMAT

This checks the flow variable REPORT\_FORMAT to decide 'xml' or 'json'.
    - iv. Passthrough Node
      - XML\_CONVERT

This node receives an extended validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.
    - v. Format Converter Node
      - JSON\_CONVERT

This node receives an extended validation report in XML format and converts it to JSON before passing it to the appropriate target node.
    - vi. Target Node
      - rslt\_xml

This node contains the resulting translation in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.

      - rslt\_json

This node contains the resulting translation in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_MT.
  - b. It uses the following flow variables:
    - JVC\_VALIDATION\_LEVEL  
Flow variable JVC\_VALIDATION\_LEVEL is set without any default value.
    - INPUT\_FILE  
Default value for the flow variable INPUT\_FILE is ..//tools/mt\_validation/data/mtxxx.inp. This is the data file to be used for translation and can be customized. It is used in the Source node mt\_input.
    - OUTPUT\_RESULT\_JSON  
Default value for the flow variable OUTPUT\_RESULT\_JSON is mt\_validation\_results.json. This is the location of the output file in json format. It can be customized.
    - OUTPUT\_RESULT\_XML  
Default value for the flow variable OUTPUT\_RESULT\_XML is mt\_validation\_results.xml. This is the location of the output file in xml format. It can be customized.
    - REPORT\_FORMAT  
Default value for the flow variable REPORT\_FORMAT is xml. It can be customized.
  3. In Design Server, create a package that contains the input files and one flow mt\_validation. The maps will automatically be included during deployment of the package onto the runtime server.  
Note: Check for the jvalccyy.prop file. It should be present with the latest FinPay installation (<finpay\_install\_dir>/swift/mt/jvc/maps) or it will be available in the swiftMTjvcConfig.tar.gz.
  - [Additional configuration for MT JVC validation](#)
  - [Configuration files for Design Server](#)
  - [Run the example using three different methods](#)  
You can run the example using three different methods:

---

## Additional configuration for MT JVC validation

### Pre-requisites

The swiftMTjvcConfig.tar.gz file is contained within the UIProjectImports directory.

The UIProjectImports directory is located in the following location:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/UIProjectImports

Where, <install\_dir> is the location where the pack zip distro was extracted and n.n.n.n is the current version of the pack.

Extract the following from swiftMTjvcConfig.tar.gz file:

- jvcwrap.jar
- jvalccyy.jar

For Design Studio, will require administrative rights:

Copy jars to <TX\_install\_dir>/extjar.

For Design Server installation:

See Configuration files for Design Server for the steps to perform before you import <project>.zip file.

where <project>.zip can be any of the following:

cbpr\_translation.zip

---

## Configuration files for Design Server

The swiftMTjvcConfig.tar.gz file is contained within the UIProjectImports directory.

The UIProjectImports directory is located in the following location:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/UIProjectImports

Where, <install\_dir> is the location where the pack zip distro was extracted and n.n.n.n is the current version of the pack..

Use these steps to run this file:

Extract the swiftMTjvcConfig.tar.gz file.

Follow the below steps, before you import <project>.zip file.

Perform the steps in the same directory location as the Design Server is installed:

1. Create a temp directory called packs.

Example: /home/user/packs

2. For the UNIX environment, FTP (in binary mode) the swiftMTjvcConfig.tar.gz to the pack's directory defined in Step 1.

3. Untar the swiftMTjvcConfig.tar.gz file.

Example: \$ tar -zxf swiftMTjvcConfig.tar.gz

4. For Container based Design Server installation:

- a. Run the **jvcsetup.sh** script.

Example: \$ ./jvcsetup.sh

- b. The script copies the following to the ITX server:

- jvcwrap.jar
- jvalccyy.jar

packs/swift folder and subfolders include the jvalccyy.prop and XML metadata.

**Optional:**

- a. Run the **cleanjvc.sh** script.

Example: \$ ./cleanjvc.sh

- b. The script removes the following to the ITX server:

- jvcwrap.jar
- jvalccyy.jar

packs/swift folder and subfolders include the jvalccyy.prop and XML metadata.

5. For Native based installation:

- a. Copy the jvalccyy.jar and jvcwrap.jar into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlibs.

- b. Restart the application running ./ITX stop and then ./ITX start.

6. After importing cbpr\_translation.zip project:

- a. Copy the jvalccyy.prop file to the workdir directory under directory set in the config.yaml server.persistence.files, the default settings is /opt/txfiles/workdir.

- b. On the project, update the map rule on the validate\_message\_enh map, on output card #1 item JvalPropPath. Change the map rule from =NONE to the location of the jvalccyy.prop.

Example:

- On UNIX

```
="DS_DATA_DIR/workdir"
```

- On WINDOWS  
="DS\_DATA\_DIR\\workdir

where DS\_DATA\_DIR refers to the Design Server data directory, set in the config.yamlserver.persistence.files previously TX\_FILE\_DIR

7. Restart the Design Server: ./ITX stop and ./ITX start.

Note: To reflect any jvalccyy.prop updates, repeat step 7.

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

Note:

Flow variable jvc.validation.level can be set to either 0 or 1 or 2 or no input:

0 - only do Syntax validation

1 - Network rule validation/Check Methods enforced

2 - Network rule validation/Check Methods/BIC enabled no input - will take default jvc settings

- [Run the example from the Design Server user interface](#)

Use the following steps to run the example from the Design Server user interface:

- [Run the example using the Swagger interface](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

- [Run the example using the flow command server process \(flowcmdserver\)](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open mt\_validation flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file mtxxx.inp.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed, if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You should see a mt\_validation section having two actions: A PUT /v2/run/mt\_validation and a POST /v2/run/mt\_validation.
6. In the PUT action:
  - a. Expand the PUT action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/tests_dir/data/mtxxx.inp",
 "REPORT_FORMAT": "json",
 "OUTPUT_RESULT_JSON": "C:/tests_dir/data/mt_validation_results.json",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

or

```
{
 "INPUT_FILE": "C:/tests_dir/data/mtxxx.inp",
 "OUTPUT_RESULT_XML": "C:/tests_dir/data/mt_validation_results.xml",
 "AUDIT_LOG": "C:/tests_dir/data/audit_log.json"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. You can see information about the process flow in the Response body.

7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select the Try it out.
9. In the Name field, enter the name you gave it to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. The below command is for SWIFT MT mtxxx.inp message:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow mt_validation.json
--var "INPUT_FILE=C:\ftpserver\deployment\tools\mt_validation\data\mtxxx.inp"
--var "OUTPUT_RESULT_XML=C:\ftpserver\deployment\tools\mt_validation\data\mt_validation_results.xml"
--audit "C:\ftpserver\deployment\tools\mt_validation\data\mtxxx.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server
Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\ftpserver\\deployment\\tools\\mt_validation\\data\\mtxxx.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result file mt\_validation\_results.xml and the audit file mtxxx.json.

## CBPR+ Translation Examples using maps:

- [CBPR+ MX to MT \(camt.029.001.09 to MT196/MT296\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (camt.029.001.09 to MT196/MT296) message translation using maps.

- [CBPR+ MX to MT \(camt.052.001.08 to MT942\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (camt.052.001.08 to MT942) message translation using maps.

- [CBPR+ MX to MT \(camt.053.001.08 to MT940\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (camt.053.001.08 to MT940) message translation using maps.

- [CBPR+ MX to MT \(camt.054.001.08 to MT900/MT910\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (camt.054.001.08 to MT900/MT910) message translation using maps.

- [CBPR+ MX to MT \(camt.056.001.08 to MT192/MT292\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (camt.056.001.08 to MT192/MT292) message translation using maps.

- [CBPR+ MX to MT \(camt.057.001.06 to MT210\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (camt.057.001.06 to MT210) message translation using maps.

- [CBPR+ MX to MT \(camt.058.001.08 to MT292\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (camt.058.001.08 to MT292) message translation using maps.

- [CBPR+ MX to MT \(camt.107.001.01 to MT110\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (camt.107.001.01 to MT110) message translation using maps.

- [CBPR+ MX to MT \(camt.108.001.01 to MT111\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (camt.108.001.01 to MT111) message translation using maps.

- [CBPR+ MX to MT \(camt.109.001.01 to MT112\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (camt.109.001.01 to MT112) message translation using maps.

- [CBPR+ MX to MT \(pacs.002.001.10 to MT199/MT299\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (pacs.002.001.10 to MT199/MT299) message translation using maps.

- [CBPR+ MX to MT \(pacs.008.001.08 SWIFT Go to MT103\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (pacs.008.001.08 SWIFT Go to MT103) message translation using maps.

- [CBPR+ MX to MT \(pacs.009.001.08 to MT202 \(CORE/ADV/COVE\)\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (pacs.009.001.08 to MT202 (CORE/ADV/COVE)) message translation using maps.

- [CBPR+ MX to MT \(pacs.009.001.08 to MT205 \(CORE/COVE\)\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (pacs.009.001.08 to MT205 (CORE/COVE)) message translation using maps.

- [CBPR+ MX to MT \(pacs.004.001.09 to MT103 RETN/MT202 RETN/MT205 RETN\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (pacs.004.001.09 to MT103 RETN/MT202 RETN/MT205 RETN) message translation using maps.

- [CBPR+ MX to MT \(pacs.008.001.08 to MT103\) Translation Example](#)

This example demonstrates the CBPR+ MX to MT (pacs.008.001.08 to MT103) message translation using maps.

- [CBPR+ MT to MX \(MT900/MT910 to camt.054.001.08\) Translation Example](#)

This example demonstrates the CBPR+ MT to MX (MT900/MT910 to camt.054.001.08) message translation using maps.

- [CBPR+ MT to MX \(MT192/MT292 to camt.056.001.08\) Translation Example](#)

This example demonstrates the CBPR+ MT to MX (MT192/MT292 to camt.056.001.08) message translation using maps.

- [CBPR+ MT to MX \(MT196/MT296 to camt.029.001.09\) Translation Example](#)

This example demonstrates the CBPR+ MT to MX (MT196/MT296 to camt.029.001.09) message translation using maps.

- [CBPR+ MT to MX \(MT103 COR/MT103 STP to pacs.008.001.08 or MT103 COR RETN to pacs.004.001.09\) Translation Example](#)

This example demonstrates the CBPR+ MT to MX (MT103 COR/MT103 STP to pacs.008.001.08 or MT103 COR RETN to pacs.004.001.09) message translation using maps.

- [CBPR+ MT to MX \(MT103 SWIFT Go to pacs.008.001.08\) Translation Example](#)

This example demonstrates the CBPR+ MT to MX (MT103 SWIFT Go to pacs.008.001.08) message translation using maps.

- **[CBPR+ MT to MX \(MT202 \(core/adv/cove\) to pacs.009.001.08 \(core/adv/cove\) or MT202 \(RETN\) to pacs.004.001.09\) Translation Example](#)**  
This example demonstrates the CBPR+ MT to MX (MT202 (core/adv/cove) to pacs.009.001.08 (core/adv/cove) or MT202 (RETN) to pacs.004.001.09) message translation using maps.
- **[CBPR+ MT to MX \(MT205 \(core/cove\) to pacs.009.001.08 \(core/cove\) or MT205 \(RETN\) to pacs.004.001.09\) Translation Example](#)**  
This example demonstrates the CBPR+ MT to MX (MT205 (core/cove) to pacs.009.001.08 (core/cove) or MT205 (RETN) to pacs.004.001.09) message translation using maps.

This example shows how TX maps can be used for translating CBPR+ MX to MT message formats.

---

## CBPR+ MX to MT (camt.029.001.09 to MT196/MT296) Translation Example

This example demonstrates the CBPR+ MX to MT (camt.029.001.09 to MT196/MT296) message translation using maps.

- **[What the example contains](#)**  
Files included in this example are as follows:
- **[How to run the example](#)**  
This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT196 or MT296 message output from a CBPR+ camt.029.001.09 XML message.

---

### What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_029\_mt196\_valid.xml
    - env\_camt\_029\_mt296\_valid.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_029.xsd
    - camt.029.001.09.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2520\_camt029\_framework
    - cbpr2501\_mxmt\_setvarlog
    - cbpr2522\_camt029\_translate
    - cbpr2523\_camt029\_mtn96
- cbprJnodesConfigIBM.tar.gz

---

### How to run the example

This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT196 or MT296 message output from a CBPR+ camt.029.001.09 XML message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlabs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.
  2. Open the cbpr\_translation project in Design Server and build the following maps:
    - cbpr2520\_camt029\_framework
    - cbpr2501\_mxmt\_setvarlog
    - cbpr2522\_camt029\_translate
    - cbpr2523\_camt029\_mtn96
  3. Run the main map cbpr2520\_camt029\_framework.
- The following output files will be generated:
- mt\_out.txt  
File contains the translated MT196 or MT296 SWIFT message from CBPR+ camt\_029 message based on the <OrgnlMsgNmId>.
  - audit\_msg.json  
Reports translation logs, including failure due to the pre-conversion checks.

## CBPR+ MX to MT (camt.052.001.08 to MT942) Translation Example

This example demonstrates the CBPR+ MX to MT (camt.052.001.08 to MT942) message translation using maps.

- **What the example contains**

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_052\_mt942\_valid.xml
    - env\_camt\_052\_mt942\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_052.xsd
    - camt.052.001.08.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2546\_camt052\_framework
    - cbpr2547\_camt052\_translate
    - cbpr2501\_mxmt\_setvarlog
    - cbpr2548\_camt052\_mt942
- cbprJnodesConfigIBM.tar.gz

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_052\_mt942\_valid.xml
    - env\_camt\_052\_mt942\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_052.xsd
    - camt.052.001.08.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2546\_camt052\_framework
    - cbpr2547\_camt052\_translate
    - cbpr2501\_mxmt\_setvarlog
    - cbpr2548\_camt052\_mt942
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT942 message output from a CBPR+ camt.052.001.08 XML message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2546\_camt052\_framework
- cbpr2547\_camt052\_translate
- cbpr2548\_camt052\_mt942
- cbpr2501\_mxmt\_setvarlog

3. Run the main map cbpr2546\_camt052\_framework.

The following output files will be generated:

- mt\_out.txt

File contains the translated MT942 from CBPR+ camt\_052 message.

- audit\_msg.json

Reports translation logs, including failure due to the pre-conversion checks:

- <ElctrncSeqNb> must be present in <BkToCstmrAcctRpt><Rpt><ElctrncSeqNb> and its length must be less than or equal to 5.

OR

<LglSeqNb> must be present in <BkToCstmrAcctRpt><Rpt><LglSeqNb> and its length must be less than or equal to 5.

- There must be a maximum 190 occurrence of <Ntry> in <BkToCstmrAcctRpt><Rpt><Ntry>.

- There must be present any ONE of the following:

- <BkToCstmrAcctRpt><Rpt><Ntry>
- <BkToCstmrAcctRpt><Rpt><TxSummry><TtlCdtNtries><NbOfNtries> AND <BkToCstmrAcctRpt><Rpt><TxSummry><TtlCdtNtries><Sum>
- <BkToCstmrAcctRpt><Rpt><TxSummry><TtlDbtNtries><NbOfNtries> AND <BkToCstmrAcctRpt><Rpt><TxSummry><TtlDbtNtries><Sum>

- For all occurrence of <BkToCstmrAcctRpt><Rpt><Ntry>, value of <Ccy> in <BkToCstmrAcctRpt><Rpt><Ntry><Amt><Ccy> must be equal to value of <Ccy> in <BkToCstmrAcctRpt><Rpt><Acct><Ccy>, TotalNumberOfDigits <BkToCstmrAcctRpt><Rpt><Ntry><Amt> must be less than or equal to 14.

## CBPR+ MX to MT (camt.053.001.08 to MT940) Translation Example

This example demonstrates the CBPR+ MX to MT (camt.053.001.08 to MT940) message translation using maps.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT940 message output from a CBPR+ camt.053.001.08 XML message.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT940 message output from a CBPR+ camt.053.001.08 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_053\_mt940\_valid.xml
    - env\_camt\_053\_mt940\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_053.xsd
    - camt.053.001.08.xsd
    - trx\_config.xsd

- infoset.mtt
- swift\_iso7775\_ccyy.mtt
- swiftroute\_funds.mtt
- Maps:
  - cbpr2530\_camt053\_framework
  - cbpr2531\_camt053\_translate
  - cbpr2501\_mxmt\_setvarlog
  - cbpr2534\_camt053\_mt940
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT940 message output from a CBPR+ camt.053.001.08 XML message.

Extract from `<packs_install_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz` file.

- jnodes0.jar

The following jars needs to be copied from `<TX_install_dir>/jars`:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to `<TX_install_dir>/extjar`

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2530\_camt053\_framework
- cbpr2531\_camt053\_translate
- cbpr2534\_camt053\_mt940
- cbpr2501\_mxmt\_setvarlog

3. Run the main map cbpr2530\_camt053\_framework.

The following output files will be generated:

- mt\_out.txt  
File contains the translated MT940 from CBPR+ camt\_053 message.
- audit\_msg.json  
Reports translation logs, including failure due to the pre-conversion checks as:

- **<ElctrncSeqNb>** must be present in **<BkToCstmrStmt><Stmt><ElctrncSeqNb>** and its length must be less than or equal to 5.

OR

**<LglSeqNb>** must be present in **<BkToCstmrStmt><Stmt><LglSeqNb>** and its length must be less than or equal to 5.

- If **<PgNb>** in **<BkToCstmrStmt><Stmt><StmtPgntr><PgNb>** is equal to 1, then there must be only 1 occurrence of **<Cd>** with value OPBD in **<BkToCstmrStmt><Stmt><Bal><Tp><CdOrPrtry><Cd>** and if **<Cd>** is present in **<BkToCstmrStmt><Stmt><Bal><Tp><SubTp><Cd>**, then the value must be different from INTM.
- If **<PgNb>** in **<BkToCstmrStmt><Stmt><StmtPgntr><PgNb>** is greater than 1 then there must be only 1 occurrence of **<Cd>** with value OPBD in **<BkToCstmrStmt><Stmt><Bal><Tp><CdOrPrtry><Cd>** and **<Cd>** must be present in **<BkToCstmrStmt><Stmt><Bal><Tp><SubTp><Cd>**, value must be INTM.
- If **<LastPgInd>** in **<BkToCstmrStmt><Stmt><StmtPgntr><LastPgInd>** is equal to true then there must be only 1 occurrence of **<Cd>** with value CLBD in **<BkToCstmrStmt><Stmt><Bal><Tp><CdOrPrtry><Cd>** and if **<Cd>** is present in **<BkToCstmrStmt><Stmt><Bal><Tp><SubTp><Cd>**, then the value must be different from INTM.

- If <LastPgInd> in <BkToCstmrStmt><Stmt><StmtPgntr><LastPgInd> is equal to false then there must be only 1 occurrence of <Cd> with value CLBD in <BkToCstmrStmt><Stmt><Bal><Tp><CdOrPrtry><Cd> and <Cd> must be present in <BkToCstmrStmt><Stmt><Bal><Tp><SubTp><Cd>, value must be INTM.
- There must be only 1 occurrence of <Cd> with value CLAV in <BkToCstmrStmt><Stmt><Bal><Tp><CdOrPrtry><Cd>.
- There must be a maximum 190 occurrence of <Ntry> in <BkToCstmrStmt><Stmt><Ntry>.
- For all occurrence of <BkToCstmrStmt><Stmt><Ntry>, value of <Ccy> in <BkToCstmrStmt><Stmt><Ntry><Amt><Ccy> must be equal to value of <Ccy> in <BkToCstmrStmt><Stmt><Acct><Ccy>, TotalNumberOfDigits <BkToCstmrStmt><Stmt><Ntry><Amt> must be less than or equal to 14.
- For the occurrence of <BkToCstmrStmt><Stmt><Bal>, if <Cd> is present with value OPBD in <BkToCstmrStmt><Stmt><Bal><Tp><CdOrPrtry><Cd> then first two char of currency code must be the same for other occurrence of <BkToCstmrStmt><Stmt><Bal> in <BkToCstmrStmt><Stmt><Bal><Tp><CdOrPrtry><Cd> with value CLBD OR CLAV.

## CBPR+ MX to MT (camt.054.001.08 to MT900/MT910) Translation Example

This example demonstrates the CBPR+ MX to MT (camt.054.001.08 to MT900/MT910) message translation using maps.

- [What the example contains](#)

Files included in this example are as follows:

- [How to run the example](#)

This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT900 or MT910 message output from a CBPR+ camt.054.001.08 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_054\_bad.xml
    - env\_camt\_054\_crdt.xml
    - env\_camt\_054\_dbit.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_054.xsd
    - camt.054.001.08.xsd
    - trx\_config.xsd
    - infoSet.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftRoute\_funds.mtt
  - Maps:
    - cbpr2510\_camt054\_framework
    - cbpr2501\_mxmt\_setvarlog
    - cbpr2512\_camt054\_translate
    - cbpr2513\_camt054\_mt900
    - cbpr2514\_camt054\_mt910
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT900 or MT910 message output from a CBPR+ camt.054.001.08 XML message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlbs:

- jvcwrap.jar

- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2510\_camt054\_framework
- cbpr2501\_mxmt\_setvarlog
- cbpr2512\_camt054\_translate
- cbpr2513\_camt054\_mt900
- cbpr2514\_camt054\_mt910

3. Run the main map cbpr2510\_camt054\_framework.

The following output files will be generated:

- mt\_out.txt

File contains the translated MT900 or MT910 SWIFT message from CBPR+ camt\_054 message based on the **<CdtDbtInd>** which could be CRDT (will generate MT910) or DBIT (will generate MT900).

- audit\_msg.json

Reports translation logs, including failure due to the pre-conversion checks as:

- Either **<CdtDbtInd>** is not one of these (CRDT, DBIT) or **<Sts><Cd>** is not BOOK.
- **TotalNumberOfDigits <Ntry><Amt>** less than or equal to 14.
- Only one occurrence is allowed for **<Ntfctn>, <Ntry>, <NtryDtls>, and <TxDtls>**.
- Either one must exist **<Ntfctn><Ntry><ValDt> or <Ntfctn><Ntry><NtryDtls><TxDtls><RltdDts><IntrBkSttlmDt>**.

## CBPR+ MX to MT (camt.056.001.08 to MT192/MT292) Translation Example

This example demonstrates the CBPR+ MX to MT (camt.056.001.08 to MT192/MT292) message translation using maps.

- **[What the example contains](#)**

Files included in this example are as follows:

- **[How to run the example](#)**

This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT192 or MT292 message output from a CBPR+ camt.056.001.08 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_056\_mt192\_valid.xml
    - env\_camt\_056\_mt292\_valid.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_056.xsd
    - camt.056.001.08.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2540\_camt056\_framework
    - cbpr2501\_mxmt\_setvarlog
    - cbpr2542\_camt056\_translate
    - cbpr2543\_camt056\_mtn92
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT192 or MT292 message output from a CBPR+ camt.056.001.08 XML message.

Extract from **<packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz** file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txls:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart <brand>-server**

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart <brand>-server**

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2540\_camt056\_framework
- cbpr2501\_mxmt\_setvarlog
- cbpr2542\_camt056\_translate
- cbpr2543\_camt056\_mtn92

3. Run the main map cbpr2540\_camt056\_framework.

The following output files will be generated:

- mt\_out.txt  
File contains the translated MT192 or MT292 SWIFT message from CBPR+ camt\_056 message based on the <OrgnlMsgNmId>.
- audit\_msg.json  
Reports translation logs, including failure due to the pre-conversion checks.

## CBPR+ MX to MT (camt.057.001.06 to MT210) Translation Example

This example demonstrates the CBPR+ MX to MT (camt.057.001.06 to MT210) message translation using maps.

- [What the example contains](#)

Files included in this example are as follows:

- [How to run the example](#)

This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT210 message output from a CBPR+ camt.057.001.06 XML message.

### What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_057\_bad.xml
    - env\_camt\_057\_valid.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_057.xsd
    - camt.057.001.06.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2600\_camt057\_framework
    - cbpr2601\_camt057\_translate
    - cbpr2501\_mxmt\_setvarlog
    - cbpr2605\_camt057\_mt210

- cbprJnodesConfigIBM.tar.gz

---

## How to run the example

This mx-*mt* translation will use the sample files to demonstrate the generation of SWIFT MT210 message output from a CBPR+ camt.057.001.06 XML message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2600\_camt057\_framework
- cbpr2601\_camt057\_translate
- cbpr2501\_mxmt\_setvarlog
- cbpr2605\_camt057\_mt210

3. Run the main map cbpr2600\_camt057\_framework.

The following output files will be generated:

- mt\_out.txt  
File contains the translated MT210 from CBPR+ camt\_057 message.

- audit\_msg.json

Reports translation logs, including failure due to the pre-conversion checks as:

- **NumberOfOccurrences <Ntfctn><Itm>** should not be greater than 1.
- Currency should not be any of these {XAU, XAG, XPD, XPT} for <Ntfctn><Itm><Amt><Ccy>.
- **TotalNumberOfDigits <Ntry><Amt>** less than or equal to 14.

---

## CBPR+ MX to MT (camt.058.001.08 to MT292) Translation Example

This example demonstrates the CBPR+ MX to MT (camt.058.001.08 to MT292) message translation using maps.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This mx-*mt* translation will use the sample files to demonstrate the generation of SWIFT MT292 message output from a CBPR+ camt.058.001.08 XML message.

---

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_058\_valid.xml

- env\_camt\_058\_bad.xml
- trx\_config.xml
- Schemas:
  - head.001.001.02\_camt\_058.xsd
  - camt.058.001.08.xsd
  - trx\_config.xsd
  - infoset.mtt
  - swift\_iso7775\_ccyy.mtt
  - swiftroute\_funds.mtt
- Maps:
  - cbpr2610\_camt058\_framework
  - cbpr2611\_camt058\_translate
  - cbpr2612\_camt058\_mt292
  - cbpr2501\_mxmt\_setvarlog
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT292 message output from a CBPR+ camt.058.001.08 XML message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlbs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brands>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and build the following maps:
  - cbpr2610\_camt058\_framework
  - cbpr2611\_camt058\_translate
  - cbpr2612\_camt058\_mt292
  - cbpr2501\_mxmt\_setvarlog

3. Run the main map cbpr2610\_camt058\_framework.

The following output files will be generated:

- mt\_out.txt  
File contains the translated MT292 SWIFT message from CBPR+ camt.058 message.
- audit\_msg.json  
Reports translation logs, including failure if the input message is not camt.058.001.08

## CBPR+ MX to MT (camt.107.001.01 to MT110) Translation Example

This example demonstrates the CBPR+ MX to MT (camt.107.001.01 to MT110) message translation using maps.

- **What the example contains**

Files included in this example are as follows:

- [How to run the example](#)

This mx-*mt* translation will use the sample files to demonstrate the generation of SWIFT MT110 message output from a CBPR+ camt.107.001.01 XML message.

---

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_107\_valid.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_107.xsd
    - camt.107.001.01.xsd
    - trx\_config.xsd
    - infoSet.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftRoute\_funds.mtt
  - Maps:
    - cbpr2620\_camt107\_framework
    - cbpr2621\_camt107\_translate
    - cbpr2622\_camt107\_mt110
    - cbpr2501\_mxmt\_setvarlog
- cbprJnodesConfigIBM.tar.gz

---

## How to run the example

This mx-*mt* translation will use the sample files to demonstrate the generation of SWIFT MT110 message output from a CBPR+ camt.107.001.01 XML message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlbs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2620\_camt107\_framework
- cbpr2621\_camt107\_translate
- cbpr2622\_camt107\_mt110
- cbpr2501\_mxmt\_setvarlog

3. Run the main map cbpr2620\_camt107\_framework.

The following output files will be generated:

- mt\_out.txt  
File contains the translated MT110 from SWIFT message from CBPR+ camt.107 message.
- audit\_msg.json  
Reports translation logs, including failure if the input message is not camt.107.001.01

---

## CBPR+ MX to MT (camt.108.001.01 to MT111) Translation Example

This example demonstrates the CBPR+ MX to MT (camt.108.001.01 to MT111) message translation using maps.

- **What the example contains**

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_108\_valid.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_108.xsd
    - camt.108.001.01.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2630\_camt108\_framework
    - cbpr2631\_camt108\_translate
    - cbpr2632\_camt108\_mt111
    - cbpr2501\_mxmt\_setvarlog
- cbprJnodesConfigIBM.tar.gz

---

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_108\_valid.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_108.xsd
    - camt.108.001.01.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2630\_camt108\_framework
    - cbpr2631\_camt108\_translate
    - cbpr2632\_camt108\_mt111
    - cbpr2501\_mxmt\_setvarlog
- cbprJnodesConfigIBM.tar.gz

---

## How to run the example

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT111 message output from a CBPR+ camt.108.001.01 XML message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlxlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and build the following maps:
  - cbpr2630\_camt108\_framework

- cbpr2631\_camt108\_translate
  - cbpr2632\_camt108\_mt111
  - cbpr2501\_mxmt\_setvarlog
3. Run the main map cbpr2630\_camt108\_framework.
- The following output files will be generated:
- mt\_out.txt  
File contains the translated MT111 SWIFT message from CBPR+ camt.108 message.
  - audit\_msg.json  
Reports translation logs, including failure if the input message is not camt.108.001.01

## CBPR+ MX to MT (camt.109.001.01 to MT112) Translation Example

This example demonstrates the CBPR+ MX to MT (camt.109.001.01 to MT112) message translation using maps.

- **What the example contains**  
Files included in this example are as follows:
- **How to run the example**  
This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT112 message output from a CBPR+ camt.109.001.01 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_camt\_109\_valid.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_camt\_109.xsd
    - camt.109.001.01.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2640\_camt109\_framework
    - cbpr2641\_camt109\_translate
    - cbpr2642\_camt109\_mt112
    - cbpr2501\_mxmt\_setvarlog
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT112 message output from a CBPR+ camt.109.001.01 XML message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/

- Restart the design server, that is, **docker restart <brand>-server**

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart <brand>-server**

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2640\_camt109\_framework
- cbpr2641\_camt109\_translate
- cbpr2642\_camt109\_mt112
- cbpr2501\_mxmt\_setvarlog

3. Run the main map cbpr2640\_camt109\_framework.

The following output files will be generated:

- mt\_out.txt  
File contains the translated MT112 from SWIFT message from CBPR+ camt.109 message.
- audit\_msg.json  
Reports translation logs, including failure if the input message is not camt.109.001.01

## CBPR+ MX to MT (pacs.002.001.10 to MT199/MT299) Translation Example

This example demonstrates the CBPR+ MX to MT (pacs.002.001.10 to MT199/MT299) message translation using maps.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**
- This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT199 or MT299 message output from a CBPR+ pacs.002.001.10 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_pacs\_002\_199.xml
    - env\_pacs\_002\_299.xml
    - env\_pacs\_002\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_002.xsd
    - pacs.002.001.10.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2500\_pacs002\_framework
    - cbpr2501\_mxmt\_setvarlog
    - cbpr2502\_pacs002\_translate
    - cbpr2503\_pacs002\_mtn99
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT199 or MT299 message output from a CBPR+ pacs.002.001.10 XML message.

Extract from <pacs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart <brand>-server**

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart <brand>-server**

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2500\_pacs002\_framework
- cbpr2501\_mxmt\_setvarlog
- cbpr2502\_pacs002\_translate
- cbpr2503\_pacs002\_mtn99

3. Run the main map cbpr2500\_pacs002\_framework.

The following output files will be generated:

- mt\_out.txt

File contains the translated MT199 or MT299 SWIFT message from CBPR+ pacs.002 message based on the <OrgnlMsgNmId> which could be pacs.008 or MT103 (will generate MT199) or pacs.009 or MT202 or MT205 (will generate MT299).

- audit\_msg.json

Reports translation logs, including failure due to the pre-conversion checks as:

- Either <OrgnlMsgNmId> is not one of these (pacs.008, MT103, pacs.009, MT202, MT205) or <TxSts> transaction status is not RJCT.

## CBPR+ MX to MT (pacs.008.001.08 SWIFT Go to MT103) Translation Example

This example demonstrates the CBPR+ MX to MT (pacs.008.001.08 SWIFT Go to MT103) message translation using maps.

- [What the example contains](#)

Files included in this example are as follows:

- [How to run the example](#)

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT103 message output from a CBPR+ pacs.008.001.08 SWIFT Go XML message.

### What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_pacs\_008\_SGO.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_008.xsd
    - pacs.008.001.08.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2700\_pacs008\_framework
    - cbpr2701\_pacs008\_translate
    - cbpr2704\_pacs008\_mt103\_sgo
    - cbpr2501\_mxmt\_setvarlog
- cbprJnodesConfigIBM.tar.gz

### How to run the example

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT103 message output from a CBPR+ pacs.008.001.08 SWIFT Go XML message.

Extract from <pacs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txls:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and build the following maps:
  - cbpr2700\_pacs008\_framework
  - cbpr2701\_pacs008\_translate
  - cbpr2704\_pacs008\_mt103\_sgo
  - cbpr2501\_mxmt\_setvarlog
3. Run the main map cbpr2700\_pacs008\_framework.

The following output files will be generated:

- mt\_out.txt  
File contains the translated MT103 SWIFT message from CBPR+ pacs.008 SWIFT Go message.
- audit\_msg.json  
Reports translation logs, including failure due to the pre-conversion checks as:
  - <IntrBkSttlmAmt> Commodities currencies {XAU, XAG, XPD, XPT} Not allowed in Field 32A and 32B.
  - Number Of Occurrences of <CreditTransferTransactionInformation> is greater than 1.

## CBPR+ MX to MT (pacs.009.001.08 to MT202 (CORE/ADV/COVE)) Translation Example

This example demonstrates the CBPR+ MX to MT (pacs.009.001.08 to MT202 (CORE/ADV/COVE)) message translation using maps.

- **[What the example contains](#)**

Files included in this example are as follows:

- **[How to run the example](#)**

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT202 (CORE/ADV/COVE) message output from a CBPR+ pacs.009.001.08 XML message.

### What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_pacs\_009\_adv\_valid.xml
    - env\_pacs\_009\_adv\_bad.xml
    - env\_pacs\_009\_mt202cor\_valid.xml
    - env\_pacs\_009\_cor\_bad.xml
    - env\_pacs\_009\_mt202cov\_valid.xml
    - env\_pacs\_009\_cov\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_009\_adv.xsd
    - head.001.001.02\_pacs\_009\_cov.xsd

- head.001.001.02\_pacs\_009.xsd
  - pacs.009.001.08\_adv.xsd
  - pacs.009.001.08\_cov.xsd
  - pacs.009.001.08.xsd
  - trx\_config.xsd
  - infoset.mtt
  - swift\_iso7775\_ccyy.mtt
  - swiftroute\_funds.mtt
  - Maps:
    - cbpr2710\_pacs009\_mt202\_framework
    - cbpr2501\_mxmt\_setvarlog
    - cbpr2713\_pacs009\_mt202adv\_trx
    - cbpr2714\_pacs009\_mt202cov\_trx
    - cbpr2712\_pacs009\_mt202\_trx
    - cbpr2715\_pacs009\_mt202
  - cbprJnodesConfigIBM.tar.gz
- 

## How to run the example

This mx-xt translation will use the sample files to demonstrate the generation of SWIFT MT202 (CORE/ADV/COVE) message output from a CBPR+ pacs.009.001.08 XML message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlxlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart <brand>-server**

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart <brand>-server**

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2710\_pacs009\_mt202\_framework
- cbpr2501\_mxmt\_setvarlog
- cbpr2713\_pacs009\_mt202adv\_trx
- cbpr2714\_pacs009\_mt202cov\_trx
- cbpr2712\_pacs009\_mt202\_trx
- cbpr2715\_pacs009\_mt202

3. Run the main map cbpr2710\_pacs009\_mt202\_framework.

The following output files will be generated:

- mt\_out.txt  
File contains the translated MT202 (CORE/ADV/COVE) SWIFT message from CBPR+ pacs.009 message.

- audit\_msg.json  
Reports translation logs, including failure due to the pre-conversion checks as:

• <**IntrBkSttlmAmt**> Commodities currencies {XAU, XAG, XPD, XPT} Not allowed in Field 32A and 32B.

## CBPR+ MX to MT (pacs.009.001.08 to MT205 (CORE/COVE)) Translation Example

This example demonstrates the CBPR+ MX to MT (pacs.009.001.08 to MT205 (CORE/COVE)) message translation using maps.

- [What the example contains](#)

Files included in this example are as follows:

- [How to run the example](#)

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT205 (CORE/COVE) message output from a CBPR+ pacs.009.001.08 XML message.

---

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_pacs\_009\_mt205cor\_valid.xml
    - env\_pacs\_009\_cor\_bad.xml
    - env\_pacs\_009\_mt205cov\_valid.xml
    - env\_pacs\_009\_cov\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_009\_adv.xsd
    - head.001.001.02\_pacs\_009\_cov.xsd
    - head.001.001.02\_pacs\_009.xsd
    - pacs.009.001.08\_adv.xsd
    - pacs.009.001.08\_cov.xsd
    - pacs.009.001.08.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2724\_pacs009\_mt205\_framework
    - cbpr2501\_mxmt\_setvarlog
    - cbpr2726\_pacs009\_mt205cov\_trx
    - cbpr2727\_pacs009\_mt205
- cbprJnodesConfigIBM.tar.gz

---

## How to run the example

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT205 (CORE/COVE) message output from a CBPR+ pacs.009.001.08 XML message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlxlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2724\_pacs009\_mt205\_framework
  - cbpr2501\_mxmt\_setvarlog
  - cbpr2726\_pacs009\_mt205cov\_trx
  - cbpr2727\_pacs009\_mt205
3. Run the main map cbpr2724\_pacs009\_mt205\_framework.
- The following output files will be generated:
- mt\_out.txt  
File contains the translated MT205 (CORE/COVE) SWIFT message from CBPR+ pacs.009 message.
  - audit\_msg.json  
Reports translation logs, including failure due to the pre-conversion checks as:
    - <IntrBkSttlmAmt> Commodities currencies {XAU, XAG, XPD, XPT} Not allowed in Field 32A and 32B.

## CBPR+ MX to MT (pacs.004.001.09 to MT103 RETN/MT202 RETN/MT205 RETN) Translation Example

This example demonstrates the CBPR+ MX to MT (pacs.004.001.09 to MT103 RETN/MT202 RETN/MT205 RETN) message translation using maps.

- [What the example contains](#)  
Files included in this example are as follows:
- [How to run the example](#)  
This mt-mx translation will use the sample files to demonstrate the generation of SWIFT MTnnn RETN message output from a CBPR+ pacs.004.001.09 XML message.

### What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_pacs\_004\_mt202 rtn\_valid.xml

    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2850\_pacs004\_mttnnn\_RTN\_frw
    - cbpr2851\_pacs004RTN\_trx
    - cbpr2852\_pacs004\_mt202RTN
    - cbpr2853\_pacs004\_mt205RTN
    - cbpr2857\_pacs004\_mt103RTN
    - cbpr2501\_mxmt\_setvarlog
- cbprJnodesConfigIBM.tar.gz

### How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of SWIFT MTnnn RETN message output from a CBPR+ pacs.004.001.09 XML message.

Extract from <pacs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlbs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2850\_pacs004\_mtnnn\_RTN\_frw
- cbpr2851\_pacs004RTN\_trx
- cbpr2852\_pacs004\_mt202RTN
- cbpr2853\_pacs004\_mt205RTN
- cbpr2857\_pacs004\_mt103RTN
- cbpr2501\_mxmt\_setvarlog

3. Run the main map cbpr2850\_pacs004\_mtnnn\_RTN\_frw.

The following output files will be generated:

- mt\_out.txt

File contains the translated MT103 RETN/MT202 RETN/MT205 RETN SWIFT message from CBPR+ pacs.004 message.

- audit\_msg.json

Reports translation logs, including failure due to the pre-conversion checks as:

- <IntrBkSttlmAmt> Commodities currencies {XAU, XAG, XPD, XPT} Not allowed in Field 32A and 32B.
- Count of <TxInf> is greater than 1.
- <RtrChain><Dbtr><Pty> is present.
- <RtrChain><Cdtr><Pty> is present.

## CBPR+ MX to MT (pacs.008.001.08 to MT103) Translation Example

This example demonstrates the CBPR+ MX to MT (pacs.008.001.08 to MT103) message translation using maps.

- [What the example contains](#)

Files included in this example are as follows:

- [How to run the example](#)

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT103 message output from a CBPR+ pacs.008.001.08 XML message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - env\_pacs\_008\_103.xml
    - env\_pacs\_008\_STP.xml
    - env\_pacs\_008\_bad.xml
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_008.xsd
    - pacs.008.001.08.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2700\_pacs008\_framework
    - cbpr2701\_pacs008\_translate
    - cbpr2703\_pacs008\_mt103
    - cbpr2709\_pacs008\_stp\_translate
    - cbpr2501\_mxmt\_setvarlog
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mx-mt translation will use the sample files to demonstrate the generation of SWIFT MT103 message output from a CBPR+ pacs.008.001.08 XML message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlbs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2700\_pacs008\_framework
- cbpr2701\_pacs008\_translate
- cbpr2703\_pacs008\_mt103
- cbpr2709\_pacs008\_stp\_translate
- cbpr2501\_mxmt\_setvarlog

3. Run the main map cbpr2700\_pacs008\_framework.

The following output files will be generated:

- mt\_out.txt  
File contains the translated MT103 SWIFT message from CBPR+ pacs.008 message.
- audit\_msg.json  
Reports translation logs, including failure due to the pre-conversion checks as:
  - <IntrBkSttlmAmt> Commodities currencies {XAU, XAG, XPD, XPT} Not allowed in Field 32A and 32B.

## CBPR+ MT to MX (MT900/MT910 to camt.054.001.08) Translation Example

This example demonstrates the CBPR+ MT to MX (MT900/MT910 to camt.054.001.08) message translation using maps.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ camt.054.001.08 XML message output from a SWIFT MT900 or MT910 message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - MT900.inp
    - MT910.inp
  - Schemas:
    - head.001.001.02\_camt\_054.xsd
    - camt.054.001.08.xsd
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
    - infoset.mtt

- Maps:
  - cbpr1500\_mt9n0\_framework
  - cbpr1501\_mt9n0\_camt\_054
  - cbpr1502\_mtmx\_setvarlog
- cbprJnodesConfigIBM.tar.gz

---

## How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ camt.054.001.08 XML message output from a SWIFT MT900 or MT910 message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and build the following maps:
  - cbpr1500\_mt9n0\_framework
  - cbpr1501\_mt9n0\_camt\_054
  - cbpr1502\_mtmx\_setvarlog
3. Run the main map cbpr1500\_mt9n0\_framework.

The following output files will be generated:

- mx\_out.xml  
File contains the translated CBPR+ camt.054.001.08 message from MT900 or MT910 SWIFT message.
- audit\_msg.json  
Reports translation logs, including failure due to the pre-conversion checks as:
  - If the input file is a SWIFT message other than MT900 or MT910 or not a SWIFT message.

---

## CBPR+ MT to MX (MT192/MT292 to camt.056.001.08) Translation Example

This example demonstrates the CBPR+ MT to MX (MT192/MT292 to camt.056.001.08) message translation using maps.

- [What the example contains](#)

Files included in this example are as follows:

- [How to run the example](#)

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ camt.056.001.08 XML message output from a SWIFT MT192 or MT292 message.

---

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip

- Files:
  - MT192.inp
  - MT292.inp
- Schemas:
  - head.001.001.02\_camt\_056.xsd
  - camt.056.001.08.xsd
  - swift\_iso7775\_ccyy.mtt
  - swiftroute\_funds.mtt
  - infoset.mtt
- Maps:
  - cbpr2840\_mtn92\_framework
  - cbpr2841\_mtn92\_camt056
  - cbpr1502\_mttx\_setvarlog
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ camt.056.001.08 XML message output from a SWIFT MT192 or MT292 message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2840\_mtn92\_framework
- cbpr2841\_mtn92\_camt056
- cbpr1502\_mttx\_setvarlog

3. Run the main map cbpr2840\_mtn92\_framework.

The following output files will be generated:

- mx\_out.xml  
File contains the translated CBPR+ camt.056.001.08 message from MT192 or MT292 SWIFT message.

- audit\_msg.json

Reports translation logs, including failure due to the pre-conversion checks as:

- If the input file is a SWIFT message other than MT192 or MT292 or not a SWIFT message.

## CBPR+ MT to MX (MT196/MT296 to camt.029.001.09) Translation Example

This example demonstrates the CBPR+ MT to MX (MT196/MT296 to camt.029.001.09) message translation using maps.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ camt.029.001.09 XML message output from a SWIFT MT196 or MT296 message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - MT196.inp
    - MT296.inp
  - Schemas:
    - head.001.001.02\_camt\_029.xsd
    - camt.029.001.09.xsd
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
    - infoset.mtt
  - Maps:
    - cbpr2820\_mtn96\_framework
    - cbpr2821\_mtn96\_camt029
    - cbpr1502\_mttx\_setvarlog
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ camt.029.001.09 XML message output from a SWIFT MT196 or MT296 message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlxlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2820\_mtn96\_framework
- cbpr2821\_mtn96\_camt029
- cbpr1502\_mttx\_setvarlog

3. Run the main map cbpr2820\_mtn96\_framework.

The following output files will be generated:

- mx\_out.xml  
File contains the translated CBPR+ camt.029.001.09 message from MT196 or MT296 SWIFT message.

- audit\_msg.json

Reports translation logs, including failure due to the pre-conversion checks as:

- If the input file is a SWIFT message other than MT196 or MT296 or not a SWIFT message.

---

## CBPR+ MT to MX (MT103\_COR/MT103\_STP to pacs.008.001.08 or MT103\_COR RETN to pacs.004.001.09) Translation Example

This example demonstrates the CBPR+ MT to MX (MT103\_COR/MT103\_STP to pacs.008.001.08 or MT103\_COR RETN to pacs.004.001.09) message translation using maps.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ pacs.008.001.08/pacs.004.001.09 XML message output from a SWIFT MT103 or MT103\_STP or MT103\_COR RETN message.

---

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - MT103.inp
    - MT103\_RETN.inp
    - MT103\_STP.inp
  - Schemas:
    - head.001.001.02\_pacs\_004.xsd

  - Maps:
    - cbpr2800\_mt103\_framework
    - cbpr2801\_mt103\_pacs008
    - cbpr2802\_mt103\_pacs008\_stp
    - cbpr2799\_mt103\_pacs004
    - cbpr1502\_mtnx\_setvarlog
- cbprJnodesConfigIBM.tar.gz

---

## How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ pacs.008.001.08/pacs.004.001.09 XML message output from a SWIFT MT103 or MT103\_STP or MT103\_COR RETN message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart <brand>-server**

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
  - Restart the design server, that is, **podman restart** <brand>-server
1. Import the cbpr\_translation.zip project into the Design Server.
  2. Open the cbpr\_translation project in Design Server and build the following maps:
    - cbpr2800\_mt103\_framework
    - cbpr2801\_mt103\_pacs008
    - cbpr2802\_mt103\_pacs008\_stp
    - cbpr2799\_mt103\_pacs004
    - cbpr1502\_mtmx\_setvarlog
  3. Run the main map cbpr2800\_mt103\_framework.
- The following output files will be generated:
- mx\_out.xml  
File contains the translated CBPR+ pacs.008.001.08/pacs.004.001.09 message from MT103\_COR or MT103\_STP/MT103\_COR RETN SWIFT message.
  - audit\_msg.json  
Reports translation logs, including failure due to the pre-conversion checks as:
    - If the input file is a SWIFT message other than MT103 or MT103\_STP or MT103 COR RETN or not a SWIFT message.

## CBPR+ MT to MX (MT103 SWIFT Go to pacs.008.001.08) Translation Example

This example demonstrates the CBPR+ MT to MX (MT103 SWIFT Go to pacs.008.001.08) message translation using maps.

- **What the example contains**  
Files included in this example are as follows:
- **How to run the example**  
This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ pacs.008.001.08 XML message output from a MT103 SWIFT Go message.

### What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - MT103\_SGO.inp
  - Schemas:
    - head.001.001.02\_pacs\_008.xsd
    - pacs.008.001.08.xsd
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
    - infoset.mtt
  - Maps:
    - cbpr2800\_mt103\_framework
    - cbpr\_t9n\_mt103\_pacs008\_sgo
    - cbpr1502\_mtmx\_setvarlog
- cbprJnodesConfigIBM.tar.gz

### How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ pacs.008.001.08 XML message output from a MT103 SWIFT Go message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlxlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2800\_mt103\_framework
- cbpr\_t9n\_mt103\_pacs008\_sgo
- cbpr1502\_mtnx\_setvarlog

3. Run the main map cbpr2800\_mt103\_framework.

The following output files will be generated:

- mx\_out.xml

File contains the translated CBPR+ pacs.008.001.08 message from MT103 SWIFT Go SWIFT message.

- audit\_msg.json

Reports translation logs, including failure due to the pre-conversion checks as:

- If the input file is a SWIFT message other than MT103 SWIFT Go or not a SWIFT message.
- IF Field 72, Line 1 starts with "/REJT/" OR "/RETN/".

## CBPR+ MT to MX (MT202 (core/adv/cove) to pacs.009.001.08 (core/adv/cove) or MT202 (RETN) to pacs.004.001.09) Translation Example

This example demonstrates the CBPR+ MT to MX (MT202 (core/adv/cove) to pacs.009.001.08 (core/adv/cove) or MT202 (RETN) to pacs.004.001.09) message translation using maps.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ pacs.009.001.08 (core/adv/cove) XML message from a SWIFT MT202 (core/adv/cove) message or CBPR+ pacs.004.001.09 output from a MT202 RETN message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - MT202\_COR.inp
    - MT202\_COR\_bad.inp
    - MT202\_ADV.inp
    - MT202\_ADV\_bad.inp
    - MT202\_COV.inp
    - MT202\_COV\_bad.inp
    - MT202\_RTN.inp
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_004.xsd
    - head.001.001.02\_pacs\_009\_adv.xsd
    - head.001.001.02\_pacs\_009\_cov.xsd
    - head.001.001.02\_pacs\_009.xsd
    - pacs.004.001.09.xsd
    - pacs.009.001.08\_adv.xsd
    - pacs.009.001.08\_cov.xsd
    - pacs.009.001.08.xsd
    - trx\_config.xsd
    - infoset.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftroute\_funds.mtt
  - Maps:
    - cbpr2810\_mt202\_framework
    - cbpr1502\_mtnx\_setvarlog
    - cbpr2814\_mt202\_pacs009\_adv
    - cbpr2815\_mt202\_pacs009\_cov
    - cbpr2813\_mt202\_pacs009
    - cbpr2824\_mt202RTN\_pacs004
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ pacs.009.001.08 (core/adv/cove) XML message from a SWIFT MT202 (core/adv/cove) message or CBPR+ pacs.004.001.09 output from a MT202 RETN message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.

2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2810\_mt202\_framework
- cbpr1502\_mtmx\_setvarlog
- cbpr2814\_mt202\_pacs009\_adv
- cbpr2815\_mt202\_pacs009\_cov
- cbpr2813\_mt202\_pacs009
- cbpr2824\_mt202RTN\_pacs004

3. Run the main map cbpr2810\_mt202\_framework.

The following output files will be generated:

- mx\_out.xml  
File contains the translated CBPR+ pacs.009.001.08 (core/adv/cove) XML message from SWIFT MT202 (core/adv/cove) message or pacs.004.001.09 XML message from SWIFT MT202 (RETN) message.

- audit\_msg.json

Reports translation logs, including failure due to the pre-conversion checks as:

- Field 72, Line[1] should not start with /REJT/.
- If Field 72, Line[1] starts with /RETN/, <Tag121><EndToEndTxnRef> should not be absent.

## CBPR+ MT to MX (MT205 (core/cove) to pacs.009.001.08 (core/cove) or MT205 (RETN) to pacs.004.001.09) Translation Example

This example demonstrates the CBPR+ MT to MX (MT205 (core/cove) to pacs.009.001.08 (core/cove) or MT205 (RETN) to pacs.004.001.09) message translation using maps.

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ pacs.009.001.08 (core/cove) XML message from a SWIFT MT205 (core/cove) message or CBPR+ pacs.004.001.09 output from a MT205 (RETN) message.

## What the example contains

Files included in this example are as follows:

- cbpr\_translation.zip
  - Files:
    - MT205\_COR.inp
    - MT205\_COR\_bad.inp
    - MT205\_COV.inp
    - MT205\_COV\_bad.inp
    - MT205\_RTN.inp
    - trx\_config.xml
  - Schemas:
    - head.001.001.02\_pacs\_004.xsd
    - head.001.001.02\_pacs\_009\_adv.xsd
    - head.001.001.02\_pacs\_009\_cov.xsd
    - head.001.001.02\_pacs\_009.xsd
    - pacs.004.001.09.xsd
    - pacs.009.001.08\_adv.xsd
    - pacs.009.001.08\_cov.xsd
    - pacs.009.001.08.xsd
    - trx\_config.xsd
    - infoSet.mtt
    - swift\_iso7775\_ccyy.mtt
    - swiftRoute\_funds.mtt
  - Maps:
    - cbpr2810\_mt205\_framework
    - cbpr1502\_mtmx\_setvarlog
    - cbpr2820\_mt205\_pacs009\_cov
    - cbpr2819\_mt205\_pacs009
    - cbpr2825\_mt205RTN\_pacs004
- cbprJnodesConfigIBM.tar.gz

## How to run the example

This mt-mx translation will use the sample files to demonstrate the generation of CBPR+ pacs.009.001.08 (core/cove) XML message from a SWIFT MT205 (core/cove) message or CBPR+ pacs.004.001.09 output from a MT205 (RTN) message.

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txls:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Import the cbpr\_translation.zip project into the Design Server.
2. Open the cbpr\_translation project in Design Server and build the following maps:

- cbpr2811\_mt205\_framework
- cbpr1502\_mtmx\_setvarlog
- cbpr2820\_mt205\_pacs009\_cov
- cbpr2819\_mt205\_pacs009
- cbpr2825\_mt205RTN\_pacs004

3. Run the main map cbpr2811\_mt205\_framework.

The following output files will be generated:

- mx\_out.xml

File contains the translated CBPR+ pacs.009.001.08 (core/cove) XML message from SWIFT MT205 (core/cove) message or pacs.004.001.09 XML message from SWIFT MT205 (RETN) message.

- audit\_msg.json  
Reports translation logs, including failure due to the pre-conversion checks as:
  - Field 72, Line[1] should not start with /REJT/ OR /RETN/.
  - Field 72, Line[1] should not start with /REJT/.
  - If Field 72, Line[1] starts with /RETN/, <Tag121><EndToEndTxnRef> should not be absent.

---

## CBPR+ MT to MX Translation (using TX maps) Example

This example shows how TX maps can be used for translating CBPR+ MT to MX message formats.

- [What the example contains](#)  
Files included in this example are as follows:
- [Run the example in Design Studio](#)
- [Run the example in Design Server User Interface](#)

---

### What the example contains

Files included in this example are as follows:

- Maps:  
The maps directory contains the following map source:
  - cbpr\_t9n\_mt\_frmwrk\_maps.mms
    - cbpr1500\_mt9n0\_framework  
Main map to transform MT900/MT910 into camt.054.001.08
    - cbpr2800\_mt103\_framework  
Main map to transform MT103 COR/STP into pacs.008.001.08 COR or MT103 COR RETN to pacs.004.001.09
    - cbpr2808\_mt103sgo\_framework  
Main map to transform MT103 SGO into pacs.008.001.08 SGO
    - cbpr2810\_mt202\_framework  
Main map to transform MT202 COR/COV into pacs.009.001.08 ADV/COR/COV or MT202 RETN into pacs.004.001.09
    - cbpr2811\_mt205\_framework  
Main map to transform MT205 COR/COV into pacs.009.001.08 COR/COV or MT205 RETN into pacs.004.001.09
    - cbpr2820\_mtn96\_framework  
Main map to transform MT196/296 into camt.029.001.09
    - cbpr2840\_mtn92\_framework  
Main map to transform MT192/292 into camt.056.001.08
  - cbpr\_t9n\_mt\_setvarlog.mms  
Utility used to report translation logs.
  - cbpr\_t9n\_mt103\_pacs004.mms  
Utility used to populate pacs.004.001.09
  - cbpr\_t9n\_mt103\_pacs008.mms  
Utility used to populate pacs.008.001.08
  - cbpr\_t9n\_mt103\_pacs008\_sgo.mms  
Utility used to populate pacs.008.001.08 SGO
  - cbpr\_t9n\_mt103\_pacs008\_stp.mms  
Utility used to populate pacs.008.001.08 STP
  - cbpr\_t9n\_mt202\_pacs009\_adv.mms  
Utility used to populate pacs.009.001.08 ADV
  - cbpr\_t9n\_mt20n\_pacs009.mms  
Utility used to populate pacs.009.001.08 COR
  - cbpr\_t9n\_mt20n\_pacs009\_cov.mms  
Utility used to populate pacs.009.001.08 COV
  - cbpr\_t9n\_mt20nRTN\_pacs004.mms  
Utility used to populate pacs.004.001.09
  - cbpr\_t9n\_mt9n0\_camt054.mms  
Utility used to populate camt.054.001.08
  - cbpr\_t9n\_mtn92\_camt056.mms  
Utility used to populate camt.056.001.08

- cbpr\_t9n\_mtn96\_camt029.mms  
Utility used to populate camt.029.001.09

- Schemas:

The schemas directory contains the following files downloaded from SWIFT MyStandards MT/ISO 20022 Translation portal:

- camt.029.001.09.xsd
- camt.054.001.08.xsd
- camt.056.001.08.xsd
- head.001.001.02\_camt\_029.xsd
- head.001.001.02\_camt\_054.xsd
- head.001.001.02\_camt\_056.xsd
- head.001.001.02\_pacs\_004.xsd
- head.001.001.02\_pacs\_008.xsd
- head.001.001.02\_pacs\_008\_stp.xsd
- head.001.001.02\_pacs\_009.xsd
- head.001.001.02\_pacs\_009\_adv.xsd
- head.001.001.02\_pacs\_009\_cov.xsd
- pacs.004.001.09.xsd
- pacs.008.001.08.xsd
- pacs.008.001.08\_stp.xsd
- pacs.009.001.08.xsd
- pacs.009.001.08\_adv.xsd
- pacs.009.001.08\_cov.xsd
- trx\_config.xsd

Schema for the translation configuration file.

Each will have corresponding .mtx files used internally to manage RESTART attributes.

- Trees:

The trees directory contains the following files:

- infoset.mtt  
Metadata used to represent input messages into JSON.
- swift\_iso7775\_ccyy.mtt  
Metadata supporting SWIFT MT ISO7775 FIN structures.
- swiftroute\_funds.mtt  
Multi-purpose metadata structures.

- Data:

The data directory contains the following file:

- Sample SWIFT MT messages:
  - MT103.inp
  - MT103\_RETN.inp
  - MT103\_SGO.inp
  - MT103\_STP.inp
  - MT103\_STP\_RETN.inp
  - MT192.inp
  - MT196.inp
  - MT196\_bad.inp
  - MT202\_ADV.inp
  - MT202\_ADV\_bad.inp
  - MT202\_COR.inp
  - MT202\_COR\_bad.inp
  - MT202\_COV.inp
  - MT202\_RTN.inp
  - MT205\_COR.inp
  - MT205\_COR\_bad.inp
  - MT205\_COV.inp
  - MT205\_COV\_bad.inp
  - MT205\_RTN.inp
  - MT292.inp
  - MT296.inp
  - MT296\_bad.inp
  - MT900.inp
  - MT910.inp
  - trx\_config.xml

Translation configuration file.

## Run the example in Design Studio

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlxlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Build all the maps in the .mms files listed in What the example contains section.

2. Replace the input card 1 in any of the main maps (under cbpr\_t9n\_mt\_frmwrk\_maps.mms file) with desired input file.

3. Run any of the main router map:

- cbpr1500\_mt9n0\_framework (MT900/MT910 into camt.054.001.08)
- cbpr2800\_mt103\_framework (MT103 COR/STP into pacs.008.001.08 COR)
- cbpr2808\_mt103sgo\_framework (MT103 SGO into pacs.008.001.08 SGO)
- cbpr2810\_mt202\_framework (MT202 COR/COV/ADV into pacs.009.001.08 COR/COV or MT202 RETN into pacs.004.001.09)
- cbpr2811\_mt205\_framework (MT205 COR/COV into pacs.009.001.08 COR/COV or MT205 RETN into pacs.004.001.09)
- cbpr2820\_mtn96\_framework (MT196/MT296 into camt.029.001.09)
- cbpr2840\_mtn92\_framework (MT192/MT292 into camt.056.001.08)

You will see the output file in the data folder called mx\_out.xml and translation logs in the data folder called audit\_msg.json.

## Run the example in Design Server User Interface

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/tlxlibs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart** <brand>-server

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If the project does not exist, import cbpr\_translation.zip.

4. If absent, create a package containing all the Maps, Files, and Flows.
5. Build package in desired server (to build all maps).
6. Open project.
7. In the Maps tab, open any of the main maps:
  - cbpr1500\_mt9n0\_framework (MT900/MT910 into camt.054.001.08)
  - cbpr2800\_mt103\_framework (MT103 COR/STP into pacs.008.001.08 COR)
  - cbpr2808\_mt103sgo\_framework (MT103 SGO into pacs.008.001.08 SGO)
  - cbpr2810\_mt202\_framework (MT202 COR/COV/ADV into pacs.009.001.08 COR/COV or MT202 RETN into pacs.004.001.09)
  - cbpr2811\_mt205\_framework (MT205 COR/COV into pacs.009.001.08 COR/COV or MT205 RETN into pacs.004.001.09)
  - cbpr2820\_mtn96\_framework (MT196/MT296 into camt.029.001.09)
  - cbpr2840\_mtn92\_framework (MT192/MT292 into camt.056.001.08)
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map from Step 8.
10. Right click on the output card 3 on canvas and select View translation results.
11. Right click on the output card 4 on canvas and select View translation logs.

## CBPR+ MX to MT Translation (using TX maps) Example

This example shows how TX maps can be used for translating CBPR+ MX to MT message formats.

- [What the example contains](#)
- Files included in this example are as follows:
- [Run the example in Design Studio](#)
- [Run the example in Design Server User Interface](#)

### What the example contains

Files included in this example are as follows:

- Maps:  
The maps directory contains the following map source:
  - cbpr\_t9n\_mx\_frmwrk\_maps.mms
    - cbpr2510\_camt054\_framework  
Main map to transform camt.054.001.08 into MT900/MT910.
    - cbpr2520\_camt029\_framework  
Main map to transform camt.029.001.09 into MT196/MT296.
    - cbpr2530\_camt053\_framework  
Main map to transform camt.053.001.08 into MT940.
    - cbpr2540\_camt056\_framework  
Main map to transform camt.056.001.08 into MT192/MT292.
    - cbpr2546\_camt052\_framework  
Main map to transform camt.052.001.08 into MT942.
    - cbpr2600\_camt057\_framework  
Main map to transform camt.057.001.06 into MT210.
    - cbpr2610\_camt058\_framework  
Main map to transform camt.058.001.08 into MT292.
    - cbpr2620\_camt107\_framework  
Main map to transform camt.107.001.01 into MT110.
    - cbpr2630\_camt108\_framework  
Main map to transform camt.108.001.01 into MT111.
    - cbpr2640\_camt109\_framework  
Main map to transform camt.109.001.01 into MT112.
    - cbpr2500\_pacs002\_framework  
Main map to transform pacs.002.001.10 into MT199/MT299.
    - cbpr2700\_pacs008\_framework  
Main map to transform pacs.008.001.08 COR/SGO into MT103 COR/STP/SGO.
    - cbpr2710\_pacs009\_mt202\_framework  
Main map to transform pacs.009.001.08 ADV/COR/COV into MT202 COR/COV.
    - cbpr2724\_pacs009\_mt205\_framework  
Main map to transform pacs.009.001.08 COR/COV into MT205 COR/COV.
    - cbpr2850\_pacs004\_mtnnn\_RTN\_frw  
Main map to transform pacs.004.001.09 into MT103RETN/MT202RETN/MT205RETN.
  - cbpr\_t9n\_mx\_setvarlog.mms

Utility used to report translation logs.

- cbpr\_t9n\_mx\_camt029\_mtn96.mms  
Utility used to populate MT196/MT296.
- cbpr\_t9n\_mx\_camt029\_translate.mms  
Utility used to normalize camt.029.001.09 into JSON.
- cbpr\_t9n\_mx\_camt052\_mt942.mms  
Utility used to populate MT942.
- cbpr\_t9n\_mx\_camt052\_translate.mms  
Utility used to normalize camt.052.001.08 into JSON.
- cbpr\_t9n\_mx\_camt053\_mt940.mms  
Utility used to populate MT940.
- cbpr\_t9n\_mx\_camt053\_translate.mms  
Utility used to normalize camt.053.001.08 into JSON.
- cbpr\_t9n\_mx\_camt054\_mt900.mms  
Utility used to populate MT900.
- cbpr\_t9n\_mx\_camt054\_mt910.mms  
Utility used to populate MT910.
- cbpr\_t9n\_mx\_camt054\_translate.mms  
Utility used to normalize camt.054.001.08 into JSON.
- cbpr\_t9n\_mx\_camt056\_mtn92.mms  
Utility used to populate MT192/MT292.
- cbpr\_t9n\_mx\_camt056\_translate.mms  
Utility used to normalize camt.056.001.08 into JSON.
- cbpr\_t9n\_mx\_camt057\_mt210.mms  
Utility used to populate MT210.
- cbpr\_t9n\_mx\_camt057\_translate.mms  
Utility used to normalize camt.057.001.06 into JSON.
- cbpr\_t9n\_mx\_camt058\_mt292.mms  
Utility used to populate MT292.
- cbpr\_t9n\_mx\_camt058\_translate.mms  
Utility used to normalize camt.058.001.08 into JSON.
- cbpr\_t9n\_mx\_camt107\_mt110.mms  
Utility used to populate MT110.
- cbpr\_t9n\_mx\_camt107\_translate.mms  
Utility used to normalize camt.107.001.01 into JSON.
- cbpr\_t9n\_mx\_camt108\_mt111.mms  
Utility used to populate MT111.
- cbpr\_t9n\_mx\_camt108\_translate.mms  
Utility used to normalize camt.108.001.01 into JSON.
- cbpr\_t9n\_mx\_camt109\_mt112.mms  
Utility used to populate MT112.
- cbpr\_t9n\_mx\_camt109\_translate.mms  
Utility used to normalize camt.109.001.01 into JSON.
- cbpr\_t9n\_mx\_pacs002\_mtn99.mms  
Utility used to populate MT199/MT299.
- cbpr\_t9n\_mx\_pacs002\_translate.mms  
Utility used to normalize pacs.002.001.10 into JSON.
- cbpr\_t9n\_mx\_pacs004\_mt103RTN.mms  
Utility used to populate MT103RTN.
- cbpr\_t9n\_mx\_pacs004\_mt20nRTN.mms  
Utility used to populate MT202RTN/MT205RTN.
- cbpr\_t9n\_mx\_pacs004\_translate.mms  
Utility used to normalize pacs.004.001.09 into JSON.
- cbpr\_t9n\_mx\_pacs008\_mt103.mms  
Utility used to populate MT103 COR/STP.
- cbpr\_t9n\_mx\_pacs008\_mt103\_sgo.mms  
Utility used to populate MT103 SGO.
- cbpr\_t9n\_mx\_pacs008\_stp\_translate.mms

Utility used to normalize pacs.008.001.08 STP into JSON.

- cbpr\_t9n\_mx\_pacs008\_translate.mms  
Utility used to normalize pacs.008.001.08 into JSON.
- cbpr\_t9n\_mx\_pacs009\_adv\_translate.mms  
Utility used to normalize pacs.009.001.08 ADV into JSON.
- cbpr\_t9n\_mx\_pacs009\_cov\_translate.mms  
Utility used to normalize pacs.009.001.08 COV into JSON.
- cbpr\_t9n\_mx\_pacs009\_mt20n.mms  
Utility used to populate MT202 COR/COV/ADV.
- cbpr\_t9n\_mx\_pacs009\_translate.mms  
Utility used to normalize pacs.009.001.08 into JSON.

- Schemas:

- Translation configuration file.

## Run the example in Design Studio

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlbs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart <brand>-server**

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **podman restart <brand>-server**

1. Build all the maps in the .mms files listed in What the example contains section.

2. Replace the input card 1 in any of the main maps (under cbpr\_t9n\_mx\_frmwrk\_maps.mms) with desired input file.

3. Run any of the main router map:

- cbpr2510\_camt054\_framework (camt.054.001.08 into MT900/MT910)
- cbpr2520\_camt029\_framework (camt.029.001.09 into MT196/MT296)
- cbpr2530\_camt053\_framework (camt.053.001.08 into MT940)
- cbpr2540\_camt056\_framework (camt.056.001.08 into MT192/MT292)
- cbpr2546\_camt052\_framework (camt.052.001.08 into MT942)
- cbpr2600\_camt057\_framework (camt.057.001.06 into MT210)
- cbpr2610\_camt058\_framework (camt.058.001.08 into MT292)
- cbpr2620\_camt107\_framework (camt.107.001.01 into MT110)
- cbpr2630\_camt108\_framework (camt.108.001.01 into MT111)
- cbpr2640\_camt109\_framework (camt.109.001.01 into MT112)
- cbpr2500\_pacs002\_framework (pacs.002.001.10 into MT199/MT299)
- cbpr2700\_pacs008\_framework (pacs.008.001.08 COR/SGO into MT103 COR/STP/SGO)
- cbpr2710\_pacs009\_mt202\_framework (pacs.009.001.08 into MT202 COR/COV/ADV)
- cbpr2724\_pacs009\_mt205\_framework (pacs.009.001.08 into MT205 COR/COV)
- cbpr2850\_pacs004\_mtnnn\_RTN\_frw (pacs.004.001.09 into MT103RETN/MT202RETN/MT205RETN)

You will see the output file in the data folder called mt\_out.xml and translation logs in the data folder called audit\_msg.json.

## Run the example in Design Server User Interface

Extract from <packs\_install\_dir>/UIProjectImports/cbprJnodesConfigIBM.tar.gz file.

- jnodes0.jar

The following jars needs to be copied from <TX\_install\_dir>/jars:

- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

Or visit <https://repo1.maven.org/maven2/com/fasterxml/jackson/core/> for download.

Note: Recommend using the latest version.

For the non-Docker environments,

- Copy jars to <TX\_install\_dir>/extjar

For TX V11.0.1 and up, native based Design Server installation,

Copy the following into the directory defined in config.yaml server.persistence.libs, by default, this is set to /opt/txlbs:

- jvcwrap.jar
- jvalccyy.jar

Restart the running application ./ITX stop and then ./ITX start.

For the Docker environments,

- docker cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
- Restart the design server, that is, **docker restart** <brand>-server

Note: For RHEL, Docker is not supported. Podman can be used as a substitute since it provides a command line interface similar to Docker. Following is an example of using Podman.

- podman cp jnodes0.jar <brand>-server:/opt/<company>/<brand>/libs/
  - Restart the design server, that is, **podman restart** <brand>-server
1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
  2. Enter user and password credentials.
  3. If the project does not exist, import cbpr\_translation.zip.
  4. If absent, create a package containing all the Maps, Files, and Flows.
  5. Build package in desired server (to build all maps).
  6. Open project.
  7. In the Maps tab, open any of the main maps:
    - cbpr2510\_camt054\_framework (camt.054.001.08 into MT900/MT910)
    - cbpr2520\_camt029\_framework (camt.029.001.09 into MT196/MT296)
    - cbpr2530\_camt053\_framework (camt.053.001.08 into MT940)
    - cbpr2540\_camt056\_framework (camt.056.001.08 into MT192/MT292)
    - cbpr2545\_camt052\_framework (camt.052.001.08 into MT942)
    - cbpr2600\_camt057\_framework (camt.057.001.06 into MT210)
    - cbpr2610\_camt058\_framework (camt.058.001.08 into MT292)
    - cbpr2620\_camt107\_framework (camt.107.001.01 into MT110)
    - cbpr2630\_camt108\_framework (camt.108.001.01 into MT111)
    - cbpr2640\_camt109\_framework (camt.109.001.01 into MT112)
    - cbpr2500\_pacs002\_framework (pacs.002.001.10 into MT199/MT299)
    - cbpr2700\_pacs008\_framework (pacs.008.001.08 COR/SGO into MT103 COR/STP/SGO)
    - cbpr2710\_pacs009\_mt202\_framework (pacs.009.001.08 into MT202 COR/COV/ADV)
    - cbpr2724\_pacs009\_mt205\_framework (pacs.009.001.08 into MT205 COR/COV)
    - cbpr2850\_pacs004\_mtnnn\_RTN\_frw (pacs.004.001.09 into MT103RETN/MT202RETN/MT205RETN)
  8. Modify the settings for input card 1 on design canvas to point to the desired test file.
  9. Save, build, and run the map from Step 8.
  10. Right click on the output card 2 on canvas and select View translation results.
  11. Right click on the output card 3 on canvas and select View translation logs.

## CHAPS L4L/ENH Examples:

- **[CHAPS L4L Examples: \(Deprecated\)](#)**  
CHAPS L4L examples are as follow:
- **[CHAPS ENH Examples:](#)**  
CHAPS ENH examples are as follow:

## CHAPS L4L Examples: (Deprecated)

CHAPS L4L examples are as follow:

- **[CHAPS L4L enhanced MX validation \(using flows\) Example](#)**  
This example demonstrates the CHAPS L4L enhanced MX validation for CHAPS L4L messages using the flow server.
- **[CHAPS L4L enhanced MX validation \(using maps\) Example](#)**  
This example demonstrates the CHAPS L4L enhanced MX validation for CHAPS L4L messages using maps only.
- **[CHAPS L4L schema validation \(using maps\) Example](#)**  
This example demonstrates the CHAPS L4L schema validation for CHAPS L4L messages using maps only.

## CHAPS L4L enhanced MX validation (using flows) Example

This example demonstrates the CHAPS L4L enhanced MX validation for CHAPS L4L messages using the flow server.

The flow can perform following level of validation:

- MX extended validation includes following checks:
  - BIC lookup
  - Country code lookup
  - Currency code lookup
  - IBAN format
  - Allowed maximum fractional digits per currency
  - Usage guideline rules, see mxconfig.xml for list of rules
- Schema validation
- **[What the example contains](#)**  
Files included in this example are as follows:
- **[How to run the example](#)**  
This CHAPS L4L MX Validation will use the sample files to demonstrate the generation of validation report as output from a CHAPS L4L XML message.

- [How to customize the mxconfig.xml file](#)

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

---

## What the example contains

Files included in this example are as follows:

- chaps\_l4l.zip
  - Test Data Files:
    - chlf\_pacs\_009\_cov.xml
    - chlf\_pacs\_009\_cov\_bad\_rule.xml
    - chlf\_pacs\_009\_cov\_bad\_schema.xml
  - Validation Files:
    - mxconfig.xml
    - bic.xml
    - currencycodedecimals.xml
  - Schemas:
    - bic.xsd  
Metadata that represents the bic.xml repository file structure.
    - ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
    - mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.
    - mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
    - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.

## How to run the example

This CHAPS L4L MX Validation will use the sample files to demonstrate the generation of validation report as output from a CHAPS L4L XML message.

The stopValidation.json file will report the validation failure due to the pre-conversion checks:

**If input file is other than any of the supported CHAPS L4L messages as per schema list indicated above.**

1. Import the chaps\_l4l.zip project into the Design Server.
  2. Open the chaps\_l4l project in Design Server and view the flow chaps\_l4l\_validation\_flow.
- a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:

- @packagemap=chaps\_l4l/validation/mx\_extended/maps/chaps\_l4l\_mx\_camt\_validation\_enh/chlf8056\_head112\_camt052
- @packagemap=chaps\_l4l/validation/mx\_extended/maps/chaps\_l4l\_mx\_camt\_validation\_enh/chlf8006\_camt\_052\_001\_08
- @packagemap=chaps\_l4l/validation/mx\_extended/maps/chaps\_l4l\_mx\_camt\_validation\_enh/chlf8055\_head112\_camt053
- @packagemap=chaps\_l4l/validation/mx\_extended/maps/chaps\_l4l\_mx\_camt\_validation\_enh/chlf8005\_camt\_053\_001\_08

a. It utilizes the following nodes:

i. Source Nodes:

- mx\_input

This node identifies the input data to be validated in the flow. It uses the INPUT\_FILE variable to set the location of the data.

ii. Map Nodes:

- MX pre-check

Runs map mxut1002\_bizsvc\_chaps which sets flow variables, checks pre-validation conditions and creates infoset.json for validation.

- EXT\_VAL

Runs map chlf8100\_val which calls the appropriate map to perform extended validation of a CHAPS L4L message.

- XSD\_VAL

Runs map chlf8200\_val which calls the appropriate map to perform schema validation of a CHAPS L4L message.

Note: The maps chlf8100\_val and chlf8200\_val internally call all the other maps identified in the above Flow Description step.

iii. Decision Nodes:

- pre-valid chk

This node checks the flow variable stopValidation to decide if further validation/processing is not required.

- EXT\_RESULT\_FORMAT

This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for extended validation should be generated in XML (default) or JSON.

- XSD\_RESULT\_FORMAT

This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for schema-only validation should be generated in XML (default) or JSON.

iv. Route Nodes:

- **VAL\_TYPE**  
This node checks the variable VALIDATION\_TYPE to determine if the process will do extended validation or schema-only validation on the data.
- v. Log Nodes:
  - **FAILURE**  
In case of no validation due to precondition check failures, this node creates a log file specified by the flow variable FAILURE\_LOG.
- vi. Fail Node:
  - **STOP**  
It generates error message setup in the node in case of no validation performed.
- vii. Passthrough Nodes:
  - **EXT\_XML\_CONVERT**  
This node receives an extended validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.
  - **XSD\_XML\_CONVERT**  
This node receives a schema-only validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.
- viii. Format Converter Nodes:
  - **EXT\_JSON\_CONVERT**  
This node receives an extended validation report in XML format and converts it to JSON before passing it to the appropriate target node.
  - **XSD\_JSON\_CONVERT**  
This node receives a schema-only validation report in XML format and converts it to JSON before passing it to the appropriate target node.
- ix. Target Nodes:
  - **ext\_xml**  
This node contains the resulting extended validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.
  - **ext\_json**  
This node contains the resulting extended validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.
  - **xsd\_xml**  
This node contains the resulting schema-only validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.
  - **xsd\_json**  
This node contains the resulting schema-only validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.

b. It utilizes the following variables:

Flow variables:

- **VALIDATION\_TYPE**  
The default value is extended.  
  
For schema-only validation, it can be changed to schema. This is used in Route node VAL\_TYPE.
- **REPORT\_FORMAT**  
The default value is xml.  
  
It can be changed to json. This is used in Decision nodes EXT\_RESULT\_FORMAT and XSD\_RESULT\_FORMAT.
- **INPUT\_FILE**  
The default value is ..../tools/mx\_service/data/chlf\_pacs\_009\_cov.xml.  
  
This is the data file to be used for validation and can be customized. This is used in Source node mx\_input.
- **BIC\_FILE**  
The default value is ..../data/bic.xml.  
  
This is the location of the bic cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.
- **CCY\_FILE**  
The default value is ..../data/currencycodedecimals.xml.  
  
This is the location of the country code cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.
- **MXCONFIG\_FILE**  
The default value is ..../data/mxconfig.xml.  
  
This is the location of the file containing the rule validation settings that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.
- **OUTPUT\_RESULT\_XML**  
The default value is validation\_result.xml.  
  
This is the location of the validation report file in xml format. It is used in Target nodes ext\_xml and xsd\_xml. It can be customized.
- **OUTPUT\_RESULT\_JSON**  
The default value is validation\_result.json.  
  
This is the location of the validation report file in json format. It is used in Target nodes ext\_json and xsd\_json. It can be customized.

- FAILURE\_LOG  
The default value is stopMXValidation.json.  
  
This is the location of the failure log. It is used in Log node FAILURE. It can be customized.
  - bizSvc  
For internal use in the Map node MX pre-check to determine the type of data being read in the input file.
  - stopValidation  
For internal use in the Map node MX pre-check and is checked in Decision node pre-valid chk to cause a Failure log in case a data file was not recognized as a valid CHAPS L4L message.
3. Open the main flow chaps\_l4l\_validation\_flow in the Design Server. It utilizes above one source node, three map nodes, three decision nodes, one route node, one log node, one fail node, two passthrough nodes, two format converter nodes and four target nodes
4. In Design Server, create a package chaps\_l4l\_mx\_validation that contains the input files and one flow chaps\_l4l\_validation\_flow. The maps will automatically be included during deployment of the package onto the runtime server.  
Note: Not required for running flows on Design Server user interface directly.
- [Run the example using three different methods](#)  
You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
  2. Deploying the example to tx-rest and running it using the Swagger interface.
  3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).
- [Run the example from the Design Server user interface](#)  
Use the following steps to run the example from the Design Server user interface:
  - [Run the example using the Swagger interface](#)  
To run the example, deploy to tx-rest and run it using the Swagger interface.
  - [Run the example using the flow command server process \(flowcmdserver\)](#)  
To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open chaps\_l4l\_validation\_flow flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file. Example is chlf\_pacs\_009\_cov.xml.  
Flow will run and report with the green check box. The reports list execution of all nodes.
3. Right click and select View Link Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You should see a Miscellaneous section having two actions: A **PUT** /v2/run/chaps\_l4l\_validation\_flow and a **POST** /v2/run/chaps\_l4l\_validation\_flow.
6. In the **PUT** action:
  - a. Expand the **PUT** action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/mydir/data/chlf_pacs_009_cov.xml",
 "OUTPUT_RESULT_JSON": "C:/mydir/data/validation_result.json",
 "REPORT_FORMAT": "json",
 "VALIDATION_TYPE": "extended"
}

or

{
 "INPUT_FILE": "C:/mydir/data/chlf_pacs_009_cov.xml",
 "OUTPUT_RESULT_XML": "C:/mydir/data/validation_result.xml",
 "REPORT_FORMAT": "xml",
 "VALIDATION_TYPE": "extended"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. This run should generate the output same as above.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select Try it out.
9. In the Name field, enter the name you gave to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. The below command is for CHAPS L4L chlf\_pacs\_009\_cov.xml message.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows
--flow chaps_141_validation_flow.json
--input "1;FILE;C:\ftpserver\deployment\tools\mx_service\data\chlf_pacs_009_cov.xml"
--audit "C:\ftpserver\deployment\tools\mx_service\data\chlf_pacs_009_cov_adt.json" -ad
```

The results will be in C:\ftpserver\deployment\flows as validation\_results.xml or validation\_results.json depending on the value of the REPORT\_FORMAT variable.

4. Use the below command to execute with the variable VALIDATION\_TYPE value defined in the Flow settings in Design Server ('extended' or 'schema').

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows
--flow chaps_141_validation_flow.json
--var "INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\chlf_pacs_009_cov.xml"
--var "VALIDATION_TYPE=schema"
--var "REPORT_FORMAT=xml"
--audit "C:\ftpserver\deployment\tools\mx_service\data\chlf_pacs_009_cov_adt.json" -ad
```

5. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\ftpserver\deployment\tools\mx_service\data\chlf_pacs_009_cov_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

6. Examine the flow output result file validation\_results.xml and the audit file chlf\_pacs\_009\_cov\_adt.json.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

### Example

To disable the BIC lookup validation feature.

### About this task

Change sub-element ExtendedValidation/BICValidation value from T to F.

### Procedure

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the flow.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

## CHAPS L4L enhanced MX validation (using maps) Example

This example demonstrates the CHAPS L4L enhanced MX validation for CHAPS L4L messages using maps only.

The maps can perform following level of validation:

- MX extended validation includes following checks:
  - BIC lookup
  - Country code lookup
  - Currency code lookup
  - IBAN format
  - Allowed maximum fractional digits per currency
  - Usage guideline rules, see mxconfig.xml for list of rules
- Schema validation
- [\*\*What the example contains\*\*](#)  
Files and directories included in this example are as follows:
- [\*\*Run the example in Design Studio\*\*](#)
- [\*\*Run the example in Design Server User Interface\*\*](#)
- [\*\*How to customize the mxconfig.xml file\*\*](#)  
Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

## What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources:
  - chaps\_l4l\_mx\_admi\_validation\_enh.mms  
Utility maps called by main map for all the admi CHAPS L4L xml message MX validation.
  - chaps\_l4l\_mx\_camt\_validation\_enh.mms  
Utility maps called by main map for all the camt CHAPS L4L xml message MX validation.
  - chaps\_l4l\_mx\_mirs\_validation\_enh.mms  
Utility maps called by main map for all the mirs CHAPS L4L xml message MX validation.
  - chaps\_l4l\_mx\_pacs\_validation\_enh.mms  
Utility maps called by main map for all the pacs CHAPS L4L xml message MX validation.
  - chaps\_l4l\_mx\_validation\_frmwrk\_map\_enh.mms  
The main map used to apply MX validation to CHAPS L4L xml messages.
- Schemas:  
The schemas directory contains the following files:
  - bic.xsd  
Metadata that represents the bic.xml repository file structure.
  - ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
  - mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.
  - adm1.004.001.02\_fqsm.xsd
  - adm1.004.001.02\_rsr.xsd
  - camt.052.001.08.xsd

Note: XML schemas were downloaded from SWIFT MyStandards Readiness CHAPS L4L portal.

- Trees:  
The trees directory contains the following files:
  - mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
  - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
- Data:  
The data directory contains the following files:
  - bic.xml  
Repository file listing all BICs which are used during validation.
  - currencycodedecimals.xml  
Repository file listing country codes, currency codes and corresponding maximum fractionally digits, used as reference for validation.
  - mxconfig.xml  
Contains the MX configuration information on how to process the message.

Sample CHAPS L4L valid files for test purpose with header envelope:

- bah\_admi\_004\_001\_02\_fqsm\_valid.xml
- bah\_admi\_004\_001\_02\_rsr\_valid.xml
- bah\_camt\_052\_001\_08\_valid.xml
- bah\_camt\_053\_001\_08\_valid.xml
- bah\_camt\_054\_001\_08\_ca\_valid.xml

---

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, chlf8000\_val (under chaps\_l4l\_mx\_validation\_frmwrk\_map\_enh.mms file) with the desired input file.
3. Run the main router map, chlf8000\_val.  
You will see the output file in the data folder called chaps\_error\_report.xml.

---

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter the user and password credentials.
3. If the project does not exist, import chaps\_l4l.zip.
4. If absent, create a package containing all the Maps, Files and Flows.
5. Build the package in the desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map chlf8000\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map chlf8000\_val.
10. Right click on the output card on canvas and select View data.

---

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

---

## Example

To disable the BIC lookup validation feature.

---

## About this task

Change sub-element ExtendedValidation/BICValidation value from T to F.

## Procedure

---

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the map.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

---

## CHAPS L4L schema validation (using maps) Example

This example demonstrates the CHAPS L4L schema validation for CHAPS L4L messages using maps only.

The maps can perform following level of validation:

- Schema validation
  - [\*\*What the example contains\*\*](#)  
Files and directories included in this example are as follows:
  - [\*\*Run the example in Design Studio\*\*](#)
  - [\*\*Run the example in Design Server User Interface\*\*](#)
- 

## What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources:
  - chaps\_l4l\_mx\_schema\_validation\_xsd.mms  
Contains maps for schema validation of any CHAPS L4L xml message.
  - chaps\_l4l\_schema\_validation\_frmwrk\_map\_xsd.mms  
The main map used to apply schema validation to CHAPS L4L xml messages.

- Schemas:  
The schemas directory contains the following files:

- admi.004.001.02\_fqsm.xsd
- admi.004.001.02\_rsr.xsd
- camt.052.001.08.xsd
- camt.053.001.08.xsd
- camt.054.001.08\_ca.xsd
- camt.054.001.08\_cld.xsd
- camt.054.001.08\_cli.xsd
- camt.054.001.08\_lpa.xsd
- camt.060.001.05.xsd
- mirs.095.001.01.xsd
- pacs.002.001.10.xsd
- pacs.004.001.09.xsd
- pacs.008.001.08.xsd
- pacs.009.001.08\_core.xsd
- pacs.009.001.08\_cov.xsd
- head.001.001.02\_admi\_004\_fqsm.xsd
- head.001.001.02\_admi\_004\_rsr.xsd
- head.001.001.02\_camt\_052.xsd
- head.001.001.02\_camt\_053.xsd
- head.001.001.02\_camt\_054\_ca.xsd
- head.001.001.02\_camt\_054\_cld.xsd
- head.001.001.02\_camt\_054\_cli.xsd
- head.001.001.02\_camt\_054\_lpa.xsd
- head.001.001.02\_camt\_060.xsd
- head.001.001.02\_mirs\_095.xsd
- head.001.001.02\_pacs\_002.xsd
- head.001.001.02\_pacs\_004.xsd
- head.001.001.02\_pacs\_008.xsd
- head.001.001.02\_pacs\_009\_core.xsd
- head.001.001.02\_pacs\_009\_cov.xsd

Note: XML schemas were downloaded from SWIFT MyStandards Readiness CHAPS L4L portal.

- Trees:  
The trees directory contains the following files:

- mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
  - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
  - Data:  
The data directory contains the following file:
- Sample CHAPS L4L valid files for test purpose with header envelope:
- bah\_admi\_004\_001\_02\_fqsm\_valid.xml
  - bah\_admi\_004\_001\_02\_rsr\_valid.xml

  - bah\_pacs\_004\_001\_09\_valid.xml
  - bah\_pacs\_008\_001\_08\_valid.xml
  - bah\_pacs\_009\_001\_08\_core\_valid.xml
  - bah\_pacs\_009\_001\_08\_cov\_valid.xml

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, chlf8200\_val (under chaps\_l4l\_schema\_validation\_frmwrk\_map\_xsd.mms file) with the desired input file.
3. Run the main router map, chlf8200\_val.  
You will see the output file in the data folder called chaps\_error\_report.xml.

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter the user and password credentials.
3. If the project does not exist, import chaps\_l4l.zip.
4. If absent, create a package containing all the Maps, Files and Flows.
5. Build the package in the desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map chlf8200\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map chlf8200\_val.
10. Right click on the output card on canvas and select View data.

## CHAPS ENH Examples:

CHAPS ENH examples are as follow:

- [\*\*CHAPS ENH enhanced MX validation \(using flows\) Example\*\*](#)  
This example demonstrates the CHAPS ENH enhanced MX validation for CHAPS ENH messages using the flow server.
- [\*\*CHAPS ENH enhanced MX validation \(using maps\) Example\*\*](#)  
This example demonstrates the CHAPS ENH enhanced MX validation for CHAPS ENH messages using maps.
- [\*\*CHAPS ENH schema validation \(using maps\) Example\*\*](#)  
This example demonstrates the CHAPS ENH schema validation for CHAPS ENH messages using maps only.

## CHAPS ENH enhanced MX validation (using flows) Example

This example demonstrates the CHAPS ENH enhanced MX validation for CHAPS ENH messages using the flow server.

The flow can perform following level of validation:

- MX extended validation includes following checks:
  - BIC lookup
  - Country code lookup
  - Currency code lookup
  - IBAN format
  - Allowed maximum fractional digits per currency
  - Usage guideline rules, see mxconfig.xml for list of rules

- Schema validation
  - [\*\*What the example contains\*\*](#)  
Files included in this example are as follows:
  - [\*\*How to run the example\*\*](#)  
This CHAPS ENH MX Validation will use the sample files to demonstrate the generation of validation reports as output from a CHAPS ENH XML message.
  - [\*\*How to customize the mxconfig.xml file\*\*](#)  
Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.
- 

## What the example contains

Files included in this example are as follows:

- chaps\_enh.zip
  - Test Data Files:
    - chen\_pacs\_009\_cov.xml
    - chen\_pacs\_009\_cov\_bad\_rule.xml
    - chen\_pacs\_009\_cov\_bad\_schema.xml
  - Validation Files:
    - mxconfig.xml
    - bic.xml
    - currencycodedecimals.xml
  - Schemas:
    - bic.xsd  
Metadata that represents the bic.xml repository file structure.
    - ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
    - mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.
    - mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
    - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
    - admi.004.001.02\_fqsm.xsd

## How to run the example

This CHAPS ENH MX Validation will use the sample files to demonstrate the generation of validation reports as output from a CHAPS ENH XML message.

The stopValidation.json file will report the validation failure due to the pre-conversion checks:

**If input file is other than any of the supported CHAPS ENH messages as per schema list indicated above.**

1. Import the chaps\_enh.zip project into the Design Server.
2. Open the chaps\_enh project in Design Server and view the flow chaps\_enh\_validation\_flow.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps:
    - @packagemap=chaps\_enh/validation/mx\_extended/maps/chaps\_enh\_mx\_camt\_validation\_enh/chen8056\_head112\_camt052

a. It utilizes the following nodes:

i. Source Nodes:

- mx\_input

This node identifies the input data to be validated in the flow. It uses the INPUT\_FILE variable to set the location of the data.

ii. Map Nodes:

- MX pre-check

Runs map mxut1002\_bizsvc\_chaps which sets flow variables, checks pre-validation conditions and creates infoset.json for validation.

- EXT\_VAL

Runs map chen8100\_val which calls the appropriate map to perform extended validation of a CHAPS ENH message.

- XSD\_VAL

Runs map chen8200\_val which calls the appropriate map to perform schema validation of a CHAPS ENH message.

Note: The maps chen8100\_val and chen8200\_val internally call all the other maps identified in the above Flow Description step.

iii. Decision Nodes:

- pre-valid chk

This node checks the flow variable stopValidation to decide if further validation/processing is not required.

- EXT\_RESULT\_FORMAT

This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for extended validation should be generated in XML (default) or JSON.

- XSD\_RESULT\_FORMAT  
This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for schema-only validation should be generated in XML (default) or JSON.

iv. Route Nodes:

- VAL\_TYPE  
This node checks the variable VALIDATION\_TYPE to determine if the process will do extended validation or schema-only validation on the data.

v. Log Nodes:

- FAILURE  
In case of no validation due to precondition check failures, this node creates a log file specified by the flow variable FAILURE\_LOG.

vi. Fail Node:

- STOP  
It generates error message setup in the node in case of no validation performed.

vii. Passthrough Nodes:

- EXT\_XML\_CONVERT  
This node receives an extended validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.
- XSD\_XML\_CONVERT  
This node receives a schema-only validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.

viii. Format Converter Nodes:

- EXT\_JSON\_CONVERT  
This node receives an extended validation report in XML format and converts it to JSON before passing it to the appropriate target node.
- XSD\_JSON\_CONVERT  
This node receives a schema-only validation report in XML format and converts it to JSON before passing it to the appropriate target node.

ix. Target Nodes:

- ext\_xml  
This node contains the resulting extended validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.
- ext\_json  
This node contains the resulting extended validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.
- xsd\_xml  
This node contains the resulting schema-only validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.
- xsd\_json  
This node contains the resulting schema-only validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.

b. It utilizes the following variables:

Flow variables:

- VALIDATION\_TYPE  
The default value is extended.

For schema-only validation, it can be changed to schema. This is used in Route node VAL\_TYPE.

- REPORT\_FORMAT  
The default value is xml.

It can be changed to json. This is used in Decision nodes EXT\_RESULT\_FORMAT and XSD\_RESULT\_FORMAT.

- INPUT\_FILE  
The default value is ..../tools/mx\_service/data/chen\_pacs\_009\_cov.xml.

This is the data file to be used for validation and can be customized. This is used in Source node mx\_input.

- BIC\_FILE  
The default value is ..../data/bic.xml.

This is the location of the bic cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.

- CCY\_FILE  
The default value is ..../data/currencycodedecimals.xml.

This is the location of the country code cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.

- MXCONFIG\_FILE  
The default value is ..../data/mxconfig.xml.

This is the location of the file containing the rule validation settings that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.

- OUTPUT\_RESULT\_XML  
The default value is validation\_result.xml.

This is the location of the validation report file in xml format. It is used in Target nodes ext\_xml and xsd\_xml. It can be customized.

- OUTPUT\_RESULT\_JSON

The default value is validation\_result.json.

This is the location of the validation report file in json format. It is used in Target nodes ext\_json and xsd\_json. It can be customized.

- FAILURE\_LOG

The default value is stopMXValidation.json.

This is the location of the failure log. It is used in Log node FAILURE. It can be customized.

- bizSvc

For internal use in the Map node MX pre-check to determine the type of data being read in the input file.

- stopValidation

For internal use in the Map node MX pre-check and is checked in Decision node pre-valid chk to cause a Failure log in case a data file was not recognized as a valid CHAPS ENH message.

3. Open the main flow chaps\_enh\_validation\_flow in the Design Server. It utilizes above one source node, three map nodes, three decision nodes, one route node, one log node, one fail node, two passthrough nodes, two format converter nodes and four target nodes

4. In Design Server, create a package chaps\_enh\_mx\_validation that contains the input files and one flow chaps\_enh\_validation\_flow. The maps will automatically be included during deployment of the package onto the runtime server.

Note: Not required for running flows on Design Server user interface directly.

- [Run the example using three different methods](#)

You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.

2. Deploying the example to tx-rest and running it using the Swagger interface.

3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- [Run the example from the Design Server user interface](#)

Use the following steps to run the example from the Design Server user interface:

- [Run the example using the Swagger interface](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

- [Run the example using the flow command server process \(flowcmdserver\)](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open chaps\_enh\_validation\_flow flow and click on Run button.

2. Set toggle switch Run On Design Server and select flow input file. Example is chen\_pacs\_009\_cov.xml.

Flow will run and report with the green check box. The reports list execution of all nodes.

3. Right click and select View Link Data on each link to examine the data.

4. Right click on the node and select View Log to see the logs.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed if you do not have a server definition to deploy in Design Server.

2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.

3. Deploy the created package to the server definition in Design Server.

4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.

5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.

You should see a Miscellaneous section having two actions: A **PUT** /v2/run/chaps\_enh\_validation\_flow and a **POST** /v2/run/chaps\_enh\_validation\_flow.

6. In the **PUT** action:

a. Expand the **PUT** action and select the Try it out button.

b. Leave the input and output sections empty.

c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/mydir/data/chen_pacs_009_cov.xml",
 "OUTPUT_RESULT_JSON": "C:/mydir/data/validation_result.json",
 "REPORT_FORMAT": "json",
 "VALIDATION_TYPE": "extended"
}
```

or

```
{
 "INPUT_FILE": "C:/mydir/data/chen_pacs_009_cov.xml",
 "OUTPUT_RESULT_XML": "C:/mydir/data/validation_result.xml",
 "REPORT_FORMAT": "xml",
 "VALIDATION_TYPE": "extended"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. This run should generate the output same as above.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json. There will be a DELETE /v2/packages/{name} action.
  8. Expand the DELETE /v2/packages/{name} action and select Try it out.
  9. In the Name field, enter the name you gave to the created package.
  10. Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. The below command is for CHAPS ENH chen\_pacs\_009\_cov.xml message.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows
--flow chaps_enh_validation_flow.json
--input "1;FILE;C:\ftpserver\deployment\tools\mx_service\data\chen_pacs_009_cov.xml"
--audit "C:\ftpserver\deployment\tools\mx_service\data\chen_pacs_009_cov_adt.json" -ad
```

- The results will be in C:\ftpserver\deployment\flows as validation\_results.xml or validation\_results.json depending on the value of the REPORT\_FORMAT variable.
4. Use the below command to execute with the variable VALIDATION\_TYPE value defined in the Flow settings in Design Server ('extended' or 'schema').

```
--flow chaps_enh_validation_flow.json
--var "INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\chen_pacs_009_cov.xml"
--var "VALIDATION_TYPE=schema"
--var "REPORT_FORMAT=xml"
--audit "C:\ftpserver\deployment\tools\mx_service\data\chen_pacs_009_cov_adt.json" -ad
```

5. The flow will report status similar to:

```
***Starting flow command server
Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\ftpserver\\deployment\\tools\\mx_service\\data\\chen_pacs_009_cov_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

6. Examine the flow output result files validation\_results.xml and the audit file chen\_pacs\_009\_cov\_adt.json.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

### Example

To disable the BIC lookup validation feature.

### About this task

Change sub-element ExtendedValidation/BICValidation value from T to F.

### Procedure

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the flow.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

## CHAPS ENH enhanced MX validation (using maps) Example

This example demonstrates the CHAPS ENH enhanced MX validation for CHAPS ENH messages using maps.

The maps can perform following level of validation:

- MX extended validation includes following checks:
  - BIC lookup
  - Country code lookup
  - Currency code lookup
  - IBAN format
  - Allowed maximum fractional digits per currency
  - Usage guideline rules, see mxconfig.xml for list of rules
- Schema validation
- **[What the example contains](#)**  
Files and directories included in this example are as follows:
- **[Run the example in Design Studio](#)**
- **[Run the example in Design Server User Interface](#)**
- **[How to customize the mxconfig.xml file](#)**  
Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

## What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources:
  - chaps\_enh\_mx\_admi\_validation\_enh.mms  
Utility maps called by main map for all the admi CHAPS ENH xml message MX validation.
  - chaps\_enh\_mx\_camt\_validation\_enh.mms  
Utility maps called by main map for all the camt CHAPS ENH xml message MX validation.
  - chaps\_enh\_mx\_mirs\_validation\_enh.mms  
Utility maps called by main map for all the mirs CHAPS ENH xml message MX validation.
  - chaps\_enh\_mx\_pacs\_validation\_enh.mms  
Utility maps called by main map for all the pacs CHAPS ENH xml message MX validation.
  - chaps\_enh\_mx\_validation\_frmwrk\_map\_enh.mms  
The Main map used to apply MX validation to CHAPS ENH xml messages.
- Schemas:  
The schemas directory contains the following files:
  - bic.xsd  
Metadata that represents the bic.xml repository file structure.
  - ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
  - mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.
  - adm1.004.001.02\_fqsm.xsd
  - adm1.004.001.02\_rsr.xsd
  - camt.052.001.08.xsd
  - camt.053.001.08.xsd

  - camt.060.001.05.xsd
  - mirs.095.001.01.xsd
  - pacs.002.001.10.xsd
  - pacs.004.001.09.xsd
  - pacs.008.001.08.xsd
  - pacs.009.001.08\_core.xsd
  - pacs.009.001.08\_cov.xsd
  - head.001.001.02\_admi\_004\_fqsm.xsd
  - head.001.001.02\_admi\_004\_rsr.xsd
  - head.001.001.02\_camt\_052.xsd
  - head.001.001.02\_camt\_053.xsd
  - head.001.001.02\_camt\_054\_ca.xsd
  - head.001.001.02\_camt\_054\_cld.xsd
  - head.001.001.02\_camt\_054\_cli.xsd
  - head.001.001.02\_camt\_054\_lpa.xsd
  - head.001.001.02\_camt\_060.xsd
  - head.001.001.02\_mirs\_095.xsd
  - head.001.001.02\_pacs\_002.xsd

- head.001.001.02\_pacs\_004.xsd
- head.001.001.02\_pacs\_008.xsd
- head.001.001.02\_pacs\_009\_core.xsd
- head.001.001.02\_pacs\_009\_cov.xsd

Note: XML schemas were downloaded from SWIFT MyStandards Readiness CHAPS ENH portal.

- Trees:

The trees directory contains the following files:

- mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
- swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.

- Data:

The data directory contains the following file:

- bic.xml  
Repository file listing all BICs which are used during validation.
- currencycodedecimals.xml  
Repository file list country codes, currency codes and corresponding maximum fractionally digits, used as reference for validation.
- mxconfig.xml  
Contains the MX configuration information on how to process the message.

Sample CHAPS ENH valid files for test purpose with header envelope:

- bah\_admi\_004\_001\_02\_fqsm\_valid.xml
- bah\_admi\_004\_001\_02\_rsr\_valid.xml
- bah\_camt\_052\_001\_08\_valid.xml
- bah\_camt\_053\_001\_08\_valid.xml
- bah\_camt\_054\_001\_08\_ca\_valid.xml
- bah\_camt\_054\_001\_08\_cld\_valid.xml
- bah\_camt\_054\_001\_08\_cli\_valid.xml
- bah\_camt\_054\_001\_08\_lpa\_valid.xml
- bah\_camt\_060\_001\_05\_valid.xml
- bah\_mirs\_095\_001\_01\_valid.xml
- bah\_pacs\_002\_001\_10\_valid.xml
- bah\_pacs\_004\_001\_09\_valid.xml
- bah\_pacs\_008\_001\_08\_valid.xml
- bah\_pacs\_009\_001\_08\_core\_valid.xml
- bah\_pacs\_009\_001\_08\_cov\_valid.xml

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, chen8000\_val (under chaps\_enh\_mx\_validation\_frmwrk\_map\_enh.mms file) with the desired input file.
3. Run the main router map, chen8000\_val.  
You will see the output file in the data folder called chaps\_error\_report.xml.

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter the user and password credentials.
3. If the project does not exist, import chaps\_enh.zip.
4. If absent, create a package containing all the Maps, Files and Flows.
5. Build the package in the desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map chen8000\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map chen8000\_val.
10. Right click on the output card on canvas and select View data.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

## Example

To disable the BIC lookup validation feature.

## About this task

---

Change sub-element ExtendedValidation/BICValidation value from T to F.

## Procedure

---

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the map.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

---

## CHAPS ENH schema validation (using maps) Example

This example demonstrates the CHAPS ENH schema validation for CHAPS ENH messages using maps only.

The maps can perform following level of validation:

- Schema validation
- [What the example contains](#)  
Files and directories included in this example are as follows:
- [Run the example in Design Studio](#)
- [Run the example in Design Server User Interface](#)

---

## What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources:
  - chaps\_enh\_mx\_schema\_validation\_xsd.mms  
Contains maps for schema validation of any CHAPS ENH xml message.
  - chaps\_enh\_schema\_validation\_frmwrk\_map\_xsd.mms  
The main map used to apply schema validation to CHAPS ENH xml messages.
- Schemas:  
The schemas directory contains the following files:
  - admi.004.001.02\_fqsm.xsd
  - admi.004.001.02\_rsr.xsd
  - camt.052.001.08.xsd
  - camt.053.001.08.xsd
  - camt.054.001.08\_ca.xsd
  - camt.054.001.08\_cld.xsd
  - camt.054.001.08\_cli.xsd
  - camt.054.001.08\_lpa.xsd
  - camt.060.001.05.xsd
  - mirs.095.001.01.xsd
  - pacs.002.001.10.xsd
  - pacs.004.001.09.xsd
  - pacs.008.001.08.xsd
  - pacs.009.001.08\_core.xsd
  - pacs.009.001.08\_cov.xsd
  - head.001.001.02\_admi\_004\_fqsm.xsd
  - head.001.001.02\_admi\_004\_rsr.xsd
  - head.001.001.02\_camt\_052.xsd
  - head.001.001.02\_camt\_053.xsd
  - head.001.001.02\_camt\_054\_ca.xsd
  - head.001.001.02\_camt\_054\_cld.xsd
  - head.001.001.02\_camt\_054\_cli.xsd
  - head.001.001.02\_camt\_054\_lpa.xsd
  - head.001.001.02\_camt\_060.xsd
  - head.001.001.02\_mirs\_095.xsd
  - head.001.001.02\_pacs\_002.xsd
  - head.001.001.02\_pacs\_004.xsd
  - head.001.001.02\_pacs\_008.xsd
  - head.001.001.02\_pacs\_009\_core.xsd
  - head.001.001.02\_pacs\_009\_cov.xsd

Note: XML schemas were downloaded from SWIFT MyStandards Readiness CHAPS ENH Portal.

- Trees:  
The trees directory contains the following files:
  - mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
  - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.

- Data:  
The data directory contains the following files:

Sample CHAPS ENH valid files for test purpose with header envelope.

---

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, chen8200\_val (under chaps\_enh\_schema\_validation\_frmwrk\_map\_xsd.mms file) with the desired input file.
3. Run the main router map, chen8200\_val.  
You will see the output file in the data folder called chaps\_error\_report.xml.

---

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter the user and password credentials.
3. If the project does not exist, import chaps\_enh.zip.
4. If absent, create a package containing all the Maps, Files and Flows.
5. Build the package in the desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map chen8200\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map chen8200\_val.
10. Right click on the output card on canvas and select View data.

---

---

## EBA E1S1 enhanced MX validation (using Flow Server) Example

This example demonstrates the EBA EURO1/STEP1 enhanced MX validation for EBA messages using the flow server.

The flow can perform following level of validation:

- MX extended validation includes following checks:
  - BIC lookup
  - Country code lookup
  - Currency code lookup
  - IBAN format

- Allowed maximum fractional digits per currency
- Usage guideline rules, see mxconfig.xml for list of rules
- Schema validation
- **[What the example contains](#)**  
Files included in this example are as follows:
- **[How to run the example](#)**  
This EBA EURO1/STEP1 MX Validation will use the sample files to demonstrate the generation of validation reports as output from an EBA EURO1/STEP1 XML message.
- **[How to customize the mxconfig.xml file](#)**  
Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

## What the example contains

Files included in this example are as follows:

- eba\_e1s1.zip
  - Test Data Files:
    - e1s1\_pacs\_009.xml
    - e1s1\_pacs\_009\_bad\_rule.xml
    - e1s1\_pacs\_009\_bad\_schema.xml
  - Validation Files:
    - mxconfig.xml
    - bic.xml
    - currencycodedecimals.xml
  - Schemas:
    - bic.xsd  
Metadata that represents the bic.xml repository file structure.
    - ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
    - mxconfig.xsd  
Meta data that represents the mxconfig.xml configuration file structure.
    - mxvalErrorReport.mtt  
Metadata that represent the mxconfig.xml configuration file structure.
    - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.

- Flows:
  - eba\_e1s1\_validation\_flow

## How to run the example

This EBA EURO1/STEP1 MX Validation will use the sample files to demonstrate the generation of validation reports as output from an EBA EURO1/STEP1 XML message.

The stopValidation.json file will report the validation failure due to the pre-conversion checks:

**If input file is other than any of the supported EBA EURO1/STEP1 messages as per schema list indicated above.**

1. Import the eba\_e1s1.zip project into the Design Server.
2. Open the eba\_e1s1 project in Design Server and view the flow eba\_e1s1\_validation\_flow.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:
    - @packagemap=eba\_e1s1/validation/mx\_extended/maps/e1s1\_mx\_pacs\_validation\_enh/e1s17101\_pacs\_002\_001\_10

b. It utilizes the following nodes:

- Source Nodes:
  - mx\_input  
This node identifies the input data to be validated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
- Map Nodes:
  - MX pre-check  
This node runs map mxut1003\_bizsvc\_e1s1 which sets the flow variables, checks pre-validation conditions and creates infoset.json for validation.
  - EXT\_VAL  
This node runs map e1s17100\_val which calls the appropriate map to perform extended validation of an EBA message.
  - XSD\_VAL  
This node runs map e1s17200\_val which calls the appropriate map to perform schema validation of an EBA message.

Note: The maps e1s17100\_val and e1s17200\_val internally call all the other maps identified in the above Flow Description step.
- Decision Nodes:
  - pre-valid chk  
This node checks the flow variable stopValidation to decide if further validation/processing is not required.
  - EXT\_RESULT\_FORMAT  
This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for extended validation should be generated in XML (default) or JSON.
  - XSD\_RESULT\_FORMAT  
This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for schema-only validation should be generated in XML (default) or JSON.
- Route Nodes:
  - VAL\_TYPE  
This node checks the variable VALIDATION\_TYPE to determine if the process will do extended validation or schema-only validation on the data.
- Log Nodes:
  - FAILURE  
This node creates a log file specified by the flow variable FAILURE\_LOG in case of no validation due to precondition check failures.
- Fail Node:
  - STOP  
It generates error message setup in the node in case of no validation performed.
- Passthrough Nodes
  - EXT\_XML\_CONVERT  
This node receives an extended validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.
  - XSD\_XML\_CONVERT  
This node receives a schema-only validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.
- Format Converter Nodes
  - EXT\_JSON\_CONVERT  
This node receives an extended validation report in XML format and converts it to JSON before passing it to the appropriate target node.
  - XSD\_JSON\_CONVERT

This node receives a schema-only validation report in XML format and converts it to JSON before passing it to the appropriate target node.

ix. Target Nodes

- ext\_xml

This node contains the resulting extended validation report in XML format and creates the output as defined by variable OUTPUT\_RESULT\_XML.

- ext\_json

This node contains the resulting extended validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.

- xsd\_xml

This node contains the resulting schema-only validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.

- xsd\_json

This node contains the resulting schema-only validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.

c. It utilizes the following variables:

Flow variables:

- VALIDATION\_TYPE

The default value is extended.

For schema-only validation, it can be changed to schema. This is used in Route node VAL\_TYPE.

- REPORT\_FORMAT

The default value is xml.

It can be changed to json. This is used in Decision nodes EXT\_RESULT\_FORMAT and XSD\_RESULT\_FORMAT.

- INPUT\_FILE

The default value is ../tools/mxservice/data/e1s1\_pacs\_009.xml.

This is the data file to be used for validation and can be customized. This is used in Source node mx\_input.

- BIC\_FILE

The default value is ../data/bic.xml.

This is the location of the bic cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.

- CCY\_FILE

The default value is ../data/currencycodedecimals.xml.

This is the location of the country code cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.

- MXCONFIG\_FILE

The default value is ../data/mxconfig.xml.

This is the location of the file containing the rule validation settings that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.

- OUTPUT\_RESULT\_XML

The default value is validation\_result.xml.

This is the location of the validation report file in xml format. It is used in Target nodes ext\_xml and xsd\_xml. It can be customized.

- OUTPUT\_RESULT\_JSON

The default value is validation\_result.json.

This is the location of the validation report file in json format. It is used in Target nodes ext\_json and xsd\_json. It can be customized.

- FAILURE\_LOG

The default value is stopMXValidation.json.

This is the location of the failure log. It is used in Log node FAILURE. It can be customized.

- bizSvc

This is for internal use in the Map node MX pre-check to determine the type of data being read in the input file.

- stopValidation

This is for internal use in the Map node MX pre-check and is checked in Decision node pre-valid chk to cause a Failure log in case a data file was not recognized as a valid EBA message.

3. Open the main flow eba\_e1s1\_validation\_flow in the Design Server. It utilizes above one source node, three map nodes, one route node, three decision nodes, one log node, one fail node, two passthrough nodes, two format converter nodes and four target nodes.

4. In Design Server, create a package eba\_e1s1\_mx\_validation that contains the input files and one flow eba\_e1s1\_validation\_flow. The maps will automatically be included during deployment of the package onto the runtime server.

Note: Not required for running flows on Design Server user interface directly.

- [Run the example using three different methods](#)

You can run the example using three different methods:

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- [Run the example from the Design Server user interface](#)

Use the following steps to run the example from the Design Server user interface:

- [Run the example using the Swagger interface](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

- [Run the example using the flow command server process \(flowcmdserver\)](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open eba\_e1s1\_validation\_flow flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file. Example is e1s1\_pacs\_009.xml.  
Note: If a default path is assigned to variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists the execution of all nodes.
3. To examine the data passed on each link, right click on each link and select View Link Data.
4. To view the target node, right click on the node input icon and select View Data.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You should see a Miscellaneous section having two actions: A **PUT** /v2/run/eba\_e1s1\_validation\_flow and a **POST** /v2/run/eba\_e1s1\_validation\_flow.
6. In the **PUT** action:
  - a. Expand the **PUT** action and select the Try it out button.
  - b. Leave the input and output files sections empty.
  - c. Under flow\_vars section, delete the entire content and replace it with the commands to run the flow. For example:

```
{
 "INPUT_FILE": "C:/mydir/data/e1s1_pacs_009.xml",
 "OUTPUT_RESULT_JSON": "C:/mydir/data/validation_result.json",
 "REPORT_FORMAT": "json",
 "VALIDATION_TYPE": "extended"
}

or

{
 "INPUT_FILE": "C:/mydir/data/e1s1_pacs_009.xml",
 "OUTPUT_RESULT_XML": "C:/mydir/data/validation_result.xml",
 "REPORT_FORMAT": "xml",
 "VALIDATION_TYPE": "extended"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. This run should generate the output same as above.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
8. Expand the DELETE /v2/packages/{name} action and select Try it out.
9. In the Name field, enter the name you gave to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.

You can see a response of 204 with a timestamp, if it is successful.

---

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. The below command is for EBA EURO1/STEP1 e1s1\_pacs\_009.xml message.

```
--flow eba_e1s1_validation_flow.json
--var "INPUT_FILE=C:/ftpserver/deployment/tools/mx_service/data/e1s1_pacs_009.xml"
--audit "C:/ftpserver/deployment/tools/mx_service/data/e1s1_pacs_009.adt.json" -ad
```

The results will be in C:\ftpserver\deployment\flows as validation\_results.xml or validation\_results.json depending on the value of the REPORT\_FORMAT variable.

4. Use the following command to execute with the variable VALIDATION\_TYPE value defined in the Flow settings in Design Server (extended or schema).

```
--flow eba_e1s1_validation_flow.json
--var "INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\e1s1_pacs_009.xml"
--var "VALIDATION_TYPE=schema"
--var "REPORT_FORMAT=json"
--audit "C:\ftpserver\deployment\tools\mx_service\data\e1s1_pacs_009_adt.json" -ad
```

5. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabeb2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\tools\\\\mx_service\\\\data\\\\e1s1_pacs_009_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

6. Examine the flow output result file validation\_results.xml and the audit file e1s1\_pacs\_009\_adt.json.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

### Example

To disable the BIC lookup validation feature.

### About this task

Change sub-element ExtendedValidation/BICValidation value from T to F.

### Procedure

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the flow.

Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

## EBA E1S1 enhanced MX validation (using maps) Example

This example demonstrates the EBA enhanced MX validation for EBA messages using maps only.

The maps can perform following level of validation:

- MX enhanced validation includes following checks:
  - BIC lookup
  - Country code lookup
  - Currency code lookup
  - IBAN format
  - Allowed maximum fractional digits per currency
  - Usage guideline rules, see mxconfig.xml for list of rules
- Schema validation:
  - Enforces validation based on XSD.
- [What the example contains](#)  
Files and directories included in this example are as follows:
- [Run the example in Design Studio](#)
- [Run the example in Design Server User Interface](#)
- [How to customize the mxconfig.xml file](#)

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

### What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources to use when running under Design Studio.

- e1s1\_mx\_camt\_validation\_enh.mms  
Utility map called by main map for all the camt EBA E1S1 xml message MX validation.
- e1s1\_mx\_pacs\_validation\_enh.mms  
Utility map called by main map for all the pacs EBA E1S1 xml message MX validation.
- e1s1\_mx\_admi\_validation\_enh.mms  
Utility map called by main map for all the admi EBA E1S1 xml message MX validation.
- e1s1\_mx\_validation\_frmwrk\_map\_enh.mms  
The Main map used to apply MX validation to EBA E1S1 xml messages.

Note: When running under Design Server, the main framework map is e1s1\_mx\_validation\_frmwrk\_map\_flw\_enh.mms

- Schemas:

The schemas directory contains the following files:

- bic.xsd  
Metadata that represents the bic.xml repository file structure.
- ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
- mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.

(Based from SWIFT MyStandards Readiness EBA Portal)

- admi.007.001.01.xsd
- camt.003.001.07.xsd
- camt.004.001.08.xsd
- camt.005.001.08.xsd
- camt.006.001.08.xsd
- camt.009.001.07.xsd
- camt.010.001.08.xsd
- camt.011.001.07.xsd
- camt.029.001.09.xsd
- camt.052.001.08.xsd

- camt.998.001.03\_gar.xsd
- camt.998.001.03\_rar.xsd
- camt.998.001.03\_gar.xsd
- sup\_camt.998.001.03\_gar.xsd
- sup\_camt.998.001.03\_rar.xsd
- pacs.002.001.10.xsd
- pacs.004.001.09.xsd
- pacs.008.001.08.xsd
- pacs.009.001.08.xsd
- pacs.010.001.03.xsd
- head.001.001.01.xsd

- Trees:

The trees directory contains the following files:

- swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
- mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.

- Data:

The data directory contains the following file:

- bic.xml  
Repository file listing all BICs which are used during validation.
- currencycodedecimals.xml  
Repository file listing country codes, currency codes and corresponding maximum fractionally digits, used as reference for validation.
- mxconfig.xml  
Contains the MX configuration information on how to process the message.

Sample EBA EURO1/STEP1 valid files without header envelope for test purposes:

- admi\_007\_001\_01\_valid.xml

Sample EBA EURO1/STEP1 valid files with header envelope for test purposes:

- bah\_admi\_007\_001\_01\_valid.xml
- bah\_camt\_003\_001\_07\_valid.xml
- bah\_camt\_004\_001\_08\_valid.xml
- bah\_camt\_005\_001\_08\_valid.xml
- bah\_camt\_006\_001\_08\_valid.xml
- bah\_camt\_009\_001\_07\_valid.xml
- bah\_camt\_010\_001\_08\_valid.xml

- bah\_camt\_011\_001\_07\_valid.xml
  - bah\_camt\_029\_001\_09\_valid.xml
  - bah\_camt\_052\_001\_08\_valid.xml
  - bah\_camt\_053\_001\_08\_valid.xml
  - bah\_camt\_054\_001\_08\_valid.xml
  - bah\_camt\_056\_001\_08\_valid.xml
  - bah\_camt\_998\_001\_03\_gar\_valid.xml
  - bah\_camt\_998\_001\_03\_rar\_valid.xml
  - bah\_pacs\_002\_001\_10\_valid.xml
  - bah\_pacs\_004\_001\_09\_valid.xml
  - bah\_pacs\_008\_001\_08\_valid.xml
  - bah\_pacs\_009\_001\_08\_valid.xml
  - bah\_pacs\_010\_001\_03\_valid.xml
- 

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
  2. Replace the input card 1 in router map, e1s17000\_val (under e1s1\_mx\_validation\_frmwrk\_map\_enh.mms file or e1s1\_mx\_validation\_frmwrk\_map\_flw\_enh.mms file if running under Design Server) with the desired input file.
  3. Run the main router map, e1s17000\_val.  
You will see the output file in the data folder called e1s1\_error\_report.xml.
- 

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
  2. Enter the user and password credentials.
  3. If the project does not exist, import eba\_e1s1.zip.
  4. If absent, create a package containing all the Maps, Files and Flows.
  5. Build the package in the desired server (to build all maps).
  6. Open the project.
  7. In the Maps tab, open the map e1s17000\_val.
  8. Modify the settings for input card 1 on design canvas to point to the desired test file.
  9. Save, build, and run the map e1s17000\_val.
  10. Right click on the output card on canvas and select View data.
- 

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

### Example

To disable the BIC lookup validation feature.

### About this task

Change sub-element ExtendedValidation/BICValidation value from T to F.

### Procedure

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the map.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

## EBA E1S1 schema MX validation (using maps) Example

This example demonstrates the EBA EURO1/STEP1 schema validation for EBA E1S1 messages using maps only.

The maps can perform following level of validation:

- Schema validation

- [What the example contains](#)

Files and directories included in this example are as follows:

- 

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
  2. Replace the input card 1 in router map, e1s17200\_val (under e1s1\_schema\_validation\_frmwrk\_map\_xsd.mms file) with desired input file.
  3. Run the main router map, e1s17200\_val.  
You will see the output file in the data folder called e1s1\_error\_report.xml.
- 

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
  2. Enter the user and password credentials.
  3. If the project does not exist, import eba\_e1s1.zip.
  4. If absent, create a package containing all the Maps, Files and Flows.
  5. Build the package in the desired server (to build all maps).
  6. Open the project.
  7. In the Maps tab, open the map e1s17200\_val.
  8. Modify the settings for input card 1 on design canvas to point to the desired test file.
  9. Save, build, and run the map e1s17200\_val.
  10. Right click on the output card on canvas and select View data.

- Flows:
  - nbor\_rgis\_validation\_flow

## How to run the example

This NBOR ReGIS schema Validation will use the sample files to demonstrate the generation of validation report as output from a NBOR ReGIS XML message.

The stopValidation.json file will report the validation failure due to the pre-conversion checks:

**If input file is other than any of the supported NBOR ReGIS messages as per schema list indicated above.**

1. Import the nbor\_rgis.zip project into the Design Server.
2. Open the nbor\_rgis project in Design Server and view the flow nbor\_rgis\_validation\_flow.

a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. This list has to be added to the description and ensure all lines start in column 1. Following is the list of maps with the description format:

- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1501\_admi\_004\_001\_02
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1502\_camt\_005\_001\_08
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1503\_camt\_006\_001\_08
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1504\_camt\_007\_001\_08
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1505\_camt\_008\_001\_08
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1506\_camt\_025\_001\_05
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1507\_camt\_029\_001\_09
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1508\_camt\_046\_001\_05
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1509\_camt\_047\_001\_06
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1510\_camt\_052\_001\_08
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1511\_camt\_053\_001\_08
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1512\_camt\_054\_001\_08
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1513\_camt\_056\_001\_08
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1514\_camt\_060\_001\_05
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1515\_pacs\_002\_001\_10

- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1566\_head112\_pacs004
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1567\_head112\_pacs008\_trz
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1568\_head112\_pacs008
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1569\_head112\_pacs009\_cov
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1570\_head112\_pacs009
- @packagemap=nbor\_rgis/validation/schema\_only/maps/nbor\_rgis\_mx\_schema\_validation\_xsd/rgis1571\_head112\_pacs029

b. It utilizes the following nodes:

- i. Source Nodes:

- mx\_input

This node identifies the input data to be validated in the flow. It uses the variable INPUT\_FILE to set the location of the data.

- ii. Map Nodes:

- MX pre-check

Runs map mxut1009\_bizsvc\_rgis which sets flow variables, checks pre-validation conditions, and creates infoset.json for validation.

- XSD\_VAL

Runs map rgis1500\_val which calls the appropriate map to perform schema validation of a NBOR ReGIS message.

Note: The map rgis1500\_val internally calls all the other maps identified in the above Flow Description step.

- iii. Decision Nodes:

- pre-valid chk

This node checks the flow variable stopTranslation to decide if further validation/processing is not required.

- XSD\_RESULT\_FORMAT

This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for schema-only validation should be generated in XML (default) or JSON.

iv. Log Nodes:

- FAILURE  
In case of no validation due to precondition check failures, this node creates a log file specified by the flow variable FAILURE\_LOG.

v. Fail Node:

- STOP  
It generates error message setup in the node in case of no validation performed.

vi. Passthrough Nodes:

- XSD\_XML\_CONVERT  
This node receives a schema-only validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.

vii. Format Converter Nodes:

- XSD\_JSON\_CONVERT  
This node receives a schema-only validation report in XML format and converts it to JSON before passing it to the appropriate target node.

viii. Target Nodes:

- xsd\_xml  
This node contains the resulting schema-only validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.

- xsd\_json  
This node contains the resulting schema-only validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.

c. It utilizes the following variables:

i. Flow variables:

- VALIDATION\_TYPE  
Default value is schema. The value extended is not supported at this time. This variable is currently not being used in any node.
- REPORT\_FORMAT  
Default value is xml. It can be changed to json. This is used in Decision node XSD\_RESULT\_FORMAT.
- INPUT\_FILE  
Default value is ../tools/mx\_service/data/rgis\_pacs\_009\_cov.xml. This is the data file to be used for validation and can be customized. It is used in the Source node mx\_input.
- OUTPUT\_RESULT\_XML  
Default value is validation\_result.xml. This is the location of the validation report file in xml format. It is used in Target node xsd\_xml. It can be customized.
- OUTPUT\_RESULT\_JSON  
Default value is validation\_result.json. This is the location of the validation report file in json format. It is used in Target node xsd\_json. It can be customized.
- FAILURE\_LOG  
Default value is stopMXValidation.json. This is the location of the failure log. It is used in Log node FAILURE. It can be customized.
- bizSvc  
For internal use in the Map node MX pre-check to determine the type of data being read in the input file.
- stopValidation  
For internal use in the Map node MX pre-check and is checked in Decision node pre-valid chk to cause a Failure log in case a data file was not recognized as a valid NBOR ReGIS message.

3. Open the main flow nbor\_regis\_validation\_flow in the Design Server. It utilizes above one Source node, two Map nodes, two Decision nodes, one Log node, one Fail node, one Passthrough node, one Format Converter node, and two Target nodes.

4. In Design Server, create a package nbor\_regis\_mx\_validation that contains the input files and one flow nbor\_regis\_validation\_flow. The maps will automatically be included during deployment of the package onto the runtime server.

Note: Not required for running flows on Design Server user interface directly.

• [Run the example using three different methods](#)

You can run the example using three different methods:

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

• [Run the example from the Design Server user interface](#)

Use the following steps to run the example from the Design Server user interface:

• [Run the example using the Swagger interface](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

- [Run the example using the flow command server process \(flowcmdserver\)](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open nbor\_regs\_validation\_flow flow and click Run button.
2. Set the toggle switch Run On Design Server and select flow input file. Example is rgis\_pacs\_009\_cov.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, the value defined for the variable will be used if an input file is not selected.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Link Data on each link to examine the data.
4. View target node by clicking on the node, doing right click on the Input icon and selecting View Data.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server:  
`<DTX_HOME>/restapi/tomcat/dtxtomcat start tx-rest`

3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI:  
`<DTX_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest`

5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see a Miscellaneous section having two actions:

- **PUT** /v2/run/nbor\_regs\_validation\_flow
- **POST** /v2/run/nbor\_regs\_validation\_flow

6. In the **PUT** action:
  - a. Expand the **PUT** action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/mydir/data/rgis_pacs_009_cov.xml",
 "OUTPUT_RESULT_JSON": "C:/mydir/data/validation_result.json",
 "REPORT_FORMAT": "json"
}
```

or

```
{
 "INPUT_FILE": "C:/mydir/data/rgis_pacs_009_cov.xml",
 "OUTPUT_RESULT_XML": "C:/mydir/data/validation_result.xml",
 "REPORT_FORMAT": "xml"
}
```

- d. Click Execute blue bar for running the flow.

When flow completes execution, 200 response code is shown in the Server Response section. This run should generate the output same as above.

7. To delete the deployed package, refresh the browser to get the Swagger and explore back to /tx-rest/openapi.json.

There will be a DELETE /v2/packages/{name} action.

8. Expand the DELETE /v2/packages/{name} action and select Try it out.

9. In the Name field, enter the name you gave to the created package.

10. Select the true option from the stop query drop down, then select the blue Execute bar.

You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. The below command is for NBOR ReGIS rgis\_pacs\_009\_cov.xml message.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow nbor_regs_validation_flow.json --var
"INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\rgis_pacs_009_cov.xml" --audit
"C:\ftpserver\deployment\tools\mx_service\data\rgis_pacs_009_cov_adt.json" -ad
```

The results will be in C:\ftpserver\deployment\flows as validation\_results.xml or validation\_results.json depending on the value of the REPORT\_FORMAT variable.

This command will execute with the variable VALIDATION\_TYPE value defined in the Flow settings in Design Server (schema).

To change, the following command can be used:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow nb0r_regis_validation_flow.json --var
"INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\rgis_pacs_009_cov.xml" --var "VALIDATION_TYPE=schema" --var
"REPORT_FORMAT=xml" --audit "C:\ftpserver\deployment\tools\mx_service\data\rgis_pacs_009_cov_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\tools\\\\mx_service\\\\data\\\\rgis_pacs_009_cov_adt.json"
Flow completed successfully
Elapsed time: 1048ms
```

5. Examine the flow output result files validation\_results.xml and the audit file rgis\_pacs\_009\_cov\_adt.json.

---

## NBOR ReGIS schema validation (using maps) example

This example demonstrates the schema validation for NBOR ReGIS messages using maps only.

The maps can perform following level of validation:

- Schema validation
- [What the example contains](#)  
Files and directories included in this example are as follows:
- [Run the example in Design Studio](#)
- [Run the example in Design Server User Interface](#)

---

## What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources:
  - nb0r\_regis\_mx\_schema\_validation\_xsd.mms  
Contains maps for schema validation of any NBOR ReGIS message.
  - nb0r\_regis\_schema\_validation\_frmwrk\_map\_xsd.mms  
The main map used to apply schema validation to NBOR ReGIS xml messages.
- Schemas:  
The schemas directory contains the following files:
  - XML schemas based on SWIFT MyStandards Readiness NBOR ReGIS Portal:
    - admi.004.001.02.xsd
    - camt.005.001.08.xsd
    - camt.006.001.08.xsd
    - camt.007.001.08.xsd
    - camt.008.001.08.xsd
    - camt.025.001.05.xsd
    - camt.029.001.09.xsd
    - camt.046.001.05.xsd
    - camt.047.001.06.xsd
    - camt.052.001.08.xsd
    - camt.053.001.08.xsd
    - camt.054.001.08.xsd
    - camt.056.001.08.xsd
    - camt.060.001.05.xsd
    - pacs.002.001.10.xsd
    - pacs.004.001.09.xsd
    - pacs.008.001.08.xsd
    - pacs.008.001.08\_TREZROBU.xsd
    - pacs.009.001.08.xsd
    - pacs.009.001.08\_cov.xsd
    - pacs.029.001.01.xsd
    - head.001.001.02\_admi\_004.xsd
    - head.001.001.02\_camt\_005.xsd
    - head.001.001.02\_camt\_006.xsd
    - head.001.001.02\_camt\_007.xsd
    - head.001.001.02\_camt\_008.xsd
    - head.001.001.02\_camt\_025.xsd
    - head.001.001.02\_camt\_029.xsd
    - head.001.001.02\_camt\_046.xsd
    - head.001.001.02\_camt\_047.xsd
    - head.001.001.02\_camt\_052.xsd
    - head.001.001.02\_camt\_053.xsd
    - head.001.001.02\_camt\_054.xsd

- head.001.001.02\_camt\_056.xsd
- head.001.001.02\_camt\_060.xsd
- head.001.001.02\_pacs\_002.xsd
- head.001.001.02\_pacs\_004.xsd
- head.001.001.02\_pacs\_008.xsd
- head.001.001.02\_pacs\_008\_TREZROBU.xsd
- head.001.001.02\_pacs\_009.xsd
- head.001.001.02\_pacs\_009\_cov.xsd
- head.001.001.02\_pacs\_029.xsd
- Trees:  
The trees directory contains the following files:
  - mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
  - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
- Data:  
The data directory contains the following file:
  - Sample NBOR ReGIS valid files for test purpose with header envelope:
    - bah\_admi\_004\_001\_02\_valid.xml
    - bah\_camt\_005\_001\_08\_valid.xml
    - bah\_camt\_006\_001\_08\_valid.xml
    - bah\_camt\_007\_001\_08\_valid.xml
    - bah\_camt\_008\_001\_08\_valid.xml
    - bah\_camt\_025\_001\_05\_valid.xml
    - bah\_camt\_029\_001\_09\_valid.xml
    - bah\_camt\_046\_001\_05\_valid.xml
    - bah\_camt\_047\_001\_06\_valid.xml
    - bah\_camt\_052\_001\_08\_valid.xml
    - bah\_camt\_053\_001\_08\_valid.xml

    - bah\_pacs\_008\_001\_08\_TREZROBU\_valid.xml
    - bah\_pacs\_008\_001\_08\_valid.xml
    - bah\_pacs\_009\_001\_08\_cov\_valid.xml
    - bah\_pacs\_009\_001\_08\_valid.xml
    - bah\_pacs\_029\_001\_01\_valid.xml

---

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, rgis1500\_val (under nbor\_regis\_schema\_validation\_frmwrk\_map\_xsd.mms file) with desired input file.
3. Run the main router map, rgis1500\_val.  
You will see the output file in the data folder called rgis\_error\_report.xml.

---

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If the project does not exist, import nbor\_rgis.zip.
4. If absent, create a package containing all the Maps, Files, and Flows.
5. Build package in desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map rgis1500\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map rgis1500\_val.
10. Right click on the output card on canvas and select View data.

---

## TARGET2 CLM/RTGS/CoCo/Securities Examples:

- **TARGET2 CLM Examples:**  
TARGET2 CLM examples are as follow:
- **TARGET2 RTGS Examples:**  
TARGET2 RTGS examples are as follow:
- **TARGET2 CoCo Examples:**  
TARGET2 CoCo examples are as follow:

- **TARGET2 Securities Examples:**

TARGET2 Securities examples are as follow:

---

## TARGET2 CLM Examples:

TARGET2 CLM examples are as follow:

- **T2 CLM enhanced MX validation (using Flow Server) example**

This example demonstrates the TARGET2 CLM enhanced MX validation for TARGET2 CLM messages using the flow server.

- **T2 CLM enhanced MX validation (using maps) example**

This example demonstrates the enhanced MX validation for TARGET2 CLM messages using maps only.

- **T2 CLM schema validation (using maps) example**

This example demonstrates the schema validation for TARGET2 CLM messages using maps only.

---

## T2 CLM enhanced MX validation (using Flow Server) example

This example demonstrates the TARGET2 CLM enhanced MX validation for TARGET2 CLM messages using the flow server.

The flow can perform following level of validation:

- MX extended validation includes following checks:

- BIC lookup
- Country code lookup
- Currency code lookup
- IBAN format
- Allowed maximum fractional digits per currency
- Usage guideline rules, see mxconfig.xml for list of rules

- Schema validation

- **What the example contains**

Files included in this example are as follows:

- **How to run the example**

This TARGET2 CLM MX validation will use the sample files to demonstrate the generation of validation report as output from a TARGET2 CLM XML message.

- **How to customize the mxconfig.xml file**

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

---

## What the example contains

Files included in this example are as follows:

- **t2\_clm.zip**

- Test Data Files:
  - t2clm\_pacs\_009.xml
  - t2clm\_pacs\_009\_bad\_rule.xml
  - t2clm\_pacs\_009\_bad\_schema.xml
- Validation Files:
  - mxconfig.xml
  - bic.xml
  - currencycodedecimals.xml
- Schemas:
  - bic.xsd  
Metadata that represents the bic.xml repository file structure.
  - ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
  - mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.
  - mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
  - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
- XML schemas based on SWIFT MyStandards Readiness TARGET2 CLM Portal:
  - admi.004.001.02.xsd
  - admi.005.001.01.xsd
  - admi.007.001.01.xsd
  - camt.003.001.07.xsd
  - camt.004.001.08.xsd

  - Flows:
    - t2\_clm\_validation\_flow

## How to run the example

This TARGET2 CLM MX validation will use the sample files to demonstrate the generation of validation report as output from a TARGET2 CLM XML message.

The stopValidation.json file will report the validation failure due to the pre-conversion checks:

**If input file is other than any of the supported TARGET2 CLM messages as per schema list indicated above.**

1. Import the t2\_clm.zip project into the Design Server.

2. Open the t2\_clm project in Design Server and view the flow t2\_clm\_validation\_flow.

a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. This list has to be added to the description and ensure all lines start in column 1. Following is the list of maps with the description format:

- @packagemap=t2\_clm/validation/mx\_extended/maps/t2\_clm\_mx\_camt\_validation\_enh/t2cl9051\_head111\_camt
- @packagemap=t2\_clm/validation/mx\_extended/maps/t2\_clm\_mx\_camt\_validation\_enh/t2cl9001\_camt\_054\_001\_08

b. It utilizes the following nodes:

i. Source Nodes:

- mx\_input

This node identifies the input data to be validated in the flow. It uses the variable INPUT\_FILE to set the location of the data.

ii. Map Nodes:

- MX pre-check

Runs map mxut1004\_bizsvc\_t2clm which sets flow variables, checks pre-validation conditions, and creates infoset.json for validation.

- EXT\_VAL

Runs map t2cl9100\_val which calls the appropriate map to perform extended validation of a TARGET2 CLM message.

- XSD\_VAL

Runs map t2cl9500\_val which calls the appropriate map to perform schema validation of a TARGET2 CLM message.

Note: The maps t2cl9100\_val and t2cl9500\_val internally call all the other maps identified in the above Flow Description step.

iii. Decision Nodes:

- pre-valid chk

This node checks the flow variable stopTranslation to decide if further validation/processing is not required.

- EXT\_RESULT\_FORMAT

This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for extended validation should be generated in XML (default) or JSON.

- XSD\_RESULT\_FORMAT

This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for schema-only validation should be generated in XML (default) or JSON.

iv. Route Nodes:

- VAL\_TYPE

This node checks the variable VALIDATION\_TYPE to determine if the process will do extended validation or schema-only validation on the data.

v. Log Nodes:

- FAILURE

In case of no validation due to precondition check failures, this node creates a log file specified by the flow variable FAILURE\_LOG.

vi. Fail Node:

- STOP

It generates error message setup in the node in case of no validation performed.

vii. Passthrough Nodes:

- EXT\_XML\_CONVERT

This node receives an extended validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.

- XSD\_XML\_CONVERT

This node receives a schema-only validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.

viii. Format Converter Nodes:

- EXT\_JSON\_CONVERT

This node receives an extended validation report in XML format and converts it to JSON before passing it to the appropriate target node.

- XSD\_JSON\_CONVERT

This node receives a schema-only validation report in XML format and converts it to JSON before passing it to the appropriate target node.

ix. Target Nodes:

- ext\_xml

This node contains the resulting extended validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.

- ext\_json

This node contains the resulting extended validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.

- xsd\_xml  
This node contains the resulting schema-only validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.
- xsd\_json  
This node contains the resulting schema-only validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.

c. It utilizes the following variables:

i. Flow variables:

- VALIDATION\_TYPE  
Default value is extended. For schema-only validation, it can be changed to schema. It is used in Route node VAL\_TYPE.
- REPORT\_FORMAT  
Default value is xml. It can be changed to json. It is used in Decision nodes EXT\_RESULT\_FORMAT and XSD\_RESULT\_FORMAT.
- INPUT\_FILE  
Default value is ../tools/mx\_service/data/t2clm\_pacs\_009.xml. This is the data file to be used for validation and can be customized. It is used in the Source node mx\_input.
- BIC\_FILE  
Default value is ../data/bic.xml. This is the location of the bic cross-reference file that is used in all the maps executed by the map in the node EXT\_VAL. It can be customized.
- CCY\_FILE  
Default value is ../data/currencycodedecimals.xml. This is the location of the country code cross-reference file that is used in all the maps executed by the map in the node EXT\_VAL. It can be customized.
- MXCONFIG\_FILE  
Default value is ../data/mxconfig.xml. This is the location of the file containing the rule validation settings that is used in all the maps executed by the map in the node EXT\_VAL. It can be customized.
- OUTPUT\_RESULT\_XML  
Default value is validation\_result.xml. This is the location of the validation report file in xml format. It is used in Target nodes ext\_xml and xsd\_xml. It can be customized.
- OUTPUT\_RESULT\_JSON  
Default value is validation\_result.json. This is the location of the validation report file in json format. It is used in Target nodes ext\_json and xsd\_json. It can be customized.
- FAILURE\_LOG  
Default value is stopMXValidation.json. This is the location of the failure log. It is used in Log node FAILURE. It can be customized.
- bizSvc  
For internal use in the Map node MX pre-check to determine the type of data being read in the input file.
- stopValidation  
For internal use in the Map node MX pre-check and is checked in Decision node pre-valid chk to cause a Failure log in case a data file was not recognized as a valid TARGET2 CLM message.

3. Open the main flow t2\_clm\_validation\_flow in the Design Server. It utilizes the above one Source node, three Map nodes, one Route node, three Decision nodes, one Log node, one Fail node, two Passthrough nodes, two Format Converter nodes, and four Target nodes.

4. In Design Server, create a package t2\_clm\_mx\_validation that contains the input files and one flow t2\_clm\_validation\_flow. The maps will automatically be included during deployment of the package onto the runtime server.

Note: Not required for running flows on Design Server user interface directly.

- [\*\*Run the example using three different methods\*\*](#)

You can run the example using three different methods:

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- [\*\*Run the example from the Design Server user interface\*\*](#)

Use the following steps to run the example from the Design Server user interface:

- [\*\*Run the example using the Swagger interface\*\*](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

- [\*\*Run the example using the flow command server process \(flowcmdserver\)\*\*](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open t2\_clm\_validation\_flow flow and click on Run button.
2. Set the toggle switch Run On Design Server and select flow input file. Example is t2clm\_pacs\_009.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, the value defined for the variable will be used if an input file is not selected.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Link Data on each link to examine the data.
4. View target node by clicking on the node, doing right click on the Input icon and selecting View Data.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed if you do not have a server definition to deploy in Design Server.

2. If not running, start tx-rest on the server:  
`<DTX_HOME>/restapi/tomcat/dtxtomcat start tx-rest`

3. Deploy the created package to the server definition in Design Server.

4. Bring up the tx-rest Swagger UI:  
`<DTX_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest`

5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.

You can see a Miscellaneous section having two actions:

- **PUT** /v2/run/t2\_clm\_validation\_flow
- **POST** /v2/run/t2\_clm\_validation\_flow

6. In the **PUT** action:

- a. Expand the **PUT** action and select the Try it out button.
- b. Leave the input and output sections empty.

- c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/mydir/data/t2clm_pacs_009.xml",
 "OUTPUT_RESULT_JSON": "C:/mydir/data/validation_result.json",
 "REPORT_FORMAT": "json",
 "VALIDATION_TYPE": "extended"
}
```

or

```
{
 "INPUT_FILE": "C:/mydir/data/t2clm_pacs_009.xml",
 "OUTPUT_RESULT_XML": "C:/mydir/data/validation_result.xml",
 "REPORT_FORMAT": "xml",
 "VALIDATION_TYPE": "extended"
}
```

- d. Click Execute blue bar for running the flow.

When flow completes execution, 200 response code is shown in the Server Response section. This run should generate the output same as above.

7. To delete the deployed package, refresh the browser to get the Swagger and explore back to /tx-rest/openapi.json.

There will be a DELETE /v2/packages/{name} action.

8. Expand the DELETE /v2/packages/{name} action and select Try it out.

9. In the Name field, enter the name you gave to the created package.

10. Select the true from the stop query drop down, then select the blue Execute bar.

You can see a response of 204 with a timestamp, if it is successful.

---

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed if you do not have a server local definition or ftp execution definition to deploy in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. The below command is for TARGET2 CLM t2clm\_pacs\_009.xml message.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow t2_clm_validation_flow.json --var
"INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\t2clm_pacs_009.xml" --audit
"C:\ftpserver\deployment\tools\mx_service\data\t2clm_pacs_009_adt.json" -ad
```

The results will be in C:\ftpserver\deployment\flows as validation\_results.xml or validation\_results.json depending on the value of the REPORT\_FORMAT variable.

This command will execute with the variable VALIDATION\_TYPE value defined in the Flow settings in Design Server (extended or schema).

To change, the following command can be used:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow t2_clm_validation_flow.json --var
"INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\t2clm_pacs_009.xml" --var "VALIDATION_TYPE=schema" --var
"REPORT_FORMAT=json" --audit "C:\ftpserver\deployment\tools\mx_service\data\t2clm_pacs_009_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server
```

```
Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\tools\\\\mx_service\\\\data\\\\t2clm_pacs_009_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result files validation\_results.xml and the audit file t2clm\_pacs\_009\_adt.json.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

### Example

To disable the BIC lookup validation feature.

### About this task

Change sub-element ExtendedValidation/BICValidation value from T to F.

### Procedure

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the flow.

Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

## T2 CLM enhanced MX validation (using maps) example

This example demonstrates the enhanced MX validation for TARGET2 CLM messages using maps only.

The maps can perform following level of validation:

- MX extended validation includes following checks:
  - BIC lookup
  - Country code lookup
  - Currency code lookup
  - IBAN format
  - Allowed maximum fractional digits per currency
  - Usage guideline rules, see mxconfig.xml for list of rules
- Schema validation
- [What the example contains](#)  
Files and directories included in this example are as follows:
- [Run the example in Design Studio](#)
- [Run the example in Design Server User Interface](#)
- [How to customize the mxconfig.xml file](#)

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

## What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources to use when running under Design Studio:
  - t2\_clm\_mx\_admi\_validation\_enh.mms  
Utility maps called by main map for all the admi TARGET2 CLM xml message MX validation.
  - t2\_clm\_mx\_camt\_validation\_enh.mms  
Utility maps called by main map for all the camt TARGET2 CLM xml message MX validation.
  - t2\_clm\_mx\_pacs\_validation\_enh.mms  
Utility maps called by main map for all the pacs TARGET2 CLM xml message MX validation.
  - t2\_clm\_mx\_validation\_frmwrk\_map\_enh.mms  
The main map used to apply MX validation to TARGET2 CLM xml messages.

Note: When running under Design Server, the main framework map is t2\_clm\_mx\_validation\_frmwrk\_map\_flw\_enh.mms.

- Schemas:

The schemas directory contains the following files:

- bic.xsd  
Metadata that represents the bic.xml repository file structure.
- ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
- mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.
- XML schemas based on SWIFT MyStandards Readiness TARGET2 CLM Portal:
  - admi.004.001.02.xsd
  - admi.005.001.01.xsd
  - admi.007.001.01.xsd
  - camt.003.001.07.xsd
  - camt.004.001.08.xsd
  - camt.005.001.08.xsd
  - camt.006.001.08.xsd
  - camt.018.001.05.xsd
  - camt.019.001.07.xsd
  - camt.025.001.05.xsd
  - camt.029.001.09.xsd
  - camt.046.001.05.xsd
  - camt.047.001.06.xsd
  - camt.048.001.05.xsd
  - camt.049.001.05.xsd
  - camt.050.001.05.xsd
  - camt.053.001.08\_btcs.xsd
  - camt.053.001.08\_tsgl.xsd
  - camt.054.001.08.xsd
  - camt.056.001.08.xsd
  - camt.998.001.03\_apmr.xsd
  - camt.998.001.03\_gpmr.xsd
  - camt.998.001.03\_ibmr.xsd
  - camt.998.001.03\_ivrmr.xsd
  - camt.998.001.03\_mcl.xsd
  - camt.998.001.03\_rpimr.xsd
  - camt.998.001.03\_rpmr.xsd
  - pacs.002.001.10.xsd
  - pacs.009.001.08.xsd
  - pacs.010.001.03.xsd
  - head.001.001.01.xsd
- XML schema based on W3C XML Signature Syntax and Processing version 1.2:
  - xmldsig-core-schema.xsd

- Trees:

The trees directory contains the following files:

- mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
- swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.

- Data:

The data directory contains the following file:

- bic.xml  
Repository file listing all BICs which are used during validation.
- currencycodedecimals.xml  
Repository file list country codes, currency codes and corresponding maximum fractionally digits, used as reference for validation.
- mxconfig.xml  
Holds the MX configuration information on how to process the message.
- Sample TARGET2 CLM valid files without header envelope for test purposes:
  - admi\_007\_001\_01\_valid.xml
- Sample TARGET2 CLM valid files with header envelope for test purposes:
  - bah\_admi\_004\_001\_02\_valid.xml
  - bah\_admi\_005\_001\_01\_valid.xml
  - bah\_admi\_007\_001\_01\_valid.xml
  - bah\_camt\_003\_001\_07\_valid.xml
  - bah\_camt\_004\_001\_08\_valid.xml
  - bah\_camt\_005\_001\_08\_valid.xml
  - bah\_camt\_006\_001\_08\_valid.xml
  - bah\_camt\_018\_001\_05\_valid.xml
  - bah\_camt\_019\_001\_07\_valid.xml
  - bah\_camt\_025\_001\_05\_valid.xml
  - bah\_camt\_029\_001\_09\_valid.xml

- bah\_camt\_046\_001\_05\_valid.xml
- bah\_camt\_047\_001\_06\_valid.xml
- bah\_camt\_048\_001\_05\_valid.xml
- bah\_camt\_049\_001\_05\_valid.xml

- bah\_pacs\_002\_001\_10\_valid.xml
- bah\_pacs\_009\_001\_08\_valid.xml
- bah\_pacs\_010\_001\_03\_valid.xml

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
  2. Replace the input card 1 in router map, t2cl9000\_val (under t2\_clm\_mx\_validation\_frmwrk\_map\_enh.mms or t2\_clm\_mx\_validation\_frmwrk\_map\_flw\_enh.mms file if running under Design Server) with desired input file.
  3. Run the main router map, t2cl9000\_val.
- You will see the output file in the data folder called t2clm\_error\_report.xml.

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If the project does not exist, import t2\_clm.zip.
4. If absent, create a package containing all the Maps, Files, and Flows.
5. Build package in desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map t2cl9000\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map t2cl9000\_val.
10. Right click on the output card on canvas and select View data.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

### Example

To disable the BIC lookup validation feature.

### About this task

Change sub-element ExtendedValidation/BICValidation value from T to F.

### Procedure

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the map.

Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

## T2 CLM schema validation (using maps) example

This example demonstrates the schema validation for TARGET2 CLM messages using maps only.

The maps can perform following level of validation:

- Schema validation
- [What the example contains](#)  
Files and directories included in this example are as follows:
- [Run the example in Design Studio](#)
- [Run the example in Design Server User Interface](#)

---

## What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources to use when running under Design Studio:
  - t2\_clm\_mx\_schema\_validation\_xsd.mms  
Utility maps called by main map for all TARGET2 CLM xml messages schema validation.
  - t2\_clm\_schema\_validation\_frmwrk\_map\_xsd.mms  
The main map used to apply schema only validation to TARGET2 CLM xml messages.
- Schemas:  
The schemas directory contains the following files:
  - XML schemas based on SWIFT MyStandards Readiness TARGET2 CLM Portal:
    - admi.004.001.02.xsd
    - admi.005.001.01.xsd
    - admi.007.001.01.xsd
    - camt.003.001.07.xsd
    - camt.004.001.08.xsd
    - camt.005.001.08.xsd
    - camt.006.001.08.xsd
    - camt.018.001.05.xsd
    - camt.019.001.07.xsd
    - camt.025.001.05.xsd
    - camt.029.001.09.xsd
    - camt.046.001.05.xsd
    - camt.047.001.06.xsd
    - camt.048.001.05.xsd
    - camt.049.001.05.xsd
    - camt.050.001.05.xsd
    - camt.053.001.08\_btcs.xsd
    - camt.053.001.08\_tsgl.xsd
    - camt.054.001.08.xsd
    - camt.056.001.08.xsd
    - camt.998.001.03\_apmr.xsd
    - camt.998.001.03\_gpmr.xsd
    - camt.998.001.03\_ibmr.xsd
    - camt.998.001.03\_ivrnr.xsd
    - camt.998.001.03\_mcl.xsd
    - camt.998.001.03\_rpimr.xsd
    - camt.998.001.03\_rpmr.xsd
    - pacs.002.001.10.xsd
    - pacs.009.001.08.xsd
    - pacs.010.001.03.xsd
    - head.001.001.01.xsd
  - XML schemas based on W3C XML Signature Syntax and Processing version 1.2:
    - xmldsig-core-schema.xsd
- Trees:  
The trees directory contains the following files:
  - mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
  - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
- Data:  
The data directory contains the following file:
  - Sample TARGET2 CLM valid files without header envelope for test purposes:
    - admi\_007\_001\_01\_valid.xml
  - Sample TARGET2 CLM valid files with header envelope for test purposes:
    - bah\_admi\_004\_001\_02\_valid.xml
    - bah\_admi\_005\_001\_01\_valid.xml
    - bah\_admi\_007\_001\_01\_valid.xml
    - bah\_camt\_003\_001\_07\_valid.xml

- bah\_camt\_004\_001\_08\_valid.xml
- bah\_camt\_005\_001\_08\_valid.xml

- bah\_camt\_998\_001\_03\_gpmr\_valid.xml
- bah\_camt\_998\_001\_03\_ibmr\_valid.xml
- bah\_camt\_998\_001\_03\_ivrnr\_valid.xml
- bah\_camt\_998\_001\_03\_mcl\_valid.xml
- bah\_camt\_998\_001\_03\_rpimr\_valid.xml
- bah\_camt\_998\_001\_03\_rpmr\_valid.xml
- bah\_pacs\_002\_001\_10\_valid.xml
- bah\_pacs\_009\_001\_08\_valid.xml
- bah\_pacs\_010\_001\_03\_valid.xml

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, t2cl9500\_val (under t2\_clm\_schema\_validation\_frmwrk\_map\_xsd.mms file) with desired input file.
3. Run the main router map, t2cl9500\_val.  
You will see the output file in the data folder called t2clm\_error\_report.xml.

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If the project does not exist, import t2\_clm.zip.
4. If absent, create a package containing all the Maps, Files, and Flows.
5. Build package in desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map t2cl9500\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map t2cl9500\_val.
10. Right click on the output card on canvas and select View data.

## TARGET2 RTGS Examples:

TARGET2 RTGS examples are as follow:

- [\*\*T2 RTGS enhanced MX validation \(using Flow Server\) example\*\*](#)  
This example demonstrates the TARGET2 RTGS enhanced MX validation for TARGET2 RTGS messages using flow server.
- [\*\*T2 RTGS enhanced MX validation \(using maps\) example\*\*](#)  
This example demonstrates the enhanced MX validation for TARGET2 RTGS messages using maps only.
- [\*\*T2 RTGS schema validation \(using maps\) example\*\*](#)  
This example demonstrates the schema validation for TARGET2 RTGS messages using maps only.

## T2 RTGS enhanced MX validation (using Flow Server) example

This example demonstrates the TARGET2 RTGS enhanced MX validation for TARGET2 RTGS messages using flow server.

The flow can perform following level of validation:

- MX extended validation includes following checks:
  - BIC lookup
  - Country code lookup
  - Currency code lookup
  - IBAN format
  - Allowed maximum fractional digits per currency

- Usage guideline rules, see mxconfig.xml for list of rules
  - Schema validation
  - **[What the example contains](#)**  
Files included in this example are as follows:
  - **[How to run the example](#)**  
This TARGET2 RTGS MX Validation will use the sample files to demonstrate the generation of validation report as output from a TARGET2 RTGS XML message.
  - **[How to customize the mxconfig.xml file](#)**  
Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.
- 

## What the example contains

Files included in this example are as follows:

- t2\_rtgs\_flow.zip
  - Test Data Files:
    - t2rtgs\_pacs\_009.xml
    - t2rtgs\_pacs\_009\_bad\_rule.xml
    - t2rtgs\_pacs\_009\_bad\_schema.xml
  - Validation Files:
    - mxconfig.xml
    - bic.xml
    - currencycodedecimals.xml
  - Schemas:
    - bic.xsd  
Metadata that represents the bic.xml repository file structure.
    - ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
    - mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.
    - mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
    - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
  - XML schemas based on SWIFT MyStandards Readiness TARGET2 RTGS Portal:
    - admi.004.001.02.xsd
    - admi.005.001.01.xsd
    - admi.007.001.01.xsd
    - camt.003.001.07.xsd
    - camt.004.001.08.xsd
    - camt.005.001.08.xsd
    - camt.006.001.08.xsd
    - camt.007.001.08.xsd
    - camt.009.001.07.xsd
    - camt.010.001.08.xsd
    - camt.011.001.07.xsd
    - camt.012.001.07.xsd
    - camt.018.001.05.xsd
    - camt.019.001.07.xsd
    - camt.021.001.06.xsd
    - camt.025.001.05.xsd
    - camt.029.001.09.xsd
    - camt.046.001.05.xsd
    - camt.047.001.06.xsd
    - camt.048.001.05.xsd
    - camt.049.001.05.xsd
    - camt.050.001.05.xsd
    - camt.053.001.08.xsd
    - camt.054.001.08.xsd
    - camt.056.001.08.xsd
    - pacs.002.001.10.xsd
    - pacs.004.001.09.xsd
    - pacs.008.001.08.xsd
    - pacs.009.001.08.xsd
    - pacs.010.001.03.xsd
    - pain.998.001.01\_ais.xsd
    - pain.998.001.01\_ati.xsd
    - pain.998.001.01\_atn.xsd
    - head.001.001.01.xsd
  - XML schema based on W3C XML Signature Syntax and Processing version 1.2:
    - xmldsig-core-schema.xsd  
Note: The schema xmldsig-core-schema.xsd is imported inside of schema head.001.001.01.xsd to handle signatures. It is imported three times as a FILE to the project. Once in folder location t2\_rtgs/validation/mx\_extended/schemas, second copy in folder location t2\_rtgs/validation/schema\_only/schemas, and third copy without any logical folder.

- Maps:
  - For Extended Validation:

  - t2\_rtgs\_validation\_flow

## How to run the example

This TARGET2 RTGS MX Validation will use the sample files to demonstrate the generation of validation report as output from a TARGET2 RTGS XML message.

The stopValidation.json file will report the validation failure due to the pre-conversion checks:

If input file is other than any of the supported TARGET2 RTGS messages as per schema list indicated above.

1. Import the t2\_rtgs.zip project into the Design Server.
2. Open the t2\_rtgs project in Design Server and view the flow t2\_rtgs\_validation\_flow.

a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. This list has to be added to the description and ensure all lines start in column 1. Following is the list of maps with the description format:

- @packagemap=t2\_rtgs/validation/mx\_extended/maps/t2\_rtgs\_mx\_camt\_validation\_enh/t2rt9051\_head111\_camt

b. It utilizes the following nodes:

i. Source Nodes:

- mx\_input

This node identifies the input data to be validated in the flow. It uses the variable INPUT\_FILE to set the location of the data.

ii. Map Nodes:

- MX pre-check

Runs map mxut1005\_bizsvc\_t2rtgs which sets flow variables, checks pre-validation conditions, and creates infoset.json for validation.

- EXT\_VAL

Runs map t2rt9100\_val which calls the appropriate map to perform extended validation of a TARGET2 RTGS message.

- XSD\_VAL

Runs map t2rt9100\_val which calls the appropriate map to perform schema validation of a TARGET2 RTGS message.

Note: The maps t2rt9100\_val and t2rt9500\_val internally call all the other maps identified in the above Flow Description step.

iii. Decision Nodes:

- pre-valid chk

This node checks the flow variable stopValidation to decide if further validation/processing is not required.

- EXT\_RESULT\_FORMAT

This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for extended validation should be generated in XML (default) or JSON.

- XSD\_RESULT\_FORMAT

This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for schema-only validation should be generated in XML (default) or JSON.

iv. Route Nodes:

- VAL\_TYPE

This node checks the variable VALIDATION\_TYPE to determine if the process will do extended validation or schema-only validation on the data.

v. Log Nodes:

- FAILURE

In case of no validation due to precondition check failures, this node creates a log file specified by the flow variable FAILURE\_LOG.

vi. Fail Node:

- STOP

It generates error message setup in the node in case of no validation performed.

vii. Passthrough Nodes:

- EXT\_XML\_CONVERT

This node receives an extended validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.

- XSD\_XML\_CONVERT

This node receives a schema-only validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.

viii. Format Converter Nodes:

- EXT\_JSON\_CONVERT

This node receives an extended validation report in XML format and converts it to JSON before passing it to the appropriate target node.

- XSD\_JSON\_CONVERT

This node receives a schema-only validation report in XML format and converts it to JSON before passing it to the appropriate target node.

ix. Target Nodes:

- ext\_xml

This node contains the resulting extended validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.

- ext\_json

This node contains the resulting extended validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.

- xsd\_xml

This node contains the resulting schema-only validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.

- xsd\_json

This node contains the resulting schema-only validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.

c. It utilizes the following variables:

i. Flow variables:

- VALIDATION\_TYPE

Default value is extended. For schema-only validation, it can be changed to schema. It is used in Route node VAL\_TYPE.

- REPORT\_FORMAT

Default value is xml. It can be changed to json. It is used in Decision nodes EXT\_RESULT\_FORMAT and XSD\_RESULT\_FORMAT.

- INPUT\_FILE  
Default value is ../tools/mx\_service/data/t2rtgs\_pacs\_009.xml. This is the data file to be used for validation and can be customized. It is used in the Source node mx\_input.
- BIC\_FILE  
Default value is ../data/bic.xml. This is the location of the bic cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.
- CCY\_FILE  
Default value is ../data/currencycodedecimals.xml. This is the location of the country code cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.
- MXCONFIG\_FILE  
Default value is ../data/mxconfig.xml. This is the location of the file containing the rule validation settings that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.
- OUTPUT\_RESULT\_XML  
Default value is validation\_result.xml. This is the location of the validation report file in xml format. It is used in Target nodes ext\_xml and xsd\_xml. It can be customized.
- OUTPUT\_RESULT\_JSON  
Default value is validation\_result.json. This is the location of the validation report file in json format. It is used in Target nodes ext\_json and xsd\_json. It can be customized.
- FAILURE\_LOG  
Default value is stopMXValidation.json. This is the location of the failure log. It is used in Log node FAILURE. It can be customized.
- bizSvc  
For internal use in the Map node MX pre-check to determine the type of data being read in the input file.
- stopValidation  
For internal use in the Map node MX pre-check and is checked in Decision node pre-valid chk to cause a Failure log in case a data file was not recognized as a valid TARGET2 RTGS message.

3. Open the main flow t2\_rtgs\_validation\_flow in the Design Server. It utilizes the above one Source node, three Map nodes, one Route node, three Decision nodes, one Log node, one Fail node, two Passthrough nodes, two Format Converter nodes, and four Target nodes.
4. In Design Server, create a package t2\_rtgs\_mx\_validation that contains the input files and one flow t2\_rtgs\_validation\_flow. The maps will automatically be included during deployment of the package onto the runtime server.  
Note: Not required for running flows on Design Server user interface directly.

- **[Run the example using three different methods](#)**

You can run the example using three different methods:

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- **[Run the example from the Design Server user interface](#)**

Use the following steps to run the example from the Design Server user interface:

- **[Run the example using the Swagger interface](#)**  
To run the example, deploy to tx-rest and run it using the Swagger interface.
  - **[Run the example using the flow command server process \(flowcmdserver\)](#)**  
To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).
- 
- ## Run the example from the Design Server user interface
- Use the following steps to run the example from the Design Server user interface:
1. In the Design Server, open t2\_rtgs\_validation\_flow flow and click on Run button.
  2. Set the toggle switch Run On Design Server and select flow input file. Example is t2rtgs\_pacs\_009.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, the value defined for the variable will be used if an input file is not selected.  
Flow will run and report with the green check box. The report lists execution of all nodes.
  3. Right click and select View Link Data on each link to examine the data.
  4. View target node by clicking on the node, doing right click on the Input icon and selecting View Data.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server:  

```
<DTX_HOME>/restapi/tomcat/dtxtomcat start tx-rest
```
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI:  

```
<DTX_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest
```
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
 You can see a Miscellaneous section having two actions:

- **PUT** /v2/run/t2\_rtgs\_validation\_flow
- **POST** /v2/run/t2\_rtgs\_validation\_flow

6. In the **PUT** action:
  - a. Expand the **PUT** action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/mydir/data/t2rtgs_pacs_009.xml",
 "OUTPUT_RESULT_JSON": "C:/mydir/data/validation_result.json",
 "REPORT_FORMAT": "json",
 "VALIDATION_TYPE": "extended"
}
```

or

```
{
 "INPUT_FILE": "C:/mydir/data/t2rtgs_pacs_009.xml",
 "OUTPUT_RESULT_XML": "C:/mydir/data/validation_result.xml",
 "REPORT_FORMAT": "xml",
 "VALIDATION_TYPE": "extended"
}
```

- d. Click Execute blue bar for running the flow.

When flow completes execution, 200 response code is shown in the Server Response section. This run should generate the output same as above.

7. To delete the deployed package, refresh the browser to get the Swagger and explore back to /tx-rest/openapi.json.

There will be a DELETE /v2/packages/{name} action.

8. Expand the DELETE /v2/packages/{name} action and select Try it out.

9. In the Name field, enter the name you gave to the created package.

10. Select the true option from the stop query drop down, then select the blue Execute bar.

You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed if you do not have a server local definition or ftp execution definition to deploy in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. The below command is for TARGET2 RTGS t2rtgs\_pacs\_009.xml message.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow t2_rtgs_validation_flow.json --var
"INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\t2rtgs_pacs_009.xml" --audit
"C:\ftpserver\deployment\tools\mx_service\data\t2rtgs_pacs_009_adt.json" -ad
```

The results will be in C:\ftpserver\deployment\flows as validation\_results.xml or validation\_results.json depending on the value of the REPORT\_FORMAT variable.

This command will execute with the variable VALIDATION\_TYPE value defined in the Flow settings in Design Server (extended or schema).

To change, the following command can be used:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow t2_rtgs_validation_flow.json --var
"INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\t2rtgs_pacs_009.xml" --var "VALIDATION_TYPE=schema" --var
"REPORT_FORMAT=json" --audit "C:\ftpserver\deployment\tools\mx_service\data\t2rtgs_pacs_009_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server
Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\ftpserver\deployment\tools\mx_service\data\t2rtgs_pacs_009_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result files validation\_results.xml and the audit file t2rtgs\_pacs\_009\_adt.json.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

## Example

---

To disable the BIC lookup validation feature.

## About this task

---

Change sub-element ExtendedValidation/BICValidation value from T to F.

## Procedure

---

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the flow.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

---

## T2 RTGS enhanced MX validation (using maps) example

This example demonstrates the enhanced MX validation for TARGET2 RTGS messages using maps only.

The maps can perform following level of validation:

- MX extended validation includes following checks:

- BIC lookup
- Country code lookup
- Currency code lookup
- IBAN format
- Allowed maximum fractional digits per currency
- Usage guideline rules, see mxconfig.xml for list of rules

- Schema validation

- **What the example contains**

Files and directories included in this example are as follows:

- **Run the example in Design Studio**

- **Run the example in Design Server User Interface**

- **How to customize the mxconfig.xml file**

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

---

## What the example contains

Files and directories included in this example are as follows:

- Maps:

The maps directory contains the following map sources to use when running under Design Studio.

- t2\_rtgs\_mx\_admi\_validation\_enh.mms  
Utility maps called by main map for all the admi TARGET2 RTGS xml message MX validation.
- t2\_rtgs\_mx\_camt\_validation\_enh.mms  
Utility maps called by main map for all the camt TARGET2 RTGS xml message MX validation.
- t2\_rtgs\_mx\_pacs\_validation\_enh.mms  
Utility maps called by main map for all the pacs TARGET2 RTGS xml message MX validation.
- t2\_rtgs\_mx\_pain\_validation\_enh.mms  
Utility maps called by main map for all the pain TARGET2 RTGS xml message MX validation.
- t2\_rtgs\_mx\_validation\_frmwrk\_map\_enh.mms  
The main map used to apply MX validation to TARGET2 RTGS xml messages.

Note: When running under Design Server, the main framework map is t2\_rtgs\_mx\_validation\_frmwrk\_map\_flw\_enh.mms.

- Schemas:

The schemas directory contains the following files:

- bic.xsd  
Metadata that represents the bic.xml repository file structure.
- ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
- mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.
- XML schemas based on SWIFT MyStandards Readiness TARGET2 RTGS Portal:

- admi.004.001.02.xsd
- admi.005.001.01.xsd
- admi.007.001.01.xsd
- camt.003.001.07.xsd
- camt.004.001.08.xsd
- camt.005.001.08.xsd
- camt.006.001.08.xsd
- camt.007.001.08.xsd
- camt.009.001.07.xsd
- camt.010.001.08.xsd
- camt.011.001.07.xsd

- camt.056.001.08.xsd
- pacs.002.001.10.xsd
- pacs.004.001.09.xsd
- pacs.008.001.08.xsd
- pacs.009.001.08.xsd
- pacs.010.001.03.xsd
- pain.998.001.01\_ais.xsd
- pain.998.001.01\_ati.xsd
- pain.998.001.01\_atn.xsd
- head.001.001.01.xsd
- XML schema based on W3C XML Signature Syntax and Processing version 1.2:
  - xmldsig-core-schema.xsd

- Trees:

The trees directory contains the following files:

- mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
- swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.

- Data:

The data directory contains the following file:

- bic.xml  
Repository file listing all BICs which are used during validation.
- currencycodedecimals.xml  
Repository file list country codes, currency codes and corresponding maximum fractionally digits, used as reference for validation.
- mxconfig.xml  
Holds the MX configuration information on how to process the message.
- Sample TARGET2 RTGS valid files without header envelope for test purposes:
  - admi\_007\_001\_01\_valid.xml
- Sample TARGET2 RTGS valid files with header envelope for test purposes:
  - bah\_admi\_004\_001\_02\_valid.xml

- bah\_pacs\_008\_001\_08\_valid.xml
- bah\_pacs\_009\_001\_08\_valid.xml
- bah\_pacs\_010\_001\_03\_valid.xml
- bah\_pain\_998\_001\_01\_ais\_valid.xml
- bah\_pain\_998\_001\_01\_ati\_valid.xml
- bah\_pain\_998\_001\_01\_atn\_valid.xml

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, t2rt9000\_val (under t2\_rtgs\_mx\_validation\_frmwrk\_map\_enh.mms file or t2\_rtgs\_mx\_validation\_frmwrk\_map\_flw\_enh.mms file if running under Design Server) with desired input file.
3. Run the main router map, t2rt9000\_val.  
You will see the output file in the data folder called t2rtgs\_error\_report.xml.

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If the project does not exist, import t2\_rtgs.zip.
4. If absent, create a package containing all the Maps, Files, and Flows.
5. Build package in desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map t2rt9000\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map t2rt9000\_val.
10. Right click on the output card on canvas and select View data.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

### Example

To disable the BIC lookup validation feature.

### About this task

Change sub-element ExtendedValidation/BICValidation value from T to F.

### Procedure

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the map.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

## T2 RTGS schema validation (using maps) example

This example demonstrates the schema validation for TARGET2 RTGS messages using maps only.

The maps can perform following level of validation:

- Schema validation

- [What the example contains](#)
  - [Run the example in Design Studio](#)
  - [Run the example in Design Server User Interface](#)
- 

## What the example contains

This example contains the following directories and files:

- Maps:

The maps directory contains the following map sources to use when running under Design Studio:

- t2\_rtgs\_mx\_schema\_validation\_xsd.mms  
Utility maps called by main map for all TARGET2 RTGS xml messages schema validation.
- t2\_rtgs\_schema\_validation\_frmwrk\_map\_xsd.mms  
The main map used to apply schema validation to TARGET2 RTGS xml messages.

- Schemas:

The schemas directory contains the following files:

- XML schemas based on SWIFT MyStandards Readiness TARGET2 RTGS Portal:

- admi.004.001.02.xsd
- admi.005.001.01.xsd
- admi.007.001.01.xsd
- camt.003.001.07.xsd
- camt.004.001.08.xsd
- camt.005.001.08.xsd
- camt.006.001.08.xsd
- camt.007.001.08.xsd
- camt.009.001.07.xsd
- camt.010.001.08.xsd
- camt.011.001.07.xsd
- camt.012.001.07.xsd
- camt.018.001.05.xsd
- camt.019.001.07.xsd
- camt.021.001.06.xsd
- camt.025.001.05.xsd
- camt.029.001.09.xsd
- camt.046.001.05.xsd
- camt.047.001.06.xsd
- camt.048.001.05.xsd
- camt.049.001.05.xsd
- camt.050.001.05.xsd
- camt.053.001.08.xsd
- camt.054.001.08.xsd
- camt.056.001.08.xsd
- pacs.002.001.10.xsd
- pacs.004.001.09.xsd
- pacs.008.001.08.xsd
- pacs.009.001.08.xsd
- pacs.010.001.03.xsd
- pain.998.001.01\_ais.xsd
- pain.998.001.01\_ati.xsd
- pain.998.001.01\_atn.xsd
- head.001.001.01.xsd

- XML schemas based on W3C XML Signature Syntax and Processing version 1.2:
  - xmldsig-core-schema.xsd

- Trees:

The trees directory contains the following files:

- mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
- swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.

- Data:

The data directory contains the following file:

- Sample TARGET2 RTGS valid files without header envelope for test purposes:
  - admi\_007\_001\_01\_valid.xml
- Sample TARGET2 RTGS valid files with header envelope for test purposes:
  - bah\_admi\_004\_001\_02\_valid.xml
  - bah\_admi\_005\_001\_01\_valid.xml
  - bah\_admi\_007\_001\_01\_valid.xml
  - bah\_camt\_003\_001\_07\_valid.xml
  - bah\_camt\_004\_001\_08\_valid.xml
  - bah\_camt\_005\_001\_08\_valid.xml
  - bah\_camt\_006\_001\_08\_valid.xml

- bah\_camt\_007\_001\_08\_valid.xml
- bah\_camt\_009\_001\_07\_valid.xml
- bah\_camt\_010\_001\_08\_valid.xml
- bah\_camt\_011\_001\_07\_valid.xml
- bah\_camt\_012\_001\_07\_valid.xml
- bah\_camt\_018\_001\_05\_valid.xml
- bah\_camt\_019\_001\_07\_valid.xml
- bah\_camt\_021\_001\_06\_valid.xml
- bah\_camt\_025\_001\_05\_valid.xml
- bah\_camt\_029\_001\_09\_valid.xml
- bah\_camt\_046\_001\_05\_valid.xml
- bah\_camt\_047\_001\_06\_valid.xml
- bah\_camt\_048\_001\_05\_valid.xml
- bah\_camt\_049\_001\_05\_valid.xml
- bah\_camt\_050\_001\_05\_valid.xml
- bah\_camt\_053\_001\_08\_valid.xml
- bah\_camt\_054\_001\_08\_valid.xml
- bah\_camt\_056\_001\_08\_valid.xml
- bah\_pacs\_002\_001\_10\_valid.xml
- bah\_pacs\_004\_001\_09\_valid.xml
- bah\_pacs\_008\_001\_08\_valid.xml
- bah\_pacs\_009\_001\_08\_valid.xml
- bah\_pacs\_010\_001\_03\_valid.xml
- bah\_pain\_998\_001\_01\_ais\_valid.xml
- bah\_pain\_998\_001\_01\_ati\_valid.xml
- bah\_pain\_998\_001\_01\_atn\_valid.xml

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, t2rt9500\_val (under t2\_rtgs\_schema\_validation\_frmwrk\_map\_xsd.mms file) with desired input file.
3. Run the main router map, t2rt9500\_val.  
You will see the output file in the data folder called t2rtgs\_error\_report.xml.

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If the project does not exist, import t2\_rtgs.zip.
4. If absent, create a package containing all the Maps, Files, and Flows.
5. Build package in desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map t2rt9500\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map t2rt9500\_val.
10. Right click on the output card on canvas and select View data.

## TARGET2 CoCo Examples:

TARGET2 CoCo examples are as follow:

- [\*\*T2 CoCo enhanced MX validation \(using Flow Server\) example\*\*](#)  
This example demonstrates the TARGET2 CoCo enhanced MX validation for TARGET2 CoCo messages using flow server.
- [\*\*T2 CoCo enhanced MX validation \(using maps\) example\*\*](#)  
This example demonstrates the TARGET2 CoCo enhanced MX validation for TARGET2 CoCo messages using maps only.
- [\*\*T2 CoCo schema validation \(using maps\) example\*\*](#)  
This example demonstrates the TARGET2 CoCo schema validation for TARGET2 CoCo messages using maps only.

## T2 CoCo enhanced MX validation (using Flow Server) example

This example demonstrates the TARGET2 CoCo enhanced MX validation for TARGET2 CoCo messages using flow server.

The flow can perform following level of validation:

- MX extended validation includes following checks:
  - BIC lookup
  - Country code lookup
  - Currency code lookup
  - IBAN format
  - Allowed maximum fractional digits per currency

- Usage guideline rules, see mxconfig.xml for list of rules
  - Schema validation
  - **[What the example contains](#)**  
Files included in this example are as follows:
  - **[How to run the example](#)**  
This TARGET2 CoCo MX Validation will use the sample files to demonstrate the generation of validation report as output from a TARGET2 CoCo XML message.
  - **[How to customize the mxconfig.xml file](#)**  
Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.
- 

## What the example contains

Files included in this example are as follows:

- t2\_coco.zip
  - Test Data Files:
    - t2coco\_camt\_009.xml
    - t2coco\_camt\_009\_bad\_rule.xml
    - t2coco\_camt\_009\_bad\_schema.xml
  - Validation Files:
    - mxconfig.xml
    - bic.xml
    - currencycodedecimals.xml
  - Schemas:
    - bic.xsd  
Metadata that represents the bic.xml repository file structure.
    - ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
    - mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.
    - mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
    - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
  - XML schemas based on SWIFT MyStandards Readiness TARGET2 CoCo Portal:

- Flows:
  - t2\_coco\_validation\_flow

## How to run the example

This TARGET2 CoCo MX Validation will use the sample files to demonstrate the generation of validation report as output from a TARGET2 CoCo XML message.

The stopValidation.json file will report the validation failure due to the pre-conversion checks:

**If input file is other than any of the supported TARGET2 CoCo messages as per schema list indicated above.**

1. Import the t2\_coco.zip project into the Design Server.
2. Open the t2\_coco project in Design Server and view the flow t2\_coco\_validation\_flow.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. This list has to be added to the description and ensure all lines start in column 1. Following is the list of maps with the description format:
    - @packagemap=t2\_coco/validation/mx\_extended/maps/t2\_coco\_mx\_camt\_validation\_enh/t2co9051\_head111\_camt

b. It utilizes the following nodes:

i. Source Nodes:

- mx\_input

This node identifies the input data to be validated in the flow. It uses the variable INPUT\_FILE to set the location of the data.

ii. Map Nodes:

- MX pre-check

Runs map mxut1006\_bizsvc\_t2coco which sets flow variables, checks pre-validation conditions, and creates infoset.json for validation.

- EXT\_VAL

Runs map t2co9100\_val which calls the appropriate map to perform extended validation of a TARGET2 CoCo message.

- XSD\_VAL

Runs map t2co9500\_val which calls the appropriate map to perform schema validation of a TARGET2 CoCo message.

Note: The maps t2co9100\_val and t2co9500\_val internally call all the other maps identified in the above Flow Description step.

iii. Decision Nodes:

- pre-valid chk

This node checks the flow variable stopTranslation to decide if further validation/processing is not required.

- EXT\_RESULT\_FORMAT

This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for extended validation should be generated in XML (default) or JSON.

- XSD\_RESULT\_FORMAT

This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for schema-only validation should be generated in XML (default) or JSON.

iv. Route Nodes:

- VAL\_TYPE

This node checks the variable VALIDATION\_TYPE to determine if the process will do extended validation or schema-only validation on the data.

v. Log Nodes:

- FAILURE

In case of no validation due to precondition check failures, this node creates a log file specified by the flow variable FAILURE\_LOG.

vi. Fail Node:

- STOP

It generates error message setup in the node in case of no validation performed.

vii. Passthrough Nodes:

- EXT\_XML\_CONVERT

This node receives an extended validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.

- XSD\_XML\_CONVERT

This node receives a schema-only validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.

viii. Format Converter Nodes:

- EXT\_JSON\_CONVERT

This node receives an extended validation report in XML format and converts it to JSON before passing it to the appropriate target node.

- XSD\_JSON\_CONVERT

This node receives a schema-only validation report in XML format and converts it to JSON before passing it to the appropriate target node.

ix. Target Nodes:

- ext\_xml

This node contains the resulting extended validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.

- ext\_json  
This node contains the resulting extended validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.
  - xsd\_xml  
This node contains the resulting schema-only validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.
  - xsd\_json  
This node contains the resulting schema-only validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.
- c. It utilizes the following variables:
- i. Flow variables:
    - VALIDATION\_TYPE  
Default value is extended. For schema-only validation, it can be changed to schema. It is used in Route node VAL\_TYPE.
    - REPORT\_FORMAT  
Default value is xml. It can be changed to json. It is used in Decision nodes EXT\_RESULT\_FORMAT and XSD\_RESULT\_FORMAT.
    - INPUT\_FILE  
Default value is ../tools/mx\_service/data/t2coco\_camt\_009.xml. This is the data file to be used for validation and can be customized. It is used in the Source node mx\_input.
    - BIC\_FILE  
Default value is ../data/bic.xml. This is the location of the bic cross-reference file that is used in all the maps executed by the map in the node EXT\_VAL. It can be customized.
    - CCY\_FILE  
Default value is ../data/currencycodedecimals.xml. This is the location of the country code cross-reference file that is used in all the maps executed by the map in the node EXT\_VAL. It can be customized.
    - MXCONFIG\_FILE  
Default value is ../data/mxconfig.xml. This is the location of the file containing the rule validation settings that is used in all the maps executed by the map in the node EXT\_VAL. It can be customized.
    - OUTPUT\_RESULT\_XML  
Default value is validation\_result.xml. This is the location of the validation report file in xml format. It is used in Target nodes ext\_xml and xsd\_xml. It can be customized.
    - OUTPUT\_RESULT\_JSON  
Default value is validation\_result.json. This is the location of the validation report file in json format. It is used in Target nodes ext\_json and xsd\_json. It can be customized.
    - FAILURE\_LOG  
Default value is stopMXValidation.json. This is the location of the failure log. It is used in Log node FAILURE. It can be customized.
    - bizSvc  
For internal use in the Map node MX pre-check to determine the type of data being read in the input file.
    - stopValidation  
For internal use in the Map node MX pre-check and is checked in Decision node pre-valid chk to cause a Failure log in case a data file was not recognized as a valid TARGET2 Coco message.

3. Open the main flow t2\_coco\_validation\_flow in the Design Server. It utilizes the above one Source node, three Map nodes, one Route node, three Decision nodes, one Log node, one Fail node, two Passthrough nodes, two Format Converter nodes, and four Target nodes.

4. In Design Server, create a package t2\_coco\_mx\_validation that contains the input files and one flow t2\_coco\_validation\_flow. The maps will automatically be included during deployment of the package onto the runtime server.

Note: Not required for running flows on Design Server user interface directly.

- [Run the example using three different methods](#)

You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- [Run the example from the Design Server user interface](#)

Use the following steps to run the example from the Design Server user interface:

- [Run the example using the Swagger interface](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

- [Run the example using the flow command server process \(flowcmdserver\)](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open t2\_coco\_validation\_flow flow and click on Run button.
2. Set the toggle switch Run On Design Server and select flow input file. Example is t2coco\_camt\_009.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, the value defined for the variable will be used if an input file is not selected.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Link Data on each link to examine the data.
4. View target node by clicking on the node, doing right click on the Input icon and selecting View Data.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed if you do not have a server definition to deploy in Design Server.

2. If not running, start tx-rest on the server:

```
<DTX_HOME>/restapi/tomcat/dtxtomcat start tx-rest
```

3. Deploy the created package to the server definition in Design Server.

4. Bring up the tx-rest Swagger UI:

```
<DTX_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest
```

5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.

You can see a Miscellaneous section having two actions:

- **PUT** /v2/run/t2\_coco\_validation\_flow
- **POST** /v2/run/t2\_coco\_validation\_flow

6. In the **PUT** action:

- a. Expand the **PUT** action and select the Try it out button.

- b. Leave the input and output sections empty.

- c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/mydir/data/t2coco_camt_009.xml",
 "OUTPUT_RESULT_JSON": "C:/mydir/data/validation_result.json",
 "REPORT_FORMAT": "json",
 "VALIDATION_TYPE": "extended"
}
```

or

```
{
 "INPUT_FILE": "C:/mydir/data/t2coco_camt_009.xml",
 "OUTPUT_RESULT_XML": "C:/mydir/data/validation_result.xml",
 "REPORT_FORMAT": "xml",
 "VALIDATION_TYPE": "extended"
}
```

- d. Click Execute blue bar for running the flow.

When flow completes execution, 200 response code is shown in the Server Response section. This run should generate the output same as above.

7. To delete the deployed package, refresh the browser to get the Swagger and explore back to /tx-rest/openapi.json.

There will be a DELETE /v2/packages/{name} action.

8. Expand the DELETE /v2/packages/{name} action and select Try it out.

9. In the Name field, enter the name you gave to the created package.

10. Select the true from the stop query drop down, then select the blue Execute bar.

You can see a response of 204 with a timestamp, if it is successful.

---

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed if you do not have a server local definition or ftp execution definition to deploy in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. The below command is for TARGET2 CoCo t2coco\_camt\_009.xml message.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow t2_coco_validation_flow.json --var
"INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\t2coco_camt_009.xml" --audit
"C:\ftpserver\deployment\tools\mx_service\data\t2coco_camt_009_adt.json" -ad
```

The results will be in C:\ftpserver\deployment\flows as validation\_results.xml or validation\_results.json depending on the value of the REPORT\_FORMAT variable.

This command will execute with the variable VALIDATION\_TYPE value defined in the Flow settings in Design Server (extended or schema).

To change, the following command can be used:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow t2_coco_validation_flow.json --var
"INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\t2coco_camt_009.xml" --var "VALIDATION_TYPE=schema" --var
"REPORT_FORMAT=json" --audit "C:\ftpserver\deployment\tools\mx_service\data\t2coco_camt_009_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server
```

```
Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\tools\\\\mx_service\\\\data\\\\t2coco_camt_009_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result files bah\_validation\_results.xml, doc\_validation\_results.xml, and the audit file t2coco\_camt\_009\_adt.json.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

### Example

To disable the BIC lookup validation feature.

### About this task

Change sub-element ExtendedValidation/BICValidation value from T to F.

### Procedure

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the flow.

Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

## T2 CoCo enhanced MX validation (using maps) example

This example demonstrates the TARGET2 CoCo enhanced MX validation for TARGET2 CoCo messages using maps only.

The maps can perform following level of validation:

- MX extended validation includes following checks:
  - BIC lookup
  - Country code lookup
  - Currency code lookup
  - IBAN format
  - Allowed maximum fractional digits per currency
  - Usage guideline rules, see mxconfig.xml for list of rules
- Schema validation
  - Enforces validation based on XSD
- [What the example contains](#)
- [Run the example in Design Studio](#)
- [Run the example in Design Server User Interface](#)
- [How to customize the mxconfig.xml file](#)

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

## What the example contains

This example contains the following directories and files:

- Maps:  
The maps directory contains the following map sources to use when running under Design Studio:
  - t2\_coco\_mx\_acmt\_validation\_enh.mrms  
Utility maps called by main map for all the acmt TARGET2 CoCo xml message MX validation.
  - t2\_coco\_mx\_admi\_validation\_enh.mrms  
Utility maps called by main map for all the admi TARGET2 CoCo xml message MX validation.
  - t2\_coco\_mx\_camt\_validation\_enh.mrms  
Utility maps called by main map for all the camt TARGET2 CoCo xml message MX validation.
  - t2\_coco\_mx\_reda\_validation\_enh.mrms  
Utility maps called by main map for all the reda TARGET2 CoCo xml message MX validation.

- t2\_coco\_mx\_validation\_frmwrk\_map\_enh.mms  
The main map used to apply MX validation to TARGET2 CoCo xml messages.

Note: When running under Design Server, the main framework map is t2\_coco\_mx\_validation\_frmwrk\_map\_flw\_enh.mms.

- Schemas:  
The schemas directory contains the following files:

- bic.xsd  
Metadata that represents the bic.xml repository file structure.
- ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
- mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.
- XML schemas based on SWIFT MyStandards Readiness TARGET2 CoCo Portal:
  - acmt.007.001.02.xsd
  - acmt.010.001.02.xsd
  - acmt.011.001.02.xsd
  - acmt.015.001.02.xsd
  - acmt.019.001.02.xsd

  - head.001.001.01.xsd
- XML schema based on W3C XML Signature Syntax and Processing version 1.2:
  - xmldsig-core-schema.xsd

- Trees:

The trees directory contains the following files:

- mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
- swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.

- Data:

The data directory contains the following file:

- bic.xml  
Repository file listing all BICs which are used during validation.
- currencycodedecimals.xml  
Repository file list country codes, currency codes and corresponding maximum fractionally digits, used as reference for validation.
- mxconfig.xml  
Holds the MX configuration information on how to process the message.
- Sample TARGET2 CoCo valid files without header envelope for test purposes:

- bah\_reda\_043\_001\_01\_valid.xml
- bah\_reda\_064\_001\_01\_valid.xml
- bah\_reda\_065\_001\_01\_valid.xml

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, t2co9000\_val (under t2\_coco\_mx\_validation\_frmwrk\_map\_enh.mms file or t2\_coco\_mx\_validation\_frmwrk\_map\_flw\_enh.mms file if running under Design Server) with desired input file.
3. Run the main router map, t2co9000\_val.  
You will see the output file in the data folder called t2coco\_error\_report.xml.

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If the project does not exist, import t2\_coco.zip.
4. If absent, create a package containing all the Maps, Files, and Flows.
5. Build package in desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map t2co9000\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map t2co9000\_val.
10. Right click on the output card on canvas and select View data.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

## Example

To disable the BIC lookup validation feature.

## About this task

Change sub-element ExtendedValidation/BICValidation value from T to F.

## Procedure

---

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the map.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

---

## T2 CoCo schema validation (using maps) example

This example demonstrates the TARGET2 CoCo schema validation for TARGET2 CoCo messages using maps only.

The maps can perform following level of validation:

- Schema validation
  - [What the example contains](#)
  - [Run the example in Design Studio](#)
  - [Run the example in Design Server User Interface](#)
- 

## What the example contains

This example contains the following directories and files:

- Maps:  
The maps directory contains the following map sources to use when running under Design Studio:
  - t2\_coco\_mx\_schema\_validation\_xsd.mms  
Utility maps called by main map for all TARGET2 CoCo messages schema validation.
  - t2\_coco\_schema\_validation\_frmwrk\_map\_xsd.mms  
The main map used to apply schema validation to TARGET2 CoCo xml messages.
- Schemas:  
The schemas directory contains the following files:
  - XML schemas based on SWIFT MyStandards Readiness TARGET2 CoCo Portal:
    - acmt.007.001.02.xsd

    - bah\_reda\_064\_001\_01\_valid.xml
    - bah\_reda\_065\_001\_01\_valid.xml

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, t2co9500\_val (under t2\_coco\_schema\_validation\_frmwrk\_map\_xsd.mms file) with desired input file.
3. Run the main router map, t2co9500\_val.  
You will see the output file in the data folder called t2coco\_error\_report.xml.

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter user and password credentials.
3. If the project does not exist, import t2\_coco.zip.
4. If absent, create a package containing all the Maps, Files, and Flows.
5. Build package in desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map t2co9500\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map t2co9500\_val.
10. Right click on the output card on canvas and select View data.

---

## TARGET2 Securities Examples:

TARGET2 Securities examples are as follow:

- [\*\*T2 Securities \(T2S\) schema validation \(using Flow Server\) example\*\*](#)  
This example demonstrates the TARGET2 Securities (T2S) schema validation for T2S messages using flow server.
  - [\*\*T2 Securities \(T2S\) schema validation \(using maps\) example\*\*](#)  
This example demonstrates the TARGET2 Securities (T2S) schema validation for T2S messages using maps only.
- 

## T2 Securities (T2S) schema validation (using Flow Server) example

This example demonstrates the TARGET2 Securities (T2S) schema validation for T2S messages using flow server.

The flow can perform following level of validation:

- Schema validation
  - [\*\*What the example contains\*\*](#)  
Files included in this example are as follows:
  - [\*\*How to run the example \(using t2\\_sec\\_validation\\_flow\)\*\*](#)  
This TARGET2 Security (T2S) schema validation will use the sample files to demonstrate the generation of validation reports as output from a T2S XML message.
  - [\*\*How to run the example \(using t2\\_sec\\_head002\\_validation\\_flow\)\*\*](#)  
This TARGET2 Security (T2S) schema validation will allow validation of files using a different header allowing for multiple payloads. Use a sample file to demonstrate the generation of validation reports as output from a T2S XML message using head\_002.001.01.
- 

## What the example contains

Files included in this example are as follows:

- t2\_sec.zip
  - Test Data Files:
    - t2se\_admi\_005.xml
    - t2se\_admi\_005\_schema.xml
  - Schemas:
    - mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
    - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
    - XML schemas based on SWIFT MyStandards Readiness Target 2 Securities (T2S) Portal:
      - admi.005.001.01.xsd
      - admi.006.001.01.xsd
      - admi.007.001.01.xsd
      - camt.003.001.07.xsd
      - camt.004.001.08.xsd
      - camt.005.001.08.xsd
      - camt.006.001.08.xsd
      - camt.009.001.07.xsd
      - camt.010.001.08.xsd
      - camt.019.001.07.xsd
      - camt.025.001.05.xsd
      - camt.050.001.05.xsd
      - camt.051.001.05.xsd
      - camt.052.001.08.xsd
      - camt.053.001.08.xsd
      - camt.054.001.08.xsd
      - camt.064.001.01.xsd
      - camt.065.001.01.xsd

- supl.021.001.01.xsd

- XML schema based on W3C XML Signature Syntax and Processing version 1.2:

- xmldsig-core-schema.xsd

Note: The schema xmldsig-core-schema.xsd is imported inside of schema head.001.001.01.xsd to handle signatures. It is imported two times as a FILE to the project. Once in the folder location t2\_sec/validation/schema\_only/schemas and a second copy without any logical folder.

Note: The schema supl.021.001.01.xsd is imported inside the following schemas:

- camt.067.001.01.xsd
- camt.068.001.01.xsd
- semt.014.001.06.xsd
- semt.015.001.07.xsd
- sese.024.001.10.xsd
- sese.025.001.09.xsd
- sese.032.001.09.xsd

It is imported into the project two times as a SCHEMA. Once in the folder t2\_sec/validation/schema\_only/schemas and a second copy without any logical folder.

- Common:
    - mxut1003\_bizsvc\_t2sec
  - Flows:
    - t2\_sec\_validation\_flow
    - t2\_sec\_head002\_validation\_flow

## How to run the example (using t2\_sec\_validation\_flow)

This TARGET2 Security (T2S) schema validation will use the sample files to demonstrate the generation of validation reports as output from a T2S XML message.

The stopValidation.json file will report the validation failure due to the pre-conversion checks:

**If input file is other than any of the supported T2S messages as per schema list indicated above.**

1. Import the t2\_sec.zip project into the Design Server.
2. Open the t2\_sec project in Design Server and view the flow t2\_sec\_validation\_flow.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. This list has to be added to the description and ensure all lines start in column 1. Following is the list of maps with the description format:
    - @packagemap=t2\_sec/validation/schema\_only/maps/t2\_sec\_mx\_schema\_validation\_xsd/t2se9501\_admi\_005\_001\_01
    - @packagemap=t2\_sec/validation/schema\_only/maps/t2\_sec\_mx\_schema\_validation\_xsd/t2se9502\_admi\_006\_001\_01
    - @packagemap=t2\_sec/validation/schema\_only/maps/t2\_sec\_mx\_schema\_validation\_xsd/t2se9503\_admi\_007\_001\_01
    - @packagemap=t2\_sec/validation/schema\_only/maps/t2\_sec\_mx\_schema\_validation\_xsd/t2se9504\_camt\_003\_001\_07
    - @packagemap=t2\_sec/validation/schema\_only/maps/t2\_sec\_mx\_schema\_validation\_xsd/t2se9505\_camt\_004\_001\_08

- @packagenode=tz\_sec

b. It utilizes the following nodes:

#### i. Source Nodes:

- mx input

This node identifies the input data to be validated in the flow. It uses the variable INPUT\_FILE to set the location of the data.

## ii) Map Nodes:

- MX pre-check

Runs map mxut1003 bizsvc t2sec which sets flow variables, checks pre-validation conditions, and creates `infoset.json` for validation.

- XSD VAL

`Runs map t2se9500_val which calls the appropriate map to perform schema validation of a T2S Plus message.`

Note: The map t2se9500\_val internally calls all the other maps identified in the above Flow Description step.

iii. Decision Nodes:

- pre-valid chk  
This node checks the flow variable stopTranslation to decide if further validation/processing is not required.
- XSD\_RESULT\_FORMAT  
This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for schema-only validation should be generated in XML (default) or JSON.

iv. Log Nodes:

- FAILURE  
This node creates a log file specified by the flow variable FAILURE\_LOG in case of no validation due to precondition check failures.

v. Fail Node:

- STOP  
It generates error message setup in the node in case of no validation performed.

vi. Passthrough Nodes:

- XSD\_XML\_CONVERT  
This node receives a schema-only validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.

vii. Format Converter Nodes:

- XSD\_JSON\_CONVERT  
This node receives a schema-only validation report in XML format and converts it to JSON before passing it to the appropriate target node.

viii. Target Nodes:

- xsd\_xml  
This node contains the resulting schema-only validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.

- xsd\_json  
This node contains the resulting schema-only validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.

c. It utilizes the following variables:

i. Flow variables:

- VALIDATION\_TYPE  
Default value is schema. The value extended is not supported at this time. This variable is currently not being used in any node.
- REPORT\_FORMAT  
Default value is xml. It can be changed to json. This is used in Decision node XSD\_RESULT\_FORMAT.
- INPUT\_FILE  
Default value is ../tools/mx\_service/data/t2sec\_admi\_005.xml. This is the data file to be used for validation and can be customized. It is used in the Source node mx\_input.
- BIC\_FILE  
Default value is ../data/bic.xml. This is the location of the bic cross-reference file that is used in validation maps. Since this flow is only doing schema validation, this variable is not used.
- CCY\_FILE  
Default value is ../data/currencycodedecimals.xml. This is the location of the country code cross-reference file that is used in validation maps. Since this flow is only doing schema validation, this variable is not used.
- MXCONFIG\_FILE  
Default value is ../data/mxconfig.xml. This is the location of the file containing the rule validation settings that is used in validation maps. Since this flow is only doing schema validation, this variable is not used.
- OUTPUT\_RESULT\_XML  
Default value is validation\_result.xml. This is the location of the validation report file in xml format. It is used in Target node xsd\_xml. It can be customized.
- OUTPUT\_RESULT\_JSON  
Default value is validation\_result.json. This is the location of the validation report file in json format. It is used in Target node xsd\_json. It can be customized.
- FAILURE\_LOG  
Default value is stopMXValidation.json. This is the location of the failure log. It is used in Log node FAILURE. It can be customized.
- bizSvc  
For internal use in the Map node MX pre-check to determine the type of data being read in the input file.
- stopValidation  
For internal use in the Map node MX pre-check and is checked in Decision node pre-valid chk to cause a Failure log in case a data file was not recognized as a valid T2S message.

3. Open the main flow t2\_sec\_validation\_flow in the Design Server. It utilizes above one Source node, two Map nodes, two Decision nodes, one Log node, one Fail node, one Passthrough nodes, one Format Converter nodes, and two Target nodes.

4. In Design Server, create a package t2\_sec\_validation\_flow that contains the input files and the flow t2\_sec\_validation\_flow. The maps will automatically be included during deployment of the package onto the runtime server.

Note: Not required for running flows on Design Server user interface directly.

• [Run the example using three different methods](#)

You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- **[Run the example from the Design Server user interface](#)**

Use the following steps to run the example from the Design Server user interface:

- **[Run the example using the Swagger interface](#)**

To run the example, deploy to tx-rest and run it using the Swagger interface.

- **[Run the example using the flow command server process \(flowcmdserver\)](#)**

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open t2\_sec\_validation\_flow flow and click on Run button.
2. Set the toggle switch Run On Design Server and select flow input file. Example is t2\_sec\_admi\_005.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, the value defined for the variable will be used if an input file is not selected.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Link Data on each link to examine the data.
4. View target node by clicking on the node, doing right click on the Input icon and selecting View Data.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed if you do not have a server definition to deploy in Design Server.

2. If not running, start tx-rest on the server:  
`<DTX_HOME>/restapi/tomcat/dtxtomcat start tx-rest`

3. Deploy the created package to the server definition in Design Server.

4. Bring up the tx-rest Swagger UI:  
`<DTX_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest`

5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.

You can see a Miscellaneous section having two actions:

- **PUT** /v2/run/t2\_sec\_validation\_flow
- **POST** /v2/run/t2\_sec\_validation\_flow

6. In the **PUT** action:

a. Expand the **PUT** action and select the Try it out button.

b. Leave the input and output sections empty.

c. Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/mydir/data/t2_sec_admi_005.xml",
 "OUTPUT_RESULT_JSON": "C:/mydir/data/validation_result.json",
 "REPORT_FORMAT": "json"
}
```

or

```
{
 "INPUT_FILE": "C:/mydir/data/t2_sec_admi_005.xml",
 "OUTPUT_RESULT_XML": "C:/mydir/data/validation_result.xml",
 "REPORT_FORMAT": "xml"
}
```

d. Click Execute blue bar for running the flow.

When flow completes execution, 200 response code is shown in the Server Response section. This run should generate the output same as above.

7. To delete the deployed package, refresh the browser to get the Swagger and explore back to /tx-rest/openapi.json.

There will be a DELETE /v2/packages/{name} action.

8. Expand the DELETE /v2/packages/{name} action and select Try it out.

9. In the Name field, enter the name you gave to the created package.

10. Select the true option from the stop query drop down, then select the blue Execute bar.

You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed if you do not have a server local definition or ftp execution definition to deploy in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. The below command is for TARGET2 Securities t2\_sec\_pacs\_009.xml message.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow t2_sec_validation_flow.json --var
"INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\t2_sec_admi_005.xml" --audit
"C:\ftpserver\deployment\tools\mx_service\data\t2_sec_admi_005.adt.json" -ad
```

The results will be in C:\ftpserver\deployment\flows as validation\_results.xml or validation\_results.json depending on the value of the REPORT\_FORMAT variable.

This command will execute with the variable VALIDATION\_TYPE value defined in the Flow settings in Design Server (only schema is supported).

To change, the following command can be used:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow t2_sec_validation_flow.json --var
"INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\t2_sec_admi_005.xml" --var "REPORT_FORMAT=json" --audit
"C:\ftpserver\deployment\tools\mx_service\data\t2_sec_admi_005.adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\tools\\\\mx_service\\\\data\\\\t2_sec_admi_005.adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result files validation\_results.xml and the audit file t2\_sec\_admi\_005.adt.json.

## How to run the example (using t2\_sec\_head002\_validation\_flow)

This TARGET2 Security (T2S) schema validation will allow validation of files using a different header allowing for multiple payloads. Use a sample file to demonstrate the generation of validation reports as output from a T2S XML message using head\_002.001.01.

1. Import the t2\_sec.zip project into the Design Server.
2. Open the t2\_sec project in Design Server and view the flow t2\_sec\_head002\_validation\_flow.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. This list has to be added to the description and ensure all lines start in column 1. Following is the list of maps with the description format:
    - @packagemap=t2\_sec/validation/schema\_only/maps/t2\_sec\_schema\_validation\_frmwrk\_map\_xsd/t2se9500\_val
    - @packagemap=t2\_sec/validation/schema\_only/maps/t2\_sec\_mx\_schema\_validation\_xsd/t2se9501\_admi\_001\_01
    - @packagemap=t2\_sec/validation/schema\_only/maps/t2\_sec\_mx\_schema\_validation\_xsd/t2se9502\_admi\_006\_001\_01

b. It utilizes the following nodes:

i. Source Nodes:

- mx\_input

This node identifies the input data to be validated in the flow. It uses the variable INPUT\_FILE to set the location of the data.

ii. Map Nodes:

- XSD\_VAL

Runs map t2se9600\_val which calls the appropriate map to perform schema validation using head\_002\_001\_01.

Note: The maps t2se9600\_val call all the other maps identified in the above Flow Description step.

iii. Decision Nodes:

- XSD\_RESULT\_FORMAT

This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for schema-only validation should be generated in XML (default) or JSON.

iv. Passthrough Nodes:

- XSD\_XML\_CONVERT

This node receives a schema-only validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.

v. Format Converter Nodes:

- XSD\_JSON\_CONVERT

This node receives a schema-only validation report in XML format and converts it to JSON before passing it to the appropriate target node.

vi. Target Nodes:

- xsd\_xml

This node contains the resulting schema-only validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.

- xsd\_json

This node contains the resulting schema-only validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.

c. It utilizes the following variables:

i. Flow variables:

- VALIDATION\_TYPE

Default value is schema. The value extended is not supported at this time. This variable is currently not being used in any node.

- REPORT\_FORMAT

Default value is xml. It can be changed to json. This is used in Decision node XSD\_RESULT\_FORMAT.

- INPUT\_FILE

Default value is ../tools/mxservice/data/t2se\_head\_002.xml. This is the data file to be used for validation and can be customized. It is used in the Source node mx\_input.

- BIC\_FILE

Default value is ../data/bic.xml. This is the location of the bic cross-reference file that is used in validation maps. Since this flow is only doing schema validation, this variable is not used.

- CCY\_FILE

Default value is ..//data/currencycodedecimals.xml. This is the location of the country code cross-reference file that is used in validation maps. Since this flow is only doing schema validation, this variable is not used.

- **MXCONFIG\_FILE**  
Default value is ..//data/mxconfig.xml. This is the location of the file containing the rule validation settings that is used in validation maps. Since this flow is only doing schema validation, this variable is not used.
  - **OUTPUT\_RESULT\_XML**  
Default value is validation\_result.xml. This is the location of the validation report file in xml format. It is used in Target node xsd\_xml. It can be customized.
  - **OUTPUT\_RESULT\_JSON**  
Default value is validation\_result.json. This is the location of the validation report file in json format. It is used in Target node xsd\_json. It can be customized.
  - **FAILURE\_LOG**  
Default value is stopMXValidation.json. This is the location of the failure log. It is used in Log node FAILURE. This variable is not used in this flow.
  - **bizSvc**  
For internal use in the Map node MX pre-check to determine the type of data being read in the input file. This variable is not used in this flow.
  - **stopValidation**  
For internal use in the Map node MX pre-check and is checked in Decision node pre-valid chk to cause a Failure log in case a data file was not recognized as a valid T2S message. This variable is not used in this flow.
3. Open the main flow t2\_sec\_head002\_validation\_flow in the Design Server. It utilizes above one Source node, one Map node, one Decision node, one Log node, one Fail node, one Passthrough node, one Format Converter node, and two Target nodes.
4. In Design Server, create a package t2\_sec\_head002\_validation that contains the input files and the flow t2\_sec\_head002\_validation\_flow. The maps will automatically be included during deployment of the package onto the runtime server.  
Note: Not required for running flows on Design Server user interface directly.
- **[Run the example using three different methods](#)**  
You can run the example using three different methods:

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- **[Run the example from the Design Server user interface](#)**  
Use the following steps to run the example from the Design Server user interface:
- **[Run the example using the Swagger interface](#)**  
To run the example, deploy to tx-rest and run it using the Swagger interface.
- **[Run the example using the flow command server process \(flowcmdserver\)](#)**  
To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open t2\_sec\_head002\_validation\_flow flow and click on Run button.
2. Set the toggle switch Run On Design Server and select flow input file. Example is t2se\_head\_002.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, the value defined for the variable will be used if an input file is not selected.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Link Data on each link to examine the data.
4. View target node by clicking on the node, doing right click on the Input icon and selecting View Data.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed if you do not have a server definition to deploy in Design Server.
  2. If not running, start tx-rest on the server:  
`<DTX_HOME>/restapi/tomcat/dtxtomcat start tx-rest`
  3. Deploy the created package to the server definition in Design Server.
  4. Bring up the tx-rest Swagger UI:  
`<DTX_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest`
  5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You can see a Miscellaneous section having two actions:
- **`PUT /v2/run/t2_sec_validation_flow`**

- **POST** /v2/run/t2\_sec\_head002\_validation\_flow
6. In the **PUT** action:
- Expand the **PUT** action and select the Try it out button.
  - Leave the input and output sections empty.
  - Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/mydir/data/t2se_head_002.xml",
 "OUTPUT_RESULT_JSON": "C:/mydir/data/validation_result.json",
 "REPORT_FORMAT": "json"
}

or

{
 "INPUT_FILE": "C:/mydir/data/t2se_head_002.xml",
 "OUTPUT_RESULT_XML": "C:/mydir/data/validation_result.xml",
 "REPORT_FORMAT": "xml"
}
```

- d. Click Execute blue bar for running the flow.

When flow completes execution, 200 response code is shown in the Server Response section. This run should generate the output same as above.

7. To delete the deployed package, refresh the browser to get the Swagger and explore back to /tx-rest/openapi.json.

There will be a **DELETE** /v2/packages/{name} action.

8. Expand the **DELETE** /v2/packages/{name} action and select Try it out.

9. In the Name field, enter the name you gave to the created package.

10. Select the true from the stop query drop down, then select the blue Execute bar.

You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

- Create a server definition where the runtime is installed if you do not have a server local definition or ftp execution definition to deploy in Design Server.
- In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
- Execute the flow using the flow command server. The below command is for TARGET2 Securities t2se\_head\_002.xml message.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow t2_sec_head002_validation_flow.json --var
"INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\t2se_head_002.xml" --audit
"C:\ftpserver\deployment\tools\mx_service\data\t2se_head_002_adt.json" -ad
```

The results will be in C:\ftpserver\deployment\flows as validation\_results.xml or validation\_results.json depending on the value of the REPORT\_FORMAT variable.

This command will execute with the variable VALIDATION\_TYPE value defined in the Flow settings in Design Server (only schema is supported).

To change, the following command can be used:

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow t2_sec_head002_validation_flow.json --var
"INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\t2se_head_002.xml" --var "REPORT_FORMAT=json" --audit
"C:\ftpserver\deployment\tools\mx_service\data\t2se_head_002_adt.json" -ad
```

4. The flow will report status similar to:

```
***Starting flow command server
Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\tools\\\\mx_service\\\\data\\\\t2se_head_002_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

5. Examine the flow output result files validation\_results.xml and the audit file t2se\_head\_002\_adt.json.

## T2 Securities (T2S) schema validation (using maps) example

This example demonstrates the TARGET2 Securities (T2S) schema validation for T2S messages using maps only.

The maps can perform following level of validation:

- Schema validation
- [What the example contains](#)
- [Run the example in Design Studio](#)
- [Run the example in Design Server User Interface](#)

## What the example contains

This example contains the following directories and files:

- Maps:  
The maps directory contains the following map sources to use when running under Design Studio:

- t2\_sec\_mx\_schema\_validation\_xsd.mms  
Utility maps called by main map for all T2S messages schema validation.
  - t2\_sec\_schema\_validation\_frmwrk\_map\_xsd.mms  
The main map used to apply schema validation to T2S xml messages.
- Schemas:  
The schemas directory contains the following files:
- XML schemas based on SWIFT MyStandards Readiness T2S Portal:
    - admi.005.001.01.xsd
    - admi.006.001.01.xsd
    - admi.007.001.01.xsd
    - camt.003.001.07.xsd
    - camt.004.001.08.xsd

- sese.031.001.08.xsd
- sese.032.001.09.xsd
- suppl.021.001.01.xsd

Note: The following schemas were modified to import schema suppl.021.001.01 to handle supplementary data:

- camt.067.001.01.xsd
- camt.068.001.01.xsd
- semt.014.001.06.xsd
- semt.015.001.07.xsd
- sese.024.001.10.xsd
- sese.025.001.09.xsd
- sese.032.001.09.xsd

- XML schemas based on W3C XML Signature Syntax and Processing version 1.2:

- xmldsig-core-schema.xsd

Note: The following schema was modified to import the signature schema xmldsig-core-schema.xsd:

- head.001.001.01.xsd

- Trees:

The trees directory contains the following files:

- swiftroute\_funds.mtt

Metadata that is used as an internal element placeholder.

- mxvalErrorReport.mtt

Metadata that represents the xml based structure of the validation report.

- Data:

The data directory contains the following file:

- Sample T2S valid files without header envelope for test purposes:

- admi\_007\_001\_01\_valid.xml

- Sample T2S valid files with header envelope for test purposes:

- bah\_admi\_005\_001\_01\_valid.xml
- bah\_admi\_006\_001\_01\_valid.xml
- bah\_admi\_007\_001\_01\_valid.xml

- Sample T2S valid files using header head.002.001.01 for test purposes:
    - head\_002\_001\_01\_valid.xml

---

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
  2. Replace the input card 1 in router map, t2se9500\_val (under t2\_sec\_schema\_validation\_frmwrk\_map\_xsd.mms file) with desired input file.
  3. Run the main router map, t2se9500\_val.  
You will see the output file in the data folder called t2sec\_error\_report.xml.
- [Test with head.002.001.01 schema](#)  
For testing with head.002.001.01 schema, complete the following steps:

---

## Test with head.002.001.01 schema

For testing with head.002.001.01 schema, complete the following steps:

1. Replace input card 1 in router map, t2se9600\_val (under t2\_sec\_schema\_validation\_frmwrk\_map\_xsd.mms file) with desired input file.
2. Run the main router map, t2se9600\_val.  
You will see the output file in the data folder called t2pyld\_error\_report.xml.

---

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
  2. Enter user and password credentials.
  3. If the project does not exist, import t2\_sec.zip.
  4. If absent, create a package containing all the Maps, Files, and Flows.
  5. Build package in desired server (to build all maps).
  6. Open the project.
  7. In the Maps tab, open the map t2se9500\_val.
  8. Modify the settings for input card 1 on design canvas to point to the desired test file.
  9. Save, build, and run the map t2se9500\_val.
  10. Right click on the output card on canvas and select View data.
- [Test with head.002.001.01 schema](#)  
For testing with head.002.001.01 schema, complete the following steps:

---

## Test with head.002.001.01 schema

For testing with head.002.001.01 schema, complete the following steps:

1. In the Maps tab, open the map t2se9600\_val.
2. Modify the settings for input card 1 on design canvas to point to the desired test file.
3. Save, build, and run the map t2se9600\_val.
4. Right click on the output card on canvas and select View data.

## SWIFT GPI/UC Examples:

- [SWIFT UC Examples:](#)  
SWIFT UC examples are as follow:
- [SWIFT GPI Examples:](#)  
SWIFT GPI examples are as follow:

## SWIFT UC Examples:

SWIFT UC examples are as follow:

- [\*\*SWIFT UC enhanced MX validation \(using Flow Server\) example\*\*](#)

This example demonstrates the SWIFT Universal Confirmation (UC) enhanced MX validation for SWIFT UC messages using the flow server.

- [\*\*SWIFT UC enhanced MX validation \(using maps\) example\*\*](#)

This example demonstrates the enhanced MX validation for SWIFT Universal Confirmation (UC) messages using maps.

- [\*\*SWIFT UC schema MX validation \(using maps\) example\*\*](#)

This example demonstrates the schema validation for SWIFT Universal Confirmation (UC) messages using maps only.

## SWIFT UC enhanced MX validation (using Flow Server) example

This example demonstrates the SWIFT Universal Confirmation (UC) enhanced MX validation for SWIFT UC messages using the flow server.

The flow can perform following level of validation:

- MX extended validation includes following checks:

- BIC lookup
- Country code lookup
- Currency code lookup
- IBAN format
- Allowed maximum fractional digits per currency
- Usage guideline rules, see mxconfig.xml for list of rules

- Schema validation

- [\*\*What the example contains\*\*](#)

Files included in this example are as follows:

- [\*\*How to run the example\*\*](#)

This SWIFT UC MX Validation will use the sample files to demonstrate the generation of validation report as output from a SWIFT UC XML message.

- [\*\*How to customize the mxconfig.xml file\*\*](#)

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

## What the example contains

Files included in this example are as follows:

- `swift_uc.zip`

- Test Data Files:

- `swuc_trck_001_uc.xml`
- `swuc_trck_001_uc_bad_rule.xml`
- `swuc_trck_001_uc_bad_schema.xml`

- Validation Files:

- `mxconfig.xml`
- `bic.xml`
- `currencycodedecimals.xml`

- Schemas:

- `bic.xsd`  
Metadata that represents the `bic.xml` repository file structure.

- `ccy.xsd`  
Metadata that represents the `currencycodedecimals.xml` repository file structure.

- `mxconfig.xsd`  
Metadata that represents the `mxconfig.xml` configuration file structure.

- `mxvalErrorReport.mtt`  
Metadata that represents the xml based structure of the validation report.

- `swiftroute_funds.mtt`  
Metadata that is used as an internal element placeholder.

- `trck.001.001.02_uc.xsd`
- `head.001.001.02_trck_001_uc.xsd`

Note: XML schemas were downloaded from SWIFT MyStandards Readiness SWIFT UC Portal.

- Maps:

- For Extended Validation:

- `swuc1000_val`
- `swuc1051_head112_trck001_uc`
- `swuc1001_trck_001_001_02_uc`

- For Schema Validation:

- `swuc1500_val`
- `swuc1551_head112_trck001_uc`
- `swuc1501_trck_001_001_02_uc`

- Common:

- mxut1007\_bizsvc\_swuc
- Flows:
  - swift\_uc\_validation\_flow

## How to run the example

This SWIFT UC MX Validation will use the sample files to demonstrate the generation of validation report as output from a SWIFT UC XML message.

The stopValidation.json file will report the validation failure due to the pre-conversion checks:

**If input file is other than any of the supported SWIFT UC messages as per schema list indicated above.**

1. Import the swift\_uc.zip project into the Design Server.
2. Open the swift\_uc project in Design Server and view the flow swift\_uc\_validation\_flow.
  - a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps:
    - @packagemap=swift\_uc/validation/mx\_extended/maps/swift\_uc\_mx\_trck\_validation\_enh/swuc1051\_head112\_trck001\_uc
    - @packagemap=swift\_uc/validation/mx\_extended/maps/swift\_uc\_mx\_trck\_validation\_enh/swuc1001\_trck\_001\_001\_02\_uc
    - @packagemap=swift\_uc/validation/schema\_only/maps/swift\_uc\_mx\_schema\_validation\_xsd/swuc1551\_head112\_trck001\_uc
    - @packagemap=swift\_uc/validation/schema\_only/maps/swift\_uc\_mx\_schema\_validation\_xsd/swuc1501\_trck\_001\_001\_02\_uc
  - b. It utilizes the following nodes:
    - i. Source Nodes:
      - mx\_input  
This node identifies the input data to be validated in the flow. It uses the INPUT\_FILE variable to set the location of the data.
    - ii. Map Nodes:
      - MX pre-check  
This node runs map mxut1007\_bizsvc\_swuc which sets the flow variables, checks pre-validation conditions and creates infoset.json for validation.
      - EXT\_VAL  
This node runs map swuc1100\_val which calls the appropriate map to perform extended validation of a SWIFT UC message.
      - XSD\_VAL  
This node runs map swuc1500\_val which calls the appropriate map to perform schema validation of a SWIFT UC message.
    - Note: The maps swuc1100\_val and swuc1500\_val internally call all the other maps identified in the above Flow Description step.
    - iii. Decision Nodes:
      - pre-valid chk  
This node checks the flow variable stopValidation to decide if further validation/processing is not required.
      - EXT\_RESULT\_FORMAT  
This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for extended validation should be generated in XML (default) or JSON.
      - XSD\_RESULT\_FORMAT  
This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for schema-only validation should be generated in XML (default) or JSON.
    - iv. Route Nodes:
      - VAL\_TYPE  
This node checks the variable VALIDATION\_TYPE to determine if the process will do extended validation or schema-only validation on the data.
    - v. Log Nodes:
      - FAILURE  
This node creates a log file specified by the flow variable FAILURE\_LOG in case of no validation due to precondition check failures.
    - vi. Fail Node:
      - STOP  
It generates error message setup in the node in case of no validation performed.
    - vii. Passthrough Nodes
      - EXT\_XML\_CONVERT  
This node receives an extended validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.
      - XSD\_XML\_CONVERT  
This node receives a schema-only validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.
    - viii. Format Converter Nodes
      - EXT\_JSON\_CONVERT  
This node receives an extended validation report in XML format and converts it to JSON before passing it to the appropriate target node.
      - XSD\_JSON\_CONVERT  
This node receives a schema-only validation report in XML format and converts it to JSON before passing it to the appropriate target node.
    - ix. Target Nodes
      - ext\_xml  
This node contains the resulting extended validation report in XML format and creates the output as defined by variable OUTPUT\_RESULT\_XML.
      - ext\_json

This node contains the resulting extended validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.

- xsd\_xml  
This node contains the resulting schema-only validation report in XML format and creates the output as defined by the variable OUTPUT\_RESULT\_XML.
- xsd\_json  
This node contains the resulting schema-only validation report in JSON format and creates the output as defined by the variable OUTPUT\_RESULT\_JSON.

c. It utilizes the following variables:

Flow variables:

- VALIDATION\_TYPE  
The default value is `extended`.  
  
For schema-only validation, it can be changed to `schema`. This is used in Route node VAL\_TYPE.
- REPORT\_FORMAT  
The default value is `xml`.  
  
It can be changed to `json`. This is used in Decision nodes EXT\_RESULT\_FORMAT and XSD\_RESULT\_FORMAT.
- INPUT\_FILE  
The default value is `../tools/mx_service/data/swuc_trck_001_uc.xml`.  
  
This is the data file to be used for validation and can be customized. This is used in Source node mx\_input.
- BIC\_FILE  
The default value is `../data/bic.xml`.  
  
This is the location of the bic cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.
- CCY\_FILE  
The default value is `../data/currencycodedecimals.xml`.  
  
This is the location of the country code cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.
- MXCONFIG\_FILE  
The default value is `../data/mxconfig.xml`.  
  
This is the location of the file containing the rule validation settings that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.
- OUTPUT\_RESULT\_XML  
The default value is `validation_result.xml`.  
  
This is the location of the validation report file in xml format. It is used in Target nodes ext\_xml and xsd\_xml. It can be customized.
- OUTPUT\_RESULT\_JSON  
The default value is `validation_result.json`.  
  
This is the location of the validation report file in json format. It is used in Target nodes ext\_json and xsd\_json. It can be customized.
- FAILURE\_LOG  
The default value is `stopMXValidation.json`.  
  
This is the location of the failure log. It is used in Log node FAILURE. It can be customized.
- bizSvc  
This is for internal use in the Map node MX pre-check to determine the type of data being read in the input file.
- stopValidation  
This is for internal use in the Map node MX pre-check and is checked in Decision node pre-valid chk to cause a Failure log in case a data file was not recognized as a valid SWIFT UC message.

3. Open the main flow swift\_uc\_validation\_flow in the Design Server. It utilizes above one source node, three map nodes, one route node, three decision nodes, one log node, one fail node, two passthrough nodes, two format converter nodes and four target nodes.

4. In Design Server, create a package swift\_uc\_mx\_validation that contains the input files and one flow swift\_uc\_validation\_flow. The maps will automatically be included during deployment of the package onto the runtime server.

Note: Not required for running flows on Design Server user interface directly.

- **Run the example using three different methods**

You can run the example using three different methods:

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- Run the example from the Design Server user interface**  
Use the following steps to run the example from the Design Server user interface:
- Run the example using the swagger interface**  
To run the example, deploy to tx-rest and run it using the swagger interface.
- Run the example using the flow command server process (flowcmdserver)**  
To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

- In the Design Server, open swift\_uc\_validation\_flow flow and click on Run button.
- Set toggle switch Run On Design Server and select flow input file. Example is swuc\_trck\_001\_uc.xml.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report list execution of all nodes.
- Right click and select View Link Data on each link to examine the data.
- Right click on the node and select View Log to see the logs.

## Run the example using the swagger interface

To run the example, deploy to tx-rest and run it using the swagger interface.

- Create a Web type server definition where the runtime tx-rest is installed if you do not have a server definition to deploy in Design Server.
- If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
- Deploy the created package to the server definition in Design Server.
- Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
- In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You should see a Miscellaneous section having two actions: A **PUT** /v2/run/swift\_uc\_validation\_flow and a **POST** /v2/run/swift\_uc\_validation\_flow.
- In the **PUT** action:
  - Expand the **PUT** action and select the Try it out button.
  - Leave the input and output sections empty.
  - Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/mydir/data/swuc_trck_001_uc.xml",
 "OUTPUT_RESULT_JSON": "C:/mydir/data/validation_result.json",
 "REPORT_FORMAT": "json",
 "VALIDATION_TYPE": "extended"
}

or

{
 "INPUT_FILE": "C:/mydir/data/swuc_trck_001_uc.xml",
 "OUTPUT_RESULT_XML": "C:/mydir/data/validation_result.xml",
 "REPORT_FORMAT": "xml",
 "VALIDATION_TYPE": "extended"
}
```

- Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. This run should generate the output same as above.
- Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json.  
There will be a DELETE /v2/packages/{name} action.
- Expand the DELETE /v2/packages/{name} action and select Try it out.
- In the Name field, enter the name you gave to the created package.
- Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

- Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
- In Design Server, deploy the created package to the server definition.
- Execute the flow using the flow command server. The below command is for SWIFT UC swuc\_trck\_001\_uc.xml message.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow swift_uc_validation_flow.json
--var "INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\swuc_trck_001_uc.xml"
--audit "C:\ftpserver\deployment\tools\mx_service\data\swuc_trck_001_uc_adt.json" -ad
```

- The results will be in C:\ftpserver\deployment\flows as validation\_results.xml or validation\_results.json depending on the value of the REPORT\_FORMAT variable.
- Use the below command to execute with the variable VALIDATION\_TYPE value defined in the Flow settings in Design Server (extended or schema).

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows
--flow swift_uc_validation_flow.json
--var "INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\swuc_trck_001_uc.xml"
--var "VALIDATION_TYPE=schema"
```

```
--var "REPORT_FORMAT=json"
--audit "C:\ftpserver\deployment\tools\mx_service\data\swuc_trck_001_uc_adt.json" -ad

5. The flow will report status similar to:

***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\\\\ftpserver\\\\deployment\\\\tools\\\\mx_service\\\\data\\\\swuc_trck_001_uc_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

6. Examine the flow output result file validation\_results.xml and the audit file swuc\_trck\_001\_uc\_adt.json.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

### Example

To disable the BIC lookup validation feature.

### About this task

Change sub-element ExtendedValidation/BICValidation value from T to F.

### Procedure

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the flow.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

## SWIFT UC enhanced MX validation (using maps) example

This example demonstrates the enhanced MX validation for SWIFT Universal Confirmation (UC) messages using maps.

The maps can perform following level of validation:

- MX extended validation includes following checks:
  - BIC lookup
  - Country code lookup
  - Currency code lookup
  - IBAN format
  - Allowed maximum fractional digits per currency
  - Usage guideline rules, see mxconfig.xml for list of rules
- Schema validation
- [What the example contains](#)  
Files and directories included in this example are as follows:
- [Run the example in Design Studio](#)
- [Run the example in Design Server User Interface](#)
- [How to customize the mxconfig.xml file](#)

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

### What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources to use when running under Design Studio:
  - swift\_uc\_mx\_trck\_validation\_enh.mms  
Utility maps called by main map for all the trck SWIFT UC xml message MX validation.
  - swift\_uc\_mx\_validation\_frmwrk\_map\_enh.mms  
The main map used to apply MX validation to SWIFT UC xml messages.

Note: When running under Design Server, the main framework map is swift\_uc\_mx\_validation\_frmwrk\_map\_flw\_enh.mms.

- Schemas:  
The schemas directory contains the following files:

- bic.xsd  
Metadata that represents the bic.xml repository file structure.
- ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
- mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.
- trck.001.001.02\_uc.xsd
- head.001.001.02\_trck\_001\_uc.xsd

Note: XML schemas were downloaded from SWIFT MyStandards Readiness SWIFT UC Portal.

- Trees:  
The trees directory contains the following files:

- mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
- swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.

- Data:  
The data directory contains the following file:

- bic.xml  
Repository file listing all BICs which are used during validation.
- currencycodedecimals.xml  
Repository file listing country codes, currency codes and corresponding maximum fractionally digits, used as reference for validation.
- mxconfig.xml  
Holds the MX configuration information on how to process the message.

Sample SWIFT UC valid files with header envelope for test purposes:

- bah\_trck\_001\_001\_02\_uc\_valid.xml

---

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, swuc1000\_val (under swift\_uc\_mx\_validation\_frmwrk\_map\_enh.mms or swift\_uc\_mx\_validation\_frmwrk\_map\_flw\_enh.mms file if running under Design Server) with the desired input file.
3. Run the main router map, swuc1000\_val.  
You will see the output file in the data folder called swuc\_error\_report.xml.

---

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter the user and password credentials.
3. If the project does not exist, import swift\_uc.zip.
4. If absent, create a package containing all the Maps, Files and Flows.
5. Build the package in the desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map swuc1000\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map swuc1000\_val.
10. Right click on the output card on canvas and select View data.

---

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

---

## Example

To disable the BIC lookup validation feature.

## About this task

---

Change sub-element ExtendedValidation/BICValidation value from T to F.

## Procedure

---

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the map.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

---

## SWIFT UC schema MX validation (using maps) example

This example demonstrates the schema validation for SWIFT Universal Confirmation (UC) messages using maps only.

The maps can perform following level of validation:

- Schema validation
- [\*\*What the example contains\*\*](#)  
Files and directories included in this example are as follows:
- [\*\*Run the example in Design Studio\*\*](#)
- [\*\*Run the example in Design Server User Interface\*\*](#)

---

## What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources:
  - swift\_uc\_mx\_schema\_validation\_xsd.mms  
Utility maps called by main map for all SWIFT UC xml messages schema validation.
  - swift\_uc\_schema\_validation\_frmwrk\_map\_xsd.mms  
The main map used to apply schema only validation to SWIFT UC xml messages.
- Schemas:  
The schemas directory contains the following files:
  - trck.001.001.02\_uc.xsd
  - head.001.001.02\_trck\_001\_uc.xsd
- Note: XML schemas were downloaded from SWIFT MyStandards Readiness SWIFT UC Portal.
- Trees:  
The trees directory contains the following files:
  - mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
  - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
- Data:  
The data directory contains the following file:  
Sample SWIFT UC valid files with header envelope for test purposes:
  - bah\_trck\_001\_001\_02\_uc\_valid.xml

---

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, swuc1500\_val (under swift\_uc\_schema\_validation\_frmwrk\_map\_xsd.mms file) with the desired input file.
3. Run the main router map, swuc1500\_val.  
You will see the output file in the data folder called swuc\_error\_report.xml.

---

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
  2. Enter the user and password credentials.
  3. If the project does not exist, import swift\_uc.zip.
  4. If absent, create a package containing all the Maps, Files and Flows.
  5. Build the package in the desired server (to build all maps).
  6. Open the project.
  7. In the Maps tab, open the map swuc1500\_val.
  8. Modify the settings for input card 1 on design canvas to point to the desired test file.
  9. Save, build, and run the map swuc1500\_val.
  10. Right click on the output card on canvas and select View data.
- 

## SWIFT GPI Examples:

SWIFT GPI examples are as follow:

- [\*\*SWIFT GPI enhanced MX validation \(using Flow Server\) example\*\*](#)

This example demonstrates the SWIFT GPI enhanced MX validation for SWIFT GPI messages using the flow server.

- [\*\*SWIFT GPI enhanced MX validation \(using maps\) example\*\*](#)

This example demonstrates the enhanced MX validation for SWIFT GPI messages using the maps.

- [\*\*SWIFT GPI schema MX validation \(using maps\) example\*\*](#)

This example demonstrates the schema validation for SWIFT gpi messages using the maps.

---

## SWIFT GPI enhanced MX validation (using Flow Server) example

This example demonstrates the SWIFT GPI enhanced MX validation for SWIFT GPI messages using the flow server.

The flow can perform following level of validation:

- MX extended validation includes following checks:

- BIC lookup
- Country code lookup
- Currency code lookup
- IBAN format
- Allowed maximum fractional digits per currency
- Usage guideline rules, see mxconfig.xml for list of rules

- Schema validation

- [\*\*What the example contains\*\*](#)

Files included in this example are as follows:

- [\*\*How to run the example\*\*](#)

This SWIFT GPI MX Validation will use the sample files to demonstrate the generation of validation report as output from a SWIFT GPI XML message.

- [\*\*How to customize the mxconfig.xml file\*\*](#)

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

---

## What the example contains

Files included in this example are as follows:

- [\*\*swift\\_gpi.zip\*\*](#)

- Test Data Files:

- swgp\_trck\_001\_gCCTINST.xml
- swgp\_trck\_001\_gCCTINST\_bad\_rule.xml
- swgp\_trck\_001\_gCCTINST\_bad\_schema.xml

- Validation Files:

- mxconfig.xml
- bic.xml
- currencycodedecimals.xml

- Schemas:

- bic.xsd  
Metadata that represents the bic.xml repository file structure.

- ccy.xsd

Metadata that represents the currencycodedecimals.xml repository file structure.

- mxconfig.xsd

Metadata that represents the mxconfig.xml configuration file structure.

- mxvalErrorReport.mtt

Metadata that represents the xml based structure of the validation report.

- swiftroute\_funds.mtt

Metadata that is used as an internal element placeholder.

- head.001.001.02\_trck\_001\_gCCT.xsd

- head.001.001.02\_trck\_001\_gCCTINST.xsd

- Flows:
  - swift\_gpi\_validation\_flow

## How to run the example

This SWIFT GPI MX Validation will use the sample files to demonstrate the generation of validation report as output from a SWIFT GPI XML message.

The stopValidation.json file will report the validation failure due to the pre-conversion checks:

**If input file is other than any of the supported SWIFT GPI messages as per schema list indicated above.**

1. Import the swift\_gpi.zip project into the Design Server.

2. Open the swift\_gpi project in Design Server and view the flow swift\_gpi\_validation\_flow.

a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps:

- @packagemap=swift\_gpi/validation/mx\_extended/maps/swift\_gpi\_mx\_trck\_validation\_enh/swgp1051\_head112\_trck001\_gINST
- @packagemap=swift\_gpi/validation/mx\_extended/maps/swift\_gpi\_mx\_trck\_validation\_enh/swgp1052\_head112\_trck002\_gINST
- @packagemap=swift\_gpi/validation/mx\_extended/maps/swift\_gpi\_mx\_trck\_validation\_enh/swgp1053\_head112\_trck001\_gCCT
- @packagemap=swift\_gpi/validation/mx\_extended/maps/swift\_gpi\_mx\_trck\_validation\_enh/swgp1054\_head112\_trck002\_gCCT
- @packagemap=swift\_gpi/validation/mx\_extended/maps/swift\_gpi\_mx\_trck\_validation\_enh/swgp1055\_head112\_trck001\_gCOV

- @packagemap=swift\_gpi/validation/schema\_only/maps/swift\_gpi\_mx\_schema\_validation\_xsd/swgp1513\_trck\_005\_001\_02

b. It utilizes the following nodes:

i. Source Nodes:

- mx\_input

This node identifies the input data to be validated in the flow. It uses the INPUT\_FILE variable to set the location of the data.

ii. Map Nodes:

- MX pre-check  
This node runs map mxut1008\_bizsvc\_swgp which sets the flow variables, checks pre-validation conditions and creates `infoset.json` for validation.

- EXT\_VAL  
This node runs map swgp1100\_val which calls the appropriate map to perform extended validation of a SWIFT gpi message.
- XSD\_VAL  
This node runs map swgp1500\_val which calls the appropriate map to perform schema validation of a SWIFT gpi message.

Note: The maps `swgp1100_val` and `swgp1500_val` internally call all the other maps identified in the above Flow Description step.

iii. Decision Nodes:

- pre-valid chk  
This node checks the flow variable `stopValidation` to decide if further validation/processing is not required.
- EXT\_RESULT\_FORMAT  
This node checks the value of the flow variable `REPORT_FORMAT` to determine if the resulting report for extended validation should be generated in XML (default) or JSON.
- XSD\_RESULT\_FORMAT  
This node checks the value of the flow variable `REPORT_FORMAT` to determine if the resulting report for schema-only validation should be generated in XML (default) or JSON.

iv. Route Nodes:

- VAL\_TYPE  
This node checks the variable `VALIDATION_TYPE` to determine if the process will do extended validation or schema-only validation on the data.

v. Log Nodes:

- FAILURE  
This node creates a log file specified by the flow variable `FAILURE_LOG` in case of no validation due to precondition check failures.

vi. Fail Node:

- STOP  
It generates error message setup in the node in case of no validation performed.

vii. Passthrough Nodes

- EXT\_XML\_CONVERT  
This node receives an extended validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.
- XSD\_XML\_CONVERT  
This node receives a schema-only validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.

viii. Format Converter Nodes

- EXT\_JSON\_CONVERT  
This node receives an extended validation report in XML format and converts it to JSON before passing it to the appropriate target node.
- XSD\_JSON\_CONVERT  
This node receives a schema-only validation report in XML format and converts it to JSON before passing it to the appropriate target node.

ix. Target Nodes

- ext\_xml  
This node contains the resulting extended validation report in XML format and creates the output as defined by variable `OUTPUT_RESULT_XML`.
- ext\_json  
This node contains the resulting extended validation report in JSON format and creates the output as defined by the variable `OUTPUT_RESULT_JSON`.
- xsd\_xml  
This node contains the resulting schema-only validation report in XML format and creates the output as defined by the variable `OUTPUT_RESULT_XML`.
- xsd\_json  
This node contains the resulting schema-only validation report in JSON format and creates the output as defined by the variable `OUTPUT_RESULT_JSON`.

c. It utilizes the following variables:

Flow variables:

- VALIDATION\_TYPE  
The default value is `extended`.  
For schema-only validation, it can be changed to `schema`. This is used in Route node `VAL_TYPE`.
- REPORT\_FORMAT  
The default value is `xml`.  
It can be changed to `json`. This is used in Decision nodes `EXT_RESULT_FORMAT` and `XSD_RESULT_FORMAT`.
- INPUT\_FILE  
The default value is `../tools/mx_service/data/swgp_trck_001_gCCTINST.xml`.  
This is the data file to be used for validation and can be customized. This is used in Source node `mx_input`.
- BIC\_FILE

The default value is `../data/bic.xml`.

This is the location of the bic cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.

- CCY\_FILE

The default value is `../data/currencycodedecimals.xml`.

This is the location of the country code cross-reference file that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.

- MXCONFIG\_FILE

The default value is `../data/mxconfig.xml`.

This is the location of the file containing the rule validation settings that is used in all the maps executed by the map in node EXT\_VAL. It can be customized.

- OUTPUT\_RESULT\_XML

The default value is `validation_result.xml`.

This is the location of the validation report file in xml format. It is used in Target nodes ext\_xml and xsd\_xml. It can be customized.

- OUTPUT\_RESULT\_JSON

The default value is `validation_result.json`.

This is the location of the validation report file in json format. It is used in Target nodes ext\_json and xsd\_json. It can be customized.

- FAILURE\_LOG

The default value is `stopMXValidation.json`.

This is the location of the failure log. It is used in Log node FAILURE. It can be customized.

- bizSvc

This is for internal use in the Map node MX pre-check to determine the type of data being read in the input file.

- stopValidation

This is for internal use in the Map node MX pre-check and is checked in Decision node pre-valid chk to cause a Failure log in case a data file was not recognized as a valid SWIFT gpi message.

3. Open the main flow `swift_gpi_validation_flow` in the Design Server. It utilizes above one source node, three map nodes, one route node, three decision nodes, one log node, one fail node, two passthrough nodes, two format converter nodes and four target nodes.

4. In Design Server, create a package `swift_gpi_mx_validation` that contains the input files and one flow `swift_gpi_validation_flow`. The maps will automatically be included during deployment of the package onto the runtime server.

Note: Not required for running flows on Design Server user interface directly.

- [Run the example using three different methods](#)

You can run the example using three different methods:

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
2. Deploying the example to tx-rest and running it using the Swagger interface.
3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).

- [Run the example from the Design Server user interface](#)

Use the following steps to run the example from the Design Server user interface:

- [Run the example using the Swagger interface](#)

To run the example, deploy to tx-rest and run it using the Swagger interface.

- [Run the example using the flow command server process \(flowcmdserver\)](#)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open `swift_gpi_validation_flow` flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file. Example is `swgp_trck_001_gCCTINST.xml`.  
Note: If a default path is assigned to the variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists execution of all nodes.
3. Right click and select View Link Data on each link to examine the data.
4. Right click on the node and select View Log to see the logs.

---

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

- Create a Web type server definition where the runtime tx-rest is installed if you do not have a server definition to deploy in Design Server.
- If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
- Deploy the created package to the server definition in Design Server.
- Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
- In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.  
You should see a Miscellaneous section having two actions: A **PUT** /v2/run/swift\_gpi\_validation\_flow and a **POST** /v2/run/swift\_gpi\_validation\_flow.
- In the **PUT** action:
  - Expand the **PUT** action and select the Try it out button.
  - Leave the input and output sections empty.
  - Under flow\_vars section, delete the entire content and replace with the commands to run the flow, for example:

```
{
 "INPUT_FILE": "C:/mydir/data/swgp_trck_001_gCCTINST.xml",
 "OUTPUT_RESULT_JSON": "C:/mydir/data/validation_result.json",
 "REPORT_FORMAT": "json",
 "VALIDATION_TYPE": "extended"
}

or

{
 "INPUT_FILE": "C:/mydir/data/swgp_trck_001_gCCTINST.xml",
 "OUTPUT_RESULT_XML": "C:/mydir/data/validation_result.xml",
 "REPORT_FORMAT": "xml",
 "VALIDATION_TYPE": "extended"
}
```

- Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. This run should generate the output same as above.
- Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json. There will be a **DELETE** /v2/packages/{name} action.
- Expand the **DELETE** /v2/packages/{name} action and select Try it out.
- In the Name field, enter the name you gave to the created package.
- Select the true option from the stop query drop down, select the blue Execute bar.  
You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

- Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
- In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
- Execute the flow using the flow command server. The below command is for SWIFT GPI swgp\_trck\_001\_gCCTINST.xml message.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows --flow swift_gpi_validation_flow.json
--var "INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\swgp_trck_001_gCCTINST.xml"
--audit "C:\ftpserver\deployment\tools\mx_service\data\swgp_trck_001_gCCTINST_adt.json" -ad
```

The results will be in C:\ftpserver\deployment\flows as validation\_results.xml or validation\_results.json depending on the value of the REPORT\_FORMAT variable.

- Use the below command to execute with the variable VALIDATION\_TYPE value defined in the Flow settings in Design Server ('extended' or 'schema').

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows
--flow swift_gpi_validation_flow.json
--var "INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\swgp_trck_001_gCCTINST.xml"
--var "VALIDATION_TYPE=schema"
--var "REPORT_FORMAT=json"
--audit "C:\ftpserver\deployment\tools\mx_service\data\swgp_trck_001_gCCTINST_adt.json" -ad
```

- The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is:
"C:\ftpserver\deployment\tools\mx_service\data\swgp_trck_001_gCCTINST_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

- Examine the flow output result file validation\_results.xml and the audit file swgp\_trck\_001\_gCCTINST\_adt.json.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

## Example

To disable the BIC lookup validation feature.

## About this task

---

Change sub-element ExtendedValidation/BICValidation value from T to F.

## Procedure

---

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the flow.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

---

## SWIFT GPI enhanced MX validation (using maps) example

This example demonstrates the enhanced MX validation for SWIFT GPI messages using the maps.

The flow can perform following level of validation:

- MX extended validation includes following checks:
  - BIC lookup
  - Country code lookup
  - Currency code lookup
  - IBAN format
  - Allowed maximum fractional digits per currency
  - Usage guideline rules, see mxconfig.xml for list of rules
- Schema validation
- [\*\*What the example contains\*\*](#)  
Files and directories included in this example are as follows:
- [\*\*Run the example in Design Studio\*\*](#)
- [\*\*Run the example in Design Server User Interface\*\*](#)
- [\*\*How to customize the mxconfig.xml file\*\*](#)

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

---

## What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources:
  - swift\_gpi\_mx\_trck\_validation\_enh.mms  
Utility maps called by main map for all the trck SWIFT GPI xml message MX validation.
  - swift\_gpi\_mx\_validation\_frmwrk\_map\_enh.mms  
The main map used to apply MX validation to SWIFT GPI xml messages.

Note: When running under Design Server, the main framework map is swift\_gpi\_mx\_validation\_frmwrk\_map\_flw\_enh.mms.

- Schemas:  
The schemas directory contains the following files:
  - bic.xsd  
Metadata that represents the bic.xml repository file structure.
  - ccy.xsd  
Metadata that represents the currencycodedecimals.xml repository file structure.
  - mxconfig.xsd  
Metadata that represents the mxconfig.xml configuration file structure.
  - head.001.001.02\_trck\_001\_gCCT.xsd
  - head.001.001.02\_trck\_001\_gCCTINST.xsd
  - head.001.001.02\_trck\_001\_gCOV.xsd
  - head.001.001.02\_trck\_001\_gFIT.xsd
  - head.001.001.02\_trck\_001\_Swiftgo.xsd
  - head.001.001.02\_trck\_002\_gCCT.xsd
  - head.001.001.02\_trck\_002\_gCCTINST.xsd
  - head.001.001.02\_trck\_002\_gCOV.xsd
  - head.001.001.02\_trck\_002\_gFIT.xsd
  - head.001.001.02\_trck\_002\_Swiftgo.xsd
  - head.001.001.02\_trck\_003.xsd
  - head.001.001.02\_trck\_004\_g4C.xsd
  - head.001.001.02\_trck\_005.xsd
  - trck.001.001.02\_gCCTINST.xsd

- trck.001.001.03\_gCCT.xsd
- trck.001.001.03\_gCOV.xsd
- trck.001.001.03\_gFIT.xsd
- trck.001.001.03\_Swiftgo.xsd
- trck.002.001.01\_gCCTINST.xsd
- trck.002.001.02\_gCCT.xsd
- trck.002.001.02\_gCOV.xsd
- trck.002.001.02\_gFIT.xsd
- trck.002.001.02\_Swiftgo.xsd
- trck.003.001.02.xsd
- trck.004.001.02\_g4C.xsd
- trck.005.001.02.xsd

Note: XML schemas were downloaded from SWIFT MyStandards Readiness SWIFT GPI Portal.

- Trees:

The trees directory contains the following files:

- mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
- swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.

- Data:

The data directory contains the following files:

- bic.xml  
Repository file listing all BICs which are used during validation.
- currencycodedecimals.xml  
Repository file listing country codes, currency codes and corresponding maximum fractionally digits, used as reference for validation.
- mxconfig.xml  
Holds the MX configuration information on how to process the message.

Sample SWIFT GPI valid files for test purpose with header envelope:

- bah\_trck\_001\_001\_02\_gCCTINST\_valid.xml
- bah\_trck\_001\_001\_03\_gCCT\_valid.xml
- bah\_trck\_001\_001\_03\_gCOV\_valid.xml
- bah\_trck\_001\_001\_03\_gFIT\_valid.xml
- bah\_trck\_001\_001\_03\_Swiftgo\_valid.xml
- bah\_trck\_002\_001\_01\_gCCTINST\_valid.xml
- bah\_trck\_002\_001\_02\_gCCT\_valid.xml
- bah\_trck\_002\_001\_02\_gCOV\_valid.xml
- bah\_trck\_002\_001\_02\_gFIT\_valid.xml
- bah\_trck\_002\_001\_02\_Swiftgo\_valid.xml
- bah\_trck\_003\_001\_02\_valid.xml
- bah\_trck\_004\_001\_02\_g4C\_valid.xml
- bah\_trck\_005\_001\_02\_valid.xml

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, swgp1000\_val (under swift\_gpi\_mx\_validation\_frmwrk\_map\_enh.mms file or swift\_gpi\_mx\_validation\_frmwrk\_map\_flw\_enh.mms file if running under Design Server) with the desired input file.
3. Run the main router map, swgp1000\_val.  
You will see the output file in the data folder called swgp\_error\_report.xml.

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter the user and password credentials.
3. If the project does not exist, import swift\_gpi.zip.
4. If absent, create a package containing all the Maps, Files and Flows.
5. Build the package in the desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map swgp1000\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map swgp1000\_val.
10. Right click on the output card on canvas and select View data.

## How to customize the mxconfig.xml file

Rules enforced by the MX validation framework can be customized by editing the mxconfig.xml located under the validation/mx\_extended/data folder.

All the rules enforced by the MX validation map are under element ExtendedValidation.

Any of the sub-elements under ExtendedValidation can be enabled by setting the value to T or disabled by setting to F.

## Example

---

To disable the BIC lookup validation feature.

## About this task

---

Change sub-element ExtendedValidation/BICValidation value from T to F.

## Procedure

---

1. Download the mxconfig.xml file from the Files tab.
2. Open the mxconfig.xml file and edit the sub-element ExtendedValidation/BICValidation value setting from T to F, then save the file.
3. Upload the edited mxconfig.xml file to the project.
4. Run the map.  
Run using an input with BIC lookup validation issue.

Right click on the output card on canvas and select View data. No BIC lookup validation reported.

## SWIFT GPI schema MX validation (using maps) example

---

This example demonstrates the schema validation for SWIFT gpi messages using the maps.

The maps can perform following level of validation:

- Schema validation
- [What the example contains](#)  
Files and directories included in this example are as follows:
- [Run the example in Design Studio](#)
- [Run the example in Design Server User Interface](#)

## What the example contains

---

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources to use when running under Design Studio:
  - swift\_gpi\_mx\_schema\_validation\_xsd.mms  
Utility maps called by main map for all SWIFT gpi xml messages schema validation.
  - swift\_gpi\_schema\_validation\_frmwrk\_map\_xsd.mms  
The main map used to apply schema validation to SWIFT GPI xml messages.
- Schemas:  
The schemas directory contains the following files:
  - head.001.001.02\_trck\_001\_gCCT.xsd
  - head.001.001.02\_trck\_001\_gCCTINST.xsd
  - head.001.001.02\_trck\_001\_gCOV.xsd
  - head.001.001.02\_trck\_001\_gFIT.xsd
  - head.001.001.02\_trck\_001\_Swiftgo.xsd
  - head.001.001.02\_trck\_002\_gCCT.xsd
  - head.001.001.02\_trck\_002\_gCCTINST.xsd
  - head.001.001.02\_trck\_002\_gCOV.xsd
  - head.001.001.02\_trck\_002\_gFIT.xsd
  - head.001.001.02\_trck\_002\_Swiftgo.xsd
  - head.001.001.02\_trck\_003.xsd
  - head.001.001.02\_trck\_004\_g4C.xsd
  - head.001.001.02\_trck\_005.xsd
  - trck.001.001.02\_gCCTINST.xsd
  - trck.001.001.03\_gCCT.xsd
  - trck.001.001.03\_gCOV.xsd
  - trck.001.001.03\_gFIT.xsd
  - trck.001.001.03\_Swiftgo.xsd
  - trck.002.001.01\_gCCTINST.xsd
  - trck.002.001.02\_gCCT.xsd
  - trck.002.001.02\_gCOV.xsd
  - trck.002.001.02\_gFIT.xsd
  - trck.002.001.02\_Swiftgo.xsd
  - trck.003.001.02.xsd

- trck.004.001.02\_g4C.xsd
- trck.005.001.02.xsd

Note: XML schemas were downloaded from SWIFT MyStandards Readiness SWIFT GPI Portal.

- Trees:  
The trees directory contains the following files:

- mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
- swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.

- Data:  
The data directory contains the following file:

Sample SWIFT gpi valid files with header envelope for test purposes:

- bah\_trck\_001\_001\_02\_gCCTINST\_valid.xml
- bah\_trck\_001\_001\_03\_gCCT\_valid.xml
- bah\_trck\_001\_001\_03\_gCOV\_valid.xml
- bah\_trck\_001\_001\_03\_gFIT\_valid.xml
- bah\_trck\_001\_001\_03\_Swiftgo\_valid.xml
- bah\_trck\_002\_001\_01\_gCCTINST\_valid.xml
- bah\_trck\_002\_001\_02\_gCCT\_valid.xml
- bah\_trck\_002\_001\_02\_gCOV\_valid.xml
- bah\_trck\_002\_001\_02\_gFIT\_valid.xml
- bah\_trck\_002\_001\_02\_Swiftgo\_valid.xml
- bah\_trck\_003\_001\_02\_valid.xml
- bah\_trck\_004\_001\_02\_g4C\_valid.xml
- bah\_trck\_005\_001\_02\_valid.xml

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
2. Replace the input card 1 in router map, swgp1500\_val (under swift\_gpi\_schema\_validation\_frmwrk\_map\_xsd.mms file) with the desired input file.
3. Run the main router map, swgp1500\_val.  
You will see the output file in the data folder called swgp\_error\_report.xml.

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
2. Enter the user and password credentials.
3. If the project does not exist, import swift\_gpi.zip.
4. If absent, create a package containing all the Maps, Files and Flows.
5. Build package in the desired server (to build all maps).
6. Open the project.
7. In the Maps tab, open the map swgp1500\_val.
8. Modify the settings for input card 1 on design canvas to point to the desired test file.
9. Save, build, and run the map swgp1500\_val.
10. Right click on the output card on canvas and select View data.

## SIC (SIX Interbank Clearing) Validation Examples:

- [\*\*SIC \(SIX Interbank Clearing\) Schema validation \(using flows\) Example\*\*](#)  
This example demonstrates the SIC schema validation for SIC messages using flow server.
- [\*\*SIC \(SIX Interbank Clearing\) Schema validation \(using maps\) Example\*\*](#)  
This example demonstrates the schema validation for SIC messages using maps only.

## SIC (SIX Interbank Clearing) Schema validation (using flows) Example

This example demonstrates the SIC schema validation for SIC messages using flow server.

The flow can perform following level of validation:

- Schema validation
- [\*\*What the example contains\*\*](#)  
Files included in this example are as follows:
- [\*\*How to run the example\*\*](#)  
This SIC schema validation will use the sample files to demonstrate the generation of validation report as output from a SIC XML message.

## What the example contains

Files included in this example are as follows:

- sic\_rtgs.zip
  - Test Data Files:
    - sirt\_pacs\_009\_bad\_schema.xml
    - sirt\_pacs\_009.xml
  - Schemas:
    - mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
    - swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.
  - Maps:
    - For Schema Validation:
      - sirt3500\_val
      - sirt3501\_acmt\_010\_001\_03
      - sirt3502\_acmt\_011\_001\_03
      - sirt3503\_acmt\_015\_001\_03
      - sirt3504\_camt\_003\_001\_07
      - sirt3505\_camt\_004\_001\_08
      - sirt3506\_camt\_005\_001\_08
      - sirt3507\_camt\_006\_001\_08
      - sirt3508\_camt\_007\_001\_08
      - sirt3509\_camt\_008\_001\_08

      - sirt3511\_camt\_019\_001\_07
      - sirt3512\_camt\_025\_001\_05
      - sirt3513\_camt\_027\_001\_07
      - sirt3514\_camt\_029\_001\_09
      - sirt3515\_camt\_048\_001\_05
      - sirt3516\_camt\_050\_001\_05
      - sirt3517\_camt\_052\_001\_08
      - sirt3518\_camt\_054\_001\_08
      - sirt3519\_camt\_056\_001\_08
      - sirt3520\_camt\_087\_001\_06
      - sirt3521\_pacs\_002\_001\_10
      - sirt3522\_pacs\_004\_001\_09
      - sirt3523\_pacs\_008\_001\_08
      - sirt3524\_pacs\_009\_001\_08
      - sirt3525\_pacs\_028\_001\_03
      - sirt3526\_reda\_015\_001\_01
      - sirt3527\_reda\_017\_001\_01
    - Common:
      - mxut1010\_business\_svc\_sicrt
    - Flows:

- sic\_rtgs\_validation\_flow

## How to run the example

This SIC schema validation will use the sample files to demonstrate the generation of validation report as output from a SIC XML message.

The stopValidation.json file will report the validation failure due to the pre-conversion checks:

**If input file is other than any of the supported SIC messages as per schema list indicated above.**

1. Import the sic\_rtgs.zip project into the Design Server.
  2. Open the sic\_rtgs\_validation\_flow project in Design Server and view the sic\_rtgs\_validation\_flow.
- a. The Flow Description points to all the maps to be executed during the flow process, which will be called from within some of the map nodes in the flow. The following is a list of maps invoked using RUN built-in function during the flow process:

- @packagemap=sic\_rtgs/validation/schema\_only/maps/sic\_rtgs\_mx\_schema\_validation\_xsd/sirt3501\_acmt\_010\_001\_03
- @packagemap=sic\_rtgs/validation/schema\_only/maps/sic\_rtgs\_mx\_schema\_validation\_xsd/sirt3502\_acmt\_011\_001\_03
- @packagemap=sic\_rtgs/validation/schema\_only/maps/sic\_rtgs\_mx\_schema\_validation\_xsd/sirt3503\_acmt\_015\_001\_03

- @packagemap=sic\_rtgs/validation/schema\_only/maps/sic\_rtgs\_mx\_schema\_validation\_xsd/sirt3521\_pacs\_002\_001\_10
- @packagemap=sic\_rtgs/validation/schema\_only/maps/sic\_rtgs\_mx\_schema\_validation\_xsd/sirt3522\_pacs\_004\_001\_09
- @packagemap=sic\_rtgs/validation/schema\_only/maps/sic\_rtgs\_mx\_schema\_validation\_xsd/sirt3523\_pacs\_008\_001\_08
- @packagemap=sic\_rtgs/validation/schema\_only/maps/sic\_rtgs\_mx\_schema\_validation\_xsd/sirt3524\_pacs\_009\_001\_08
- @packagemap=sic\_rtgs/validation/schema\_only/maps/sic\_rtgs\_mx\_schema\_validation\_xsd/sirt3525\_pacs\_028\_001\_03
- @packagemap=sic\_rtgs/validation/schema\_only/maps/sic\_rtgs\_mx\_schema\_validation\_xsd/sirt3526\_reda\_015\_001\_01
- @packagemap=sic\_rtgs/validation/schema\_only/maps/sic\_rtgs\_mx\_schema\_validation\_xsd/sirt3527\_reda\_017\_001\_01

- b. It utilizes the following nodes:

i. Source Nodes:

- mx\_input

This node identifies the input data to be validated in the flow. It uses the INPUT\_FILE variable to set the location of the data.

ii. Map Nodes:

- MX pre-check

Runs map mxut1010\_bizsvc\_sirt which sets flow variables, checks pre-validation conditions and creates infoset.json for validation.

- XSD\_VAL

Runs map sirt3500\_val which calls the appropriate map to perform schema validation of a SIC RTGS message.

Note: The map sirt3500\_val internally calls all the other maps identified in the above Flow Description step.

iii. Decision Nodes:

- pre-valid chk

This node checks the flow variable stopValidation to decide if further validation/processing is not required.

- XSD\_RESULT\_FORMAT

This node checks the value of the flow variable REPORT\_FORMAT to determine if the resulting report for schema-only validation should be generated in XML (default) or JSON.

iv. Log Nodes:

- FAILURE

In case of no validation due to precondition check failures, this node creates a log file specified by the flow variable FAILURE\_LOG.

v. Fail Node:

- STOP

It generates error message setup in the node in case of no validation performed.

vi. Passthrough Nodes:

- XSD\_XML\_CONVERT

This node receives a schema-only validation report in XML format and does not modify the content, thus passing it as is to the appropriate target node.

vii. Format Converter Nodes:

- XSD\_JSON\_CONVERT

This node receives a schema-only validation report in XML format and converts it to JSON before passing it to the appropriate target node.

viii. Target Nodes:

- xsd\_xml  
This node contains the resulting schema-only validation report in XML format and creates the output as defined by variable OUTPUT\_RESULT\_XML.
  - xsd\_json  
This node contains the resulting schema-only validation report in JSON format and creates the output as defined by variable OUTPUT\_RESULT\_JSON.
- c. It utilizes the following variables:
- Flow variables:
- VALIDATION\_TYPE  
The default value is schema.  
  
The value extended is not supported at this time. This variable is currently not being used in any node.
  - REPORT\_FORMAT  
The default value is xml.  
  
It can be changed to json. This is used in Decision node XSD\_RESULT\_FORMAT.
  - INPUT\_FILE  
The default value is ../tools/mxservice/data/sirt\_pacs\_009.xml.  
  
This is the data file to be used for validation and can be customized. This is used in Source node mx\_input.
  - OUTPUT\_RESULT\_XML  
The default value is validation\_result.xml.  
  
This is the location of the validation report file in xml format. It is used in Target node xsd\_xml. It can be customized.
  - OUTPUT\_RESULT\_JSON  
The default value is validation\_result.json.  
  
This is the location of the validation report file in json format. It is used in Target node xsd\_json. It can be customized.
  - FAILURE\_LOG  
The default value is stopMXValidation.json.  
  
This is the location of the failure log. It is used in Log node FAILURE. It can be customized.
  - bizSvc  
For internal use in the Map node MX pre-check to determine the type of data being read in the input file.
  - stopValidation  
For internal use in the Map node MX pre-check and is checked in Decision node pre-valid chk to cause a Failure log in case a data file was not recognized as a valid SIC message.
3. Open the main flow sic\_rtgs\_validation\_flow in the Design Server. It utilizes above one source node, two map nodes, two decision nodes, one log node, one fail node, one passthrough node, one format converter node and two target nodes
4. In Design Server, create a package sic\_rtgs\_mx\_validation that contains the input files and one flow sic\_rtgs\_validation\_flow. The maps will automatically be included during deployment of the package onto the runtime server.  
Note: Not required for running flows on Design Server user interface directly.
- [Run the example using three different methods](#)  
You can run the example using three different methods:

---

## Run the example using three different methods

You can run the example using three different methods:

1. Running the example from the Design Server user interface.
  2. Deploying the example to tx-rest and running it using the Swagger interface.
  3. Deploying locally or to ftp server and using the flow command server process (flowcmdserver).
- [Run the example from the Design Server user interface](#)  
Use the following steps to run the example from the Design Server user interface:
  - [Run the example using the Swagger interface](#)  
To run the example, deploy to tx-rest and run it using the Swagger interface.
  - [Run the example using the flow command server process \(flowcmdserver\)](#)  
To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

---

## Run the example from the Design Server user interface

Use the following steps to run the example from the Design Server user interface:

1. In the Design Server, open sic\_rtgs\_validation\_flow and click on Run button.
2. Set toggle switch Run On Design Server and select flow input file. Example is sirt\_pacs\_009.xml.  
Note: If a default path is assigned to variable INPUT\_FILE, not selecting an input file will use the value defined for the variable.  
Flow will run and report with the green check box. The report lists the execution of all nodes.

3. To examine the data passed on each link, right click on each link and select View Link Data.
4. To view the target node, right click on the node input icon and select View Data.

## Run the example using the Swagger interface

To run the example, deploy to tx-rest and run it using the Swagger interface.

1. Create a Web type server definition where the runtime tx-rest is installed if you do not have a server definition to deploy in Design Server.
2. If not running, start tx-rest on the server: <DTX\_HOME>/restapi/tomcat/dtxtomcat start tx-rest.
3. Deploy the created package to the server definition in Design Server.
4. Bring up the tx-rest Swagger UI: <DTX\_HOME>/restapi/tomcat/dtxtomcat showdocs tx-rest.
5. In the Swagger Explore window, enter /tx-rest/v2/docs and click on the Explore button to view the deployed package.
- You should see a Miscellaneous section having two actions: A **PUT** /v2/run/sic\_rtgs\_validation\_flow and a **POST** /v2/run/sic\_rtgs\_validation\_flow.
6. In the **PUT** action:
  - a. Expand the **PUT** action and select the Try it out button.
  - b. Leave the input and output sections empty.
  - c. Under flow\_vars section, delete the entire content and replace it with the commands to run the flow. For example:

```
{
 "INPUT_FILE": "C:/mydir/data/sirt_pacs_009.xml",
 "OUTPUT_RESULT_JSON": "C:/mydir/data/validation_result.json",
 "REPORT_FORMAT": "json"
}

or

{
 "INPUT_FILE": "C:/mydir/data/sirt_pacs_009.xml",
 "OUTPUT_RESULT_XML": "C:/mydir/data/validation_result.xml",
 "REPORT_FORMAT": "xml"
}
```

- d. Click Execute blue bar for running the flow. When flow completes execution, 200 response code is shown in the Server Response section. This run should generate the output same as above.
7. Refresh the browser to delete the deployed package and get the Swagger Explore back to /tx-rest/openapi.json. There will be a **DELETE** /v2/packages/{name} action.
8. Expand the **DELETE** /v2/packages/{name} action and select Try it out.
9. In the Name field, enter the name you gave to the created package.
10. Select the true option from the stop query drop down, select the blue Execute bar.

You can see a response of 204 with a timestamp, if it is successful.

## Run the example using the flow command server process (flowcmdserver)

To run the example, deploy locally or to ftp server and use the flow command server process (flowcmdserver).

1. Create a server definition where the runtime is installed, if you do not have a server local definition or ftp execution definition to deploy to, in Design Server.
2. In Design Server, deploy the created package to the server definition. For example, deploy to c:\ftpserver\deployment directory.
3. Execute the flow using the flow command server. The below command is for SIC SIC sirt\_pacs\_009.xml message.

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows
--flow sic_rtgs_validation_flow.json
--var "INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\sirt_pacs_009.xml"
--audit "C:\ftpserver\deployment\tools\mx_service\data\sirt_pacs_009_adt.json" -ad
```

- The results will be in C:\ftpserver\deployment\flows as validation\_result.xml or validation\_result.json depending on the value of the REPORT\_FORMAT variable.
4. Use the following command to execute with the variable VALIDATION\_TYPE value defined in the Flow settings in Design Server (extended or schema).

```
flowcmdserver.exe --dir c:\ftpserver\deployment\flows
--flow sic_rtgs_validation_flow.json
--var "INPUT_FILE=C:\ftpserver\deployment\tools\mx_service\data\sirt_pacs_009.xml"
--var "VALIDATION_TYPE=schema"
--var "REPORT_FORMAT=xml"
--audit "C:\ftpserver\deployment\tools\mx_service\data\sirt_pacs_009_adt.json" -ad
```

5. The flow will report status similar to:

```
***Starting flow command server

Flow UUID: 85eabe2c-2302-4543-b347-9e18d65c6816
The flow audit file is: "C:\ftpserver\deployment\tools\mx_service\data\sirt_pacs_009_adt.json"
Flow completed successfully
Elapsed time: 3048ms
```

6. Examine the flow output result file validation\_results.xml and the audit file sirt\_pacs\_009\_adt.json.

## SIC (SIX Interbank Clearing) Schema validation (using maps) Example

This example demonstrates the schema validation for SIC messages using maps only.

The maps can perform following level of validation:

- Schema validation
- [What the example contains](#)

Files and directories included in this example are as follows:

---

## What the example contains

Files and directories included in this example are as follows:

- Maps:  
The maps directory contains the following map sources:

- sic\_rtgs\_mx\_schema\_validation\_xsd.mms  
Contains maps for schema validation of any SIC message.
- sic\_rtgs\_schema\_validation\_frmwrk\_map\_xsd.mms  
The main map used to apply schema validation to SIC xml messages.

- Schemas:  
The schemas directory contains the following files:

[Based from Implementation Guidelines provided by SIX Interbank Clearing Ltd Platform Releases 4.11 (RTGS services SIC and euroSIC) and 5.1 (SIC IP service)]

- acmt.010.001.03.ch.01.xsd
- acmt.011.001.03.ch.01.xsd
- acmt.015.001.03.ch.01.xsd
- camt.003.001.07.ch.02.xsd
- camt.004.001.08.ch.02.xsd
- camt.005.001.08.ch.01.xsd
- camt.006.001.08.ch.02.xsd
- camt.007.001.08.ch.01.xsd
- camt.008.001.08.ch.01.xsd
- camt.011.001.07.ch.01.xsd
- camt.019.001.07.ch.02.xsd
- camt.025.001.05.ch.02.xsd
- camt.027.001.07.ch.01.xsd
- camt.029.001.09.ch.03.xsd
- camt.048.001.05.ch.01.xsd
- camt.050.001.05.ch.01.xsd
- camt.052.001.08.ch.02.xsd
- camt.054.001.08.ch.02.xsd
- camt.056.001.08.ch.04.xsd
- camt.087.001.06.ch.01.xsd
- pacs.002.001.10.ch.02.xsd
- pacs.004.001.09.ch.02.xsd
- pacs.008.001.08.ch.02.xsd
- pacs.009.001.08.ch.03.xsd
- pacs.028.001.03.ch.01.xsd
- reda.015.001.01.ch.01.xsd
- reda.017.001.01.ch.02.xsd

- Trees:  
The trees directory contains the following files:

- mxvalErrorReport.mtt  
Metadata that represents the xml based structure of the validation report.
- swiftroute\_funds.mtt  
Metadata that is used as an internal element placeholder.

- Data:  
The data directory contains the following files:

Sample SIC valid files for test purpose:

- acmt\_010\_001\_03\_valid.xml
- acmt\_011\_001\_03\_valid.xml
- acmt\_015\_001\_03\_valid.xml
- camt\_003\_001\_07\_valid.xml
- camt\_004\_001\_08\_valid.xml
- camt\_005\_001\_08\_valid.xml
- camt\_006\_001\_08\_valid.xml
- camt\_007\_001\_08\_valid.xml
- camt\_008\_001\_08\_valid.xml
- camt\_011\_001\_07\_valid.xml
- camt\_019\_001\_07\_valid.xml
- camt\_025\_001\_05\_valid.xml
- camt\_027\_001\_07\_valid.xml
- camt\_029\_001\_09\_valid.xml

- camt\_048\_001\_05\_valid.xml
- camt\_050\_001\_05\_valid.xml
- camt\_052\_001\_08\_valid.xml
- camt\_054\_001\_08\_valid.xml
- camt\_056\_001\_08\_valid.xml
- camt\_087\_001\_06\_valid.xml
- pacs\_002\_001\_10\_valid.xml
- pacs\_004\_001\_09\_valid.xml
- pacs\_008\_001\_08\_valid.xml
- pacs\_009\_001\_08\_valid.xml
- pacs\_028\_001\_03\_valid.xml
- reda\_015\_001\_01\_valid.xml
- reda\_017\_001\_01\_valid.xml

- [Run the example in Design Studio](#)
  - [Run the example in Design Server User Interface](#)
- 

## Run the example in Design Studio

1. Build all the maps in the .mms files listed in What the example contains section.
  2. Replace the input card 1 in router map, sirt3500\_val (under sic\_rtgs\_schema\_validation\_frmwrk\_map\_xsd.mms file) with desired input file.
  3. Run the main router map, sirt3500\_val.
- You will see the output file in the data folder called sirt\_error\_report.xml.
- 

## Run the example in Design Server User Interface

1. Open a browser pointing to the installation of the IBM Sterling Transformation Extender.
  2. Enter the user and password credentials.
  3. If the project does not exist, import sic\_rtgs.zip.
  4. If absent, create a package containing all the Maps, Files and Flows.
  5. Build the package in the desired server (to build all maps).
  6. Open the project.
  7. In the Maps tab, open the map sirt3500\_val.
  8. Modify the settings for input card 1 on design canvas to point to the desired test file.
  9. Save, build, and run the map sirt3500\_val.
  10. Right click on the output card on canvas and select View data.
- 

## Overview

There are three Pack for Healthcare components:

- HIPAA EDI component
- HL7 component
- NCPDP component

The Pack for Healthcare components provide healthcare and insurance-payer organizations with an infrastructure that can do the following:

- Enable compliance with government and industry mandates.
- Control administrative costs.
- Streamline business processes.
- Facilitate accuracy and timeliness of information.
- Offer a competitive advantage.
- Conform to existing systems.
- Adapt to new technologies as they emerge.
- Integrate multiple systems and standards.

The Pack for Healthcare is based on technology that allows your applications and systems to take advantage of the full range of integration capabilities including:

- Powerful any-to-any and many-to-many data transformation.
  - Multi-platform deployment and execution.
  - Management of transaction flows between trading partners.
  - Importers for interface creation from IBM DTDs, copybooks, DBMS catalogs, and other metadata.
  - Adapters for commercial applications, messaging middleware, Internet transports, relational databases, file systems, and utilities.
  - **[Installation location](#)**  
Installation details for the Pack for Healthcare are contained in the product release notes. See <https://www.ibm.com/support/pages/node/318755>.
  - **[General constraints](#)**  
All healthcare-related schemas that are developed by IBM adhere to the current, official implementation guides or published standards documents.
- 

## Installation location

Installation details for the Pack for Healthcare are contained in the product release notes. See <https://www.ibm.com/support/pages/node/318755>.

The Pack for Healthcare contains objects, including schemas, sample data, map source files, and compiled image files for utility modules.

These objects are installed within the imported project. The schema installs within the imported project.

## General constraints

All healthcare-related schemas that are developed by IBM adhere to the current, official implementation guides or published standards documents.

Healthcare data transformation maps are expected to be accurate implementations of published crosswalks or data transformation specifications. However, the examples provided do not account for your specific requirements. Therefore, all schemas and maps that are provided are intended for use as examples only.

Your responsibility as a user is to assess suitability and conduct appropriate tests before you place the Pack for Healthcare objects into a production environment. You must also ensure that you adequately address security and privacy considerations in the applications and systems you develop using the Pack for Healthcare.

## Healthcare industry

This documentation discusses technical terms and other information used to exchange data in the Healthcare industry.

- [Healthcare information exchange participants](#)
- [Healthcare transactions and standards](#)
- [Healthcare electronic data interchange initiatives](#)

The entire healthcare industry is facing increased pressure to implement productivity and quality improvements while reducing costs. The use of electronic data interchange and industry-specific data exchange standards for healthcare transaction data is a potential source of significant benefits in these areas.

## Healthcare information exchange participants

Every encounter between a patient and a healthcare provider involves exchanging information. In addition to the basics of patient demographics, symptoms, diagnoses, and treatments, the typical scenario requires the exchange of claims and payment data and associated payer, subscriber, eligibility, and authorization information. A single encounter can involve the transmission of large volumes of information among several participants.

## Healthcare transactions and standards

The healthcare information exchange can generally be viewed as a transaction between the sender and receiver participants.

Healthcare transactions include (but are not limited to):

- Healthcare claims or encounter
- Claim payment and remittance advice
- Healthcare claim status
- Coordination of benefits
- Eligibility for a health plan
- Referral certification and authorization
- Enrollment and un-enrollment in a health plan
- Premium payments
- Claim adjudication reporting

These transactions can be transmitted electronically in compliance with healthcare transaction standards.

Healthcare data exchange standards allow the accurate and timely exchange of information between healthcare organizations. For example, a simple benefits inquiry can take 20 minutes on the phone. By using Electronic Data Interchange (EDI), this type of request can be processed almost immediately, without the need for a call to the customer service center.

## Healthcare electronic data interchange initiatives

The entire healthcare industry is facing increased pressure to implement productivity and quality improvements while reducing costs. The use of electronic data interchange and industry-specific data exchange standards for healthcare transaction data is a potential source of significant benefits in these areas.

Healthcare industry electronic interchange initiatives include the following:

- HIPAA legislation
- HIPAA transactions
- WEDI SNIP transaction types
- Council for Affordable Quality Healthcare (CAQH)
  - Operating Rules
  - Companion Guide Template
- [HIPAA legislation](#)

- [HIPAA transactions](#)
- [WEDI SNIP transaction compliance types](#)

The HIPAA Compliance Checker supports the data validation and compliance reporting for Types 1 through 7. WEDI SNIP Type 1 through 7 validation 'rules' are included in the components of the product. The rules for the higher levels of validation are user-configurable.

## HIPAA legislation

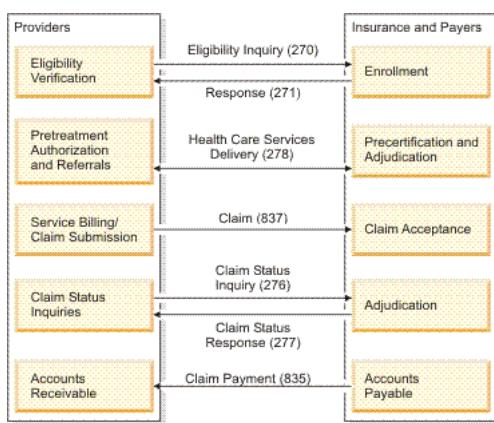

In 1996, legislation was passed to improve the overall healthcare administrative system. This legislation is known as the Health Insurance Portability and Accountability Act (HIPAA).

This pack addresses the administrative simplification aspects of HIPAA legislation, including the electronic standardization of patient health information, as well as administrative and financial data.

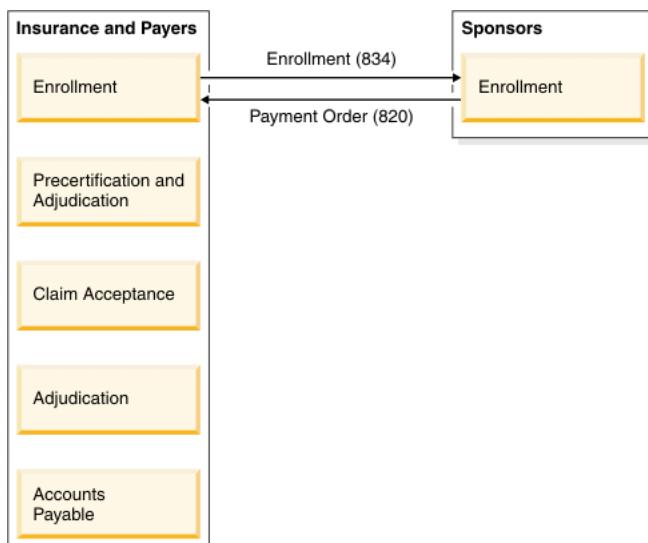

HIPAA regulations affect payers, health plans, clearinghouses, and those providers who conduct financial and administrative transactions electronically.

## HIPAA transactions

The following diagram shows the flow of information between healthcare providers, insurance, and payers and the associated HIPAA-mandated transaction numbers. These numbers refer to specific HIPAA X12 transaction sets supported in the Packs for Healthcare.

The following diagram shows the flow of information between insurance and payers and healthcare plan sponsors and the associated HIPAA-mandated transactions. Again, the parenthetical numbers refer to specific HIPAA X12 transaction sets.

## WEDI SNIP transaction compliance types

The HIPAA Compliance Checker supports the data validation and compliance reporting for Types 1 through 7. WEDI SNIP Type 1 through 7 validation 'rules' are included in the components of the product. The rules for the higher levels of validation are user-configurable.

Types 1 through 7 of HIPAA data transmission testing are defined as follows:

- Type 1 EDI Standard Integrity Testing
- Type 2 HIPAA Implementation Guide Requirement Testing
- Type 3 HIPAA Balance Testing
- Type 4 HIPAA Inter-Segment Situation Testing
- Type 5 HIPAA External Code Set Testing
- Type 6 HIPAA Line of Service Testing
- Type 7 Companion Guide Requirement Testing

## HIPAA EDI component

The documentation provided here describes the HIPAA EDI component.

Standards information and related data embedded in the [Licensee] Software, Outsourcing Services, and Combined Software Solutions are protected by copyright and other intellectual property of X12 Incorporated, a non-profit organization chartered by the American National Standards Institute to develop and maintain EDI standards and XML schemas. In order to provide and fund these activities in serving the American industry, X12 is willing to grant to all end users of the Licensee Software, Outsourcing Services, or Combined Software Solutions, a license at a royalty of \$180 per year. IBM strongly recommends that you contact X12 at [Licensing Partner: IBM](#) to obtain a license to use and access X12 metadata, represented in, for example, more than 30 versions of more than 300 transaction sets and implementation guides, through X12's online viewer, Glass.

In addition to the HIPAA EDI component, there are two other healthcare components:

- The HL7 component
- The NCPDP component
- **[Objects included in the HIPAA EDI component](#)**  
The data exchange transformation and integration requirements of the healthcare industry range from simple to complex and can vary greatly from one organization to another. The HIPAA EDI component contains predefined objects that give you the functionality and flexibility to develop a wide variety of applications and systems that meet your specific transaction and production requirements.
- **[HIPAA EDI schemas](#)**  
The Pack for Healthcare includes data transformation maps and maps for data validation. Data validation maps are either pass-through maps or related to the Compliance Check application.
- **[Maps](#)**  
The Pack for Healthcare includes data transformation maps and maps for data validation. Data validation maps are either pass-through maps or related to the Compliance Check application.
- **[Sample data](#)**  
Sample data is provided for use with the schemas and maps in the Pack for Healthcare.
- **[HIPAA Compliance Checking](#)**  
The Pack for Healthcare uses the types of HIPAA data transmission testing documented in the "Transaction Compliance and Certification" white paper developed by the workgroup for Electronic Data Interchange (WEDI) Strategic National Implementation Process (SNIP) Transactions Work Group - Testing Sub Work-Group; Dated June 11, 2002.
- **[Claim Level Rejection](#)**  
The Pack for Healthcare allows invalid claims to be rejected and valid claims to be processed. Validation is run on the document level (claim) for the 5010 837 Claims Transactions.
- **[Configurable Rules](#)**  
The Pack for Healthcare allows you to enable or disable WEDI/SNIP extended Level 2 through Level 7, as defined in the Compliance Check module.
- **[Type 5 Validation](#)**  
This support is only available with the HIPAA Data Compliance application.
- **[Type 6 Validation](#)**  
This support is only available with the HIPAA Data Compliance application.
- **[Type 7 Validation](#)**  
This support is only available with the HIPAA Data Compliance application.
- **[HIPAA EDI component examples](#)**  
This documentation describes the HIPAA EDI component examples.
- **[Performance tuning](#)**  
The HIPAA X12 data structures are hierarchical in nature, and the semantic and business rules can be complex. Some of the data files can be quite large. Given these factors, it's clear that performance is an important consideration when processing HIPAA data. There are various techniques that can be used to improve the performance of HIPAA data processing within Transformation Extender. These techniques involve separating, combining, validating, and transforming data. Some of these methods are based on the standard IBM performance tuning recommendations.
- **[Acknowledgment errors](#)**

## Objects included in the HIPAA EDI component

The data exchange transformation and integration requirements of the healthcare industry range from simple to complex and can vary greatly from one organization to another. The HIPAA EDI component contains predefined objects that give you the functionality and flexibility to develop a wide variety of applications and systems that meet your specific transaction and production requirements.

The HIPAA EDI component contains schemas, maps, sample data, and utility modules. These predefined, industry-specific objects are organized to provide flexibility to create and deploy a wide variety of applications and systems that address healthcare integration requirements. These objects are constructed to allow consistent behavior and results across all supported platforms and operating systems.

The schemas define the more commonly used healthcare industry data standards. The maps, data, and utility modules embrace typical data validation and transformation scenarios.

- **[Schemas](#)**
- **[Sample data](#)**

- [Maps](#)  
The following types of maps are included in this package:
  - [Utility modules](#)  
The utility modules are discussed in "Compliance Checking".
- 

## Schemas

The schemas in the Pack for Healthcare support the following 4050 and 5010 healthcare standards:

- HIPAA
  - PACDR (Post Adjudicated Claims Data Reporting)
  - HIX (Health Insurance Exchange)
  - CMS
  - 277CA
  - 4050 Claims Attachments
- 

## Sample data

Data files are included for the Pack for Healthcare. The data files fall into one of two general categories. Data files contain either transaction data in one or more of the data exchange formats associated with a particular healthcare industry standard; or application data used by the Compliance Check application for validating HIPAA X12 data.

The sample data files in the Pack for Healthcare conform to the following standards:

- HIPAA
  - CMS
  - HIX
  - PACDR
- 

## Maps

The following types of maps are included in this package:

- HIPAA X12 validation and reporting
  - Pass-through maps
  - Data transformation
- 

## Utility modules

The utility modules are discussed in "Compliance Checking".

---

## HIPAA EDI schemas

The documentation provided here discusses the schemas included with the Pack for HIPAA EDI.

The schemas are organized under the following headings:

- HIPAA X12 schemas
  - Utility schemas
  - CMS schemas
  - [Overview](#)
  - [What the schemas support](#)
  - [General schema information](#)  
Most of the schemas in the Pack for Healthcare include a category: %\_Type\_Tree\_Information.
  - [HIPAA X12 schemas](#)  
HIPAA X12 schemas describe the data exchange formats associated with HIPAA X12 transaction sets.
  - [ICD-10 support](#)  
The use of the International Classification of Disease, 10th Revision (ICD-10) in HIPAA has a compliance date of October 1, 2015. To be compliant, the schemas in the Pack for Healthcare have been modified to allow only ICD-10 codes.
- 

## Overview

The Pack for Healthcare includes schemas with data definitions for significant healthcare industry standards. The schema in these packages depicts the structure, relationships, and data element attributes as described in published specification documents. In practical terms, this means data that meets the specification requirements is considered valid, while data that does not meet the requirements is rejected. Other schemas attributes include the following:

- Compatibility with other IBM product offerings.
- Flexibility to modify or merge with other schemas.
- Ability to support reliable and efficient mapping.
- Easily maintainable.

The schemas are installed within the imported project.

There are two kinds of schemas in the packages: the schemas that define the data exchange formats associated with Healthcare industry data standards and the schemas that describe data formats used by application maps in the packages.

The schemas for healthcare application maps are described in "Compliance Checking" documentation.

## What the schemas support

The schemas included with the Pack for Healthcare support WEDI/SNIP Type 1, Type 2, Type 3, and Type 4, for HIPAA 5010 finalized transactions.

The schema variants that enforce the HIPAA Type 2, Type 3, and Type 4 tests are designed to work interchangeably (that is, "plug-and-play") in data transformation maps. Wherever possible, HIPAA X12 transaction set definitions and their corresponding addenda definitions are consistent with the intent to preserve the ability to merge and modify HIPAA X12 transaction set definitions and allow maximum flexibility.

The schemas do not produce acknowledgement responses. To generate acknowledgement responses, the Compliance Check application map must be used.

## General schema information

Most of the schemas in the Pack for Healthcare include a category: %\_Type\_Tree\_Information.

You can single-click on the %\_Description or %\_Revision\_History, then select **Restrictions**, to see a narrative description of the schema, or the schema revision history.

## HIPAA X12 schemas

HIPAA X12 schemas describe the data exchange formats associated with HIPAA X12 transaction sets.

The following schemas are included with the Pack for Healthcare:

- hipaa\_x12
- hipaa\_x12\_type\_1
- hipaa\_x12\_type\_2
- hipaa\_x12\_ruleless

The definitions of the HIPAA X12 schemas in the Pack for Healthcare are based on the HIPAA X12 Implementation Guide specification documents published by Washington Publishing Company.

For the Pack for Healthcare, published documents take precedence in cases where the table data and the standards documents do not agree.

The origin of the HIPAA X12 schemas in this package is from the X12 standard schema definitions in the Pack for Healthcare. There have been HIPAA-specific modifications to the X12 standard definitions in accordance with the HIPAA X12 Implementation Guides.

The HIPAA X12 schemas are described in this documentation.

- [hipaa\\_x12 schema](#)
- [Center for Medicare and Medicaid Services \(CMS\) schemas](#)
- [Utility schema](#)

## hipaa\_x12 schema

The hipaa\_x12 schema provides type 3 and 4 checking for 4050 and 5010 data and also provides type 2 and type 1 checking. The top-level group is HeaderInfo. This schema is used in x12t4precontentcheck.mmc for type 4 pass-through validation.

The hipaa\_x12 schema describes the HIPAA X12 transaction sets and enveloping structures associated with the following finalized HIPAA X12 transaction sets:

Transaction	Description	4050 version	5010 version	6020 version
270	Health Plan Eligibility Inquiry	-	005010X279A1	-
271	Health Plan Eligibility Response	-	005010X279A1	-
275	Additional Information to Support a Health Care Services Review	-	-	006020X316
276	Claim Status Request	-	005010X212	-
277	Claim Status Response	-	005010X212	-
278(N/A)	Review Notification and Acknowledgment	-	005010X216	-
278(Q/R)	Referral Request and Response	-	005010X217	006020X315
278(I/R)	Health Care Services Review - Inquiry and Response	-	005010X215	-
820	Health Plan Premium Payment	-	005010X218	-
834	Health Plan Enrollment	-	005010X220A1	-

<b>Transaction</b>	<b>Description</b>	<b>4050 version</b>	<b>5010 version</b>	<b>6020 version</b>
834	Plan Member Reporting	-	005010X318	-
835	Health Care Claim Payment	-	005010X221A1	-
837(I)	Health Care Claim and COB: Institutional	-	005010X223A2	-
837(D)	Health Care Claim and COB: Dental	-	005010X224A2	-
837(P)	Health Care Claim and COB: Professional	-	005010X222A1	-
837(I)	Post Adjudicated Claims Data Reporting Institutional	-	V5010X299A1	-
837(D)	Post Adjudicated Claims Data Reporting Dental	-	V5010X300A1	-
837(P)	Post Adjudicated Claims Data Reporting Professional	-	V5010X298A1	-
275	Additional Information to support a health care claim or Encounter	004050X151	005010X210	006020X314
277	Claim Request for Additional Information	004050X150	005010X213	006020X313
820	Health Insurance Exchange Related	-	005010X306	-
997	Functional Acknowledgment for Health Care Insurance	-	005010X230	-
999	Implementation Acknowledgment	-	005010X231A1	-
277CA	Health Care Claim Acknowledgment	-	005010X214	-
277DRA	Data Reporting Acknowledgment	-	005010X365	-

This schema enforces compliance of HIPAA X12 transmission data with the following WEDI/SNIP transaction compliance types:

- Type 1 - EDI Standard Integrity Testing
- Type 2 - HIPAA Implementation Guide Requirement Testing rules
- Type 3 - HIPAA balance testing
- Type 4 - HIPAA inter-segment situation testing

For a detailed description of Type 1, 2, 3 and 4 testing, see WEDI/SNIP HIPAA Transaction Compliance Types.

Partner X12 Inbound and Outbound Transmission EDI are the top-level definitions in this schema.

The hipaa\_x12 schema is utilized in the following source maps:

- hipaa\_x12\_pass\_through
- hipaa\_276\_5010\_to\_cms\_flat
- cms\_276\_5010\_flat\_to\_hipaa
- hipaa\_277\_5010\_to\_cms\_flat
- cms\_277\_5010\_flat\_to\_hipaa
- hipaa\_835\_5010\_to\_cms\_flat
- cms\_835\_5010\_flat\_to\_hipaa
- hipaa\_837i\_5010\_to\_cms\_flat
- cms\_837i\_5010\_flat\_to\_hipaa
- hipaa\_837p\_5010\_to\_cms\_flat
- cms\_837p\_5010\_flat\_to\_hipaa
- cms\_277ca\_5010\_flat\_to\_hipaa
- hipaa\_277ca\_5010\_to\_cms\_flat
- **hipaa\_x12\_type\_1\_schema**
- **hipaa\_x12\_type\_2\_schema**  
The hipaa\_x12\_type\_2 schema contains 5010 HIPAA X12 transaction standards.
- **hipaa\_x12\_ruleless\_schema**  
This hipaa\_x12\_ruleless schema contains the minimum number of component rules and restrictions required to properly identify the structure of a HIPAA X12 Transmission for the 4050 and 5010 HIPAA transaction sets.

## hipaa\_x12\_type\_1 schema

The hipaa\_x12\_type\_1 schema describes the HIPAA X12 transaction sets and enveloping structures associated with the finalized HIPAA X12 transaction standards. This schema enforces compliance of HIPAA X12 transmission data with WEDI/SNIP Type 1 EDI Standard Integrity Testing rules, including checks for:

- Valid segments
- Segment order
- Maximum segment and loop occurrences
- Element attributes (for example, size and data type)
- Adherence to X12 syntax rules as defined in the X12 Standard

Partner X12 Inbound and Outbound Transmission EDI are the top-level definitions of this schema. To prevent data from being rejected by the data transformation map, the hipaa\_x12\_type\_1 schema should be used as the input schema whenever the HIPAA X12 data has been validated against only the Type 1 - EDI Standard Integrity Testing Compliance checks.

## hipaa\_x12\_type\_2 schema

The hipaa\_x12\_type\_2 schema contains 5010 HIPAA X12 transaction standards.

This schema enforces compliance with HIPAA X12 transmission data for the following:

- Type 1 Standard Integrity Testing
- Type 2 HIPAA Implementation Guide Requirement Testing rules
- HIPAA Implementation Guide Requirements Testing. Partner X12 Inbound and Outbound Transmission EDI are the top-level definitions in this schema.

---

## hipaa\_x12\_ruleless schema

This hipaa\_x12\_ruleless schema contains the minimum number of component rules and restrictions required to properly identify the structure of a HIPAA X12 Transmission for the 4050 and 5010 HIPAA transaction sets.

The hipaa\_x12\_ruleless schema can be used for transformation when the data is known to be valid after it has been checked for compliance. Performance is therefore enhanced as the data does not need re-checking for validity.

---

## Center for Medicare and Medicaid Services (CMS) schemas

The CMS schemas describe the healthcare data interface formats as specified by the CMS. The following schemas are delivered with the Pack for Healthcare:

Note: The Center for Medicare and Medicaid Services (CMS) was formerly the Health Care Financing Administration (HCFA).

- cms\_276\_277\_5010\_flat
- cms\_277ca\_5010\_flat
- cms\_835\_5010a1\_flat
- cms\_837i\_5010a2\_flat
- cms\_837p\_5010a1\_flat

- **[cms\\_276\\_277\\_5010\\_flat schema](#)**

The cms\_276\_277\_5010\_flat schema defines the contents of the CMS (formerly HCFA) Part A and Part B 276 and 277 Health Care Claim Status Request and Response Flat files that correspond to the HIPAA 5010X212 formats.

- **[cms\\_277ca\\_5010\\_flat schema](#)**

The cms\_277ca\_5010\_flat schema defines the content of the CMS (formerly HCFA) and 277ca Health Care Claim Acknowledgment Flat files that correspond to the HIPAA 5010X214 formats.

- **[cms\\_835\\_5010a1\\_flat schema](#)**

The cms\_835\_5010a1\_flat schema defines the contents of the CMS (formerly HCFA) Part A and Part B 835 Health Care Claim Payment Flat file that corresponds to the HIPAA 5010X221 Addenda format.

- **[cms\\_837i\\_5010a2\\_flat schema](#)**

The cms\_837i\_5010a2\_flat schema defines the contents of the CMS (formerly HCFA) Part A 837 Institutional Claim Flat file that corresponds to the HIPAA 5010X223 Addenda format.

- **[cms\\_837p\\_5010a1\\_flat schema](#)**

The cms\_837p\_5010a1\_flat schema defines the contents of the CMS (formerly HCFA) Part B 837 Professional Claim Flat file that corresponds to the HIPAA 5010X222 Addenda format.

---

## cms\_276\_277\_5010\_flat schema

The cms\_276\_277\_5010\_flat schema defines the contents of the CMS (formerly HCFA) Part A and Part B 276 and 277 Health Care Claim Status Request and Response Flat files that correspond to the HIPAA 5010X212 formats.

The cms\_276\_277\_5010\_flat schema is used in the following source maps:

- cms\_276\_277\_5010\_flat\_pass\_through
- cms\_277\_5010\_flat\_pass\_through
- hipaa\_276\_5010\_to\_cms\_flat
- hipaa\_277\_5010\_to\_cms\_flat
- cms\_276\_277\_5010\_flat\_to\_hipaa
- cms\_277\_5010\_flat\_to\_hipaa

---

## cms\_277ca\_5010\_flat schema

The cms\_277ca\_5010\_flat schema defines the content of the CMS (formerly HCFA) and 277ca Health Care Claim Acknowledgment Flat files that correspond to the HIPAA 5010X214 formats.

The cms\_277ca\_5010\_flat schema is used in the following source maps:

- cms\_277ca\_5010\_flat\_pass\_through
- cms\_277ca\_5010\_flat\_to\_hipaa
- hipaa\_277ca\_5010\_to\_cms\_flat

---

## cms\_835\_5010a1\_flat schema

The cms\_835\_5010a1\_flat schema defines the contents of the CMS (formerly HCFA) Part A and Part B 835 Health Care Claim Payment Flat file that corresponds to the HIPAA 5010X221 Addenda format.

The cms\_835\_5010a1\_flat schema is used in the following source maps:

- cms\_835\_5010\_flat\_pass\_through

- cms\_835\_5010\_flat\_to\_hipaa
- hipaa\_835\_5010\_to\_cms

---

## cms\_837i\_5010a2\_flat schema

The cms\_837i\_5010a2\_flat schema defines the contents of the CMS (formerly HCFA) Part A 837 Institutional Claim Flat file that corresponds to the HIPAA 5010X223 Addenda format.

The cms\_837i\_5010a2\_flat schema is used in the following source maps:

- cms\_837i\_flat\_5010\_pass\_through
- cms\_837i\_5010\_flat\_to\_hipaa
- hipaa\_837i\_5010\_to\_cms\_flat

---

## cms\_837p\_5010a1\_flat schema

The cms\_837p\_5010a1\_flat schema defines the contents of the CMS (formerly HCFA) Part B 837 Professional Claim Flat file that corresponds to the HIPAA 5010X222 Addenda format.

The cms\_837p\_5010a1\_flat schema is used in the following source maps:

- cms\_837p\_5010\_flat\_pass\_through
- cms\_837p\_5010\_flat\_to\_hipaa
- hipaa\_837p\_5010\_to\_cms\_flat

---

## Utility schema

The hipaa\_x12\_v5010x214\_277ca utility schema is included with the Pack for Healthcare.

- [hipaa\\_x12\\_v5010x214\\_277ca schema](#)

The hipaa\_x12\_v5010x214\_277ca schema contains the definition of the X12N 005010X214 format for the Health Care Claim Acknowledgement (277CA). This schema can be used for input validation, transformation, or output generation of the 277 Claims Acknowledgment.

---

## hipaa\_x12\_v5010x214\_277ca schema

The hipaa\_x12\_v5010x214\_277ca schema contains the definition of the X12N 005010X214 format for the Health Care Claim Acknowledgement (277CA). This schema can be used for input validation, transformation, or output generation of the 277 Claims Acknowledgment.

The hipaa\_x12\_v5010x214\_277ca schema remains in the Pack. However, the structure of the 005010X214 277CA is now included in the following schemas:

- hipaa\_x12
- hipaa\_x12\_type\_2
- hipaa\_x12\_ruleless

The following source map files use the hipaa\_x12 schemas:

- hipaa\_277ca\_to\_cms\_flat
- cms\_277ca\_5010\_flat\_pass\_through
- cms\_277ca\_5010\_flat\_to\_hipaa

---

## ICD-10 support

The use of the International Classification of Disease, 10th Revision (ICD-10) in HIPAA has a compliance date of October 1, 2015. To be compliant, the schemas in the Pack for Healthcare have been modified to allow only ICD-10 codes.

To assist with the transition to ICD-10, the following set of schemas are provided in the pack to allow both the ICD-9 and ICD-10 qualifiers.

- hipaa\_x12\_type\_2\_icd9\_icd10
- hipaa\_x12\_icd9\_icd10
- hipaa\_x12\_ruleless\_icd9\_icd10
- hipaa\_x12\_segment\_icd9\_icd10

If these schemas are required, the following steps must be followed to replace the schemas in the compliance check application.

- [Replacing the ICD-10 compliant schemas](#)

If both the ICD-9 and ICD-10 codes are required, you must replace the schemas in the compliance\_check source map and the pass-through maps.

---

## Replacing the ICD-10 compliant schemas

If both the ICD-9 and ICD-10 codes are required, you must replace the schemas in the compliance\_check source map and the pass-through maps.

- [Changing maps impacted in the compliance\\_check source map](#)  
If both the ICD-9 and ICD-10 codes are required, the schemas in the compliance\_check source map file must be replaced.
- [Changing maps impacted in the hipaa\\_x12\\_pass\\_through source map](#)  
If both the ICD-9 and ICD-10 codes are required, the schemas in the hipaa\_x12\_pass\_through source map must be replaced.
- [Changing other maps](#)  
This documentation describes changes to other maps in the Pack for Healthcare.

## Changing maps impacted in the compliance\_check source map

If both the ICD-9 and ICD-10 codes are required, the schemas in the compliance\_check source map file must be replaced.

### About this task

Follow the procedure to replace the default schema with the appropriate ICD-9 and ICD-10 schema.

Maps impacted	Input card number and name	Default type schema	ICD-9 and ICD-10 type schema
x12t2precontentcheck	#1 X12_Func_Group	hipaa_x12_type_2	hipaa_x12_type_2_icd9_icd10
x12t4precontentcheck	#1 X12_Func_Group	hipaa_x12	hipaa_x12_icd9_icd10
xhipaasegmentdataaudit	#1 Transaction_Set_Segments	hipaa_x12_segment	hipaa_x12_segment_icd9_icd10

### Procedure

1. Open map source file compliance\_check in the Design Server.
2. Double-click the executable map to select the map for modification.
3. Edit the input card for the map to point to the appropriate \*\_icd9\_icd10 schema instead of the default schema.
4. Select YES when prompted, then replace all similar schema paths in all maps.
5. Build all maps.

## Changing maps impacted in the hipaa\_x12\_pass\_through source map

If both the ICD-9 and ICD-10 codes are required, the schemas in the hipaa\_x12\_pass\_through source map must be replaced.

### About this task

Follow this procedure for each map that is impacted in the hipaa\_x12\_pass\_through source map.

Maps impacted	Input card number and name	Default type schema	ICD-9 and ICD-10 schema
hipaa_x12_pass_through	#1 HIPAA_X12_Inbound_Transmission	hipaa_x12	hipaa_x12_icd9_icd10
hipaa_x12_pass_through	#2 HIPAA_X12_Outbound_Transmission	hipaa_x12	hipaa_x12_icd9_icd10
hipaa_x12_type_1	No changes are required.	-	-
hipaa_x12_type_2	#1 HIPAA_X12_Inbound_Transmission	hipaa_x12_type_2	hipaa_x12_type_2_icd9_icd10
hipaa_x12_type_2	#2 HIPAA_X12_Outbound_Transmission	hipaa_x12_type_2	hipaa_x12_type_2_icd9_icd10

### Procedure

1. Open source map hipaa\_x12\_pass\_through by using Design Server.
2. Double-click on the executable map to select it for modification.
3. Edit the input card that is listed to point to the appropriate \*\_icd9\_icd10 schema instead of the default type schema.
4. Select NO when prompted, then replace all similar schema paths in all of the maps.
5. Edit the Output card with the same number as the input card that you modified to point to the appropriate \*\_icd9\_icd10 schema instead of the default schema.
6. Select NO when prompted, then replace all similar schema paths in all maps.
7. Build the maps after all maps are updated.

## Changing other maps

This documentation describes changes to other maps in the Pack for Healthcare.

### About this task

Follow these procedures to change any of the remaining maps.

### Procedure

1. Open the map source by using the Design Server.
2. Double-click the executable map to select it for modification.
3. Edit the input of the output card that is using the hipaa\_x12 schema as the default schema to point to the hipaa\_x12\_icd9\_icd10 schema.

4. Select YES when prompted, then replace all similar schema paths in all maps.
  5. Build the maps after they are updated.
- 

## Maps

The Pack for Healthcare includes data transformation maps and maps for data validation. Data validation maps are either pass-through maps or related to the Compliance Check application.

- **[Data transformation maps](#)**

The data transformation maps that are included in the Pack for Healthcare convert data from one healthcare data format to another. The data transformation maps are described here.

- **[Data validation maps](#)**

The data validation maps that are included in the Pack for Healthcare are used for data validation and reporting.

- **[Compliance checking maps](#)**

The compliance checking maps verify compliance with HIPAA standards.

---

## Data transformation maps

The data transformation maps that are included in the Pack for Healthcare convert data from one healthcare data format to another. The data transformation maps are described here.

All data transformation maps have self-describing names with `_to_` separating the names of the source and target data formats. The executable map name is the same as the map name. By default, an execution summary audit log named `<executable-map-name>.log` is created in the map directory when the data transformation map is executed.

The maps included in the maps folder of the Pack for Healthcare fall into four categories:

- Institutional claims and coordination of benefits
- Professional claims and coordination of benefits
- Healthcare claims payments
- Healthcare claims status request and response

The maps install within the imported project.

- [\*\*Institutional claims and coordination of benefits\*\*](#)
  - [\*\*Professional claims and coordination of benefits maps\*\*](#)
  - [\*\*Healthcare claims payments maps\*\*](#)
  - [\*\*Healthcare claims status request and response maps\*\*](#)
- 

## Institutional claims and coordination of benefits

The following maps are used for institutional claims and benefit coordination:

- `cms_837i_5010_flat_to_hipaa`
  - `hipaa_837i_5010_to_cms_flat`
  - [\*\*`cms\_837i\_5010\_flat\_to\_hipaa.map`\*\*](#)
  - [\*\*`hipaa\_837p\_5010\_to\_cms\_flatmap.map`\*\*](#)
- 

## [\*\*cms\\_837i\\_5010\\_flat\\_to\\_hipaa map\*\*](#)

The `cms_837i_5010_flat_to_hipaa` map accepts CMS (formerly HCFA) Part A 5010 claims in flat-file format and generates a HIPAA transmission containing institutional claim and coordination of benefits (837i) transaction sets.

---

## [\*\*hipaa\\_837p\\_5010\\_to\\_cms\\_flatmap map\*\*](#)

The `hipaa_837p_5010_to_cms_flat` map accepts HIPAA professional claim (837p) data and generates the CMS Part A flat file.

---

## Professional claims and coordination of benefits maps

Professional claims and coordination of benefits maps, include these maps:

- `cms_837p_5010_flat_to_hipaa`
- `hipaa_837p_5010_to_cms_flat`
- [\*\*`cms\_837p\_5010\_flat\_to\_hipaa.map`\*\*](#)

- [hipaa\\_837p\\_5010\\_to\\_cms\\_flatmap.map](#)

---

## cms\_837p\_5010\_flat\_to\_hipaa map

The cms\_837p\_5010\_flat\_to\_hipaa map accepts CMS Part B 5010 claim data in flat file format and generates a HIPAA transmission containing professional claim and coordination of benefits (837p) transaction sets.

---

## hipaa\_837p\_5010\_to\_cms\_flatmap map

The hipaa\_837p\_5010\_to\_cms\_flat map accepts HIPAA professional claim (837p) data and generates the CMS Part A flat file.

---

## Healthcare claims payments maps

The following are healthcare claims payments maps:

- [cms\\_835\\_5010\\_flat\\_to\\_hipaa](#)
- [hipaa\\_835\\_5010\\_to\\_cms\\_flat](#)
- [\*\*cms\\_835\\_5010\\_flat\\_to\\_hipaa map\*\*](#)  
The cms\_835\_5010\_flat\_to\_hipaa map is used for data transformation from the CMS 835 professional and institutional flat file format to HIPAA transmissions containing 835 payment transactions.
- [\*\*hipaa\\_835\\_5010\\_to\\_cms\\_flat map\*\*](#)  
The hipaa\_835\_5010\_to\_cms\_flat map is for HIPAA transmissions containing 835 payment transactions in the CMS 835 professional and institutional flat-file format.

---

## cms\_835\_5010\_flat\_to\_hipaa map

The cms\_835\_5010\_flat\_to\_hipaa map is used for data transformation from the CMS 835 professional and institutional flat file format to HIPAA transmissions containing 835 payment transactions.

---

## hipaa\_835\_5010\_to\_cms\_flat map

The hipaa\_835\_5010\_to\_cms\_flat map is for HIPAA transmissions containing 835 payment transactions in the CMS 835 professional and institutional flat-file format.

---

## Healthcare claims status request and response maps

This section describes the following maps:

- [hipaa\\_276\\_5010\\_to\\_cms\\_flat](#)
- [cms\\_276\\_5010\\_flat\\_to\\_hipaa](#)
- [hipaa\\_277\\_5010\\_to\\_cms\\_flat](#)
- [cms\\_277\\_5010\\_flat\\_to\\_hipaa](#)
- [hipaa\\_277ca\\_5010\\_to\\_cms\\_flat](#)
- [cms\\_277ca\\_5010\\_flat\\_to\\_hipaa](#)
- [\*\*hipaa\\_276\\_5010\\_to\\_cms\\_flat map\*\*](#)  
The hipaa\_276\_5010\_to\_cms\_flat map accepts a HIPAA X12 transmission containing institutional claim status request 276 transaction sets. It generates professional and institutional claim status requests in CMS Part A and Part B flat file formats.
- [\*\*cms\\_276\\_5010\\_flat\\_to\\_hipaa map\*\*](#)  
The cms\_276\_5010\_flat\_to\_hipaa map accepts claim status requests in CMS Part A and Part B flat-file format and generates a HIPAA X12 transmission containing professional and institutional claim status request 276 transaction sets
- [\*\*hipaa\\_277\\_5010\\_to\\_cms\\_flat map\*\*](#)  
The hipaa\_277\_5010\_to\_cms\_flat map accepts HIPAA X12 transmission containing institutional claim status response 277 transaction sets and generates professional and institutional claim status response in CMS Part A and Part B flat file format.
- [\*\*cms\\_277\\_5010\\_flat\\_to\\_hipaa map\*\*](#)  
The cms\_277\_5010\_flat\_to\_hipaa map accepts claim status responses in CMS Part A and Prt B flat file format and generates a HIPAA X12 transmission containing professional and institutional claim status response 277 transaction sets.
- [\*\*hipaa\\_277ca\\_5010\\_to\\_cms\\_flat map\*\*](#)  
The hipaa\_277ca\_5010\_to\_cms\_flat map accepts a HIPAA X12 transmission containing claim acknowledgment 277ca transaction sets and generates claim acknowledgment in CMS flat file format.
- [\*\*cms\\_277ca\\_5010\\_flat\\_to\\_hipaa map\*\*](#)  
The cms\_277ca\_5010\_flat\_to\_hipaa map accepts claim acknowledgment in CMS flat file format and generates a HIPAA X12 transmission containing claim acknowledgment 277ca transaction sets.

## **hipaa\_276\_5010\_to\_cms\_flat map**

The hipaa\_276\_5010\_to\_cms\_flat map accepts a HIPAA X12 transmission containing institutional claim status request 276 transaction sets. It generates professional and institutional claim status requests in CMS Part A and Part B flat file formats.

## **cms\_276\_5010\_flat\_to\_hipaa map**

The cms\_276\_5010\_flat\_to\_hipaa map accepts claim status requests in CMS Part A and Part B flat-file format and generates a HIPAA X12 transmission containing professional and institutional claim status request 276 transaction sets

## **hipaa\_277\_5010\_to\_cms\_flat map**

The hipaa\_277\_5010\_to\_cms\_flat map accepts HIPAA X12 transmission containing institutional claim status response 277 transaction sets and generates professional and institutional claim status response in CMS Part A and Part B flat file format.

## **cms\_277\_5010\_flat\_to\_hipaa map:**

The cms\_277\_5010\_flat\_to\_hipaa map accepts claim status responses in CMS Part A and Prt B flat file format and generates a HIPAA X12 transmission containing professional and institutional claim status response 277 transaction sets.

## **hipaa\_277ca\_5010\_to\_cms\_flat map**

The hipaa\_277ca\_5010\_to\_cms\_flat map accepts a HIPAA X12 transmission containing claim acknowledgment 277ca transaction sets and generates claim acknowledgment in CMS flat file format.

## **cms\_277ca\_5010\_flat\_to\_hipaa map:**

The cms\_277ca\_5010\_flat\_to\_hipaa map accepts claim acknowledgment in CMS flat file format and generates a HIPAA X12 transmission containing claim acknowledgment 277ca transaction sets.

## **Data validation maps**

The data validation maps that are included in the Pack for Healthcare are used for data validation and reporting.

These maps are either pass-through maps, or they are related to the Compliance Check application for HIPAA X12 data validation.

- [Pass-through maps](#)

## **Pass-through maps**

Also known as validation maps, pass-through maps validate data definitions by using the same schema for the input cards as the output cards.

Pass-through maps have self-describing names with \_pass\_through following the name of the data format. The executable map name is the same as the map source file name. By default, an execution summary audit log named <executable-map-name>.log is created in the map directory when the pass-through map is executed.

This section describes the following map source files:

- hipaa\_x12\_pass\_through
- cms\_276\_5010\_flat\_pass\_through
- cms\_277\_5010\_flat\_pass\_through
- cms\_277ca\_5010\_flat\_pass\_through
- cms\_835\_5010\_flat\_pass\_through
- cms\_837i\_5010\_flat\_pass\_through
- cms\_837p\_5010\_flat\_pass\_through
- [Source map: hipaa\\_x12\\_pass\\_through](#)  
The hipaa\_x12\_pass\_through source map uses the hipaa\_x12 schema and checks WEDI/SNIP Type 1 through Type 4. The map validates HIPAA X12 transmission data against the Partner X12 Inbound Transmission EDI and Partner X12 Outbound Transmission EDI definitions in the hipaa\_x12 schema.
- [Source map: cms\\_276\\_5010\\_flat\\_pass\\_through](#)  
The cms\_276\_5010\_flat\_pass\_through.mms source map validates CMS claim status request (276) flat file data against the cms\_276\_5010 flat file data definition

- in the **cms\_276\_277\_5010\_flat** schema.
- **Source map: cms\_277\_5010\_flat\_pass\_through**  
The **cms\_277\_5010\_flat\_pass\_through** source map validates CMS claim status response (277) flat file data against the **cms\_277\_5010\_flat** file data definition in the **cms\_276\_277\_5010\_flat** schema.
  - **Source map: cms\_277ca\_5010\_flat\_pass\_through**  
The **cms\_277ca\_5010\_flat\_pass\_through** source map validates CMS claim acknowledgment (277ca) flat file data against the **cms\_277ca\_5010\_flat** file data definition in the **cms\_277ca\_5010\_flat** schema.
  - **Source map: cms\_835\_5010\_flat\_pass\_through**  
The **cms\_835\_5010\_flat\_pass\_through** source map validates CMS claim payment 835 flat file data against the **cms\_835\_5010a1\_flat\_file** data definition in the **cms\_835\_5010a1\_flat** schema.
  - **Source map: cms\_837i\_5010\_flat\_pass\_through**  
The **cms\_837i\_5010\_flat\_pass\_through** source map validates CMS institutional claim and coordination of benefits 837I flat file data against the **cms\_837i\_5010a2\_flat\_file** data definition in the **cms\_837i\_5010a2\_flat** schema.
  - **Source map: cms\_837p\_5010\_flat\_pass\_through**  
The **cms\_837p\_5010\_flat\_pass\_through** source map validates CMS professional claim and coordination of benefits 837P flat file data against the **cms\_837p\_5010a1\_flat\_file** data definition in the **cms\_837p\_5010a1\_flat** schema.
- 

## Source map: hipaa\_x12\_pass\_through

The **hipaa\_x12\_pass\_through** source map uses the **hipaa\_x12** schema and checks WEDI/SNIP Type 1 through Type 4. The map validates HIPAA X12 transmission data against the Partner X12 Inbound Transmission EDI and Partner X12 Outbound Transmission EDI definitions in the **hipaa\_x12** schema.

This map also includes some pre-defined data audit log settings that can be left as-is or modified and then activated by setting Data SettingsAudit in MapAudit to ON.

## Source map: cms\_276\_5010\_flat\_pass\_through

The **cms\_276\_5010\_flat\_pass\_through.mms** source map validates CMS claim status request (276) flat file data against the **cms\_276\_5010** flat file data definition in the **cms\_276\_277\_5010\_flat** schema.

## Source map: cms\_277\_5010\_flat\_pass\_through

The **cms\_277\_5010\_flat\_pass\_through** source map validates CMS claim status response (277) flat file data against the **cms\_277\_5010\_flat** file data definition in the **cms\_276\_277\_5010\_flat** schema.

## Source map: cms\_277ca\_5010\_flat\_pass\_through

The **cms\_277ca\_5010\_flat\_pass\_through** source map validates CMS claim acknowledgment (277ca) flat file data against the **cms\_277ca\_5010\_flat** file data definition in the **cms\_277ca\_5010\_flat** schema.

## Source map: cms\_835\_5010\_flat\_pass\_through

The **cms\_835\_5010\_flat\_pass\_through** source map validates CMS claim payment 835 flat file data against the **cms\_835\_5010a1\_flat\_file** data definition in the **cms\_835\_5010a1\_flat** schema.

## Source map: cms\_837i\_5010\_flat\_pass\_through

The **cms\_837i\_5010\_flat\_pass\_through** source map validates CMS institutional claim and coordination of benefits 837I flat file data against the **cms\_837i\_5010a2\_flat** file data definition in the **cms\_837i\_5010a2\_flat** schema.

## Source map: cms\_837p\_5010\_flat\_pass\_through

The **cms\_837p\_5010\_flat\_pass\_through** source map validates CMS professional claim and coordination of benefits 837P flat file data against the **cms\_837p\_5010a1\_flat\_file** data definition in the **cms\_837p\_5010a1\_flat** schema.

## Compliance checking maps

The compliance checking maps verify compliance with HIPAA standards.

The following compliance checking maps are provided in the Pack for Healthcare:

- compliance\_check
  - utilities\_validation\_check
- 

## Sample data

Sample data is provided for use with the schemas and maps in the Pack for Healthcare.

- [Overview of sample data](#)

The data files contain either transaction data in one or more data exchange formats or application data used by the Compliance Check application for HIPAA X12 data validation.

- [Transaction data](#)

This contains sample transaction data for HIPAA X12 and CMS.

- [Compliance check data](#)

The Pack for Healthcare contains data files that are used by the Compliance Check application for HIPAA X12 data validation.

---

## Overview of sample data

The data files contain either transaction data in one or more data exchange formats or application data used by the Compliance Check application for HIPAA X12 data validation.

The Pack for Healthcare provides sample data for HIPAA X12, CMS, and Compliance Checker. For more information about the Compliance Checker data files, see [HIPAA Compliance Checking](#).

The data files are installed within the imported project where they are used, as there are multiple projects that reference different sample data.

---

## Transaction data

This contains sample transaction data for HIPAA X12 and CMS.

- [HIPAA X12](#)

The HIPAA X12 sample data includes transmission data for the finalized HIPAA X12 transaction set definitions.

- [CMS sample data](#)

The CMS sample data includes transmission data for the flat file interface data formats associated with the HIPAA 5010 transaction definitions, and the finalized addenda definitions.

---

## HIPAA X12

The HIPAA X12 sample data includes transmission data for the finalized HIPAA X12 transaction set definitions.

There is one file per version, or industry code, and one file that contains all of the sample data.

The naming convention includes the hipaa transaction version, and the x12 transaction number(s).

For example, the sample data for the 276 transaction defined in the HIPAA 5010X212 TR3 is named hipaa\_5010\_x212\_276\_sample.dat.

There is also a sample data file that contains all the transactions supported. This is named all\_hipaa\_5010\_transaction\_sets.dat.

---

## CMS sample data

The CMS sample data includes transmission data for the flat file interface data formats associated with the HIPAA 5010 transaction definitions, and the finalized addenda definitions.

The sample data is based on transformations of the HIPAA X12 transaction sets data included with the Pack for Healthcare.

The naming convention includes the HIPAA transaction version, and x12 transaction number(s).

For example, the sample for the CMS 276 flat file format is cms\_flat\_5010\_x212\_276\_sample.dat.

---

## Compliance check data

The Pack for Healthcare contains data files that are used by the Compliance Check application for HIPAA X12 data validation.

The following Compliance Check data files are provided:

- compliance\_check\_5010\_parameter.dat (default)
- hipaa\_x12\_qualifier.dat
- hipaa\_x12\_structure.dat

- hipaa\_x12\_type\_6\_value.dat
  - hipaa\_x12\_type\_7\_value.dat
  - tack\_codetable.dat
  - compliance\_check\_tack.css
  - plus.gif
  - minus.gif
- 

## HIPAA Compliance Checking

The Pack for Healthcare uses the types of HIPAA data transmission testing documented in the "Transaction Compliance and Certification" white paper developed by the workgroup for Electronic Data Interchange (WEDI) Strategic National Implementation Process (SNIP) Transactions Work Group - Testing Sub Work-Group; Dated June 11, 2002.

HIPAA Compliance Check for HIPAA X12 data validation and compliance reporting contains a series of executable maps used to validate HIPAA X12 transmission data and to report compliance with industry requirements. The compliance\_check file is the source file for the HIPAA Compliance Check. This provides a non-partner configurable way to check WEDI/SNIP Type 1 through Type 4.

HIPAA Data compliance has greater capabilities than the HIPAA Compliance Check. In addition to checking WEDI/SNIP Type 1 through Type 4, it also enables checking WEDI/SNIP Type 5 through Type 7. External Code set values will be checked against values loaded into a MongoDB or similar noSQL Database.

- [\*\*WEDI SNIP transaction compliance types\*\*](#)

The HIPAA Compliance Checker supports the data validation and compliance reporting for Types 1 through 7. WEDI SNIP Type 1 through 7 validation 'rules' are included in the components of the product. The rules for the higher levels of validation are user-configurable.

- [\*\*Type 1 EDI Standard Integrity Testing\*\*](#)

Type 1 EDI Standard Integrity Testing validates the basic syntactical integrity of the EDI submission.

- [\*\*Type 2 HIPAA Implementation Guide Requirement Testing\*\*](#)

Type 2 testing involves testing for HIPAA implementation guide-specific syntax requirements.

- [\*\*Type 3 HIPAA Balance Testing\*\*](#)

Type 3 balance testing ensures that the sum of the claim line item amounts is equal to the total claim amount.

- [\*\*Type 4 HIPAA Inter-segment Situation Testing\*\*](#)

Type 4 involves testing specific inter-segment situations described in the HIPAA implementation guides, such that if A occurs, then B must be populated. This is considered to include the validation of situational fields given values or situational elements present in other data segments. For example, the accident date must be present if the claim is for an accident.

- [\*\*Type 5 HIPAA External Code Set Testing\*\*](#)

Type 5 validation involves validating data content against code sets from external code sources as explicitly defined in the implementation guides for use with HIPAA standards. Examples of HIPAA X12 code sets include the 508 Health Care Claim Status Codes, available from Washington Publishing Company. Another example is the 537 National Provider Identifiers which are available from the Centers for Medicare and Medicaid (CMS).

- [\*\*Type 6 HIPAA Line of Service Testing\*\*](#)

Type 6 validation is used to ensure that HIPAA transaction data for claims meets specific requirements that are related to specialized healthcare service, or products such as medically related transport, durable medical equipment, or chiropractic treatment.

- [\*\*Type 7 Companion Guide Testing\*\*](#)

Some HIPAA specific Medicare, Medicaid and Indian Health requirements are contained in the HIPAA Implementation Guides. Not all trading partners, however, require compliance with these requirements. If a trading partner wants to exchange transactions with one of these payers, Type 7 validation is required.

- [\*\*Parameters for HIPAA processing\*\*](#)

---

## WEDI SNIP transaction compliance types

The HIPAA Compliance Checker supports the data validation and compliance reporting for Types 1 through 7. WEDI SNIP Type 1 through 7 validation 'rules' are included in the components of the product. The rules for the higher levels of validation are user-configurable.

Types 1 through 7 of HIPAA data transmission testing are defined as follows:

- Type 1 EDI Standard Integrity Testing
  - Type 2 HIPAA Implementation Guide Requirement Testing
  - Type 3 HIPAA Balance Testing
  - Type 4 HIPAA Inter-Segment Situation Testing
  - Type 5 HIPAA External Code Set Testing
  - Type 6 HIPAA Line of Service Testing
  - Type 7 Companion Guide Requirement Testing
- 

## Type 1 EDI Standard Integrity Testing

Type 1 EDI Standard Integrity Testing validates the basic syntactical integrity of the EDI submission.

Type 1 testing conducts a test of the EDI file for the following:

- valid segments
- segment order
- element attributes
- numeric values in numeric data elements
- validation of X12 syntax
- compliance with X12 semantic rules

Reporting options for Type 1 exceptions identified by the Transformation Extender HIPAA Compliance Checker includes the TA1 interchange acknowledgment, the standard X12 997 functional acknowledgment, the HIPAA 999 implementation acknowledgment, and the Translated Acknowledgment report.

## Type 2 HIPAA Implementation Guide Requirement Testing

Type 2 testing involves testing for HIPAA implementation guide-specific syntax requirements.

Type 2 testing checks for the following:

- Limits on repeat counts
- Used and not used qualifiers
- Elements and segments

There is also testing for:

- HIPAA required or intra-segment situational data elements
- Values and codes explicitly called out in the HIPAA Implementation Guides.
- Values and codes noted in the implementation guide (by means of an X12 code list or table)
- HL, LX, ENT, IT1 sequencing
- HL parent-child relationships

The options for reporting Type 2 exceptions identified by the Transformation Extender HIPAA Compliance Checker include the TA1 interchange acknowledgment, the HIPAA 999 implementation acknowledgment, and the Translated Acknowledgement report.

## Type 3 HIPAA Balance Testing

Type 3 balance testing ensures that the sum of the claim line item amounts is equal to the total claim amount.

Type 3 testing involves checking a transaction for the following conditions:

- Balanced field totals
- Financial balancing of claims or remittance advice
- Balancing of summary fields (if appropriate)

The options for reporting Type 3 exceptions identified by the Transformation Extender HIPAA Compliance Checker include the HIPAA 999 implementation acknowledgment and the Translated Acknowledgment report.

## Type 4 HIPAA Inter-segment Situation Testing

Type 4 involves testing specific inter-segment situations described in the HIPAA implementation guides, such that if A occurs, then B must be populated. This is considered to include the validation of situational fields given values or situational elements present in other data segments. For example, the accident date must be present if the claim is for an accident.

If the XML\_Validation parameter is set to X or S, validation of the XML data in the BIN segment of the 4050 or 5010 275 (Additional Information to Support a Health Care Claim) is supported under Type 4 testing.

The options for reporting Type 4 exceptions identified by the Transformation Extender HIPAA Compliance Checker includes the HIPAA 999 implementation acknowledgment and the Translated Acknowledgement report.

## Type 5 HIPAA External Code Set Testing

Type 5 validation involves validating data content against code sets from external code sources as explicitly defined in the implementation guides for use with HIPAA standards. Examples of HIPAA X12 code sets include the 508 Health Care Claim Status Codes, available from Washington Publishing Company. Another example is the 537 National Provider Identifiers which are available from the Centers for Medicare and Medicaid (CMS).

The options for reporting Type 5 exceptions include the HIPAA 999 implementation acknowledgment and the Translated Acknowledgment report.

Applicable Type 5 rules for the Claim Transactions (837) will now use the service date from the claim and not the processing date to determine if the code is valid for this particular date.

## Date Segments used for Type 5 Validation

For Type 5 validation for codes within segments in the Claim (2300) Loop, such as HI:

- Institutional Claim validation will use 2300 Statement Dates, DTP\*434, a required segment that specifies a date range.
- Professional Claim validation will use the range of dates from the earliest to the latest Service Level Dates in the 2400 DTP\*472.
- Dental claim validation will use the 2300 Service Date, DTP\*472, if present. This can be a single date or a range. If this is not present, the range of 2400 DTP\*472 Service Dates will be used.

For Type 5 validation for codes within segments in the Service (2400) Loop, such as SV1, SV2, and SV3:

- Institutional claim validation will use 2400 Service Date if present. If this is not present, the 2300 Statement Date DTP\*434 will be used.

- Professional claim validation will use the Service Level Date in 2400 DTP\*472.
- Dental claim validation will use the 2400 Service Date, DTP\*472, if present. If this is not present, the 2300 DTP\*472 Service Date will be used.

## Code list applicable for Service Date used in Type 5 Validation

The following code lists are used in fields present in the claim and service loops of claim transactions, which represent medical code sets that could have start and/or end dates for the code value usage.

For some of these, the default validation is Pattern Match, as the Healthcare Pack does not include these code sets for licensing or other reasons. For the new Service Date functionality to be used with these, the user will need to load those code sets with included start and/or end dates and update the corresponding rules to use CV or Code Value instead of PM or Pattern Match.

Code source	Description
130	Healthcare Common Procedural Coding System
131	International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM)
132	National Uniform Billing Committee
133	Current Procedural Terminology (CPT) Codes
135	American Dental Association
229	Diagnosis-Related Group Number
240	National Drug Code by Format
513	Home Infusion EDI Coalition (HIEC) Product/Service Code List
576	Workers Compensation Specific Procedure and Supply Codes
716	Health Insurance Prospective Payment System (HIPPS) Rate Code for Skilled Nursing Facilities
843	Advanced Billing Concepts (ABC) Codes
896	International Classification of Diseases, 10th Revision, Procedure Coding System (ICD-10-PCS)
897	International Classification of Diseases, 10th Revision, Clinical Modification (ICD-10-CM)

## Type 6 HIPAA Line of Service Testing

Type 6 validation is used to ensure that HIPAA transaction data for claims meets specific requirements that are related to specialized healthcare service, or products such as medically related transport, durable medical equipment, or chiropractic treatment.

For example, the Situational Rule for the Ambulance Transport Information (CR1 Segment in the Claim Information (2300) Loop of the Health Care Claim: Professional (X222A1 -837)) transaction set states that the segment is "Required on all claims involving ambulance transport services."

- **HIPAA operating rules**

HIPAA Operating Rules Section of the Affordable Care Act (ACA) was enacted and amended in March 2010 and requires the adoption of a single set of operating rules for each of the transactions listed in the ACA.

## HIPAA operating rules

HIPAA Operating Rules Section of the Affordable Care Act (ACA) was enacted and amended in March 2010 and requires the adoption of a single set of operating rules for each of the transactions listed in the ACA.

There are several types of Operating Rules in CAQH CORE Phase I and Phase II, and the rules surrounding the standard compliance of the data content are the type of rules that are implemented in the HIPAA Compliance Check module. Other categories of rules (such as rules governing response time and rules related to the formatting of Implementation Guides) are not enforced by the Compliance Check module. These rules are expressed as if they were WEDI/SNIP Type 4 rules, which allows them to be reported on the 999 Business Acknowledgment. By default, these rules are disabled when the product is installed and must be manually enabled in order for these data extra checks to be performed.

The rule text reported on a failure of one of these rules will begin with an Operating Rule Indicator ("OR") plus the phase of CAQH CORE which describes the rule ("I" or "II"). For example:

"ORI - 2110C EB05 required when 2110C present"

## Type 7 Companion Guide Testing

Some HIPAA specific Medicare, Medicaid and Indian Health requirements are contained in the HIPAA Implementation Guides. Not all trading partners, however, require compliance with these requirements. If a trading partner wants to exchange transactions with one of these payers, Type 7 validation is required.

When a trading partner is certified for compliance, the certification service must indicate whether or not the payer specific requirements are met.

Trading partners can have their own business requirements, but the requirements must be listed in the HIPAA Implementation Guides in order to meet HIPAA requirements.

## Parameters for HIPAA processing

- **HIPAA Data Compliance Parameters**

Parameters for the HIPAA Data Compliance are set in the JSON formatted parameter file, hipaa\_data\_compliance\_parameter.json.

- **HIPAA Compliance Check Parameters**

Parameters used for the Compliance Check application are set in the compliance\_check\_5010\_paramater.dat file.

## HIPAA Data Compliance Parameters

Parameters for the HIPAA Data Compliance are set in the JSON formatted parameter file, hipaa\_data\_compliance\_parameter.json.

This file contains a meaningful grouping of parameters:

- GeneralValidation
- ValidationLevels
- Acknowledgments
- Tuning

The following table has details of the setting allowed. If any field is not included in the hipaa\_data\_compliance\_parameter.json file, the default will be used.

In the following table, the \* (asterisk) indicates the default value.

Since the format of this parameter file is JSON, the name and parameter values that are text strings must always be enclosed in double quotes. The value, if Boolean is true or false, does not need to be quoted. A few of the parameters are numeric values, and they do not need to be quoted either.

Examples:

"Enabled": false

"WhenIfEnabled": "Errors"

It is recommended that a JSON aware editor is used, that will flag invalid syntax such as missing or extra commas and quotes.

Parameter tag name	Values	Description
Environment ProductName	H	The ProductName parameter is used to identify the product that has invoked the compliance check application. If parameter is used, it should always be H.
Environment OperatingSystem	L A U M W	The OperatingSystem parameter is used to override the dynamic determination of the UNIX operating system from the format of the input data file. It is always recommended to specify the operating system using this parameter. Allowable settings include: L (Linux), A (AIX), U (USS), M (MVS - z/OS), W (Windows)
Environment BaseMapDirectory	C:\\DIR\\ Or /dir/	The BaseMapDirectory parameter specifies the directory for compiled maps that will be executed by hipaa_data_compliance.mmc via the RUN function. There is NO default setting for this parameter. If the parameter is not specified, then the directory from which hipaa_data_compliance.mmc is being executed will be used. This parameter cannot be used for z/OS. Note: Final slash must be used. Since the input is in JSON Format back slash must be doubled if specifying directory on Windows.
Environment BaseExitDirectory	C:\\DIR\\ Or /dir/	The BaseExitDirectory parameter specifies the directory for executables invoked via the EXIT function. There is NO default setting for this parameter. If the parameter is not specified, then the system library path will be used. This parameter cannot be used for z/OS. Note: Final slash must be used. Since the input is in JSON Format back slash must be doubled if specifying directory on Windows.
Environment DataBaseQueryType	JDBC MONGO*	The DataBaseQueryType is used to indicate the type of database access for Code List validation in Type 5 and higher checks. The MRN file must still be updated for the specific access parameters.
GeneralValidation Validation Method	Map* Compliance Both	Map: This default setting sends all data through the pass through validation maps and only the invalid data goes through the subsequent processing, and also valid data that must be processed for rules only supported by the detailed compliance check processing. This is the recommended, and the default setting.  Compliance: This setting causes all data to be passed to the detailed processing done by the Compliance Check application.  Both: This setting causes all data to be processed both by the pass through validation maps and the detailed compliance check validation. If there is a large amount of data, this option can slow the process. This option is used for troubleshooting purposes, logic modules, or both.
GeneralValidation RejectUnsupported5010Version	true* - Reject unsupported 5010 versions in the envelope checking process.  false - Don't reject unsupported versions, and validate them at currently supported versions.	Indicates whether to reject an unsupported HIPAA 5010 version or whether to validate the data to the currently supported errata version.
GeneralValidation BINSegXMLValidation Enabled	true* - Validate Contents of BIN segment according to SchemaOrWellFormed Value. false - Never validate the contents of the BIN segment.	Indicates the validation level for XML BIN/BDS segment content.

Parameter tag name	Values	Description
GeneralValidation BINSegXMLValidation SchemaOrWellFormed	Schema - Validate the contents of the BIN segment for proper XML formatting and against the schema. XML - Validate the contents of the BIN segment for proper XML formatting and against the schema.	Type of validation to perform on BIN/BDS segment.
GeneralValidation n DuplicateISAChecks	true* false	Indicates whether interchange (ISA) envelopes should be checked for duplicates.
GeneralValidation n DuplicateIGSChecks	true false*	Indicates whether Functional Group control numbers should be checked for duplicates within an interchange.
GeneralValidation n DuplicateSTChecks (No I)	true* false	Indicates whether transaction set (ST) envelopes should be checked for duplicates.
GeneralValidation n Allow_GS_Leading_0	true false*	Indicates whether to allow leading zeros in the Functional Group control number (such as 0001) in the GS and GE segments.
GeneralValidation n ClaimLevelRejection Enabled	true false*	Indicates whether the transaction set is still accepted and the claim(s) in error are removed from the valid data. This parameter is only available to be used when the input HIPAA EDI data is a Claim (837).
GeneralValidation n ClaimLevelRejection Level	All – Only reject transaction set when all claims are in error or when an error is outside the Provider loops. If error is at the provider, subscriber, or patient level, all claims for that provider, subscriber, or patient will be rejected.  Claim - Reject transaction set when all claims are in error, or when error is outside of Claim Loop.	If the ClaimLevelRejection Enabled is true, this controls at which level the valid and invalid claims are separated.
ClaimLevelRejection DuplicateCLMCheckFullSegment	true false*	The Duplicate CLMCheckFullSegment controls whether just CLM01 or the full CLM segment is used to determine if claim level rejection processing can continue for this transaction.  If the parameter is set to true - Disable Claim level rejection, if the entire CLM segment is not unique for all claims in the transaction.  Note: Only CLM01 is used to populate the TRN information in the 277CA, so the user may have to handle any ambiguity in the resultant acknowledgment, if true is used
ClaimLevelRejection ReportErrorInSTC	true false*	Set the sub elements in the STC01 element at all 277CA and 277DR loop levels to reflect if all valid or an error was detected at that level or below and include a valid entity code instead of the generic Ack/Receipt code.
Tack HTMLOrJSON	HTML* JSON BOTH	Use the HTMLOrJSON parameter set to JSON or BOTH to optionally create ..../data/compliance_check_TAck.json in output card 13.  When either HTML or BOTH is used, the /data/compliance_check_TAck.html is produced in output card 11.  Note: Both creation and content are still controlled by the other parameters in the Tack group. This parameter only controls how the Tack is formatted.
ValidationLevels Type1 Enabled	true false*	Indicates whether WEDI/SNIP Type 1 checks should be performed on the input data. (Note any Type 1 error will be found if Type 2 is enabled; this only runs the Type 1 validation as a separate step, so it is not recommended).
ValidationLevels Type2 Enabled	true* false	Indicates whether WEDI/SNIP Type 2 checks should be performed on the input data.
ValidationLevels Type2 RelaxedStructureCheck	true false*	Indicates whether relaxed structure should be performed on the input data if it fails the type 2 structure checking process. This check will only be performed if there are errors found during the type 2 structure checking process - if no errors are found, it will be bypassed. It also can only be executed if type 2 checks are enabled.
ValidationLevels Type3 Enabled	true* false	Indicates whether WEDI/SNIP Type 3 checks should be performed on the input data.
ValidationLevels Type4 Enabled	true* false	Indicates whether WEDI/SNIP Type 4 checks should be performed on the input data.
ValidationLevels Type5 Enabled	true false*	Indicates whether WEDI/SNIP Type 5 checks should be performed on the input data.

Parameter tag name	Values	Description
ValidationLevels Type6 Enabled	true false*	Indicates whether WEDI/SNIP Type 6 checks should be performed on the input data.
ValidationLevels Type7 Enabled	true false*	Indicates whether WEDI/SNIP Type 7 checks should be performed on the input data.
ValidationLevels Type7 RejectLevel	Errors	Exceptions found in the custom user exit are treated as errors, and data will be rejected.
ValidationLevels Type7 ExitType	Java C None*	Indicates the language in which the custom user exit is written.
ValidationLevels Type7 ExitName	(User specific value) None*	Indicates the name of the custom user exit library name if the exit is written in C or jar file if the exit is written in Java.
ValidationLevels Type7 ExitFunction	(User specific value) None*	Indicates the name of the custom user exit function name within the library or jar file.
ValidationLevels Type7 ExitPartnerDetail	true false*	Include ISA Sender and Receiver IDs, ISA Control number, GS Sender and Receiver Codes and GS Control number in the transaction data passed to the Type 7 user exit.
Acknowledgments TA1 Enabled	true false*	Indicates whether the results from the WEDI/SNIP Type 1 interchange envelope checks should be reported using the X12 standard TA1 segment.
Acknowledgments TA1 WhenEnabled	Errors* - Generate an X12 standard TA1 for the interchange only when the results of the compliance check indicate the presence of Type 1 errors in the interchange envelope.  Always - Always generate an X12 standard TA1 for all interchanges even if compliance check does not indicate the presence of Type 1 errors in the interchange envelope.  Requested - Generate an X12 standard TA1 for all interchanges based on the value in the input ISA14.  Input ISA14 value of 0 - No Interchange Acknowledgment Requested will identify the same behavior as Never.  Input ISA14 value of 1 - Interchange Acknowledgment Requested (TA1) will identify the same behavior as Always.	If Enabled, determine when the TA1 is generated.
Acknowledgments TA1 Separate	true* false	Indicates whether TA1 acknowledgments should be created in a separate response transmission or be combined with the response transmission that contains the 997 acknowledgment transaction sets.
Acknowledgments 997 Enabled	true false*	Indicates whether the results from the WEDI/SNIP Type 1 checks should be reported using the X12 standard 997 transaction set.  If Type 1 checks are not enabled, this will be set to false.
Acknowledgments 997 WhenEnabled	Errors* - Generate an X12 standard 997 for the interchange only when the results of the compliance check indicate the presence of Type 1 errors in the interchange  Always - Always generate an X12 standard 997 for all interchanges even if compliance check does not indicate the presence of Type 1 errors.	Indicates when the results from the WEDI/SNIP Type 1 checks should be reported using the X12 standard 997 transaction set.
Acknowledgments 997 DetailMax	(User-specified numeric value) 9999*	Indicates when we should stop producing detailed 997 error information for a single transaction. If the number of error lines, not total errors, to be produced in the 997 for the received transaction exceeds this limit, then the logic to generate the detailed error information in the AK3/AK4 loop will be bypassed. As the number of errors for a single transaction increases, the processing time required to detect and report these also increases, so increasing this limit will decrease performance when processing transactions containing numerous errors.  The setting for this value will determine the maximum number of error lines produced in the 997 for a single transaction.

Parameter tag name	Values	Description
Acknowledgments_HIPAA_TA1_Enabled	true false*	Indicates whether the results from the WEDI/SNIP Type 2 interchange envelope checks using HIPAA specific code values should be reported using the TA1 segment.
Acknowledgments_HIPAA_TA1_WhenIfEnabled	Errors* - Generates an X12 standard TA1 for the interchange only Type 1 errors present in the interchange envelope.  Always - Always generates an X12 standard TA1 for all interchanges, even if Type 1 errors are not present in the interchange envelope.  Requested - Generates an X12 standard TA1 for all interchanges based on the value in the input ISA14.  Input ISA14 value of 0 - No Interchange Acknowledgment Requested will identify the same behavior as Never.  Input ISA14 value of 1 - Interchange Acknowledgment Requested (TA1) will identify the same behavior as Always.	If Enabled, determine when the TA1 is generated.
Acknowledgments_999_Enabled	true false*	Indicates whether the results from the WEDI/SNIP checks should be reported using the HIPAA specific 999 transaction set.
Acknowledgments_999_WhenIfEnabled	Errors - Generates only when WEDI/SNIP type errors are present in the interchange.  Always* - Always generates even if WEDI/SNIP type errors are not present in interchange.	Indicates when the results from the WEDI/SNIP checks should be reported using a HIPAA specific 999.
Acknowledgments_999_IK3MissingSeg	true false*	For implementation dependent missing segments (I6), use true for this setting if the missing segment is to be reported in the IK3. This will result in more information in the 999 by allowing the existing segment to be included in a CTX segment. Since the segment is missing, the segment position indicated will vary – it may be the position of the existing segment that caused the requirement, the segment location in the transaction where it was determined the missing segment was not present, or the end of a loop.  Use false to report the existing segment, which caused the requirement for the missing segment to be reported in the IK3.
Acknowledgments_999_DetailMax	(User specified numeric value) 9999*	Indicates when we should stop producing detailed HIPAA 999 error information for a single transaction. If the number of error lines, not total errors, to be produced in the HIPAA 999 for the received transaction exceeds this limit, then the logic to generate the detailed error information in the AK3/AK4 loop will be bypassed.  As the number of errors for a single transaction increases, the processing time required to detect and report these also increases, so increasing this limit will decrease performance when processing transactions containing numerous errors.  The setting for this value will determine the maximum number of error lines produced in the HIPAA 999 for a single transaction.
Acknowledgments_277CA_Enabled	true false*	Indicates whether the results from the Claim Level Rejection process should be reported using the 5010 277CA transaction set.
Acknowledgments_277CA_WhenIfEnabled	true false*	Indicates when the results from the WEDI/SNIP checks should be reported using a 277CA.
Acknowledgments_277CA_Level	Provider* - 277CA reports details at the Provider Level. This option will not provide specific details on each claim, only on the totals accepted/rejected for each Provider.  Claim - 277CA reports details at the Claim Level. This option will provide specific details on each Claim within the transaction.  All - 277CA reports all details at both Provider and Claim. If there are no errors, then the reporting will include the Patient/Claim details.	Indicates the level at which the HIPAA 277 Claims Acknowledgment reports. It can show details at the Provider level, or it can show details down to the Patient/Claim Level. This parameter will only have an impact if the Claim Level Rejection is enabled and the input HIPAA EDI data is a Claim (837). If there are no errors in the HIPAA EDI 837 data, then reporting will only go to the Provider Level, regardless of the setting.  Using options Claim or All may impact performance if there is a large quantity of claims in the data.

Parameter tag name	Values	Description
Acknowledgments 277CA UniqueBHT03	true false*	Indicates whether to produce a BHT03 value based on the interchange, functional group, and transaction control numbers of the source 837 being validated.  If false, 277X2140001 is always set as a value for the BHT03 element.
Acknowledgments TACK Enabled	true false*	Indicates whether the Translated Acknowledgment Report will be produced. This report transforms the 997 and 999 acknowledgments into a more readable report.
Acknowledgments TACK WhenIfEnabled	Errors* - Generate only when WEDI/SNIP type errors are present in the interchange.  Always - Always generate even if WEDI/SNIP type errors are not present in interchange.	Indicates when the results from the WEDI/SNIP checks should be reported using Tack report.
Acknowledgments TACK IncludeAccepted	true false*	Indicates the level of reporting in the Translated Acknowledgment Report.  If true, report all data, including those accepted and rejected. If false, only generate the report based on the data in error.
Acknowledgments TACK TAck_EDI	Full* – Generates TAck_EDI.html file with all the transactions in the data.  Partial - Generates TAck_EDI.html file with only the transactions in error.  None	Indicates whether the TAck_EDI file, which is a html tagged version of the transactions being validated, is produced with all the original data, or just the transactions that have errors reported.  If Acknowledgments Tack Enabled is false, this parameter is not used.  If Acknowledgments Tack Enabled is true, the default for this is Full.  Options Partial or None may help overall performance.
Acknowledgments LoopIDInAck Enabled	true* false	Include loop identifier in the acknowledgment. If a 997 is requested and this parameter is set to true, then the AK303 will contain the loop identifier of the segment in error. If a 999 is requested and this parameter is set to true, then the IK303 will contain the loop identifier of the segment in error.
Acknowledgments LoopIDInAck includeIDForAll	true false*	Indicates whether to include the functional group control number in the grouping of functional groups within an acknowledgment.  If the setting is false, only the GS02, GS03, GS07, and GS08 are used to determine a unique functional group for reporting in the acknowledgment.  If the setting is true, then the GS06 is also included in the determination.
Acknowledgments IncludeISA13InAcks	true false*	The IncludeISA13InAcks parameter is used when it is desired to use the ISA13 (control number) of the input transmission file for acknowledgments produced. If the parameter is set to true, the ISA13 value of the input transmission file will be used.  If the parameter is set to false, a default control number will be used.  Note: In the case of multiple interchanges in the input transmission, the ISA13 of the first interchange will be used, as only one interchange is produced in the acknowledgments.
Acknowledgments AckFunctionalGroups IncludeGS06	true false*	Indicates whether to include the functional group control number in the grouping of functional groups within an acknowledgment.  If the setting is false, only the GS02, GS03, GS07, and GS08 are used to determine a unique functional group for reporting in the acknowledgment.  If the setting is true, then the GS06 is also included in the determination.
Acknowledgments AckFunctionalGroups UseInputFunctionalGroup	true false*	Create a functional group in acknowledgment based on functional groups in input.
Tuning Paging	-P64:8*	Indicates the page size and page count to be used for the execution of compiled maps that will be executed by hipaa_data_compliance map with the RUN function.  The first number is Page Size, and the second number is page count.  The page size value may be an even integer between 2 and 1024. The page count may be an integer between 1 and 9999.  Note: In general, larger page sizes and count settings will improve overall map performance when input data transmission is large. Determining the optimal page settings may require some experimentation. This setting is not used for all run maps that are called.
Tuning Audit	-AEWU*	Indicates the audit log setting to be used for the execution of compiled maps that will be executed with the RUN function.
Tuning WorkFile	-WDU*	Indicates work file setting to be used for the execution of compiled maps that will be executed with the RUN function.

Parameter tag name	Values	Description
Tuning LengthOfDataElementInError	(User Specified numeric value between 1 and 99) 50*	Used for customizing the length of the value produced in the AK404/IK404 elements of the reporting acknowledgments.  Setting this to a value higher than the default may have a negative impact on performance. There may be cases where the entirety of the data in the file being validated is not placed on the acknowledgment even when this parameter is configured to its maximum value: When the length of data being reported exceeds the maximum parameter value or when the length of data exceeds more than twice the defined element length if the defined element length is > 32 characters.  The maximum size is 99, and the default size is 50.
Acknowledgments 824 Enabled	true false*	Indicates whether the results from the WEDI/SNIP Type 6 and 7 checks reported as a warning should be reported using the 824 transaction set.
Acknowledgments 824 WhenIfEnabled	Errors - Generates only when WEDI/SNIP type 6 or 7 warnings are present in the interchange.  Always* - Always generates even if WEDI/SNIP type 6 or 7 warning are not present in interchange.	Indicates when the results from the WEDI/SNIP checks should be reported using a HIPAA specific 824.
Acknowledgments 824 DetailMax	(User specified numeric value) 9999*	Indicates when we should stop producing detailed 824 warning information for a single transaction. If the number of warning lines, not total errors, to be produced in the 824 for the received transaction exceeds this limit, then the logic to generate the detailed information in the TED loop will be bypassed.  The setting for this value will determine the maximum number of error lines produced in the 824 for a single transaction.
GS08	Standard Industry	Standard - Use the X12 standard value (i.e., 005010) in the GS08 element of the 824.  Industry - Use the HIPAA or industry-specific value (e.g., 005010X186A1) in the GS08 element of the 824.
Acknowledgments 999 DetailMax	(User specified numeric value) 9999*	Note: To further reduce processing time on transactions with many errors, higher level validation may be skipped if the max is hit during Type 2 validation.

## HIPAA Compliance Check Parameters

Parameters used for the Compliance Check application are set in the compliance\_check\_5010\_paramater.dat file.

The settings in this file can be edited, and take effect the next time that the Compliance Check application is executed. There is no need to rebuild or re-deploy maps. This file contains data records that adhere to the convention of Tag\_Name="Value".

The following table describes the parameter tag names and values used by the Compliance Check application.

In the following table, the \* (asterisk) indicates the default value.

Parameter tag name	Values	Description
HIPAA_997_Enabled parameter	No - Never generate a HIPAA-specific 997 transaction even if the results of the compliance check indicate the presence of Type 1 errors.  Yes* - Always generate a HIPAA-specific 997 transaction for all interchanges, even if the compliance check does not indicate the presence of Type 1 errors.	Indicates whether the results from the WEDI/SNIP Type 1 check are reported by the HIPAA-specific 997 transaction set. This parameter is only available to be set when the highest level of HIPAA Validation selected is Type 1. If higher levels of HIPAA validations are selected, this parameter is not used.
HIPAA_Type_n_Checks_Enabled Note: Where n is an integer 1-4.	Yes - Perform Type n checks on the data.  No - Do not perform Type n checks on the data.	Used to indicate whether WEDI/SNIP Type n checks should be performed on the input data. See the HIPAA_Type_n_Checks_Enabled details documentation for more information about this parameter.
XML_Validation	Never* - Never validate the contents of the BIN segment.  XML - Validates the contents of the BIN segment for proper XML formatting.  Schema - Validate the contents of the BIN segment for proper XML formatting and against the schema.	Indicates the validation level for XML BIN/BDS segment content. The parameter is used to indicate whether the data in the BIN segment of the 4050 275 transaction set is to be validated and to which level it is to be validated.

Parameter tag name	Values	Description
HIPAA_Claim_Level_Rejection	N[O] - Reject the Entire transaction regardless of the location of the error  Y[ES] - Reject transaction set when all claims are in error or when an error is outside the Claim Loop.  A[ll] - Only reject transaction set when all claims are in error or when an error is outside the Provider loops. If the error is at the Provider, subscriber or patient level, all claims for that provider, subscriber or patient will be rejected.	Indicates whether the transaction set is still accepted with an AK501=E (errors accepted), and the claim, or claims, in error are removed from the valid data. This parameter is only available when the input HIPAA EDI data is a Claim 837.
HIPAA Claim Level 277CA Reporting	Never* - Never generate a 277CA even if the results of the compliance check indicate the presence of errors in 837 Claims input data.  Exceptions - Generate a 277CA for the interchange only when the results of the compliance check indicate the presence of errors in the 837 Claims input data.  Always - Always generate a 277CA for all interchanges even if the compliance check does not indicate the presence of errors in the 837 Claims input data.	Indicates whether the results from the Claim Level Rejection process are reported using the 5010 277CA transaction set.
HIPAA_Claim_Rejection_Level	Provider* - This option is recommended for performance. The 277CA reports details at the Provider level. This option does not provide specific details on each claim, only on the totals that are accepted and rejected for each Provider.  Claim - The 277CA reports details at the Claim level. This option provides specific details on each claim within the transaction. This option might impact performance if there are a large number of claims in the data.	Indicates the level at which the HIPAA 277 Claims Acknowledgment reports. It can show detail at the Provider level, or it can show details down to the Patient/Claim level.  This parameter has an impact only when the HIPAA Claim Level Rejection envelope parameter is set to Yes, and the input HIPAA EDI data is a Claim (transaction set 837). The default setting is Provider. If there are no errors in the HIPAA EDI 837 data, reporting goes to the Provider level regardless of the setting.
Duplicate_CLM_Check_Full_Segment	Y[ES] N[O]*	The Duplicate_CLM_Check_Full_Segment controls whether just CLMO1 or the full CLM segment is used to determine if claim-level rejection processing can continue for this transaction.  If the parameter is set to Y[ES] - Disable Claim level rejection if the entire CLM segment is not unique for all claims in the transaction.  Note: Only CLM01 is used to populate the TRN information in the 277CA, so the user may have to handle any ambiguity in the resultant acknowledgment if Y[ES] is used
277_REPORT_ERROR_STC	Y[ES] N[O]*	Set the sub elements in the STC01 element at all 277CA and 277DR loop levels to reflect if all valid or an error was detected at that level or below and include a valid entity code instead of the generic Ack/Receipt code.
HIPAA_Tack_Engaged	Yes - Generate No* - Do not generate.  Summary – Generate Translated Acknowledgement file without the Tack_EDI.html  Partial - Generate Translated Acknowledgment file and the Tack_EDI.html file, but the Tack_EDI.html file only contains the transactions in error.	Determines whether the Translated Acknowledgment Report is produced. This report transforms the acknowledgments into a readable report.
HIPAA_Tack_Accepted	Always - Generate accepted error report. Exceptions* - Generate error report only.	Determines what level of reporting appears on the Translated Acknowledgment Report. The options are to produce the report for all data (accepted and rejected) or to only generate the report based on the data in error. This setting only affects the content of the compliance_check_Tack.html file, not the Tack_EDI.html file.
Validation_Method	Map* Compliance  Both	Map - This default setting sends all data through the pass-through validation maps and only the invalid data goes through the subsequent processing. This is the recommended, and the default setting.  Compliance - This setting causes all data to be passed to the detailed processing done by the Compliance Check application.  Both - This setting causes all data to be processed by the pass through validation maps and the detailed compliance check validation. If there is a large amount of data, this option can slow the process. This option is used for troubleshooting purposes, logic modules, or both.

Parameter tag name	Values	Description
HIPAA_Relaxed_T2_Structure_Check_Enabled	Yes - Perform relaxed Type 2 structure checks if WEDI/SNIP Level 2 structure checking fails. No* - Do not perform relaxed Type 2 structure checks on the data.	This parameter indicates whether the relaxed structure will be performed on the input data if the data fails WEDI/SNIP Type 2 structure checking. This processing is performed only if errors are found during Type 2 structure checking.  If errors are not present, this processing is bypassed. Also, this new processing is only executed when Type 2 checks are enabled. If only Type 1 checking is enabled, the setting is ignored.
HIPAA_277CA_Uneque_BHT03	Y[ES] - Produce a BHT03 value based on the interchange, functional group, and transaction control numbers of the source 837 being validated.  N[O] - 277X2140001 is always set as a value for the BHT03 element.	If claim level rejection is enabled, this parameter controls the value created for the BHT03 Element in the 277CA output.
LoopId_In_Acknowledgment	N[O] - No value reported.  Y[ES] - Report Loop ID value (i.e. 2310).  A[LL] - Include loop id for Element level CTX segment and for errors found in structure validation if available.	This parameter indicates whether the loop identifier is required on the acknowledgment. (Will be reported in AK303 of 997 and IK303 in 999.)
Include_ISA13_In_Acks	Y[ES]  N[O]*	The Include_ISA13_In_Acks parameter is used when it is desired to use the ISA13 (control number) of the input transmission file for acknowledgments produced. If the parameter is set to Y[ES], the ISA13 value of the input transmission file will be used.  If the parameter is set to N[O], a default control number will be used.  Note: In the case of multiple interchanges in the input transmission, the ISA13 of the first interchange will be used, as only one interchange is produced in the acknowledgments.
Paging_Parameter	8*	This parameter specifies the page count used for the execution of most run maps from within the compliance check. The page count might be an integer 1 - 9999. The default is 8 pages.
Paging_Parameter	64*	This parameter specifies the page size (in Kb) to be used for the execution of run maps from within the compliance check. The page size might be an even integer 2 - 1024. The default setting is 64 Kb. In general, larger page sizes and count settings improve overall compliance check performance when processing transaction sets are large.
Allow_GS_Leading_0	Y[ES]  N[O]*	The Allow_GS_Leading_0 parameter indicates whether to allow leading zeros in the Functional Group control number in the GS and GE segments.  Allowable settings include:  Y[ES] - Allow leading zeros in group control numbers, such as 0001. N[O] - Do not allow leading zeros.
999_IK3_Missing_Seg	Y[ES]  N[O]*	For implementation dependent missing segments (I6), use Y[ES] to report the missing segment in the IK3. This will result in more information in the 999 by allowing the existing segment to be included in a CTX segment. Since the segment is missing, the segment position indicated will vary - it may be the position of the existing segment that caused the requirement, or the segment location in the transaction where it was determined the missing segment was not present, or the end of a loop.  Use N[O] to report the existing segment that caused the requirement for the missing segment in the IK3.

- [HIPAA\\_Relaxed\\_T2\\_Structure\\_Check\\_Enabled details](#)

The validation of the HIPAA EDI component Compliance Check module is accomplished by multiple validation passes.

## HIPAA\_Relaxed\_T2\_Structure\_Check\_Enabled details

The validation of the HIPAA EDI component Compliance Check module is accomplished by multiple validation passes.

The first step validates the data through a schema to determine which transactions are valid and which transactions are invalid. Invalid transactions are then checked using a more detailed process to determine where the errors occurred within the transaction.

The first part of the detailed validation process is to validate the data structure. The data must pass basic HIPAA structure validation to determine and add loop identifiers in the data. If the data is not well structured and fails this process, the loop identification cannot be determined, and subsequent steps in the complete validation process do not execute. In order to report more errors, a relaxed structure check option has been added to the module to lessen the structure check requirements and to report more errors in such circumstances.

- [Relaxed structure check option](#)

The relaxed structure check option produces more errors, both structural and those related to HIPAA compliance, in a single pass rather than requiring two complete executions of the module.

- [R2 records](#)

Each transaction set in the hipaa\_x12\_structure.dat file has an additional structure record with a validation type of R2 (relaxed Type 2).

## Relaxed structure check option

The relaxed structure check option produces more errors, both structural and those related to HIPAA compliance, in a single pass rather than requiring two complete executions of the module.

Be aware of these points when using the relaxed structure check option:

- The Allowed Relaxed Type 2 Structure Checking in the Transformation Extender UI sets the HIPAA\_Relaxed\_T2\_Structure\_Checking parameter to allow for relaxed level 2 validation, if enabled. The default value for this setting is No.
- If the Allowed Relaxed Type 2 Structure Checking option is enabled, then relaxed structure checking is performed on the input data only if the data fails WEDI/SNIP type 2 structure checking. If errors are not present, this processing is bypassed. Also, this new processing is only executed when Type 2 checks are enabled. If only Type 1 checking is enabled, the setting is ignored.
- In order to implement the relaxed structure check option, a new set of information has been added to enable this processing called, R2 records.

---

## R2 records

Each transaction set in the hipaa\_x12\_structure.dat file has an additional structure record with a validation type of R2 (relaxed Type 2).

These rules are applied to the R2 records:

- The segments that define loops do not change. These segments must be kept intact to determine the correct loop IDs. This includes the segments: HL, NM1, N1, and ENT. If data fails both T2 (standard WEDI/SNIP type 2) and R2 (relaxed Type 2) structure checking, validation is stopped and only the structural errors are reported on the acknowledgment.
- The qualifier is removed from these records, making the checking relaxed for those segments that are used for choice and unordered loops. This includes instances of the following segments: REF, DTP, AMT, CRC, DTM, HI, III, NTE, PER, QTY, PWK. If the qualifier is not checked, any segments with invalid, or too many qualifiers, continues in the validation process.
- The cardinality of any segment that is not a loop-defining segment, is relaxed to match the cardinality of standard X12 (Type 1) validation, except in the cases where Type 2 is more relaxed than Type 1.
- The results of the first Type 2 structure check are reported along with the results of the relaxed structure check. This results in duplicate reporting, but does allow all of the errors to be reported in one pass of the compliance check application.

Any segment that is not allowed for use under HIPAA is not allowed in the relaxed validation and produces an error if encountered.

If the data fails at both standard WEDI/SNIP type 2 and relaxed type 2 structure checking, then validation stops and only the errors as reported in the structure checking are reported.

---

## Claim Level Rejection

The Pack for Healthcare allows invalid claims to be rejected and valid claims to be processed. Validation is run on the document level (claim) for the 5010 837 Claims Transactions.

Claim Level Rejection allows a transaction *not* to be rejected on the basis of one bad claim. Claim Level Rejection places a bad claim, or claims, in a separate transaction while leaving good claims in the original transaction.

Claim Level Rejection is not available for the Post Adjudicated Claims Data Reporting (PACDR) 837 transactions.

Claim Level Rejection rejects only those claims in error when it can absolutely be determined that the error is due to the claim in question. Many X12 or HIPAA compliance errors can force the entire transaction to be rejected. For example, HIPAA type 1 and type 2 structure errors are nonrecoverable errors which cause the entire transaction to be rejected. A Claim Level Rejection is not possible for these nonrecoverable errors.

- **Assumptions**

Claim Level Rejection is only provided for the 837 Professional, Dental, and Institutional claims transactions. It is available for 5010 versions of the claims transactions. It is ignored if the input HIPAA EDI data is not a claim transaction.

- **Acknowledgements**

If a transaction is structurally sound, and all errors within the transaction occur at the claim level or below, then the claim or claims in error are rejected, and the valid claims are accepted. A 997 and/or 999 indicating acceptance with errors is generated for the transaction with the value E for the Transaction Acknowledgement Code, AK501/IK501.

- **Configuration process**

Claim Level Rejection is optional and configurable.

---

## Assumptions

Claim Level Rejection is only provided for the 837 Professional, Dental, and Institutional claims transactions. It is available for 5010 versions of the claims transactions. It is ignored if the input HIPAA EDI data is not a claim transaction.

Assumptions about the Claim Level Rejection parameter are described here.

- When healthcare claims transactions are processed, the HIPAA Guidelines recommend that the value in CLM01 be unique for each claim. Although this is not a HIPAA requirement, it can be used as a means for claims to be uniquely identified and reported in an automated system. However, there are cases where Claims with the same CLM01 could be present in the input transmission being validated. One scenario is when an original and voided claim is present. In this case, the Claim Frequency Code in CLM05-03 would be different (1 and 8), but CLM01 would be the same. Therefore, Compliance Checking requires the entire CLM segment to be unique in reporting results at a claim rejection level. Suppose the concatenated value of all CLM elements is not unique. In that case, Claim Level Rejection is terminated for the transaction with the duplicate CLM segments, and a message will appear in the compliance check summary file that indicates that the Claim Level Rejection process has been terminated.
- If a transaction fails any level of structure checking, then the entire transaction set is rejected. This is the same behavior that was exhibited before Claim Level Rejection was introduced. To successfully run Claim Level Rejection, the loop id must be available for inspection. If the data fails the structure checking step, the loop id is not determinable.

- If a transaction is structurally sound, and all errors within the transaction occur at the claim level or below, then the claim, or claims in error, are rejected, and the valid claims are written to the valid file.
- If any error occurs at a level higher than the provider in the transaction set, the entire transaction is rejected. For the Claim Level Rejection process to extract any rejected claims, all of the errors in the transaction set must occur at the claim level or lower.
- The Claim Level Rejection parameter is configurable and optional. The default parameter setting is to not execute the Claim Level Rejection process.
- All valid claims are reformed into a new transaction with the EDI structures adjusted so that the transaction passes HIPAA compliance to the validation level requested. These valid claims are listed in the compliance\_check\_valid.out file.
- Rejected claims are reformed into a new transaction with the EDI structures adjusted so that the transaction only fails HIPAA compliance for the same reason or reasons as the original claim rejection. Rejected claims are listed in the compliance\_check\_invalid.out file.

## Acknowledgements

If a transaction is structurally sound, and all errors within the transaction occur at the claim level or below, then the claim or claims in error are rejected, and the valid claims are accepted. A 997 and/or 999 indicating acceptance with errors is generated for the transaction with the value E for the Transaction Acknowledgement Code, AK501/IK501.

If the AK501/IK501 is showing a status of "E", it indicates that the transaction set has claim level errors, but if there is only 1 transaction set in the Functional Group, then the AK901 status is set to "E" (Accepted, but errors noted).

The results of Claim Level Rejection are reported in the 5010X214 277 Claims Acknowledgement, 277CA or 005010X364 277DRA. By default transaction details are reported at the Provider Level. This behavior can be changed to report at the claim level if the **Clm\_Lev\_Rej\_Level** parameter is set to **C** to indicate the claim.

Note: The 227 is not generated for any non-837 input data.

If there are no errors in the HIPAA EDI 837 data, then 277 reporting only goes to the Provider Level if the **Clm\_Lev\_Rej\_Level** parameter is set to C. The results of the 277 Report do not appear in the Translated Acknowledgement Report.

If there are no errors and the **Clm\_Lev\_Rej\_Level** parameter setting is A, the 277 reporting will include patient and claim details.

## Configuration process

Claim Level Rejection is optional and configurable.

The following parameters are contained in the parameter file to control the processing.

- **Claim\_Level\_Rejection**
- **Clm\_Lev\_Rej\_Level**
- **HIPAA\_277CA\_Enabled**
- **277\_REPORT\_ERROR\_STC**

See the Compliance check parameter file documentation for details about these parameters. The same configuration is used for both 277CA and 277DRA. If the input is a standard HIPAA mandated claim, a 277CA will be produced if so configured. If the input is one of the PACDR claims, a 277DRA will be produced.

- [Enable Claim Level Rejection](#)
- [Performance tuning and debugging](#)

## Enable Claim Level Rejection

To enable Claim Level Rejection, perform the following activities.

- Set the **Claim\_Level\_Rejection** parameter to Y (the default is N). Ensure that the semicolon before the parameter is removed.
- To produce the 277CA, set the **HIPAA\_277CA\_Enabled** parameter to A or E (the default is N). If the **Claim\_Level\_Rejection** parameter is not set to Y, then the 277CA parameter is set to NEVER at map execution time. This parameter only applies to HIPAA EDI 837 input data. The 277CA is not generated for any non-837 data.
- When the 277CA is produced, the reporting level is at the Provider Level. This can be modified to report at the Claim Level when there are errors, by changing the **Clm\_Lev\_Rej\_Level** to C. Changing this parameter might have an impact on performance if there are many claims in a transaction.

## Performance tuning and debugging

To optimize system performance, it is recommended that Claim-Level Rejection is not enabled unless required by your organization.

If you are concerned about performance and the 277CA is enabled, the reporting level should be left at the Provider level. Changing it to report at the Claim-level might have a significant impact on performance. The size of the output acknowledgement file can also become very large if there are many claims per transaction report.

The results from the Claim Level Rejection process can be found in the **compliance\_check\_summary.out** file, which is output card #2 of the main compliance check map. The results from each Claim Level Rejection run map are available to be reviewed if any issues occur during execution of the compliance check application.

## Configurable Rules

The Pack for Healthcare allows you to enable or disable WEDI/SNIP extended Level 2 through Level 7, as defined in the Compliance Check module.

With the HIPAA data compliance application this can be done at run time with the use of the hipaa\_rules\_to\_change.json input file, which controls which rules are enabled or disabled differently from their default setting.

With the Compliance Check application, the Configurable Rules application, which requires the Pack for Healthcare to be installed on Design Studio, allows you to determine which rules are enabled and disabled for validation. You can then generate the schemas and the qualifier file for use in the Compliance Check application.

- [Enabling Rules with HIPAA DATA compliance](#)

The HIPAA Data compliance allows rules to be enabled or disabled at run time.

- [Enabling Rules with HIPAA Compliance Check](#)

With the Compliance Check application, the Configurable Rules application, allows you to determine which rules are enabled and disabled for validation, and generates the corresponding updated schemas and qualifier file to use with Compliance Check.

- [Configurable rules objects](#)

Configurable Rules application objects consist of data files (.dat), schemas, a type tree script file (.mts), a map source file, batch command files (.bat), and executable map (.mmc) files.

- [Configurable rules reporting](#)

The Configurable Rules report is generated during configurable rules processing and can be used to check the integrity of the customized mini qualifier file. The report that is created can be found in the data directory under configurable\_rules and is called qualifier\_report.html.

- [Basic steps for running the Configurable Rules application](#)

---

## Enabling Rules with HIPAA DATA compliance

The HIPAA Data compliance allows rules to be enabled or disabled at run time.

### Before you begin

---

Objects

- Hipaa\_x12\_qualifier.json – contains all the extended type 2, type 3-7 rules that are configurable, with all the details that are needed for each rule for the hipaa\_data\_compliance application to enforce. This should not be modified by the user except to add user-supported (not product-supported) Type 7 rules – more details on that later.
- Hipaa\_rules\_to\_change.json – this contains ONLY the rules that you wish to DISABLE that are ENABLED by default in the product or that you wish to ENABLE that is DISABLED in the product hipaa\_x12\_qualifier.json file.
- Hipaa\_x12\_rules.json – Contains all the rules in hipaa\_x12\_qualifier.json, but only with a minimum number of attributes, not all the details.
- create\_rules\_to\_change utility map. In Pack for Healthcare Design Studio installs, this is included in the hipaa\_data\_utilities source map in the map directory. This is included in the design server of the hipaa\_data\_compliance project.

Steps to enable or disable rules:

### Procedure

---

1. Make a backup copy of Hipaa\_x12\_rules.json and the hipaa\_rules\_to\_change.json.
2. In the full hipaa\_x12\_rules.json, update the OnOffIndicator to 1 for any rule you need to enable (not done in this example) and to 0 for any rule you need to disable (disable the first rule).
3. Build the create\_rules\_to\_change utility map.
4. Run the create\_rules\_to\_change utility map to generate a hipaa\_rules\_to\_change.json.  
This map uses the hipaa\_x12\_rules.json and the hipaa\_x12\_qualifier.json to generate the hipaa\_rules\_to\_change.json. This will now include the rules configured differently than the default in the hipaa\_x12\_qualifier.json file.

---

## Enabling Rules with HIPAA Compliance Check

With the Compliance Check application, the Configurable Rules application, allows you to determine which rules are enabled and disabled for validation, and generates the corresponding updated schemas and qualifier file to use with Compliance Check.

The parameter file allows the application to be run in one of several ways. A validation method of map (Validation\_Method="M") allows the data to be passed against the schema. It then sends only invalid data through the full compliance check process. This method saves processing time and resources, especially when processing data that is predominately good. As a result, most rules that are enforced for HIPAA must be defined two times. The rules are defined once during schema checking and again in the Compliance Check Rules system.

---

## Configurable rules objects

Configurable Rules application objects consist of data files (.dat), schemas, a type tree script file (.mts), a map source file, batch command files (.bat), and executable map (.mmc) files.

Because the objects listed here are used in the Configurable Rules application, changes made to them might result in inconsistent operation or might cause them to stop working completely. For this reason, do not modify Configurable Rules application objects. In the list provided here, only those files denoted with an asterisk (\*) after the file name can be safely modified.

- **Data files:**

- configurable\_rules\_mini\_qualifier.dat \*
- configurable\_rules\_component\_rules\_only.dat
- plus.gif
- minus.gif

- qualifier\_rules\_report.css
  - directory\_paths.dat
- **Schemas:**
    - t3t4\_utility
    - rule\_less
  - **Schemas script file:**
    - hipaa\_x12\_master\_rule\_stub.mts
  - **Map source file:**
    - configurable\_rules
  - **Batch command files:**
    - import\_trees.bat
    - configurable\_rules.bat
  - **Executable map files:**
    - create\_env\_check\_ruleless\_tree
    - separate\_type\_2\_tree
    - remove\_first\_cr
    - create\_rule\_less\_tree
    - separate\_tree
    - remove\_comments
    - hipaa\_type\_2
    - create\_new\_tree
  - **Data files**
  - **Schemas**

These schemas are used in the Global Configurable Rules application.
  - **Schemas script file**

The hipaa\_x12\_master\_rule\_stub.mts schema script file is updated by the configurable rules application.
  - **Map source file**
  - **Configurable Rules batch command files**
  - **Compliance Check application qualifier file**

The hipaa\_x12\_qualifier.dat file is the qualifier file that is used by the Compliance Check application. It contains a list of rules used for performing Type 2, Type 3 and Type 4 WEDI/SNIP validations.
  - **Executable map files**
- 

## Data files

The Global Configurable Rules application includes the following files. Most of these files are required as input to the map.

- **configurable\_rules\_component\_rules\_only.dat**

The configurable\_rules\_component\_rules\_only.dat file contains the schema component rules for all of the rules in the mini qualifier file.
  - **configurable\_rules\_mini\_qualifier.dat**

The configurable\_rules\_mini\_qualifier.dat file contains a listing of all of the rules and validations that can be configured in the Pack for Healthcare HIPAA EDI component.
  - **configurable\_rules\_type\_5\_mini\_qualifier.dat**
  - **minus.gif**

The minus.gif file is used to visually display a - (minus) on the report which indicates that the data can be closed.
  - **plus.gif**

The plus.gif file visually displays a + (plus) on the report, which indicates that the data can be opened.
  - **qualifier\_rules\_report.css**

The qualifier\_rules\_report.css file is a cascading style sheet which allows you to modify colors, fonts, margins, scroll regions and other display related features.
  - **directory\_paths.dat**

The directory\_paths.dat file contains the directory paths for the location of map executable files. The map executable files are used to import the schemas created by the Configurable Rules application.
- 

## configurable\_rules\_component\_rules\_only.dat

The configurable\_rules\_component\_rules\_only.dat file contains the schema component rules for all of the rules in the mini qualifier file.

This file installs within the imported project.

This file is used by the Configurable Rules application to merge the component rules for the validations that are enabled in the mini-qualifier file.

Do not modify this file.

---

## configurable\_rules\_mini\_qualifier.dat

The configurable\_rules\_mini\_qualifier.dat file contains a listing of all of the rules and validations that can be configured in the Pack for Healthcare HIPAA EDI component.

This file installs within the imported project.

Each record is delimited with a ^, and terminated with a ~<NL>.

Each record in the file constitutes an extended Type 2, Type 3, or Type 4 WEDI/SNIP level validation with the following layout:

- Rule Sequence #
- Version / Release / Identifier Code
- Transaction Set ID
- Level of Validation
- ON/OFF Indicator. This is the only information that can be modified in this file:
  - 1 = ON
  - 0 = OFF
- Rule Description Text

This is the only file in the Configurable Rules application that can be modified.

---

## configurable\_rules\_type\_5\_mini\_qualifier.dat

The configurable\_rules\_type\_5\_mini\_qualifier.dat file contains a list of all of the type 5 validations that can be configured by the Standard Processing Engine. These rules cannot be configured in the Pack for Healthcare. Do not modify the file.

---

## minus.gif

The minus.gif file is used to visually display a - (minus) on the report which indicates that the data can be closed.

This file installs within the imported project.

---

## plus.gif

The plus.gif file visually displays a + (plus) on the report, which indicates that the data can be opened.

This file installs within the imported project.

---

## qualifier\_rules\_report.css

The qualifier\_rules\_report.css file is a cascading style sheet which allows you to modify colors, fonts, margins, scroll regions and other display related features.

This file installs within the imported project.

---

## directory\_paths.dat

The directory\_paths.dat file contains the directory paths for the location of map executable files. The map executable files are used to import the schemas created by the Configurable Rules application.

This file installs within the imported project.

---

## Schemas

These schemas are used in the Global Configurable Rules application.

- [t3t4\\_utility schema](#)  
The t3t4\_utility schema is used by the executable maps in the configurable\_rules map source file.
- [Rule\\_less schema](#)  
The Rule\_less schema is based on the ttmaker60 schema, which is included in the examples directory in the Transformation Extender base product installation.

---

## t3t4\_utility schema

The t3t4\_utility schema is used by the executable maps in the configurable\_rules map source file.

The schema contains the following definitions:

- Configurable Rules results
- DirectoryPaths file
- Type Tree Component Rule

- Qualifier Report

This schema installs within the imported project.

## Rule\_less schema

The Rule\_less schema is based on the ttmaker60 schema, which is included in the examples directory in the Transformation Extender base product installation.

The Rule\_less schema contains the definition for the schema script files used in the configurable rules.

## Schemas script file

The hipaa\_x12\_master\_rule\_stub.mts schema script file is updated by the configurable rules application.

- [hipaa\\_x12\\_master\\_rule\\_stub.mts schema script file](#)

## hipaa\_x12\_master\_rule\_stub.mts schema script file

If the hipaa\_x12\_master\_rule\_stub.mts file is imported, it is missing all of the component rules that are defined as configurable, and only the rule description for a given rule appears in their place.

This file installs within the imported project.

Do not modify this file.

## Map source file

The configurable\_rules map source file included with the Configurable Rules application contains several executable maps. All of the maps are described in the documentation provided here. The configurable rules maps are used by this application. Modification of these maps might cause inconsistent operation, or might cause them to fail completely.

The configurable\_rules map source file installs within the imported project.

You must build all of the executable maps to create the compiled map files (\*.mmc) used by the RUN function calls before you run the configurable\_rules.mmc executable map.

- [Description of executable maps](#)

The Configurable Rules application executable maps are described in the table provided here.

## Description of executable maps

The Configurable Rules application executable maps are described in the table provided here.

Executable map	Output card	Description
configurablerules	1	Top-level map for the configurable_rules application. This map keeps track of the results for all steps and generates output. The output defaults to the Sink Adapter.
	2	The updated qualifier file, hipaa_x12_qualifier_updated.dat is renamed and can be reused in the Transformation Extender, stand-alone Compliance Check application.
	3	MergedRules output contains the enabled business rules and their associated component rules. The output defaults to the Sink Adapter.
	4	The qualifier_report.html file is a report that shows the results, including errors, of the Configurable Rules application.
createminifiles	1-3	Invoked from the configurable_rules map. This map reads in the Transformation Extender exported business rules and generates the mini qualifier of the Type 2 - 6 enabled business rules. The results are sent back to the main configurable rules map.
	4-6	These output cards contain the component rules taken from the Transformation Extender business rules export file for all Type 2 - 6 enabled business rules. The results are sent to the main configurable rules map.
	7-9	Generation of the qualifier report. The results are sent to the main configurable rules map.
qualifierreport	1	Invoked from the configurable rules map, this map checks the mini qualifier, qualifier, and component rules only files for content and integrity. It also reports rules that have had their status modified. The output contains potential errors from the input file.
	2	If there are no errors in output card #1, the files are reviewed to determine the differences in the enabled state of each rule.
	3	Sorts the rules from output card #2.
	4	Determines all of the enabled rules as found in the Transformation Extender business rules export data.
	5	Sorts the business rules by rule sequence number
updatemaster	4	Produces the report of the results from output cards #1, #2, and #4.
	1	Invoked from configurable_rules, this map updates the schema script file to contain the component rules for all of the Type 2 - 6 business rules that were enabled in the Transformation Extender exported business rules.

<b>Executable map</b>	<b>Output card</b>	<b>Description</b>
updateet3t4componentrules	1	Invoked from updatemaster and executed once per component rule. This map updates the enabled component rule in the schema script file.
	2	Determines if BINDABS functionality is required for the component rule.
	3	Strips off unused ampersands (&) from the component rule.
	4	Strips off unused tags from the component rule.

## Configurable Rules batch command files

- **[import\\_trees.bat](#)**  
The import\_trees.bat file is a batch file that imports the schema script files that are generated by the Global Configurable rules maps.
- **[configurable\\_rules.bat](#)**  
The configurable\_rules.bat file is a batch file that can run the entire Global Configurable Rules application. It also includes the commands to import the type tree script files generated.

### import\_trees.bat

The import\_trees.bat file is a batch file that imports the schema script files that are generated by the Global Configurable rules maps.

### configurable\_rules.bat

The configurable\_rules.bat file is a batch file that can run the entire Global Configurable Rules application. It also includes the commands to import the type tree script files generated.

This file installs within the imported project.

## Compliance Check application qualifier file

The hipaa\_x12\_qualifier.dat file is the qualifier file that is used by the Compliance Check application. It contains a list of rules used for performing Type 2, Type 3 and Type 4 WEDI/SNIP validations.

This file installs within the imported project.

## Executable map files

The executable map files install with the imported project.

These maps start by validating the schema script file generated by the Global Configurable Rules application.

The maps then generate each of the HIPAA schemas that are included in the HIPAA EDI component:

- [hipaa\\_x12\\_type\\_2](#)
- [hipaa\\_x12](#)
- [hipaa\\_x12\\_ruleless](#)

## Configurable rules reporting

The Configurable Rules report is generated during configurable rules processing and can be used to check the integrity of the customized mini qualifier file. The report that is created can be found in the data directory under configurable\_rules and is called qualifier\_report.html.

The report contains these sections:

- Validation results
- Modified rules
- Unchanged rules
- Enabled non-configured rules
- **[Validation results](#)**  
The validation map, modifyqualifier.mmc, checks the basic integrity of all records in the configurable\_rules\_mini\_qualifier.dat file. Basic validation is performed on fields and error text fields that exceed 60 characters.
- **[Modified rules](#)**  
Modified rules are listed in this section. The count identified, is the count of the number of modified rules relative to the hipaa\_x12\_qualifier.dat file.
- **[Unchanged rules](#)**  
Some configurable rules have no modifications.

- [Enabled non-configured rules](#)

Rules that are enabled but not configurable are located in this section.

- [Configurable rules assumptions](#)

---

## Validation results

The validation map, modifyqualifier.mmc, checks the basic integrity of all records in the configurable\_rules\_mini\_qualifier.dat file. Basic validation is performed on fields and error text fields that exceed 60 characters.

Some rules are dependent on other rules, and this dependency is verified to ensure that the ON/OFF flags match. If one rule is enabled, but it has a dependency on another rule that is disabled, this is reported and, processing stops. The ON/OFF flags must match. This means that both must be on, or both must be off.

As part of the validation process, a flat file, Errors.out, is generated. This file contains a list of verified dependent rules and can be found in the configurable\_rules\maps directory.

Additional checking for duplicate rules is performed. Both the rule numbers and the entire rule contents are checked for duplication. A warning message is in turn, generated for any rule found in the customized qualifier file that has not been defined for the compliance check application. Rules that fail validation checks are reported in this section, along with the total number of records found in the customized qualifier file, configurable\_rules\_mini\_qualifier.dat. The total number of records that fail the validation steps is also reported.

---

## Modified rules

Modified rules are listed in this section. The count identified, is the count of the number of modified rules relative to the hipaa\_x12\_qualifier.dat file.

The rules are sorted based on version id. The content of each modified rule is identified. The original value for the rule is identified with the notation:  
<<< ORIGINAL VALUE >>>

---

## Unchanged rules

Some configurable rules have no modifications.

The count that is identified, is the count of the number of unchanged rules relative to the hipaa\_x12\_qualifier.dat file. The rules are sorted based on version id. The content of each rule is identified.

---

## Enabled non-configured rules

Rules that are enabled but not configurable are located in this section.

The count identified, is the count of the number of modified rules relative to the hipaa\_x12\_qualifier.dat file. The rules are sorted based on version id. The content of each rule is identified.

---

## Configurable rules assumptions

The following assumptions are part of the first phase of the Configurable Rules application:

- Configurable rules are only available for the HIPAA 5010 version extended level 2, 3, and 4 validations that are found in the mini qualifier file: configurable\_rules\_mini\_qualifier.dat
- Validations for 4050 version transactions cannot be configured.
- Only extended level 2 validations found in the qualifier file are configurable. Standard level 2 validations not found in the qualifier file are not configurable.
- There is no ability to configure any level 6 or 7 validations.
- There are some validations that are dependent on each other. These rules must be either both enabled or both disabled for in the mini qualifier file for Configurable Rules to execute successfully. A full listing of these rules is available on the Configurable Rules report (qualifier\_report.html).
- The only file that is available for users to update is the configurable\_rules\_mini\_qualifier.dat file.  
If this file is not updated correctly, the html error report indicates the nature of the problem and processing stops. The schemas and qualifier files have not been updated.
- The application is only available for execution on Windows.
- The application can be launched from either the Design Server or by using the Command Server. The batch files that are included with the installation can be used to execute the application using the Command Server.
- The Configurable Rules application only needs to be used if you have modified the mini-qualifier file. If you do not modify that file, running the Configurable Rules application is unnecessary.

---

## Basic steps for running the Configurable Rules application

The following are the basic steps required to run the Configurable Rules application. For detailed instructions on how to run the application, see [Instructions for running the Configurable rules application](#).

1. Determine which extended level 2, 3, and 4 rules must be changed from their default on and off states.
2. Back up the qualifier data file and the schemas to a safe location.
3. Modify the mini-qualifier file to change the state of the on and off indicator for each rule needed.
4. Run the configurable\_rules map.
5. Verify the outputs (results).
6. Run the batch files to generate the schemas using the Command Server, or import the schemas using the Design Server.
7. Rename the updated qualifier file.
8. Copy the renamed qualifier file to the main HIPAA\data directory.
9. Rebuild all the maps in the Compliance Check application before executing with the updated components.

Continue with the detailed steps provided here to run the Configurable Rules application.

- [Instructions for running the Configurable rules application](#)

---

## Instructions for running the Configurable rules application

These instructions describe how to run the Configurable Rules application.

1. Determine which extended level 2, 3, and level 4 rules must be changed from their default on and off states. These defaults might not have to be changed, but they must be changed if either of the following conditions occur:
  - If an unwanted rule failure exists on an acknowledgement. Note the rule number and investigate. After investigation, it might be determined that validation might not be required for that rule.
  - If an expected failure is not observed upon acknowledgement. If an investigation determines that the rule is in the mini qualifier file, but has not been enabled.
2. Back up installed files to a safe location. During the process of configuring the rules, a new qualifier data file and a new set of HIPAA EDI schemas are generated. Save these files in a safe location:

```
install_dir\packs_healthcare_vn.n.n\hipaa\configurable_rules\data\
 • configurable_rules_mini_qualifier.dat
install_dir\packs_healthcare_vn.n.n\hipaa\data\
 • hipaa_x12_qualifier.dat
install_dir\packs_healthcare_vn.n.n\hipaa\trees\
 • hipaa_x12.mtt
 • hipaa_x12_type_2.mtt
 • hipaa_x12_ruleless.mtt
```

If the Configurable Rules application is run multiple times, save both of the out-of-the-box pack files, as well as interim versions of the files created.

3. Modify the mini qualifier file to change the on and off states of the rules that are identified in step 1 of this procedure. To change the usage of the rules, you must edit the configurable\_rules\_mini\_qualifier.dat file at this directory location:

```
install_dir\packs_healthcare_vn.n.n\hipaa\configurable_rules\data\
```

The configurable\_rules\_mini\_qualifier.dat file is organized as follows:

- One rule (record) per line, delimited by "^."
- Field 1: Rule number, internal Transformation Extender reference
- Field 2: Transaction version reference, matching the GS08.
- Field 3: Transaction ID
- Field 4: WEDI/SNIP validation level
- Field 5: ON/OFF indicator. 0 (zero) indicates off, and 1 (one) indicates on. This is the only information that can be changed in this file. Save the file after changes are made.
- Field 6: Description of Rule

4. Run the configurable rules map file, configurable\_rules.mms, in the map source. This file is located at this directory location:

```
install_dir\packs\healthcare_vn.n.n\hipaa\configurable_rules\maps\
```

The executable map is configurable\_rules. Run the map as follows:

- a. Open configurable\_rules.mms in the Design Server.
- b. Build all of the maps.
- c. Run the configurable\_rules map.
- d. Verify the results by viewing the qualifier\_report.html file at this directory location:  

```
install_dir\packs\healthcare_vn.n.n\hipaa\configurable_rules\data\
```

5. Verify the results and ensure that the type tree script files listed in this step are created in this directory:

```
install_dir\packs\healthcare_vn.n.n\hipaa\configurable_rules\trees
 • hipaa_x12.mts
 • hipaa_x12_type_2.mts
 • hipaa_x12_ruleless.mts
 • hipaa_x12_master_rule_updated.mts
```

6. If you are running the Command Server, execute the import\_trees.bat file. This file imports the type trees that are required by the Compliance Check application. It is located in the following directory:

```
install_dir\packs\healthcare_vn.n.n\hipaa\configurable_rules\master
```

This file can be executed by using a command prompt or by double-clicking on the file name in the Windows directory. Verify that the files listed in this step are generated in this directory:

```
install_dir\packs\healthcare_vn.n.n\hipaa\configurable_rules\trees
```

- hipaa\_x12.mtt
  - hipaa\_x12\_type\_2.mtt
  - hipaa\_x12\_ruleless.mtt
7. If you are not running the Command Server, the type trees must be imported one at a time using the Design Server. See the Design Server documentation for instructions on importing type trees.
8. Move the type trees generated in Step 7 of this procedure to the following directory:  
`install_dir\packs\healthcare_vn.n.n\hipaa\trees\`
9. Rename the `hipaa_x12_qualifier_updated.dat` file, which is located in the directory to `hipaa_x12_qualifier.dat`. Move the renamed file to:  
`install_dir\packs\healthcare_vn.n.n\hipaa\data`
10. Rebuild all of the executable maps in the `compliance_check.mms` file.
- 

## Type 5 Validation

This support is only available with the HIPAA Data Compliance application.

### Overview

Type 5 Validation can be defined as the process of confirming that HIPAA X12 transaction data content complies with the requirements of the External Code Sources as documented in the Implementation Guides.

Each HIPAA X12 Implementation Guide contains descriptive information about External Code Sources in an appendix. This, typically, is Appendix A of the TR3. This information generally consists of the code source name and identifier, contact information, and an abstract of the related code set contents for each External Code Source referenced in the document.

Specifics about the data content to be validated using External Code Sources are embedded throughout the Implementation Guides, primarily in the Segment Detail portion of the guides. Typically, these External Code Source references are placed at either the data element or qualifier data element level. They include the Code Source identifier followed by the name. In the Pack for Healthcare, the following principles have been applied to distinguish between Type 5 and other validation types in the WEDI/SNIP model.

The validation of a data element against a set of one or more code values that are explicitly listed in the HIPAA Implementation Guide is considered a Type 2 check rather than a Type 5 check. For example, the entry for the BGN05 Time Zone Code element in the 834 Benefit Enrollment and Maintenance document references Code Source 94: International Organization for Standardization (Date and Time). However, the External Code Source reference is followed by an explicit list of values. The validation of this element against the list of permitted values is implemented as a Type 2 check.

The validation of a data element against a set of code values that are referenced in the HIPAA Implementation Guide is considered a Type 5 check. For example, the entry for N402 (State or Province Code) may reference CODE SOURCE 22: States and Provinces. When this reference is made and no specific states or provinces are listed in the implementation guide then this is considered to be a Type 5 check.

Type 5 Validation checks for conformance with published code sets that apply globally to all HIPAA X12 transactions processed. Any partner-specific external code set validation is considered to be beyond the scope of WEDI/SNIP Type 5.

- **Type 5 Validation Methods**

The Pack for Healthcare supports two methods of Type 5 Validation: Code Value and Pattern Match. The choice of validation method is generally determined by the requirements of your organization, the nature of the code list, and access to code list contents.

- **Configuration**

Database requirements

- **Code list identifiers table**

This table lists the unique code list identifiers used by the Pack for Healthcare along with their associated external code source, or sources. The table also provides information about the contents of the code list.

---

## Type 5 Validation Methods

The Pack for Healthcare supports two methods of Type 5 Validation: Code Value and Pattern Match. The choice of validation method is generally determined by the requirements of your organization, the nature of the code list, and access to code list contents.

The `hipaa_X12_qualifier.json` file contains Type 5 rules that can be checked. These rules will have a validation type of T5, with the syntax "ValidationType": "T5." Each Type 5 rule also has additional attributes to indicate what method of Type 5 validation to use, which code table to reference, or which pattern to match.

The Code Value method, with "ValidationSubType": "CV", checks that the data content selected for Type 5 validation is in a particular code list. The Code Table ID, or "CodeTableID" is used to specify the Code List collection that contains the list of all acceptable code items. An example is "CodeTableID": "T5\_022". This method also includes the option to define start and/or end dates for individual code list items. The transaction processing date determines whether the code item falls within the effective date restrictions.

The Pattern Match method, with "ValidationSubType": "PM", checks that the data content is consistent with a particular format or pattern. The Pattern Identifier, or "PatternID", is used to specify the Regular Expression to be used for validation. A Regular Expression, or regex for short, is a codified text string describing a search pattern. Examples of Pattern IDs that are used in the Pack include:

- [0-9A-Z]{2} Exactly two uppercase alphabetic or numeric characters.
- [0-9]{9} Exactly nine numeric characters.
- [A-Z]{3,5} Between three and five uppercase alphabetic characters.

If the Type 5 validation is enabled, all elements that contain an HIPAA National Provider Identifier (NPI) have specific rules to validate:

- The first digit of the NPI must be either 1 or 2.
- The check digit(last digit) is correct, based on the assumed prefix of 80840.

The rules of this element include the PatternID of NPI.

You can calculate the NPI check digit using the Luhn formula, a method for computing the modulus 10 double-add-double check digit:

1. Double the value of alternate digits, start from the rightmost digit.
2. Add a constant of 24 to account for the 80840 prefix present on a card issuer identifier, in addition to the individual digits of products of doubling, and the unaffected digits.
3. Subtract the result from the next higher number that ends in zero.

## Configuration

### Database requirements

The Pack for Healthcare does not come with a packaged database application. To use the Code Value Type 5 validation, you must have a Database server accessible that has MongoDB interface or JDBC support for queries and load.

The maps provided in the External Code List Utilities example, the primary map being load\_all\_code\_sets, can be run to load the code set collections with the documents that represent the list of allowed code values for that code set. There may be code sets that are updated between Pack releases, and the values need to be updated in the database. Updates for individual code values, to add/remove values, or to add a start date or end date can be done by reloading a full updated code list in the JSON format that the utility map uses or using any of the UI tooling supported by your database server.

The Pack for Healthcare does not provide JSON files to load all the code sets listed in the HIPAA Implementation guides. In some cases, due to the size of the code set if all data values were included, such as the ISO Country Code set 5, we do not include the full set. Users can generate the JSON files directly to include only those values they expect to be in the transactions being processed. In some cases, the data for the code set must be separately licensed.

Note on terminology for NoSQL databases, and how code set support is implemented for the Pack for Healthcare: All the code source sets will be loaded into one Database (default used is hipaa\_code\_sets). A collection is defined for each code source. The collection contains multiple documents, with each document containing an individual code source value, with a description and optional start/end dates.

The document format for each code set entry must conform to the JSON structure in code\_set\_template.json, provided in the External Code List Utilities example.

- [Enabling Type 5 Validation and Rules](#)

To enable Type 5 validation, the following, found in the "ValidationLevels" section, must be set in the hipaa\_data\_compliance\_parameter.json file.

## Enabling Type 5 Validation and Rules

To enable Type 5 validation, the following, found in the "ValidationLevels" section, must be set in the hipaa\_data\_compliance\_parameter.json file.

```
"Type5": {"Enabled": true}
```

By default, Type 5 rules are enabled in the hipaa\_x12\_qualifier.json file. To modify these rules, add them to the hipaa\_rules\_to\_change.json file. Use the field **OnOffIndicator: 1** to enable a rule, and **OnOffIndicator: 0** to disable it. For more detailed instructions, refer to the Configurable rules section of this documentation.

## Code list identifiers table

This table lists the unique code list identifiers used by the Pack for Healthcare along with their associated external code source, or sources. The table also provides information about the contents of the code list.

The code lists that default to PM (pattern match) do not have corresponding \*.json load files. These codes are not shipped because of the following reasons:

- Due to licensing/legal requirements, code lists are not redistributed.
- Lists are available, but prohibitively large, and it is expected that customers would maintain either the full list or a subset of the list that is applicable for their implementation.

If a customer is providing their own data for a table that is not shipped, the corresponding rules that are only set as PM can be updated to CV by including the rules in hipaa\_rules\_to\_change.json and updating the ValidationSubType field.

The rules that use the ICD-10 code sets are set to PM by default, and can be switched to CV, but only the full lists of procedure (T5\_896\_P) and diagnosis (T5\_897\_A) codes are included in the pack. There are no specific guidelines that indicate which subset is allowed for T5\_896\_R Principal Procedure Codes or T5\_897\_C Admitting Diagnosis Codes, and business/medical conditions beyond the scope of data validation could dictate which are allowed. Customers can optionally provide their own subset of codes to use for T5\_896\_R and T5\_897\_C, or update the rules using them to reference T5\_896\_P and T5\_897\_A using the hipaa\_rules\_change.json file.

Note: The Pack for Healthcare provides the maps to transform the source code lists to the xml/json format needed for the Type 5 load and these can be referenced as a model for implementations by the customers to create their own code lists for Type 5 checking.

## Type 6 Validation

This support is only available with the HIPAA Data Compliance application.

### Overview

Type 6 validation can be defined as the process of confirming that HIPAA X12 transaction data for claims complies with a specific line of service requirements. Details about line of service requirements are included in the HIPAA X12 Implementation Guides.

These line of service requirements are generally expressed as situational rules and may be associated with segments or data elements. Line of service categories such as ambulance, chiropractic, and podiatry are given as examples of line of service categories in the Type 6 definition. In the Pack for Healthcare, the following principles have been applied to distinguish line of service requirements from recommendations or other types of situational rules:

- Self-contained requirements - A self-contained requirement is one where all situational criteria can be evaluated using only the information present in the transaction set. A situational rule that includes a condition such as "when the distance of transportation is known" or "when the data is present in the UMO's system" is a recommendation, not a requirement.
- Unambiguous requirements - A requirement is considered unambiguous if all of its criteria can be evaluated using information from identifiable locations.
- Distinct requirements - A distinct line of service requirement is one that is not already enforced by another HIPAA X12 validation, such as a syntax rule enforcing the presence of related elements.

The scope of Type 6 validation is limited to the Health Care Claim (837) and Health Care Services Review (278) transaction sets.

- **Implementation**  
To understand how these Type 6 rules are processed in hipaa\_data\_compliance, consider the following three aspects of Type 6 rules:
- **Configuration**  
Database requirements

## Implementation

To understand how these Type 6 rules are processed in hipaa\_data\_compliance, consider the following three aspects of Type 6 rules:

1. What the line of service is – e.g. ambulance.
2. What segment/element in the transaction determines whether the claim involves this line of service.

The first is the rule that is present in the hipaa\_x12\_qualifier.json rules file.

The second aspect is encoded as a category within the code set name in the hipaa\_x12\_qualifier.json file, such as AMB for an ambulance in the code table ID field "CodeTableID" : "T6\_ST\_MRT\_AMB".

The final aspect is also encoded as a service location, in the code table id, such as "ST" in "CodeTableID" : "T6\_ST\_MRT\_AMB".

Table 1. Type 6 Service Categories

Category code	Description
ANE	Anesthesia
CHR	Chiropractic (spinal manipulation)
DEN	Dental
DME	Durable Medical Equipment
HHC	Home Health Care Services
HPC	Hospice
MBH	Mental and Behavioral Health
MRT	Medically Related Transportation
OXY	Oxygen Therapy
PEN	Parenteral / Enteral Nutrition
POD	Podiatry
RXD	Prescription Drug
SUG	Surgery
VIS	Vision (optometry)

Table 2. Type 6 Service Locations

Transaction Set	Source Type Code ST	Product or Service Identification PS	Form Identification code FC
278	2000E UM03 2000F UM03	2000F SV101-01 + SV101-02 2000F SV202-01 + SV202-02 2000F SV301-01 + SV301-02	

Transaction Set	Source Type Code ST	Product or Service Identification PS	Form Identification code FC
837		2400 SV101-01 + SV101-02 2400 SV202-01 + SV202-02 2400 SV301-01 + SV301-02	2440 LQ01+02

## Configuration

### Database requirements

The code values that indicate a particular line of service are checked with a database query, just as the Type 5 code values are checked.

The Pack for Healthcare does not come with a packaged database application. To use Type 6 validation, you must have a Database server accessible that has MongoDB interface support for queries and load.

The maps provided in the External Code List Utilities example, the primary map being load\_all\_code\_sets, can be run to load the code set collections with the documents that represent the list of allowed code values for the line of service for the Type 6 rules that are implemented in the Pack for Healthcare. If these values need to be updated between Pack releases, they need to be updated in the database. Updates for individual code values, to add/remove values, or to add a start date or end date can be done by reloading a full updated code list in the JSON format that the utilities map uses or by using any of the UI tooling supported by your database server.

If you need to modify the values in the code sets, the key difference in Type 6 tables is that if the value that indicates a particular line of service is represented by two different elements or subelements, the values are concatenated with an underscore in the table.

```
{
 "code" : "HC_A0170"
 "description" : "Transport parking fees/tolls",
 "startDate" : "1982-01-01"
}
```

- [Enabling Type 6 Validation and Rules](#)

To enable Type 6 validation, the following, found in the “ValidationLevels” section, must be set in the hipaa\_data\_compliance\_parameter.json file.

## Enabling Type 6 Validation and Rules

To enable Type 6 validation, the following, found in the “ValidationLevels” section, must be set in the hipaa\_data\_compliance\_parameter.json file.

```
"Type6": {"Enabled": true}
```

By default, Type 5 rules are enabled in the hipaa\_x12\_qualifier.json file. To modify these rules, add them to the hipaa\_rules\_to\_change.json file. Use the field **OnOffIndicator: 1** to enable a rule, and **OnOffIndicator: 0** to disable it. For more detailed instructions, refer to the Configurable rules section of this documentation.

## Type 7 Validation

This support is only available with the HIPAA Data Compliance application.

### Overview

In the original WEDI SNIP compliance testing model, Type 7 validation was limited to those explicit requirements specified in the HIPAA Implementation Guides for a small set of payer entities.

Within the healthcare industry, however, the term Type 7 validation is typically used in a broader sense that encompasses generalized, business-to-business testing based on requirements from additional sources. The Pack for Healthcare supports this expanded interpretation.

In the IBM Transformation Extender Pack for Healthcare, validation requirements are classified as Type 7 if either or both of the following conditions are true:

- The requirement is more restrictive than the standard requirements as documented in the HIPAA X12 Implementation Guides.
- The requirement does not apply globally to all defined business partners.

The scope of the validation performed by Types 1 through 6 is limited to enforcing the ‘standard’ requirements documented in the HIPAA X12 Implementation Guides (TR3s) and applying those requirements globally to all business partners. Type 7 validation extends that scope with an additional layer of checking that allows selective enforcement of business-specific requirements.

- [Implementation](#)
- [Configuration](#)

Database requirements

## Implementation

Type 7 Rules specified in the Qualifier file

Type 7 validation with a custom user exit

The HIPAA data compliance application is not a full trading partner application. Still, the new features allow for basic customization based on the value in the data's functional group Application Receiver ID (GS03).

For each "Institution" in the hipaa\_x12\_type\_7\_value.json input file to hipaa\_data\_compliance, if the Type 7 rule in the hipaa\_x12\_qualifier.json contains this same keyword, AND the GS03 value of the transaction being validated matches the "GS03Value" field in the hipaa\_x12\_type\_7\_value.json input file, then hipaa\_data\_compliance will validate the rest of the rule as defined in the hipaa\_x12\_qualifier.json.

Type 7 validation with a custom user exit

In addition to the Type 7 rules defined in the hipaa\_x12\_qualifier.json file, you can also provide a custom user exit in Java or C++ .

The custom user exit must be designed to use HIPAA data and delimiters in a specific format. The custom user exit must conform to the format of the data that is generated during run time by the hipaa data compliance application, which is only available during run time.

The string of delimiters must follow this format:

- Element Separator (ISA Element separator)
- Repetition Separator (ISA11)
- Component Element Separator (ISA16)
- Segment Terminator (ISA Terminator)

The string of HIPAA EDI starts with the segment identifier followed by the loop ID. For example:

ST\*\*270\*1235\*005010X279A1~

BHT\*\*0022\*13\*10001235\*20060501\*1320~

HL\*2000A\*1\*\*20\*1~

NM1\*2100A\*PR\*2\*ABC COMPANY\*\*\*\*\*PI\*842610001~

HL\*2000B\*2\*1\*21\*1~

NM1\*2100B\*1P\*1\*PENWISE\*MARCUS\*\*\*XX\*0202034209~

REF\*2100B\*JD\*178583840~

REF\*2100B\*EO\*477563928~

SE\*\*22\*1235~

## Configuration

Database requirements

To enable partner-specific code set or line of service checking, you must have the code set values loaded into the database, just as the code values for Type 5 and Type 6 are configured.

The Pack for Healthcare does not come with a packaged database application. To use Type 7 validation for partner-specific code value checking, you must have a Database server accessible that has MongoDB interface support for queries and load.

Refer to the Type 5 validation configuration section for additional details on database configuration and load requirements.

- [Enabling Type 7 Validation and Rules](#)

To enable Type 7 validation, found in the "ValidationLevels" section, must be set in the hipaa\_data\_compliance\_parameter.json file.

## Enabling Type 7 Validation and Rules

To enable Type 7 validation, the following, found in the "ValidationLevels" section, must be set in the hipaa\_data\_compliance\_parameter.json file.

"Type7": {"Enabled": true}

By default, Type 5 rules are enabled in the hipaa\_x12\_qualifier.json file. To modify these rules, add them to the hipaa\_rules\_to\_change.json file. Use the field **OnOffIndicator**: 1 to enable a rule, and **OnOffIndicator**: 0 to disable it. For more detailed instructions, refer to the Configurable rules section of this documentation.

## HIPAA EDI component examples

This documentation describes the HIPAA EDI component examples.

- [ICD-10](#)

The International Statistical Classification of Diseases and Related Health Problems 10th Revision (ICD-10) is a set of codes classified by the World Health Organization (WHO) used by physicians, hospitals, and other healthcare organizations to identify patient diagnosis and medical procedures. In the United States, the codes are used by providers and payers for many uses within health care systems, including patient care decision support and claims adjudication.

- [\*\*278N example\*\*](#)  
The 278N example contains sample mapping with the 278 transaction, "Health Care Services Review Information – Notification". By using sample input data with multiple 278 transactions, the example creates an XML based report for the notifications included in the input.
  - [\*\*HIX example\*\*](#)  
The Health Insurance Exchange (HIX) example demonstrates structures and concepts that surround the HIX processing structures.
  - [\*\*Preview Draft 80X0\*\*](#)  
The ASC X12 Insurance Subcommittee, called X12N, is currently managing a series of public review periods to define new implementation guides for the healthcare insurance industry. These implementation guides will eventually replace the HIPAA-adopted TR3s.
  - [\*\*X12N example\*\*](#)  
This example contains schemas that support X12 standard integrity checking (WEDI SNIP Type 1 Validation) for a set of healthcare industry implementation guides produced by ASC X12's Insurance Subcommittee (X12N). These schemas do not conform to the industry TR3s but to the base X12 standard. They are useful for data transformation purposes; they should not be used for data validation for any WEDI/SNIP level above 1.
  - [\*\*External Code List Utilities example\*\*](#)  
The External Code List Utilities example contains a utility map that loads the code set database with the external code sets that are supported in the pack into a MongoDB NoSQL database.

To support ways for the payer community to leverage existing B2B infrastructure while also beginning to work with HL7 CDA R2 and FHIR (in Json or XML), X12 has a draft implementation guide that describes the use of the AXC X12 Patient Information (275) transaction set for the business purpose of transferring Personal Health Record (PHR) information between different health plans.
- 

## ICD-10

The International Statistical Classification of Diseases and Related Health Problems 10th Revision (ICD-10) is a set of codes classified by the World Health Organization (WHO) used by physicians, hospitals, and other healthcare organizations to identify patient diagnosis and medical procedures. In the United States, the codes are used by providers and payers for many uses within health care systems, including patient care decision support and claims adjudication.

The ICD-10-CM and ICD-10-PCS code sets replace the current ICD-9 diagnosis and procedure codes. The ICD-10 code sets that replace the ICD-9 codesets are required for all HIPAA transactions, including outpatient claims (with dates of service), and inpatient claims (with dates of discharge), on and after October 1, 2013. The change to ICD-10 impacts coding for all HIPAA participants.

- [\*\*ICD-10 example\*\*](#)
- 

## ICD-10 example

In the health care industry, there is a short-term need for 'cross-walking' between the old ICD-9 and new ICD-10 code sets to help the industry migrate systems, applications, and data. Since there is not always a one-to-one code equivalent between the coding systems, software such as Transformation Extender ILOG JRules can be used to apply intelligent rules and logic for appropriate code selections.

- [\*\*Insulating legacy systems\*\*](#)  
In some cases, you, as a HIPAA participant, might want to temporarily insulate your legacy systems from the impact of the ICD-10 changes. In such situations, you must accept HIPAA 5010 transactions with ICD-10 codes and then exchange them for ICD-9 codes that your system understands.

This topic identifies the directory location of the ICD-10 example files.
  - [\*\*Using the ICD-10 example files\*\*](#)  
This topic describes how to use the ICD-10 example files.
- 

## Insulating legacy systems

In some cases, you, as a HIPAA participant, might want to temporarily insulate your legacy systems from the impact of the ICD-10 changes. In such situations, you must accept HIPAA 5010 transactions with ICD-10 codes and then exchange them for ICD-9 codes that your system understands.

Such a process typically includes parsing the HIPAA EDI data to isolate the ICD-10 codes, communicating the codes to be cross-walked to the rules/cross-walking engine, converting the codes based on pre-defined criteria, using the cross-walked codes in legacy systems, and tracking the changes made to the codes for audit and historical reporting. This example demonstrates a small portion of such a system. The Transformation Extender processes incoming HIPAA EDI data and communicates with a rules engine such as "IBM ILOG JRules," using an XML file, and sends the rules to the engine a structure containing the codes that must be cross-walked.

In this scenario, the rules engine (not included) performs the actual cross walk and returns a structure that contains both the original ICD-10 codes and the replacement ICD-9 codes. The resulting XML structure is then used by the Transformation Extender Platform to replace the codes in the original HIPAA EDI data.

It should be noted that this example is a black box inside of a black box. It does not show the orchestration of the various components. An orchestration tool, such as business Process Management, would call on the various transformation and crosswalking components to coordinate their efforts. Also, the rules engine is treated as a black box. In the example, one set of cross-walked test data is shown. There is no functioning rules engine in the example. This example is not intended to be used as a confirmation of the crosswalking done, as the test case is fictitious.

The process behind this specific example is to map ICD-10 codes from a HIPAA 837 professional claim transaction (837P) into an XML format described by a schema. The XML instance document generated by the Transformation Extender Platform is expected as input into a rules engine. A simulated modified XML instance document that contains both the ICD-10 codes and the equivalent ICD-9 codes is returned to the Transformation Extender, where that information is used to replace the ICD-10 codes in the original claim transaction. This cross-walking usually occurs during the process of a real transformation, for example, a transformation between the HIPAA EDI and a

proprietary format. For the sake of simplicity, the transformation in this example does not reformat the data; it simply includes the new codes. A true cross-walking service would do much more than take one code and map it to another, it could have the intelligence to handle one code in, many codes out, multiple codes in, one code out, or exception cases where human process flows should be initialized.

---

## Locating the ICD-10 example files

This topic identifies the directory location of the ICD-10 example files.

The ICD-10 example is located in the following folder:

*install\_dir\packs\healthcare\_vn.n.n\hipaa\examples\ICD-10\_iLog*

Note: Throughout this documentation, *install\_dir* indicates the location of the Transformation Extender Platform, and *n.n.n* indicates the version number of the Pack for Healthcare.

The Transformation Extender type tree, *icd\_transaction\_report.mtt*, is located in the following folder:

*install\_dir\...\ICD-10\_iLog\trees*

This is a representation of the XML schema *icd\_transaction\_report.xsd* located in the following folder:

*install\_dir\...\ICD-10\_iLog\mapsandschemas*

The type tree is used to create XML output and parse XML input, for example.

---

## Using the ICD-10 example files

This topic describes how to use the ICD-10 example files.

### About this task

Perform the following steps to use the example:

### Procedure

1. Open the map source file, *claim\_to\_ilog.mms*, in the ...\\mapsandschemas folder and then build all maps.
  2. Execute the run map *to\_ilog*. The input file, *837p\_5010a1\_icd10\_example.dat*, can be found in the ...\\mapsandschemas\\data folder. The map execution produces the XML output file *toilLog.xml*, which contains the ICD-10 codes. The output file from this step can be found in ...\\mapsandschemas\\data folder.
  3. Execute the run map *from\_ilog*. The input files *837p\_5010a1\_icd10\_example.dat* (input to step 2) and *fromilLog.xml* (output from step 2, enhanced by rules ending processing) can be found in the folder ...\\mapsandschemas\\data. The file *fromilLog.xml* is an example file created by a rules engine. The map execution produces the HIPAA 837 professional file (*837p\_5010a1\_out.dat*) containing the ICD-9 codes. The output file can be found in the ...\\mapsandschemas\\data folder.
  4. Execution of the run map *val\_edi* can be used to ensure the file *837p\_5010a1\_out.dat* is valid.
- 

## 278N example

The 278N example contains sample mapping with the 278 transaction, "Health Care Services Review Information – Notification". By using sample input data with multiple 278 transactions, the example creates an XML based report for the notifications included in the input.

The coded information for Purpose Code (from BHT02), event category and type, from the UM segment along with patient event trace numbers, are mapped in the output XML file.

The example files install within the imported project.

- [Location of the 278N example files](#)  
This topic identifies the directory location of the 278N example files.
  - [Using the 278N example](#)  
This topic describes how to use the 278N example files.
- 

## Location of the 278N example files

This topic identifies the directory location of the 278N example files.

The 278N example is located in the following folder:

*install\_dir\packs\healthcare\_vn.n.n\hipaa\examples\278N*

Note: Throughout this documentation, *install\_dir* refers to the installation location of the base product, and *n.n.n* indicates the version number of the Pack for Healthcare.

---

## Using the 278N example

This topic describes how to use the 278N example files.

Perform these steps to use the 278N example:

1. Open the map **service\_notification** in the ..\mapsandschemas folder, then build the **service\_notification** map.
2. Execute the **service\_notification** map. The input file, **278n\_5010\_examples.dat**, can be found in the ..\data directory. The output file, **service\_notifications.xml**, also found in the ..\data directory, is produced using **service\_notification.mtt**, based on the **service\_notification.xsd** schema in the ..\mapsandschemas directory.

For convenience, the 278N example contains a schema that only contains the 278 transaction.

For any production use of validation or mapping with the 278 transaction, the schemas in the following directory should be used. The schemas in this directory are supported with the latest fixes and enhancements:

```
install_dir\packs\healthcare_vn.n.n\hipaa\trees
```

## HIX example

The Health Insurance Exchange (HIX) example demonstrates structures and concepts that surround the HIX processing structures.

The HIX 820 is the 005010X306 transaction set, for which full support is included in the Pack for Healthcare. The HIX 834 or HIPAA FFE 834 is the 005010X220A1 plus FFE Companion Guide. The existing HIPAA 834 is supported in the pack, but this example incorporates the FFE (Federally Funded Exchange) Companion guide, which is a set of rules that is above HIPAA and is related to specific use for a specific task. In typical WEDI/SNIP terminology, this is WEDI/SNIP type 7. The 834 support beyond HIPAA is shown in this example.

The example files install within the imported project.

- [Locating the HIX example files](#)  
This topic identifies the directory location of the HIX example files.
- [HIX example executable maps](#)  
There are two executable maps in the HIX example, init\_enroll\_ffe\_to\_qhp and init\_enroll\_conf\_qhp\_to\_ffe.
- [Using the HIX example files](#)  
This topic describes how to use the HIX example files.

## Locating the HIX example files

This topic identifies the directory location of the HIX example files.

The HIX example is located in the following folder:

```
install_dir\packs\healthcare_vn.n.n\hipaa\examples\hix
```

Note: Throughout this documentation, *install\_dir* indicates the location of the base product, and *n.n.n* indicates the version number of the Pack for Healthcare.

## HIX example executable maps

There are two executable maps in the HIX example, init\_enroll\_ffe\_to\_qhp and init\_enroll\_conf\_qhp\_to\_ffe.

- [HIPAA to HIX example map](#)  
This example shows how a HIX 834 is created. The map, init\_enroll\_ffe\_to\_qhp, takes an initial enrollment structure and transforms it into an FFE compliance 834 for transmission to a qualified health plan.
- [HIX to HIX example map](#)  
The init\_enroll\_conf\_qhp\_to\_ffe example map takes the HIX enrollment created by init\_enroll\_ffe\_to\_qhp and generates a HIX Enrollment Confirmation, which is returned for the exchange.

## HIPAA to HIX example map

This example shows how a HIX 834 is created. The map, init\_enroll\_ffe\_to\_qhp, takes an initial enrollment structure and transforms it into an FFE compliance 834 for transmission to a qualified health plan.

There are two inputs to this map.

- Input 1 - HIPAA\_834\_Transmission - HIPAA 834 enrollment message. This is the same HIPAA message that is used to enroll members into private payer plans. Although the HIPAA 834 and the HIX 834 are similar (and based on the same transaction) there are some differences. This example map shows one possible way to fill in the gaps.
- Input 2 - MemberReportingCategories - This input is a proprietary file that is used for lookup and data embellishment. This case uses a set of Member Reporting Categories with 'Maintenance Reason Codes'. The reason codes equate to the reason that this message is created, such as for a new enrollment, or to modify an existing enrollment.

There are two outputs from this map:

- Output 1 - HIX\_834\_Transmission - Temporary card output designed for interim results.
- Output 2 - HIX\_834\_Transmission - Manipulates the output 1 and is the final transformed product.

## HIX to HIX example map

The init\_enroll\_conf\_qhp\_to\_ffe example map takes the HIX enrollment created by init\_enroll\_ffe\_to\_qhp and generates a HIX Enrollment Confirmation, which is returned for the exchange.

## Using the HIX example files

This topic describes how to use the HIX example files.

### About this task

These steps describe how to run the HIX example.

The files described in the following steps are in the maps and dat sub-directories in the following location:

`install_dir\packs\healthcare_vn.n.n\hipaa\examples\hix\`

### Procedure

1. Open the map source file ..\maps\hipaa\_to\_hix.mms.
2. Build all maps.
3. Run the init\_enroll\_ffe\_to\_qhp map. The input files, hipaa\_834\_5010a1\_examples.dat and MemberReporting.txt, are in the ..\data folder. When you run the map, the file init\_enroll\_ffe\_to\_qhp.out is produced. This file contains the initial enrollment. The output file from this step is in the ..\data folder.
4. Open the map source file ..\maps\hix\_to\_hix.mms.
5. Build all maps.
6. Run the init\_enroll\_conf\_qhp\_to\_ffe map. The input file is init\_enroll\_ffe\_to\_qhp.out (output from step 3). The output Initial Enrollment Confirmation is the init\_enroll\_conf\_qhp\_to\_ffe.out file. This file is located in the ..\data folder.

## Preview Draft 80X0

The ASC X12 Insurance Subcommittee, called X12N, is currently managing a series of public review periods to define new implementation guides for the healthcare insurance industry. These implementation guides will eventually replace the HIPAA-adopted TR3s.

Because of the current status of the final versions of the implementation guides, the Pack for Healthcare includes examples that provide a preview based on the currently published but not adopted versions. The example includes a schema to allow for validation in accordance with the Type 2 HIPAA Implementation Guide Requirement Testing for the Published 8020 TR3 for these transactions:

- HP – Health Care Claim Payment/Advice – 835, Version 008020X322
- BE – Benefit Enrollment and Maintenance - 834, Version 008020X333
- HS – Eligibility, Coverage, or Benefit Inquiry – 270, Version 008020X332
- HB – Eligibility, Coverage, or Benefit Information - 271, Version 008020X332

For these transactions, step-up and step-down example maps are provided to demonstrate one way to transform data conforming to the HIPAA adopted version 5010 TR3's to the draft TR3 requirements based on X12 8020.

The step-up maps also demonstrate one possible way to enrich the data with new information that is specified in the 8020 TR3's through JSON input.

See the X12n example for X12 8020 and 8030-based schemas with transactions covered by currently published X12N implementation guides to allow for validation in accordance with WEDI/SNIP Type 1 EDI Standard Integrity Testing.

The example files install within the imported project.

- [Location of Preview Draft 80X0 example files](#)

- [Schemas and JSON metadata](#)

This topic describes the example 80x0 schemas and metadata files, as well as notes on how to use these schemas for validation.

- [Step-up and step-down maps](#)

The step-up and step-down maps provide the basis for mapping simple correspondence in unchanged elements, the changes in positioning of information within the transaction, new or changed segments loops, and other differences, both in the implementation guide changes between the two versions, and the base X12 changes.

- [Preview Draft 8010 example source maps](#)

## Location of Preview Draft 80X0 example files

When running the example in Design Studio, the example files are at `Pack_install_dir\hipaa\examples\preview_draft_80x0`.

When running the example on the Design Server, the example files are installed within the imported `hipaaExamples.zip` project.

The example files install within the imported project.

## Schemas and JSON metadata

This topic describes the example 80x0 schemas and metadata files, as well as notes on how to use these schemas for validation.

The schema hipaa\_x12\_type\_2\_v80x0 provides type 2 validation of these transactions implemented in this example:

:

- Health Care Claim Payment/Advice, or 835
- Benefit Enrollment and Maintenance, or 834
- Eligibility, Coverage, or Benefit inquiry/or information, or 270/271

### Notes for using these schemas for validation:

- Element values – for codes that have a limited set of allowed values that is different from the X12 code list, compliance is enforced through a limited restriction list on the element or with a component rule. The limited restriction list is used if all occurrences of the element in the transaction have the same set of allowed values.
- Valid X12 elements that are not used in certain segments or composites are defined in the schema as components of the segment or composite but have the component rule of **ABSENT(\$)**.
- Segments or composites that are part of the base X12 transactions but are not used per the implementation guide are not included in the schema.
- Where the implementation guides identify a limit for the maximum length of a text data element that is less than the X12 length, a component rule is used.
- Where the implementation guides identify a limit for elements that represent monetary amounts, date, or time, the schema item properties for that element enforce the limitation.
- If a situational rule within the implementation guide is based only on the data contained within a single segment, that rule is enforced with a component rule in the schema.
- Component rules that enforce the relational conditions from the base X12 definition are included in the schema if they are not superseded by any of the Type 2 component rules.

For convenience, a 5010 Type 2 schema is included that contains only the 834 and 835 transactions, as well as the segments and elements required for those transactions. This schema is: `hipaa_x12_type_2_step`

The following JSON files are used as the input metadata for the step-up maps as one way to enrich the data with new information that is specified in the Preview Draft 8020 TR3s.

- `v80x0x322_template.json`
- `v80x0x333_template.json`
- `v80x0x332_template.json`

These files do not contain objects to represent all the loops, segment, and elements in the 80x0 transactions, but only those that are changed or new for 8010 or higher version and are used in mapping rules in the step- up maps. The actual version to be used in mapping, 8020, is specified in the file.

## Step-up and step-down maps

The step-up and step-down maps provide the basis for mapping simple correspondence in unchanged elements, the changes in positioning of information within the transaction, new or changed segments loops, and other differences, both in the implementation guide changes between the two versions, and the base X12 changes.

The step-up and step-down maps use the Type 2 schemas to map the included transactions from the HIPAA 5010 base to the new 80x0 TR3 format.

The step-up maps have an additional input that uses the IBM Integration Platform native JSON support to provide a way to extend the output 80x0 data with new fields supported in the new draft implementation guides.

### Notes for using the step-up and step-down maps:

In addition to loop or segment-specific functional maps and map rules, the following notes apply to the step-up and step-down maps:

- If an element or composite is not used in 80x0, it is mapped with an **=NONE** rule, with a comment indicating that it is not used in the 80x0 TR3.
- Loop names in 80x0 schemas and functional map names in the maps reflect an abbreviation of the name in the 80x0 TR3, so they might be different from the loop name in the 5010 schema.
- Where text elements have component rules in the 80x0 schemas to enforce a maximum length, the **LEFT** function is used in step-down mapping to 5010, if the Type 2 schema enforced the length through type item properties.
- As the schema item properties are set to allow pads, and pad to min content, optional items in the mapping are wrapped in a functional map to prevent spaces to be built on output.
- Data for elements that are present in 5010 data but are no longer used in 80x0 and do not correspond to a different element in 80x0, are discarded in the step-up mapping. Similarly, data for new elements defined for use in the 80x0 TR3 that were not present in the 5010 TR3 are discarded.
- Additional map rules and functional maps are implemented where needed for mapping between the two versions.

## Preview Draft 8010 example source maps

There are six source maps in the Preview Draft 80x0 example.

Each source map contains a single executable map and requires functional maps to perform a step-up from 5010 to 80x0 or step-down from 80x0 to 5010.

The source map, `V8020x322_stepup`, contains the executable map `5010_to_8020x322` with the following inputs from the directory:

`install_dir\packs\healthcare_vn.n.n\hipaa\examples\preview_draft_80X0\data`

- **835\_5010\_stepup\_examples.dat** – contains 15 valid 835 transactions
- **v80x0x322\_examples.json** – contains data for new 8010 fields for transactions with a Transaction Control Number of 1309 and the base “ANY” transaction information for the other transactions in the 5010 input.

The single output card creates the file:

#### **835\_8020\_stepup\_examples.out**

The corresponding step-down map for the 835 is **8020x322\_to\_5010.mmc**, in source map **V80x0x322\_stepdown.mms**.

This map has a single input card, which uses the same file produced by the step-up map, **835\_80x0\_stepup\_examples.out**, producing **835\_5010\_stepdown\_examples.out**.

The source map **V70x0x333\_stepup.mms** contains the executable map **5010\_to\_8020x333** with the following inputs:

- **834\_5010\_stepup\_examples.dat** – contains 20 valid 824 transactions
- **v80x0x333\_examples.json** – contains data for new 8020 fields for transactions with a Transaction Control Number of 1289 and the base “ANY” transaction information for the other transactions in the 5010 input.

The single output card creates the file

#### **834\_8020\_stepup\_examples.out**

The corresponding step-down map for the 834 is **8020x333\_to\_5010.mmc**, in source map **V80x0x333\_stepdown.mms**.

This map has a single input card, which uses the same file produced by the step-up map, **834\_8020\_stepup\_examples.out**, producing **834\_5010\_stepdown\_examples.out**.

---

## X12N example

This example contains schemas that support X12 standard integrity checking (WEDI SNIP Type 1 Validation) for a set of healthcare industry implementation guides produced by ASC X12’s Insurance Subcommittee (X12N). These schemas do not conform to the industry TR3s but to the base X12 standard. They are useful for data transformation purposes; they should not be used for data validation for any WEDI/SNIP level above 1.

The example files install within the imported project.

- [\*\*Location of the X12N example files\*\*](#)  
This topic identifies the directory location of the X12N example files.
- [\*\*X12N schemas\*\*](#)  
This topic provides a brief description of the X12N schemas.
- [\*\*Using the X12N example files\*\*](#)  
There are no maps included in the X12N example. You can select any of the provided schemas to use in validation map, or maps created to transform to, or from, the supported versions and transactions.

---

## Location of the X12N example files

This topic identifies the directory location of the X12N example files.

The Preview Draft 7030 example is located in the following folder:

*install\_dir\packs\healthcare\_vn.n.n\hipaa\examples\x12n*

Note: Throughout this documentation, *install\_dir* indicates the location of the base product, and *n.n.n* indicates the version of the Pack for Healthcare.

---

## X12N schemas

This topic provides a brief description of the X12N schemas.

The schemas support X12 standard integrity checking through the defined items and groups that represent the X12 elements, composites, segments, loops, and transactions contained in the supported implementation guides. In addition, Relational conditions that are defined in the standard are enforced through schema component rules on the segment or composite group components.

This covers any of the relational conditions as defined in the “Relational Conditions” subsection of the X12 Application Control Structure, Definitions and Concepts (section 3.7.3.2.3 in version 7030). These conditions are:

- **P** – Paired or Multiple
- **R** - Required
- **E** – Exclusion
- **C** - Conditional
- **L** – List Conditional

For **P**-type conditions, the **ONERROR** functionality is used to provide additional detail about which component of the set was missing if Data Audit is enabled during the execution of a map using this schema.

## Using the X12N example files

There are no maps included in the X12N example. You can select any of the provided schemas to use in validation map, or maps created to transform to, or from, the supported versions and transactions.

The following table shows the versions and transactions supported by the X12N example schemas:

Version and ID	Schema name	Transaction Set ID	Document Title
003051X	x12n_3050	835	Health Care Claim Payment/Advice
003070X074	x12n_3070	186	Laboratory Results Report for Insurance Underwriting Requirements
003070X105			Paramedical Results Report for Insurance Underwriting Requirements
003070X023		270	Health Care Eligibility/Benefit Inquiry and Information Response
003070X023		271	Health Care Eligibility/Benefit Inquiry and Information Response

## External Code List Utilities example

The External Code List Utilities example contains a utility map that loads the code set database with the external code sets that are supported in the pack into a MongoDB NoSQL database.

These maps require that a MongoDB Server is accessible. This example also contains additional maps that can convert code set source files into the json format needed to load the database, if updates are needed between Pack for Healthcare releases.

- [Terminology for NoSQL databases.](#)  
Terminology for NoSQL databases, and how code set support is implemented for the Pack for Healthcare.
- [Locating](#)
- [Example components](#)
- [Using the example](#)

## Terminology for NoSQL databases.

Terminology for NoSQL databases, and how code set support is implemented for the Pack for Healthcare.

All the code source sets will be loaded into one Database (the default used is hipaa\_code\_sets). Each code source will have its own collection. The collection contains multiple documents, with each document containing an individual code source value, with a description and optional start and end dates.

## Locating

The Code List example is located in the hipaaExamplesCodeSets.zip project.

## Example components

- [Configuration files](#)

The configuration files are used for the database server location and any user credentials needed to access the database server.

- [Maps to load or delete code set information](#)

These maps load or delete code set information:

- [Maps to convert code set data](#)

These maps all begin with T5\_ (for type 5) or T6\_ (for type 6) and can be used to create the json files necessary to use in the database load maps included in this example.

- [Schemas](#)

- [Data Files](#)

The External Code List Utilities example contains the original command or tab-delimited code source values and JSON format files of these values for the code sets for which we support code value validation rules.

## Configuration files

The configuration files are used for the database server location and any user credentials needed to access the database server.

The following configuration files are used:

- hipaa\_code\_set.mrc
- hipaa\_code\_set.mrn

The server location is defaulted to mongodb://localhost:27017 in this example but should be updated if your server must be accessed through a different URL, or you have the appropriate database access information for JDBC before running the example maps.

## Maps to load or delete code set information

These maps load or delete code set information:

- load\_code\_set\_mongo – loads a single code set collection with documents for each code value in the input json file.
- load\_all\_code\_sets – loads all the external code set collections that are specified in the code\_set\_json\_list.txt input file, but calling load\_code\_set\_mongo.
- delete\_code\_set\_values – deletes all the documents from a single collection. The collection itself has not been removed from the database.
- delete\_all\_code\_set\_values – deletes all the documents from collections specified in the code\_set\_json\_list.txt input file.
- load\_code\_set\_jdbc – loads a single code set collection with documents for each code value in the input json file.
- load\_all\_code\_sets\_jdbc – loads all the external code set collections that are specified in the code\_set\_json\_list.txt input file, but calling load\_code\_set\_jdbc.
- delete\_code\_set\_values\_jdbc – deletes all the documents from a single collection. The collection itself has not been removed from the database.
- delete\_all\_code\_set\_values\_jdbc – deletes all the documents from collections specified in the code\_set\_json\_list.txt input file.

## Maps to convert code set data

These maps all begin with T5\_ (for type 5) or T6\_ (for type 6) and can be used to create the json files necessary to use in the database load maps included in this example.

The Type 5 maps also contain a code source number. The External Code Set or Source number is the number that is used for this code list in the HIPAA Implementation Guides. For example, the map that starts T5\_022, is a map for the code values for Code source 22, States and Provinces. The Type 6 map names contain the codes to indicate the line of service location and line of service category for this set of code list values.

## Schemas

- code\_set\_source – The schema that defines the command or tab-delimited input formats for the code set sources included in the example
- code\_set\_template.json - the JSON template used in creating and parsing code source json data files.

## Data Files

The External Code List Utilities example contains the original command or tab-delimited code source values and JSON format files of these values for the code sets for which we support code value validation rules.

## Using the example

- [Using the load or delete code set maps](#)
- [Using the maps to convert code set data](#)

These maps are run if you need to update a full set of code values due to code source changes after the release of the Pack for Healthcare.

## Using the load or delete code set maps

1. Update the Mongo Server location and/or credentials in configuration variables if defaults are not correct for your design environment.
  - Design Server - Update configuration variable host with correct server location. Update variables Password and userID with correct credentials.
2. Build all maps.
3. Update code\_set\_json\_list.txt if you do not want to load all code set collections, by deleting the names of code source json files that you do not want to load or remove documents from.
4. Execute load\_all\_code\_sets or delete\_all\_code\_set\_values.

## Using the maps to convert code set data

These maps are run if you need to update a full set of code values due to code source changes after the release of the Pack for Healthcare.

- Update the \*.txt file with the updated code source list.
- Build the T5\_5\* map that corresponds to your updated code source.
- Run the T5\_5\* map that corresponds to your updated code source.

## Type 7 User Exit example

This example contains a Java Program that can be used as a guide to help with the development and requirements of a Java custom user exit for Type 7 validation.

- [\*\*Location\*\*](#)  
In the Design Server, the Type 7 User Exit example is contained in the hipaaType7ExampleConfig tar.gz or zip file, depending upon the run time platform.
- [\*\*Example components\*\*](#)  
The Type 7 User Exit example contains these components:
- [\*\*Example details\*\*](#)  
The class\_name for TestJExit is com.ibm.dtx.T7jexit.TestJExit.
- [\*\*Using the Type 7 user exit example\*\*](#)  
This type of custom user exit is executed at run time by HIPAA Data Compliance, based on configuration in the hipaa\_data\_compliance\_parameter.json file.

## Location

In the Design Server, the Type 7 User Exit example is contained in the hipaaType7ExampleConfig tar.gz or zip file, depending upon the run time platform.

This is not a project to be imported into the Design server, but it contains the example components.

## Example components

The Type 7 User Exit example contains these components:

- Type7Exit.jar file created using example source, found in the \jars folder
- Java source files, found in \src\com\ibm\dtx\T7jexit, include
  - Log.java – Java source containing a logging class using coded log methods.
  - Log2.java – Java source containing a logging class using base java logging utilities.
  - TestJExit.java – Java source containing example validation methods.
  - T7ErrReturn.java – Java source containing a class defining the expected XML error return structures and processing methods.
- Sample data file – found in \data folder, hipaa\_5010\_x222a1\_837p\_type7\_sample.dat – that can be used when running the sample to confirm the error is reported

This example user exit does not contain validations related to any published Companion Guide.

## Example details

The class\_name for TestJExit is com.ibm.dtx.T7jexit.TestJExit.

The validation method (function) is Type7\_Checks and performs the following checks:

- Checks that the Subscriber Eligibility Segment EQ and the repeating element EQ01 occur less than 30 times in 005010X279A1 270 transaction sets (HIPAA Allows 99).
- For 837 transactions, checks the DTM and DTP dates for future dates and checks that DTP dates are not prior to DTM dates and also checks to ensure that the number of claims in the transaction set is less than 100.
- For 837 transactions with a GS03 (application receiver code) of STATE, limit the dollar amount in AMT02 to \$500 when AMT01 is F5 in the CLM loop.

The validation method Type7\_Checks receives the following two inputs from the hipaa\_data\_compliance maps:

1. Delims– a string that indicates the delimiters that are used in the transaction set. It is used for parsing the segments and elements. It is passed in the following format:  
 Element Separator (ISA Element separator)  
 Repetition Separator (ISA11)  
 Component Element Separator (ISA16)  
 Segment Terminator (ISA Terminator)
2. hipaaData- a string of EDI HIPAA data generated during the run time of the compliance check application. It contains the transaction set data, including the ST/SE segments, but the loop ID is also included as the first element in each segment. If the parameter ExitPartnerDetail is set to true, then the hipaaData string will have limited ISA and GS information before the transaction set data.

## Using the Type 7 user exit example

This type of custom user exit is executed at run time by HIPAA Data Compliance, based on configuration in the hipaa\_data\_compliance\_parameter.json file.

The ExitName and ExitFunction values configured are specific to this example.

As a prerequisite, in Design Server Execute the setup scripts found in hipaaType7ExampleConfig.tar.gz or zip file, dependent on the run time platform.

Follow these steps to use the example.

1. Update hipaa\_data\_compliance\_parameter.json, ValidationLevels, to enable Type7.

```
"ValidationLevels": {
 "Type7": {
 "Enabled": true,
 "RejectLevel": "Errors",
 "ExitType": "Java",
 "ExitName": "com.ibm.dtx.T7jexit.TestJExit",
 "ExitFunction": "Type7_Checks"
 }
}
```

2. Update hipaa\_data\_compliance map input 2 to use the hipaa\_5010\_x222a1\_837p\_type7\_sample.dat file.
3. Build all maps for hipaa\_data\_compliance.
4. Execute hipaa\_data\_compliance
5. View the resulting 999 acknowledgment, which will show the type 7 error reported.

## ClaimToExposure tracking example

In the era of COVID-19 many organizations will find it helpful to be able to do a quick scan of the data they already have access to in order to quickly isolate individuals with diagnosis codes of COVID-19 or indicating COVID-19 in order to take quick action.

This example shows how HIPAA 837 claims data can be used to provide an early warning report. Based on an input X12 837P transaction, this map will create an X12 standard 148 transaction, which is an EDI Report of Injury, Illness or Incident and contains basic demographic information on the patient and a list of diagnosis codes on the claim. The list of ICD-10 diagnosis codes can be modified based on current CDC guidance and organizational preferences.

- [Location](#)
- [ClaimToExposureTracking example maps](#)  
 There is one example map in this example: ClaimToExposureTracking
- [Claim to exposure tracking map details](#)

## Location

The Claim to Exposure Tracking example is located in the hipaaExamples.zip project.

## ClaimToExposureTracking example maps

There is one example map in this example: ClaimToExposureTracking

Based on an input 837P, X12 837 Professional Claim transactions, used for HIPAA and constrained by an X12N TR3 (or implementation guide) 005010X222A1, this map will create an X12 standard 148 transaction, which is an EDI Report of Injury, Illness or Incident and contains basic demographic information on the patient and a list of diagnosis codes on the claim. This same information is also generated in a simple, non-EDI text report.

## Claim to exposure tracking map details

The following are inputs to the Claim837P\_to\_ExposureReport map:

- Input 1 - HIPAA EDI claims data file
- Input 2 - A list of ICD-10 CM diagnosis codes that you want to scan. You can configure this list to fit your needs.
- Input 3 - a list of three control numbers used to create the EDI 148 transaction. One is for the interchange envelope, one is for the Functional Group envelope, and one is for the Transaction set envelope. In a production environment, these will probably be changed and looked up from a database or another system.
- Input 4 - list of diagnosis codes and their descriptions, the ICD-10 CM data to display on reports.

The outputs are the following:

- Output 1 - EDI Report – a 148 transaction, which is an EDI Report of Injury, Illness, or Incident
- Output 2 - Text Based Report

The X12 148, EDI Report, has one HL (Hierarchical Reporting) loop per claim that qualifies for inclusion on the report. It contains basic demographic data, the name of the patient and the subscriber (if different), the patient's address, and the primary and any secondary diagnoses. This report only includes claims with one diagnosis code, which matches one in input 2, but for a selected claim, all other diagnosis codes are included.

The simple text-based report includes the same basic claim information included on the X12 148 report, but with labels and diagnosis descriptions, so it is more readable for a user not familiar with X12.

Note: This example produces a report file that contains personal health information (as does the input claim itself), so ensure that regulatory policy and company policies are followed when creating and sharing these reports.

## X12N personal health records example

To support ways for the payer community to leverage existing B2B infrastructure while also beginning to work with HL7 CDA R2 and FHIR (in Json or XML), X12 has a draft implementation guide that describes the use of the AXC X12 Patient Information (275) transaction set for the business purpose of transferring Personal Health Record (PHR) information between different health plans.

This example has executable maps to generate an X12 275 transaction with imbedded PHR data in JSON format or extract PHR data from an existing 275 transaction.

- [Example location](#)
- [Example maps](#)

In the X12n Personal Health Record (PHR) Example, two executable maps are used to generate an X12 275 transaction with imbedded PHR data in JSON format or extract PHR data from an existing 275 transaction.

## Example location

The Personal Health Record Example is located in the hipaaExamples.zip project.

## Example maps

In the X12n Personal Health Record (PHR) Example, two executable maps are used to generate an X12 275 transaction with imbedded PHR data in JSON format or extract PHR data from an existing 275 transaction.

This transaction, identified currently as 007060X274, is similar to the 275 clinical attachment but with a simplified loop structure. Also, the current draft version of this implementation guide specifies HL7 CDA as the clinical payload, in this example we are using JSON.

The example contains a sample schema with the draft transaction. This schema is a simple 'ruleless' type schema with no implementation guide based rules except for any required basic structural definition.

There are two executable maps:

- `create_275_with_PHR_data` - generates a 275 with imbedded PHR data
- `extract_PHR_data_from_275` - extracts Personal Health Record data from an existing 275 transaction.

Both maps use the FHIR sample claim in JSON format for the PHR data that will be added/extracted from the 275 BDS segment.

## Performance tuning

The HIPAA X12 data structures are hierarchical in nature, and the semantic and business rules can be complex. Some of the data files can be quite large. Given these factors, it's clear that performance is an important consideration when processing HIPAA data. There are various techniques that can be used to improve the performance of HIPAA data processing within Transformation Extender. These techniques involve separating, combining, validating, and transforming data. Some of these methods are based on the standard IBM performance tuning recommendations.

Other areas for performance improvement require an analysis of site-specific and task-specific requirements and the deployment of particular architectures that optimize performance for those particular requirements.

In particular, the processing associated with HIPAA Compliance Check and reporting tends to be 'expensive' from a data processing perspective. As the HIPAA Compliance Check is highly configurable, it is possible to see large variations of performance that are based on configuration. This documentation discusses some of the processing options that are known to require substantial resources along with suggestions for their use and configuration.

- [\*\*Duplicate processing\*\*](#)

The various processing steps can include overlapping Transformation Extender functionality. Avoid overlapping functionality unless, potentially, it is necessary.

- [\*\*Unnecessary processing\*\*](#)

To increase performance, avoid all unnecessary processing of data.

- [\*\*Over reporting\*\*](#)

To maximize performance, generate only those reports that are needed by the business consumers of this information.

---

## Duplicate processing

The various processing steps can include overlapping Transformation Extender functionality. Avoid overlapping functionality unless, potentially, it is necessary.

For example, if you are developing HIPAA EDI data and then transforming that data into another format, there are multiple validation opportunities.

- Formal validation can be performed using the HIPAA Compliance check.

- Informal validation can be performed by use of the various HIPAA-level schemas that are used in the transformation map.

As an example, consider an organization that is performing HIPAA compliance checks to WEDI/SNIP level 4. If a Transformation Extender map that uses the hipaa\_x12 schema is used to transform the data, validation is performed twice.

It is performed once as part of the Compliance Check with the formal HIPAA acknowledgment reporting. Then validation is performed again to WEDI/SNIP level 4 by use of the schema. In this case, the data is already validated before transformation, and a schema with less validation might be used. To increase performance, use the hipaa\_x12\_ruleless schema in the transformation step.

---

## Unnecessary processing

To increase performance, avoid all unnecessary processing of data.

For example, the WEDI/SNIP type 5 capabilities in the HIPAA Compliance Check module can be set to check the values of external code set values that are stored in a database, against the qualified values in the data. Depending on your business requirements, this higher level checking might not be necessary.

Due to the large amount of resources that are required to perform the type 5 check, do not perform the check unless your intention is to reject such data.

Similarly, if you want to process all data with the correct HIPAA structure (WEDI/SNIP type 2), do not perform the more costly type 4 validation. Type 4 validation includes cross-segment summing and other cross-segment checks. The rules that are involved in these levels of checks require the build-up of multiple pieces of information across more than one segment of data. Therefore, these checks require more resources than the type 2 checks require.

Another way to increase performance is to use Claim Level Rejection processing only when it is necessary to meet the business requirement.

The ability to process a subset of a batch of 837 claims is important in some environments but not in all. If there is a business requirement to process all valid claim loops and report on all invalid claim loops within a single transaction set then Claim Level Rejection is necessary. However, the processing necessary to accomplish that task is complex and care must be taken to use Claim Level Rejection only when the business requirement demands this level of processing.

---

## Over reporting

To maximize performance, generate only those reports that are needed by the business consumers of this information.

For example, a translated acknowledgment report is available in the Transformation Extender Platform. This report shows a graphical representation of the errors in the data, which is shown in the same hierarchical structure. This is an informative report for you to generate if you are a non-EDI fluent user. It is often a good tool to use when the Transformation Extender Platform system is initially configured. In some cases, the technical implementation team might not be familiar with ASC X12 999. However, your business users might find the structured 999 acknowledgment sufficient for both computer-readable and human-readable use. Therefore, you might not need a duplicate version of the same information. In such cases, verify that these reports are needed after the initial implementation of the product.

---

## Acknowledgment errors

These lists show HIPAA Compliance Checker acknowledgment error codes.

- [\*\*AK304 segment level\*\*](#)

- [\*\*IK304 error code\*\*](#)

- [\*\*AK403 element level\*\*](#)

## AK304 segment level

<b>Code</b>	<b>Definition</b>
AK304 = 1	Unrecognized segment ID
AK304 = 2	Unexpected segment
AK304 = 3	Mandatory segment missing
AK304 = 4	Loop Occurs Over Maximum Times
AK304 = 5	Segment Exceeds Maximum Use
AK304 = 6	Segment Not in Defined Transaction Set
AK304 = 7	Segment Not in Proper Sequence
AK304 = 8	Segment Has Data Element Errors

---

## IK304 error code

<b>Code</b>	<b>Definition</b>
IK304 = 1	Unrecognized Segment ID
IK304 = 2	Unexpected Segment
IK304 = 16	Implementation dependent seg missing
IK304 = 4	Loop occurs > max allowed
IK304 = 5	Segment exceeds max use
IK304 = 14	Implementation "not used" seg pres
IK304 = 7	Segment not in sequence
IK304 = 8	Segment has data element errs
IK304 = 17	Implementation loop occurs < min times
IK304 = 18	Implementation segment below min use
IK304 = 19	Impl'n dependent not used seg present

---

## AK403 element level

<b>Code</b>	<b>Definition</b>
AK403 = 1	Required data element missing
AK403 = 2	Conditional required data element missing
AK403 = 3	Too many data elements
AK403 = 4	Data element too short
AK403 = 5	Data element too long
AK403 = 6	Invalid character in data element
AK403 = 7	Invalid code value
AK403 = 8	Invalid date
AK403 = 9	Invalid time
AK403 = 10	Exclusion condition violated
AK403 = 12	Too many repetitions
AK403 = 13	Too many components
AK403=I10	Implementation "Not Used" data element present
AK403=I11	Implementation too few repetitions
AK403=I12	Implementation pattern match failure
AK403=I13	Implementation dependent "Not Used" data element present
AK403=I6	Code value not used in implementation
AK403=I9	Implementation dependent data element missing

---

## IK403 error code

<b>Code</b>	<b>Description</b>
IK403 = 19	Impl'n dependent data element missing
IK403 = 2	Conditional required data element missing
IK403 = 13	Too many components
IK403 = 4	Data element too short
IK403 = 5	Data element too long
IK403 = 6	Invalid character in data element
IK403 = 16	Code value not used in implementation
IK403 = 8	Invalid date
IK403 = 9	Invalid time
IK403 = 10	Exclusion Condition Violated
IK403 = 12	Too many repetitions
IK403 = I10	Implementation "not used" data element present

<b>Code</b>	<b>Description</b>
IK403 = I11	Implementation too few repetitions
IK403 = 12	Implementation Pattern Failure Match
IK403 = 13	Implementation dependent "not used" element present

---

## AK502 transaction set level

<b>Code</b>	<b>Definition</b>
AK502 = 1	Transaction set not supported
AK502 = 2	Transaction set trailer missing
AK502 = 3	Transaction set control number in header and trailer do not match
AK502 = 4	Number of included segments does not match actual count
AK502 = 5	One or more segments in error
AK502 = 6	Missing or invalid transaction set identifier
AK502 = 7	Missing or invalid transaction set control number
AK502 = 8	Authentication key name unknown
AK502 = 9	Encryption key name unknown
AK502 = 10	Requested service (authentication or encryption) not available
AK502 = 11	Unknown security recipient
AK502 = 12	Incorrect message length (encryption only)
AK502 = 13	Message authentication code failed
AK502 = 15	Unknown security originator
AK502 = 16	Syntax error in decrypted text
AK502 = 17	Security not supplied
AK502 = 18	Transaction set not in functional group
AK502 = 19	Invalid transaction set implementation convention reference
AK502 = 23	Transaction set control number not unique within the functional group
AK502 = 24	S3E security end segment missing for S3S security start segment
AK502 = 25	S3S security start segment missing for S3E security end segment
AK502 = 26	S4E security end segment missing for S4S security start segment
AK502 = 27	S4S security start segment missing for S4E security end segment
AK502=I6	Implementation convention not supported

---

## AK905 functional group level

<b>Code</b>	<b>Definition</b>
AK905 = 1	Functional group not supported
AK905 = 2	Functional group version not supported
AK905 = 3	Envelope trailer missing
AK905 = 4	Group control number in the functional group header and trailer do not agree
AK905 = 5	Number of included transaction sets does not match actual count
AK905 = 6	Group control number violates syntax
AK905 = 10	Authentication key name unknown
AK905 = 11	Encryption key name unknown
AK905 = 12	Requested service (authentication or encryption) not available
AK905 = 13	Unknown security requirement
AK905 = 14	Unknown security originator
AK905 = 15	Syntax error in decrypted text
AK905 = 16	Security not supported
AK905 = 17	Incorrect message length (encryption only)
AK905 = 18	Message authentication code failed
AK905=19	Functional Group Control Number not unique within interchange
AK905 = 23	S3E security end segment missing for S3S security start segment
AK905 = 24	S3S security start segment missing for S3E security end segment
AK905 = 25	S4E security end segment missing for S4S security start segment
AK905 = 26	S4S security start segment missing for S4E security end segment

---

## TA105 interchange level

<b>Code</b>	<b>Definition</b>
TA105 = 000	No error
TA105 = 001	The interchange control number in the header and trailer do not match

<b>Code</b>	<b>Definition</b>
TA105 = 002	The standard as noted in the control standards identifier is not supported
TA105 = 003	This version of the controls is not supported
TA105 = 004	The segment terminator is invalid
TA105 = 005	Invalid interchange ID qualifier for sender
TA105 = 006	Invalid interchange sender ID
TA105 = 007	Invalid interchange ID qualifier for receiver
TA105 = 008	Invalid interchange receiver ID
TA105 = 009	Unknown interchange receiver ID
TA105 = 010	Invalid authorization information qualifier value
TA105 = 011	Invalid authorization information value
TA105 = 012	Invalid security information qualifier value
TA105 = 013	Invalid security information value
TA105 = 014	Invalid interchange date value
TA105 = 015	Invalid interchange time value
TA105 = 016	Invalid interchange standards identifier value
TA105 = 017	Invalid interchange version ID value
TA105 = 018	Invalid interchange control number value
TA105 = 019	Invalid acknowledgement requested value
TA105 = 020	Invalid test indicator value
TA105 = 021	Invalid number of included groups value
TA105 = 022	Invalid control structure
TA105 = 023	Improper (premature) end-of-file (transmission)
TA105 = 024	Invalid interchange content (e.g. invalid GS segment)
TA105 = 025	Duplicate interchange control number
TA105 = 026	Invalid data element separator
TA105 = 027	Invalid component element separator
TA105 = 028	Invalid delivery date in deferred delivery request
TA105 = 029	Invalid delivery time in deferred delivery request
TA105 = 030	Invalid deliver time code in deferred delivery request
TA105 = 031	Invalid grade of service code

## TED01 - error reporting/acknowledgement process

<b>Code</b>	<b>Definition</b>
TED01 = 010	Total out of balance
TED01 = 848	Incorrect data
TED01 = OTH	Used for reporting XML errors.
TED01 = 024	Other unlisted reasons.

## HL7 component

The documentation provided here describes the Pack for Healthcare HL7 component.

- [HL7 schemas](#)  
The schemas in the HL7 component, include definitions for the HL7 format.
- [HL7 component schemas](#)  
The HL7 component includes schemas with data definitions for the HL7 industry standard.
- [HL7 validation](#)
- [HL7 component examples](#)  
Examples are provided to demonstrate how to use the HL7 component.

## HL7 schemas

The schemas in the HL7 component, include definitions for the HL7 format.

The HL7 component provides health care and insurance payer organizations with an infrastructure that:

- enables compliance with government and industry mandates
- controls administrative costs
- streamlines business processes
- facilitates accuracy and timeliness of information
- offers a competitive advantage
- conforms to existing systems
- adapts to new technologies as they emerge
- integrates multiple systems and standards

# HL7 component schemas

The HL7 component includes schemas with data definitions for the HL7 industry standard.

This means that data that meets the specification requirements is considered valid, while data that does not meet the requirements is rejected. Other schema attributes include the following:

- compatibility with other IBM product offerings, such as Trading Manager
- flexibility in modifying or merging with other schemas
- ability to support reliable and efficient mapping
- easily maintainable

- **[hl7\\_v2\\_x schemas](#)**

The hl7\_v2\_x schemas provided in the HL7 component describe the data exchange formats associated with HL7.

- **[Using the Pack for HL7 schemas](#)**

The Transformation Extender user interface depicts the HL7 message structure as an expandable, contractible set of hierarchical components. The schema enforces compliance of HL7 transmission data with EDI Standard Integrity Testing rules.

## hl7\_v2\_x schemas

The hl7\_v2\_x schemas provided in the HL7 component describe the data exchange formats associated with HL7.

Note: In the hl7\_v2\_x schemas, x indicates the standard version (for example, hl7\_v2\_3, hl7\_v2\_4, etc.)

Most of the schemas in the pack include a category: **%\_Type\_Tree\_Information**. Double-click on the **%\_Description** or **%\_Revision\_History** items to see a narrative description of the schema or the schema revision history.

Some of the hl7\_v2\_x schemas are analyzed with warnings that indicate some components may not be distinguishable from other components. Such warnings can be ignored.

- **[hl7\\_v2\\_1 schema](#)**

This schema contains the data definitions used in the HL7 Version 2.1 standard.

- **[hl7\\_v2\\_2 schema](#)**

This schema contains the data definitions used in the HL7 Version 2.2 standard.

- **[hl7\\_v2\\_3 schema](#)**

This schema contains the data definitions used in the HL7 Version 2.3 standard.

- **[hl7\\_v2\\_4 schema](#)**

This schema contains the data definitions used in the HL7 Version 2.4 standard.

- **[hl7\\_v2\\_5 schema](#)**

This schema contains the data definitions used in the HL7 Version 2.5 standard.

- **[hl7\\_v2\\_5\\_1 schema](#)**

This schema contains the data definitions used in the HL7 Version 2.5.1 standard.

- **[hl7\\_v2\\_6 schema](#)**

This schema contains the data definitions used in the Health Level 7 (HL7) Version 2.6 standard. These data definitions include file, batch, and message formats. File Protocol HL7 is the top-level group in this schema.

- **[hl7\\_v2\\_7 schema](#)**

## hl7\_v2\_1 schema

This schema contains the data definitions used in the HL7 Version 2.1 standard.

The data definitions include file, batch, and message formats. File Protocol **HL7** is the top-level group in this schema.

## hl7\_v2\_2 schema

This schema contains the data definitions used in the HL7 Version 2.2 standard.

These data definitions include file, batch, and message formats. File Protocol **HL7** is the top-level group in this schema.

## hl7\_v2\_3 schema

This schema contains the data definitions used in the HL7 Version 2.3 standard.

These data definitions include file, batch, and message formats. File Protocol **HL7** is the top-level group in this schema.

The hl7\_v2\_3 schema analyzes with warnings that you can ignore, such as the following:

```
L199 - COMPONENT 10 may not be distinguishable from COMPONENT 14 that may follow in TYPE 'A06
ADT Message HL7' (warning)
```

## hl7\_v2\_4 schema

This schema contains the data definitions used in the HL7 Version 2.4 standard.

These data definitions include file, batch, and message formats. File Protocol **HL7** is the top-level group in this schema.

## hl7\_v2\_5 schema

This schema contains the data definitions used in the HL7 Version 2.5 standard.

These data definitions include file, batch, and message formats. File Protocol **HL7** is the top-level group in this schema.

## hl7\_v2\_5\_1 schema

This schema contains the data definitions used in the HL7 Version 2.5.1 standard.

These data definitions include file, batch, and message formats. File Protocol **HL7** is the top-level group in this schema.

## hl7\_v2\_6 schema

This schema contains the data definitions used in the Health Level 7 (HL7) Version 2.6 standard. These data definitions include file, batch, and message formats. File Protocol **HL7** is the top-level group in this schema.

The hl7\_v2\_6 schema analyzes with warnings that you can ignore, such as the following

L201 - Different data objects of COMPONENT 1 may not be distinguishable in  
TYPE 'Response\_LOOP O38 OPR Loop HL7' (warning)

L199 - COMPONENT 5 may not be distinguishable from COMPONENT 8 that may  
follow in TYPE 'A60 ADT Message HL7' (warning)

## hl7\_v2\_7 schema

This schema contains the data definitions used in the Health Level 7 (HL7) Version 2.7 standard. These data definitions include file, batch, and group formats. File Protocol **HL7** is the top-level group in this schema.

The hl7\_v2\_7 schema analyzes with warnings that you can ignore.

## Using the Pack for HL7 schemas

The Transformation Extender user interface depicts the HL7 message structure as an expandable, contractible set of hierarchical components. The schema enforces compliance of HL7 transmission data with EDI Standard Integrity Testing rules.

The rules check for the following:

- valid segments
- segment order
- maximum segment and loop occurrences
- element attributes (for example, size and data type)
- adherence to HL7 syntax rules as defined in the HL7 standard

Note: The examples used here are for example purposes only. They are not necessarily defined within the HL7 standard.

- [Schema data definitions](#)

The schemas contains the data definitions used in the HL7 standard. These data definitions include file, batch, and message formats. File protocol **HL7** is the top-level group in the schemas.

- [Logical grouping of fields](#)

Fields can be grouped to contain other related fields. For example, the **SendingApplication** HD Composite Field is HL7 data type HD. Grouped fields are delimited using the Comp Separator value.

## Schema data definitions

The schemas contains the data definitions used in the HL7 standard. These data definitions include file, batch, and message formats. File protocol **HL7** is the top-level group in the schemas.

An EDI message contains special characters called *delimiters*. These characters enable parsing of the message. The delimiters are:

• segment terminator	• subcomponent separator
• field separator	• repetition separator
• component separator	• escape character

The segment terminator, defined to be used with HL7 messages, is a carriage return (in ASCII, a hex 0D). The other delimiters are defined in the MSH segment, with the field separator in the fourth character position and the other delimiters occurring in the first field segment after the segment ID.

The following delimiter values specified in the MSH segment are used throughout the entire HL7 message:

MSH ~\&	
	= field separator
^	= comp separator
~	= repetition character
\	= EscapeCharacter separator
&	= subcomponent

The following example shows a segment (ERR) that contains all of the delimiters:

```
ERR|IPR^10^8~IPR||CWE^ERR03|W|CWE^ERR05||||CWE^ERR10|CWE^ERR11|PRN^PH^Add
res^034^444^5556666^Any Text^^^^^CWE&XTN Sub-Element^<cr>
```

- **Message structure**

The structure of the message is defined by message type and trigger event. For example, message type ACK and trigger event is A01. A message type may specify more than one trigger event code, but a trigger event may only be specified for a specific message type. The message type and trigger event are identified in the MSH segment. All components of a message may be defined as required, or optional.

---

## Message structure

The structure of the message is defined by message type and trigger event. For example, message type ACK and trigger event is A01. A message type may specify more than one trigger event code, but a trigger event may only be specified for a specific message type. The message type and trigger event are identified in the MSH segment. All components of a message may be defined as required, or optional.

A segment is a logical grouping of data fields. Segments might be either required or optional in a message. Segments can occur only once in a message, or they may be allowed to repeat. A unique three-character code is used to identify each segment. A segment terminator is used to identify the end of a segment. This segment terminator is the carriage return character for HL7. Segments can repeat, and they might be logically grouped together to form a loop within the message.

---

## Data fields

The data fields represent individual units of data found in the message. These fields are defined and re-used within segments and are given a data type. For example, the **DateTimeOfMessage** DTM Element Field is HL7 data type DTM. The data type identifies the characteristics of the data value and is used to validate the data. Data fields can be either required or optional in a segment. Each field is delimited within the segment using the Field Separator Message control value, which is the fourth character position in the MSH segment.

---

## Logical grouping of fields

Fields can be grouped to contain other related fields. For example, the **SendingApplication** HD Composite Field is HL7 data type HD. Grouped fields are delimited using the Comp Separator value.

When a field definition contains another field that defines a group of fields, the data type of the field within the definition is defined as a "Sub," or subcomponent in the schema. For example, ErrorCodeAndLocation ELD Composite contains **CodeIdentifyingError** CWE Sub. Both the ELD and CWE data types contain groups of related fields and can be used within a segment, or within another field. Subcomponent elements are delimited using the subcomponent separator value.

Fields can repeat and are identified as Repeat Field, such as, **ErrorLocation** ELD Repeat Field. Repeating data types are delimited using the repetition separator value.

---

## HL7 validation

Validating data that is formatted for HL7 2x or EDI poses several challenges. There are many required aspects to the syntax and semantic checking, and to report meaningful information based on flaws in the EDI data requires many checks.

- Is the data enveloped and, optionally, batched correctly?
- Are only the correct loops and segments in the data, and are they in the correct order?
- Within each segment are the fields in the correct order?
- Is the data in the field the correct size?

A recent addition to the HL7 offering is a set of XML schemas that describe the delimited EDI data as if it were XML tagged data. These schemas are available free of charge from HL7 for their members. HL7 member organizations can download these schemas and load them into the Transformation Extender HL7 validation directory structure and leverage them for data validation.

The HL7 2.x EDI format is the Intellectual Property of HL7. You must contact HL7 to use this feature.

- [Running the HL7 validation utility](#)

The HL7 Validation utility leverages the information in the XSD schemas provided by HL7 and applies the structure and data content rules from the schemas to the EDI data.

---

## Running the HL7 validation utility

The HL7 Validation utility leverages the information in the XSD schemas provided by HL7 and applies the structure and data content rules from the schemas to the EDI data.

First, the delimited HL7 2.x EDI data is transformed into its XML tagged equivalent. Then that XML data (called an XML instance document), is validated against the schema. This leverages the power of an XML parser for error reporting. An HTML formatted error report (with a very XML-centric description of errors) might be produced if desired, as well as an HL7 2.x EDI formatted ACK with a positive or negative acknowledgment indicator.

This utility also provides transformation of XML tagged Instance documents to their delimited EDI equivalents for the versions of HL7 2.x EDI that are supported by this implementation.

To run the validation utility against HL7 data:

1. Open the main map source, **hl7main**, in the Design Server.
2. Update Input card 1 to select the HL7 input data to validate. Sample file **hl7\_edi\_example\_V2.7** in the hl7\data directory is used in this card as installed. The input can be **EDI HL7** or **XML HL7**. The correct processing of the data is determined by the map by examining the data input.
3. To modify or review any configurable parameters, edit the file: **hl7parms.xml**.
4. Compile all maps in maps directory:
  - In Design Studio: Use **compilemaps.bat**.
  - In Design Server: Create and build a package with all maps.
5. Execute **hl7main** to run the HL7 Validation utility. The following output files are produced in the hl7\data directory:
  - **StatusReport.html** - Report that summarizes the final status for the validation, Message Type, Message Version, XML Scan Status (if the input is XML HL7 data), XML Validation Status, and XML > EDI or EDI > XML Conversion Status.
  - **HL7Out.xml** - If the input file was EDI HL7, this is the UTF-8 converted XML data.
  - **EDIOut.edi** - If the input file was EDI XML, this is the EDI converted data.
  - **hl7\_edi\_ack.out** - If the input was HL7 EDI, and acknowledgment was requested, an Original Mode Acknowledgment is generated in HL7 EDI format.
  - **hl7\_xml\_ack.out** - If the input is HL7 XML and acknowledgment was requested, an Original Mode Acknowledgment is generated in XML format.

---

## HL7 component examples

Examples are provided to demonstrate how to use the HL7 component.

- [NCPDP-SCRIPT / HL7 mapping example](#)

The example for NCPDP-SCRIPT/ HL7 mapping is based on the *NCPDP-HL7 Electronic Prescribing Coordination Mapping Document*. That document provides mapping requirements for interactions between systems using HL7 and systems using NCPDP Script.

- [FHIR example](#)

The FHIR examples demonstrate the mapping from HL7 Fast Healthcare Interoperability Resources to HL7 V2 format and mapping from a Da Vinci Prior Authorization Support (PAS) bundle to the HIPAA EDI Prior Authorization Request (278) and Clinical Attachment (275) transactions.

- [FHIR Example - PAS Bundle with JSON Schema](#)

The FHIR Mapping example demonstrates mapping between FHIR PAS JSON bundles for mapping between Prior Authorization Request and Responses (278) and a FHIR Da Vinci Prior Authorization Support (PAS) bundle. These crosswalk mappings are expected to be used in the industry to support several US interoperability initiatives and conform to the Implementation Guides published by X12N Insurance.

- [FHIR Validation Example](#)

- [HL7 MLLP Example](#)

The MLLP adapter provides a means of passing data to and from the Transformation Extender using the MLLP protocol over TCP/IP.

---

## NCPDP-SCRIPT / HL7 mapping example

The example for NCPDP-SCRIPT/ HL7 mapping is based on the *NCPDP-HL7 Electronic Prescribing Coordination Mapping Document*. That document provides mapping requirements for interactions between systems using HL7 and systems using NCPDP Script.

The NCPDP-SCRIPT/ HL7 mapping example shows both the HL7 to NCPDP and NCPDP to HL7 directions for a new **NEWRX** prescription message. You can use this example as a starting point for the actual maps needed for this transformation or as a general model to understand such mapping.

- [Location of HL7/NCPDP-SCRIPT mapping files](#)

This documentation identifies the directory location of the HL7/NCPDP-SCRIPT mapping example files.

- [HL7 / NCPDP-SCRIPT mapping schemas](#)

This documentation describes the HL7/NCPDP mapping schemas.

- [NCPDP-SCRIPT / HL7 example maps](#)

This documentation describes the example maps provided in the NCPDP-SCRIPT / HL7 example.

---

## Location of HL7/NCPDP-SCRIPT mapping files

This documentation identifies the directory location of the HL7/NCPDP-SCRIPT mapping example files.

The HL7/NCPDP mapping example is located in the following folder:

<install\_dir>\packs\healthcare\_vn.n.n.n\hl7\examples\hl7\_ncpdp\_script

Where <install\_dir> indicates the installed location of the Transformation Extender Platform base product, and n.n.n.n is the version number of the pack.

## HL7 / NCPDP-SCRIPT mapping schemas

This documentation describes the HL7/NCPDP mapping schemas.

The schemas and JSON metadata files install within the imported project:

- hl7\_v2\_8\_2 – a copy of the hl7 schema for version 2.8.2 of the standard.
- ncpdp\_script\_v10\_6\_201610 – NCPDP schema for script version 10.6.

These schemas are copied to the example location. Other versions of HL7 or NCPDP can be used. All versions provided in the pack are supported in the *NCPDP-HL7 Electronic Prescribing Coordination Mapping Document*.

## NCPDP-SCRIPT / HL7 example maps

This documentation describes the example maps provided in the NCPDP-SCRIPT / HL7 example.

There are two maps provided in the example, one for each direction of transformation:

- ncpdp\_script\_to\_hl7 – maps a NCPDP NEWRX message to an HL7 OMP message, using ncpdp\_input.dat, producing hl7\_output.dat
- hl7\_to\_ncpdp\_script – maps HL7 OMP to NCPDP NEWRX, using hl7\_output.dat as input.

## FHIR example

The FHIR examples demonstrate the mapping from HL7 Fast Healthcare Interoperability Resources to HL7 V2 format and mapping from a Da Vinci Prior Authorization Support (PAS) bundle to the HIPAA EDI Prior Authorization Request (278) and Clinical Attachment (275) transactions.

- [Location of the FHIR example files](#)

This documentation identifies the directory location of the FHIR example files.

- [FHIR example schemas](#)

The schemas and JSON metadata files are included for this example.

- [FHIR example maps](#)

The FHIR example provides maps to enable transformation between HL7 ORU messages in EDI format and a FHIR Observation resource in JSON or XML format.

## Location of the FHIR example files

This documentation identifies the directory location of the FHIR example files.

<install\_dir>\packs\healthcare\_vn.n.n.n\hl7\examples\fhir

Where <install\_dir> indicates the installed location of the Transformation Extender base product, and n.n.n.n is the version number of the pack.

When running the example on Design Server, the example files are installed within the imported hl7Examples.zip project.

## FHIR example schemas

The schemas and JSON metadata files are included for this example.

- hl7\_v2\_8\_2 - A copy of the HL7 schema for version 2.8.2 of the standard
- hipaa\_x12\_ruleless - A copy of the HIPAA schema used for mapping 5010 278 and 275 output
- Redistributed HL7 FHIR XML schemas, FHIR v4.0.0
- JSON template from a HL7 FHIR Observation example

## FHIR example maps

The FHIR example provides maps to enable transformation between HL7 ORU messages in EDI format and a FHIR Observation resource in JSON or XML format.

The observation\_json map performs transformations based upon whether the input is in EDI or JSON format, and produces the corresponding output. Similarly, the observation\_xml map performs transformations based upon whether the input is in EDI, or XML format.

There is an additional input file, codsystem\_lookup.txt, that is used to transform the URLs used for code systems in FHIR, to the CODE name that would be used in HL7 EDI. This lookup file is provided as an example on how transformation can be enriched with additional resources if needed.

It also provides the pas\_fhir\_to\_x12 map to create HIPAA EDI Prior Authorization Request (278) and Clinical Attachment (275) transactions from a FHIR Da Vinci Prior Authorization Support (PAS) bundle. These crosswalk mappings are expected to be used in the industry to support several US interoperability initiatives and conform to the Implementation Guides published by X12N Insurance.

- [Running the example for FHIR JSON format](#)

These steps describe how to run the example for the FHIR JSON format:

- [Running the example in FHIR XML format](#)

These steps describe how to run the example for FHIR XML format:

- [Running the FHIR PAS bundle example map](#)

These steps describe how to run the example for the FHIR PAS bundle:

---

## Running the example for FHIR JSON format

These steps describe how to run the example for the FHIR JSON format:

To convert an Observation Resource to an HL7 ORU message use observation\_example.json for the Input\_Data input in the observation\_json map.

1. Build all maps.
2. Run observation\_json.

HL7\_EDI\_Output is created, producing the file: hl7\_edi\_oru\_output.out

To convert an HL7 ORU message to an Observation resource, use the sample\_hl7\_edi.oru.dat file in the observation\_json map.

1. Build all maps
2. Run observation\_json.

FHIR\_JSON\_Output is created, producing file fhir\_json\_observation\_output.json.

---

## Running the example in FHIR XML formal

These steps describe how to run the example for FHIR XML format:

To convert an Observation Resource to an HL7 ORU message, use observation\_example.xml for the Input\_Data input in the observation\_xml map.

1. Build all maps.
2. Run observation\_xml.

HL7\_EDI\_Output is created, producing the file hl7\_edi\_oru\_output.out.

To convert an HL7 ORU message to an Observation resource, use sample\_hl7\_edi.oru.dat in the observation\_xml map.

1. Build all maps.
2. Run observation\_xml.

FHIR\_XML\_Output is created, producing the file fhir\_xml\_observaton\_output.xml.

---

## Running the FHIR PAS bundle example map

These steps describe how to run the example for the FHIR PAS bundle:

To create an X12 interchange with the 278 Health Care Services Review - Request for Review and Response (005010X217) transaction and corresponding 275 Additional Information to Support a Health Care Services Review (006020X316) transaction from a PAS bundle representing a medical services authorization, use bundle.xml input in pas\_fhir\_to\_x12 map (Source map fhir\_bundle\_to\_x12 if running in Design Studio).

1. Build all maps.
2. Run pas\_fhir\_to\_x12.

The X12\_interchange output is created, producing the file pas\_278\_275\_request.out.

---

## FHIR Example - PAS Bundle with JSON Schema

The FHIR Mapping example demonstrates mapping between FHIR PAS JSON bundles for mapping between Prior Authorization Request and Responses (278) and a FHIR Da Vinci Prior Authorization Support (PAS) bundle. These crosswalk mappings are expected to be used in the industry to support several US interoperability initiatives and conform to the Implementation Guides published by X12N Insurance.

- [Location of the PAS Bundle with JSON example files](#)

---

## Location of the PAS Bundle with JSON example files

For design studio installs, the fhir\_val.mms map is found at:

```
<install_dir>\packs\healthcare_vn.n.n.n\hl7\examples\fhirPASJson
```

Where *<install\_dir>* indicates the installed location of the Transformation Extender base product, and *n.n.n.n* is the version number of the pack.

The PAS\_Request map uses as input a Claim Request Sample Bundle in JSON format and generates the corresponding 5020X217 278 Request in X12 HIPAA EDI format.

The PAS\_Response maps take an 5010X217 278 Response and generates the corresponding ClaimResponse Bundle in JSON format.

Both maps use a modified JSON schema for validation and mapping - unused FHIR resources are removed for clearer mapping.

The mapping is based on the guidelines documented in the X12 Implementation guide for 5010X217.

---

## FHIR Validation Example

The FHIR validation example shows how a simple map or flow can invoke HL7 FHIR validation using the FHIR test server at <https://hapi.fhir.org/baseR5>.

- [Location of the FHIR Validation example files](#)

---

## Location of the FHIR Validation example files

For design studio installs, the fhir\_val.mms map is found at:

```
<install_dir>\packs\healthcare_vn.n.n.n\hl7\examples\fhirValidation
```

Where *<install\_dir>* indicates the installed location of the Transformation Extender base product, and *n.n.n.n* is the version number of the pack

When this map is ran standalone, it invokes the FHIR test server to validate the input observation resource. Two outputs are produced if the test server is accessible, and the input can be validated as an FHIR observation resource. One output (Card 2) is validation\_results.json, which is the parsed Outcome resource returned by the test server. The other output (Card3) is simply the original input passed through, with a flow variable set. However, when running this map standalone, the flow variable is extraneous – it is only in the map for its use within the flow.

The sample flow is only supported on the Design Server and is available as a project hl7fhirValidationExample.

This flow invokes HL7 Validation for a single JSON formatted FHIR Observation resource and returns Validation results as an Operation Outcome resource on one of the flow endpoints. If the validation outcome contains no warnings or errors, the map will set a flow variable *valid* to true. If this variable is set to true, a decision node in the flow will then route the original resource to be converted to XML. Select file observation\_valid to run the flow for valid data and see if the data has been transformed to XML. Select file observation\_invalid to run flow for invalid data.

If the test server is not accessible, the map, fhir\_val, that invokes the FHIR test server to validate the input observation resource will fail. The remaining nodes in the flow will not execute, and no data is returned in the endpoints. View the map log to see any details on the failure.

---

## HL7 MLLP Example

The MLLP adapter provides a means of passing data to and from the Transformation Extender using the MLLP protocol over TCP/IP.

This example demonstrates the use of the MLLP adapter in Transformation Extender maps.

A map running under the Transformation Extender Launcher System, or in a Flow is used to simulate an application that accepts an HL7 message via MLLP, and returns an acknowledgment.

- [Location of the MLLP example files](#)

The source maps and launcher system to be used with the Transformation Extender Flow Server or Launcher runtime is found in:

---

## Location of the MLLP example files

The source maps and launcher system to be used with the Transformation Extender Flow Server or Launcher runtime is found in:

```
<install_dir>\packs\healthcare_vn.n.n.n\hl7\examples\mllp
```

Where *<install\_dir>* indicates the installed location of the Transformation Extender base product, and *n.n.n.n* is the version number of the pack.

This also contains a readme.txt file with more details on how to use the example in either the Launcher or Flow Server.

The sample flow and contained nodes and maps, is supplied for the Design Server with Flow engine, and is available as a project hl7mllpExample.

---

## NCPDP component

The Pack for Healthcare NCPDP component is a solution for National Council of Prescription Drug Program (NCPDP) healthcare-industry participants. The NCPDP transactions are used exclusively in the retail pharmacy sector.

In addition to the NCPDP component, there are two other Pack for Healthcare components:

- The HIPAA EDI component
  - The HL7 component
  - [Objects included in the pack](#)
  - [NCPDP maps](#)
  - [Sample Data](#)

Sample data is provided for use with the schemas and maps in the NCPDP component.
  - [NCPDP component examples](#)

This documentation describes the NCPDP SCRIPT example and the PACDR example.
  - [NCPDP SCRIPT schemas](#)

The Transformation Extender interface shows the NCPDP SCRIPT and XML data structure as both an expandable and contractible set of hierarchical components.
  - [NCPDP validation](#)

The NCPDP component provides validation of the NCPDP Telecom version D0 Request Transactions with Batch 1.2 data standards, with regular updates to support code list changes.
- 

## Objects included in the pack

The data exchange, transformation, and integration requirements of the healthcare industry range from simple to complex and can vary greatly from one organization to another. NCPDP component contains predefined objects. These objects are flexible and allow a wide variety of applications and systems to be developed that meet your specific requirements.

The pack contains schemas, maps, sample data, and example utility modules. These predefined, industry-specific objects are organized in a way that provides the flexibility to create and deploy a wide variety of applications and systems that address NCPDP integration requirements. These objects are constructed to allow consistent behavior and results across all supported platforms and operating systems.

The schemas define the more commonly used healthcare industry data standards. The maps, data, and utility modules embrace typical data validation and transformation scenarios.

- [NCPDP schemas](#)
  - [Sample data](#)
  - [Maps](#)
- 

## NCPDP schemas

The NCPDP schemas describe the retail pharmacy telecommunications and batch data interchange formats as specified by the National Council for Prescription Drug Programs (NCPDP).

The NCPDP schemas are named based on the annual implementation version and emergency code list publications.

## Sample data

The data files included in the NCPDP component contain transaction data exchange formats associated with the National Council for Prescription Drug Program (NCPDP) health care application standard.

## Maps

The NCPDP reporting and transformation maps are included in the NCPDP component.

## NCPDP maps

The NCPDP component contains two types of maps. The NCPDP reporting maps are pass-through maps. These maps are used for data validation for NCPDP Versions 5.1, D.0, and 3.0. The NCPDP SCRIPT maps are transformation and pass-through maps for NCPDP SCRIPT Version 10.6.

## Sample Data

Sample data is provided for use with the schemas and maps in the NCPDP component.

- [Transaction data](#)

The NCPDP component includes sample transaction data for NCPDP
- 

## Transaction data

The NCPDP component includes sample transaction data for NCPDP

- [NCPDP sample data](#)

## NCPDP sample data

NCPDP sample data includes request and response data for four of the retail pharmacy transactions as specified by the National Council for Prescription Drug Programs.

NCPDP sample data files are located in the following directory:

*install\_dir\packs\healthcare\_vn.n.n\ncpdp\data*

In the above path, *install\_dir* is the location of the Transformation Extender base product, and *n.n.n* is the version number of the Pack for Healthcare.

The NCPDP sample data files include the following:

- ncpdp\_medsub\_v3\_0\_billrev\_req\_sample.dat
- ncpdp\_medsub\_v3\_0\_billrev\_res\_acc\_sample.dat
- ncpdp\_medsub\_v3\_0\_bill\_req\_sample.dat
- ncpdp\_medsub\_v3\_0\_bill\_res\_rej\_sample.dat
- ncpdp\_medsub\_v3\_0\_rebill\_req\_sample.dat
- ncpdp\_medsub\_v3\_0\_rebill\_res\_acc\_sample.dat
- ncpdp\_vd\_0\_rebill\_response.dat
- ncpdp\_vd\_0\_eligibility\_response.dat
- ncpdp\_vd\_0\_billing\_reversal\_response\_accept.dat
- ncpdp\_vd\_0\_billing\_response\_reject.dat
- ncpdp\_vd\_0\_rebill\_request.dat
- ncpdp\_vd\_0\_eligibility\_request.dat
- ncpdp\_vd\_0\_billing\_reversal\_request.dat
- ncpdp\_vd\_0\_billing\_request.dat

NCPDP example data files are located in the following directory:

*install\_dir\packs\healthcare\_vn.n.n\ncpdp\examples\SCRIPT\data*

These files include the following:

- ncpdp\_script\_v10\_6\_canres.dat
- ncpdp\_script\_v10\_6\_canrx.dat
- ncpdp\_script\_v10\_6\_census.dat
- ncpdp\_script\_v10\_6\_chgres.dat
- ncpdp\_script\_v10\_6\_error.dat
- ncpdp\_script\_v10\_6\_getmsg.dat
- ncpdp\_script\_v10\_6\_newrx.dat
- ncpdp\_script\_v10\_6\_paschg.dat
- ncpdp\_script\_v10\_6\_refreq.dat
- ncpdp\_script\_v10\_6\_refres.dat
- ncpdp\_script\_v10\_6\_resupp.dat
- ncpdp\_script\_v10\_6\_rxhres.dat
- ncpdp\_script\_v10\_6\_status.dat
- ncpdp\_script\_v10\_6\_verify.dat
- ncpdp\_script\_v10\_6\_rxchg.dat
- ncpdp\_script\_v10\_6\_rxfill.dat
- ncpdp\_script\_v10\_6\_rxhreq.dat

## NCPDP component examples

This documentation describes the NCPDP SCRIPT example and the PACDR example.

- [NCPDP SCRIPT example](#)

The mappings supplied with the NCPDP component show the transformation capabilities of the product, and provide a starting point for transformations.

- [NCPDP SCRIPT](#)

- [NCPDP PACDR example](#)

An example is included in the NCPDP component that validates the NCPDP Post Adjudication Standard Version 4.2.

## NCPDP SCRIPT example

The mappings supplied with the NCPDP component show the transformation capabilities of the product, and provide a starting point for transformations.

The example files install within the imported project.

- [Location of the Script example files](#)

The script transformation maps transform the SCRIPT input data to and from SCRIPT xml. The script pass-through maps validate the SCRIPT and SCRIPT xml input

data. The map source files are located at:

- [Release indicator](#)
- [XML validation](#)
- [Using SCRIPT examples on UNIX platforms](#)
- [Using SCRIPT example files in the z/OS environment](#)

## Location of the Script example files

The script transformation maps transform the SCRIPT input data to and from SCRIPT xml. The script pass-through maps validate the SCRIPT and SCRIPT xml input data. The map source files are located at:

install\_dir\packs\healthcare\_vn.n.n\ncpdp\examples\SCRIPT\mapsandschemas

Where <install\_dir> is the location of the Transformation Extender base product, and n.n.n is the version number of the pack.

If schema validation is desired, you must obtain the schema components required to run these maps directly from NCPDP from:

<http://www.ncpdp.org>

## Release indicator

The SCRIPT UNA Service String Advice contains the delimiters to be used for parsing. These values must be non-printable characters. The SCRIPT default Release Indicator Value is 32 (x'20). This value identifies the Release Indicator as not used.

For inbound processing, the value from the UNA is used if the value is not the default (x'20). If the UNA contains the value (x'20), the default value identified in the SCRIPT schema is used. The schema ncpdp\_script\_v10\_6 contains the default value of <ESC>(x'lb').

For outbound processing, the UNA is created using mapping commands and literal values. The Release Indicator value currently mapped is the default (x'20'). The example map, ncpdp\_xml\_to\_script\_v10\_6.mms, can be modified to identify the Release Indicator. The mapping commands are located in the functional map, UNA\_Service\_String.

The schema, ncpdp\_script\_v10\_6, contains a default value of <ESC>(x'lb'). This default can be modified by changing the schema property, **Type Syntax**, for all schema components that identify the Release Identifier.

## XML validation

Schema components required to run these maps must be obtained directly from NCPDP at:[www.ncpdp.org](http://www.ncpdp.org).

The following errors are related to XML element names that contain a space and were reported during XML validation:

	<DetailedStatusMessage> Error(-1), "XMLParser: Input XML data is invalid." SAXParseException, Error [line: 3264 column: 84] Invalid element name:'DosingBasisUnitofMeasureCode' - declaration ignored
	Error (-1), "XMLParser: Input XML data is invalid." SAXParseException, Error [line: 3294 column: 105] Invalid element name:'CalculatedDoseUnitofMeasureCodeQualifier' - declaration ignored Error (-1), "XMLParser: Input XML data is invalid." SAXParseException, Error [line: 3377 column: 81] Invalid element name:'RouteofAdministrationCode' - declaration ignored
	Error (-1), "XMLParser: Input XML data is invalid." SAXParseException, Error [line: 3465 column: 75] Invalid element name:'TimePeriodBasisText' - declaration ignored
	Error (-1), "XMLParser: Input XML data is invalid." SAXParseException, Error [line: 3598 column: 113] Invalid element name:'MaximumDoseRestrictionVariableUnitsCodeQualifier' - declaration ignored
	Error (-1), "XMLParser: Input XML data is invalid." SAXParseException, Error [line: 3667 column: 106] Invalid element name:'IndicationValueUnitofMeasureCodeQualifier' - declaration ignored
	Error (-1), "XMLParser: Input XML data is invalid."
	SAXParseException, Error [line: 2 column: 38] Unknown element 'Message'
	</DetailedStatusMessage>

## Using SCRIPT examples on UNIX platforms

On UNIX platforms, be aware of file pths and case sensitivity for schemas and DTDs. Modifications might be needed to ensure naming conventions match the case.

## Using SCRIPT example files in the z/OS environment

Be aware of the following when using the NCPDP SCRIPT example files in the z/OS environment:

- When ported to z/OS, every map, schema, and file that is ported to z/OS must have a unique 8-character DDNAME in the JCL.
- After building maps for a z/OS platform, you must rename the resulting \*.mvs compiled map to a unique 8 character name. The compiled map file, which contains maps and schemas, should be uploaded as a PDS member. Both maps and schemas must be uploaded as binary files.
- Schemas and DTDs should be uploaded to a variable blocked dataset. These files can reside with the maps in a separate PDS or sequential dataset. You must, however, be aware of the ramifications of uploading variable-length data into fixed blocked datasets. The records are padded up to the fixed size with NULL (x'00') characters. Null characters are not valid XML.

## NCPDP SCRIPT

The script transformation maps transform the SCRIPT input data to and from SCRIPT xml. The script pass-through maps validate the SCRIPT and SCRIPT xml input data. The map source files are located in the following directory:

*install\_dir\packs\healthcare\_vn.n.n\ncpdp\examples\SCRIPT\mapsandschemas*

In the above path, *install\_dir* is the location of the Transformation Extender base product, and *n.n.n* is the version number of the installed Healthcare Pack.

If schema validation is desired, you must obtain the schema components required to run these maps directly from NCPDP from:

[www.ncpdp.org](http://www.ncpdp.org)

This section describes the following maps:

- [ncpdp\\_script\\_v10\\_6\\_to\\_xml.mms](#)
- [ncpdp\\_xml\\_to\\_script\\_v10\\_6.mms](#)
- [ncpdp\\_script\\_v10\\_6\\_passthru.mms](#)
- [ncpdp\\_xml\\_v10\\_6\\_passthru.mms](#)
- [ncpdp\\_script\\_v10\\_6\\_xml\\_v201707.mms](#)
- [\*\*ncpdp\\_script\\_v10\\_6\\_to\\_xml.mms\*\*](#)
- [\*\*ncpdp\\_xml\\_to\\_script\\_v10\\_6.mms\*\*](#)
- [\*\*ncpdp\\_script\\_v10\\_6\\_passthru.mms\*\*](#)
- [\*\*ncpdp\\_xml\\_v10\\_6\\_passthru.mms\*\*](#)
- [\*\*ncpdp\\_script\\_v10\\_6\\_xml\\_v201707.mms\*\*](#)

### ncpdp\_script\_v10\_6\_to\_xml.mms

The ncpdp\_script\_v10\_6\_to\_xml.mms map source file transforms script format to xml format. The input to the map is a file that contains the NCPDP Script v10.6 Message (or Messages). The map produces script xml V10.6 output. The ncpdp\_script\_v10\_6\_transform is the top-level map. This map performs the following functions:

- Validates NCPDP request or response transmission data against definitions in the ncpdp\_script\_v10\_6 schema.
- Generates a script xml file from the transmission.

### ncpdp\_xml\_to\_script\_v10\_6.mms

The ncpdp\_xml\_to\_script\_v10\_6.mms map source file transforms xml format to script format. The input to the map is a file containing the NCPDP Script xml v10.6 Message (or Messages). The map produces script V10.6 output. The ncpdp\_xml\_v10\_6\_transform is the top-level map. Obtain the schema components required to run this map directly from NCPDP at the following location:

[www.ncpdp.org](http://www.ncpdp.org)

This map performs the following functions:

- Parses NCPDP xml request and response xml transmission data using definitions in the script\_xml\_v10\_6 schema.
- Validates the xml request, or response transmission as well formed. If schema validation is desired, the document verification setting for the input card must be set to **Always** or **Never**. The script\_xml\_10\_6\_1.xsd schema is required for schema validation and must be obtained directly from NCPDP at the website noted above. If schema validation is not required, the document verification setting for the input card must be set to well-formed.
- Generates a script file from the transmission.

### ncpdp\_script\_v10\_6\_passthru.mms

The ncpdp\_script\_v10\_6\_passthru.mms map source file validates ncpdp script transmission data against the Partner Inbound Transmission NCPDP\_SCRIPT and Partner Outbound Transmission NCPDP\_SCRIPT definitions in the ncpdp\_script\_v10\_6 schema.

The ncpdp\_v10\_6\_script\_passthru\_file is the top-level map.

## ncpdp\_xml\_v10\_6\_passthru.mms

The ncpdp\_xml\_v10\_6\_passthru.mms map source file parses ncpdp script xml transmission using the Doc XSD definitions in the script\_xml\_v10\_6 schema and validates ncpdp script xml transmission data as well formed. If schema validation is desired, the document verification setting for the input card must be set to **Always** or **Never**. The script\_xml\_10\_6\_1.xsd schema (not included) is required for schema validation and must be obtained directly from NCPDP at this website:

[www.ncpdp.org](http://www.ncpdp.org)

If schema validation is not required, the document verification setting for the input card must be set to well formed.

The ncpdp\_v10\_6\_xml\_passthru\_file is the top-level map.

## ncpdp\_script\_v10\_6\_xml\_v201707.mms

The ncpdp\_script\_v10\_6\_to\_xml\_v201707.mms map source file transforms script format to xml format. The input to the map is a file that contains the NCPDP Script v10.6 Message (or Messages). The map produces script xml v201707 output from the NCPDP provided v201707 schemas.

The v201707 schema components required to run these maps must be obtained directly from NCPDP at:

<http://www.ncpdp.org>

## NCPDP PACDR example

An example is included in the NCPDP component that validates the NCPDP Post Adjudication Standard Version 4.2.

The example files install within the imported project.

The following components are installed.

## NCPDP SCRIPT schemas

The Transformation Extender interface shows the NCPDP SCRIPT and XML data structure as both an expandable and contractible set of hierarchical components.

- [SCRIPT schema structure](#)
- [Data element type names](#)
- [Structure of XML schemas](#)  
The structure of the XML schemas in the NCPDP component is similar to the structure of the originating XML schema.
- [SCRIPT validation](#)

## SCRIPT schema structure

The structure of the SCRIPT schema is similar to an EDI schema. It includes definitions of objects used in EDI. The root type of the SCRIPT schema is NCPDP\_SCRIPT. The schema has the following categories:

- %\_Type\_Tree\_Information
- Interchange
- SCRIPT\_V10\_6
- Transmission

These categories stem from the NCPDP\_SCRIPT root type. Some categories contain Inbound and Outbound group subtypes. These are identical and have been supplied as a convenience to allow customization that is dependent on the direction of the messages.

The largest object in an EDI schema is a transmission. A transmission can include many interchanges from or to many trading partners.

The following are subtypes of the SCRIPT\_V10\_6 category:

- Control type defines the NCPDP Script control structure objects such as Envelope Segments and Delimiters.
- Msg type defines the messages for the version.
- Vxx category defines the message contents, composites, and elements in this particular version. The segment definitions for each message are defined as subtypes of that message.

## Data element type names

The type names of some data elements are abbreviated versions of the element descriptions. For example, the name of the type that defines the data element is Character encoding, which is coded as **CharEncodingCd**, and Agency Qualifier, which is coded as **AgencyQual'r**. If these, or other names, are not appropriate for your use, rename the type. Every reference to that type is then renamed automatically. You must, however, modify any mapping commands that reference these components.

## Structure of XML schemas

The structure of the XML schemas in the NCPDP component is similar to the structure of the originating XML schema.

The root of the NCPDP XML schema is the Doc XSD group. Most executable mapping will be to or from the Doc component. Under Global, the schema has the Message Element along with the other Global options defined in the schema. The Message Element contains all components to be used for mapping.

## SCRIPT validation

The **ncpdp\_script\_v10\_6** schema describes the NCPDP SCRIPT messages and enveloping structures. SCRIPT V10.6 is backward compatible with SCRIPT V8.1. This schema contains component rules and restriction lists to enforce standard syntax and data integrity, as in the following:

- valid segments
- segment order
- maximum segment and loop occurrences
- element attributes, for example, size and data
- required, or intra-segment situational data elements (element cardinality within segments)

The **ncpdp\_script\_v10\_6** schema does not enforce the following:

- inter-segment situations, for example, If A occurs, then B must be populated
- restriction lists not documented in the SCRIPT implementation guide, or external code list and data dictionary
- conflicting syntax, restriction lists, or rules based on V10.6 and V8.1 implementation guides
- balancing rules, for example, element A equals B plus C.

## NCPDP validation

The NCPDP component provides validation of the NCPDP Telecom version D0 Request Transactions with Batch 1.2 data standards, with regular updates to support code list changes.

The NCPDP validation utility produces a summary output of invalid fields or segments and a partially populated NCPDP response. This initial validation utility reports field-level errors within a segment based on the transaction type and segment-level errors for a transaction. This includes checking for missing required fields/segments, not used fields/segments that are present, and conditionally required values based on the transaction type or other fields in the same segment. It also reports errors for incorrect code values.

- **Running the NCPDP validation utility**

The NCPDP validation utility uses the existing NCPDP Telecom schemas in the pack for initial validation, with the restriction list checking disabled. The base **ncpdp\_vd\_0.mtt** and **ncpdp\_vf6.mtt** (schema if using Design Server) are used for this.

## Running the NCPDP validation utility

The NCPDP validation utility uses the existing NCPDP Telecom schemas in the pack for initial validation, with the restriction list checking disabled. The base **ncpdp\_vd\_0.mtt** and **ncpdp\_vf6.mtt** (schema if using Design Server) are used for this.

## About this task

Code values are checked against the input file **element\_restriction\_list.json**, using the **codeListDate** in the **ncpdp\_parameter.json** file to determine the start date for code list values that may have been added in recent standard updates. This file has values for both F6 and D0 versions, using a new field version at all levels to distinguish any segments, fields, or values that are only used in F6 or D0.

The situational and field format rules are defined in **segment\_rules.json** and **segment\_rules\_f6.json**. In this case both files are needed to support the two different versions, but the initial processing in the validation map will determine the version of the NCPDP input file, and select the correct segment rules input appropriately.

Failures from component rules or cardinality in the schema will be reported by error checking in the NCPDP validation utility through map rules and/or the Java exit that is invoked.

Follow these steps to run the NCPDP validation utility:

## Procedure

1. Update **ncpdp\_parameter.json** with the code list date.  
For example, to enforce the code values from **External Code** lists that correspond to the set published in 2017 for activation in 2018, use the following:
  - a. "codeListDate":"201710"
2. Update **ncpdp\_parameter.json** with the Medicaid option as desired. If validation per the Medicaid Subrogation rules is needed, use true. The default is false.
  - a. "medicaidSub":true
3. Ensure **ncpdp\_jexit.jar** is available in the Java Classpath during validation utility execution by one of the following methods:

- a. Copy from <pack\_install\_dir>\ncpdp\jars to <tx\_install\_dir> directory on Windows or <install\_dir>/libs directory on Unix.
  - b. Add a jar reference in the [External Jar Files] section of the <tx\_install\_dir> dtx.ini file to the location of the jar file in <pack\_install\_dir>\ncpdp\jars.
  - c. If running on the design server, edit the <pack\_install\_dir>\ncpdp\jars\ncpdpsetup.bat or ncpdpsetup.sh to point to your design server install, and execute the batch or shell script.
4. Open the ncpdp\_validation map.
  5. If validating data at the message level, perform the following steps:
    - a. Update Input card 1 of **ncpdp\_message\_validation** to select the NCPDP input data for validation.
    - b. Build all maps.
    - c. Execute ncpdp\_message\_validation.
    - d. Output files produced:
      - data/message\_response.dat contains the Response message or the NCPDP proscribed format.
      - data/message\_validation\_report.xml contains XML formatted report
  6. If validating data at the batch level, perform the following steps:
    - a. Update input card1 of the ncpdp\_batch\_validation map to select NCPDP data for validation.
    - b. Build all maps.
    - c. Execute ncpdp\_batch\_validation.
    - d. Output files produced:
      - data/batch\_response.dat contains the Response message or the NCPDP proscribed format.
      - data/batch\_validation\_report.xml contains XML formatted report

## Pack for Supply Chain EDI overview

The IBM Transformation Extender Pack for Supply Chain EDI is an industry accelerator that provides Business-to-Business enabling functionality to users of the Transformation Extender.

The Pack for Supply Chain EDI supports these standards.

- X12, RAIL, and TT-X12 (Travel and Transportation X12 subset)
- EDIFACT and TT-EDIFACT (Travel and Transportation EDIFACT subset)
- IATA (The International Air Transport Association) API and PNR
- TRADACOMS

The pack provides the following functionality.

- Ability to perform B2B enablement functionality for X12, RAIL, EDIFACT, IATA, and TRADACOMS data:
  - Enable data transformation by use of the IBM® B2Bi legacy mapper.
  - Enable data transformation by use of definitions in Transformation Extender schema format.
- Ability to perform X12, and EDIFACT, compliance validation, reporting, and data valid/invalid splitting.
- [About Electronic Data Interchange \(EDI\)](#)  
Electronic Data Interchange (EDI) is the electronic exchange of routine business information by using an agreed-upon file structure.
- [Example files](#)

## About Electronic Data Interchange (EDI)

Electronic Data Interchange (EDI) is the electronic exchange of routine business information by using an agreed-upon file structure.

The file structures are defined with EDI standards for the electronic documents. These uniform electronic formats are referred to as 'standards'. Standards, which are periodically updated, are referenced with versions that specify releases. For example, X12 Version 4010 is version 004, release 010; Version 3050 is version 003, release 050.

EDIFACT (Electronic Data Interchange For Administration, Commerce, and Transport) transitioned to using the **D** versions starting in the early 1990s. The **D** versioning system signifies that the release is a directory, updated twice a year, in a specific year.

- D.XXA  
Indicates the first release of the year **XX**.  
For example, **D.21A** refers to the first release of the year 2021.
- D.XXB  
Indicates the second release of the year **XX**.  
For example, **D.21B** refers to the second release of the year 2021.

## Example files

Example files are included with each pack component for both compliance checking and data transformation.

### Windows Design Studio Install:

Both EDIFACT and X12 example files are installed when you install the Pack for Supply Chain EDI.

*install\_dir\supplychain\_edi\_vn.n.n\x12\compliance\data*

*install\_dir\supplychain\_edi\_vn.n.n\x12\examples*

*install\_dir\supplychain\_edi\_vn.n.n\edifact\compliance\data*

*install\_dir\supplychain\_edi\_vn.n.n\edifact\examples*

#### **Design Server Install:**

Pack components are provided in the form of projects to be imported into the Design Server. These include Standards for custom mapping, compliance checking, and examples. Standards and compliance checking projects are provided for all pack components. X12 and EDIFACT provide additional examples with data transformation mappings.

---

## Installation and uninstallation

Installation and uninstallation procedures are described in the release notes on the Support website.

<http://www.ibm.com/support/docview.wss?uid=swg27008337>

---

## What is an EDI schema?

An EDI schema includes definitions of objects that are used in EDI.

Using these schemas, you can map directly from a data source or to a data target containing EDI data. You do not need to learn yet another format to map to and from EDI, as you do with many other translator products.

The largest object in an EDI schema is a transmission. A transmission can include many interchanges from many trading partners, or to many trading partners.

- **[ANSI X12 data](#)**

The basic business document in ANSI X12 data is called a transaction set. Transaction sets are enclosed in an envelope that separates one transaction set (ST-SE envelope) from another .

- **[EDIFACT data](#)**

EDIFACT data is similar to ANSI X12 data. The difference is that the business document in EDIFACT data is called a message and a loop in EDIFACT data is called a group.

- **[TRADACOMS data](#)**

The TRADACOM standard is primarily used in England and trading partners throughout Europe. TRADACOMS messages are used for domestic trade within the UK and cover a range of commercial transactions plus reports and master files.

- **[EDI version release schemas](#)**

The data for each EDI version is defined in a separate schema. For example, the ansi3070 schema defines ANSI X12 data version 3070.

- **[Types in EDI schemas](#)**

The type names in EDI schemas are consistent with the terminology used in the EDI standards.

- **[Modifying EDI schemas](#)**

Make your own copy of each EDI schema you are likely to use.

---

## ANSI X12 data

The basic business document in ANSI X12 data is called a transaction set. Transaction sets are enclosed in an envelope that separates one transaction set (ST-SE envelope) from another .

Groups of transaction sets that are functionally related are enclosed in a functional group envelope (GS-GE envelope). The functional group envelope separates one functional group from another. Functional groups that come from the same trading partner are grouped in an interchange envelope (ISA-IEA envelope). A series of interchanges from a variety of trading partners forms a transmission.

- **[Envelopes](#)**

Each envelope in EDI data begins with a particular segment and ends with a particular segment. For example, the transaction set envelope begins with an ST segment and ends with an SE segment.

- **[Transaction sets](#)**

Transaction sets are made up of segments and loops. A segment contains a unit of information, for example, a line item or a patient record.

- **[Segments](#)**

Segments are made up of data elements and composites.

---

## Envelopes

Each envelope in EDI data begins with a particular segment and ends with a particular segment. For example, the transaction set envelope begins with an ST segment and ends with an SE segment.

---

## Transaction sets

Transaction sets are made up of segments and loops. A segment contains a unit of information, for example, a line item or a patient record.

Each segment begins with a unique initiator that distinguishes it from all other segments. A segment also has a terminator that tells when the segment ends.

A loop is a repeating pattern of segments and other loops.

## Segments

Segments are made up of data elements and composites.

A data element is the basic unit of an EDI transaction. Data elements are the items of EDISegments, which are delimited and a delimiter separates their components. The value of this delimiter appears in the interchange envelope header, the ISA segment.

A composite is a group of related data elements.

## EDIFACT data

EDIFACT data is similar to ANSI X12 data. The difference is that the business document in EDIFACT data is called a message and a loop in EDIFACT data is called a group.

The EDIFACT standard includes many composites, whereas their use in ANSI X12 is less extensive.

## TRADACOMS data

The TRADACOM standard is primarily used in England and trading partners throughout Europe. TRADACOMS messages are used for domestic trade within the UK and cover a range of commercial transactions plus reports and master files.

There are twenty-six published files. These messages are updated as required to meet changing business needs. The following is an example of TRADACOMS data:

## EDI version release schemas

The data for each EDI version is defined in a separate schema. For example, the ansi3070 schema defines ANSI X12 data version 3070.

Each EDI schema is arranged in a similar way, so you can easily define your specific EDI trading relationships.

## Types in EDI schemas

The type names in EDI schemas are consistent with the terminology used in the EDI standards.

The root of each schema is called EDI. Each schema has an ANSI or EDIFACT category, an Interchange category, and a Transmission category.

You can combine versions and standards by selecting one schema and copying or merging other versions or standards to it. You can create a schema, which includes separate definitions for each of your trading partners by customizing a schema for one partner and then copying or merging types with definitions of other partners.

An EDI version schema includes the entire data dictionary for that particular version and the transmission and interchange objects common to all versions.

The type names of data elements are abbreviated versions of the element descriptions. For example, the name of the type that defines the data element Account Type Code is Acc'tTypeCd. If you find these or other names inappropriate for your use, rename the type - every reference to that type is renamed for you automatically. For a list of abbreviations that are used in EDI schemas and their corresponding full name, see "EDI schema abbreviations."

The data objects of a particular standard are located under a category with the version name, for example, V3050 in the ansi3050 schema. The names of particular elements, segments, transaction sets, and messages do not change from schema to schema unless the standard, itself, has changed. This naming convention makes it easier to migrate from one version to the next, if the standard does not change.

## Modifying EDI schemas

Make your own copy of each EDI schema you are likely to use.

### About this task

For example, if you are using ANSI 3050 data:

1. Open the ansi3050 schema.
2. Choose Save As from the File menu.
3. Rename this schema something new, for example, my3050.

You can then modify your own version schema. If you inadvertently delete something you need, or later decide to add more, open the original schema and copy the missing information to your own schema.

You should customize your EDI schema to suit your trading needs. For information on modifying your schema to include only those types you need, see "Create industry subsets".

## Analysis of EDI schemas

Before an EDI version schema is released, the schema is analyzed by using the Type Tree Analyzer.

Some schemas produce analysis errors because of the way data objects are defined in EDI. Most of the analysis errors were resolved by changing the schemas. These changes eliminate the analysis errors, but keep the EDI definitions intact.

A few errors cannot be resolved because resolving them requires knowledge of the user's specific data structure.

This documentation explains changes that were made to the EDI schemas and the analysis errors that occur when you analyze each EDI schemas. It also explains what to do about these errors.

- **Summary of errors**

In some cases, the size of an element code, which is defined as an item restriction, was greater than the maximum allowable size for that item.

- **X12 transaction sets that did not pass analysis**

When the definition of a transaction set is in error, you receive one error for the inbound transaction and one for the outbound one.

## Summary of errors

In some cases, the size of an element code, which is defined as an item restriction, was greater than the maximum allowable size for that item.

In these cases, the restriction was deleted:

ANSI schema	Element Type
ansi2003	AmendmentTypeCd Element
ansi2003	CommodityGeologicalConnectorCd Element
ansi2040	AmendmentTypeCd Element
ansi3030	ActionCd306 Element

Note: The type trees listed in the table are installed in the directory:  
*install\_dir\supplychain\_edi\_vn.n.n\x12\trees*

Some of the transaction sets have ambiguous definitions. These transaction sets are removed from the schemas. If you need to use any of these transaction sets, you must modify them according to how you plan to use them.

Analysis uncovered a few transaction sets whose definitions are ambiguous. These transaction sets were not removed from the schemas. However, if you use any of these transaction sets, they must be modified in accordance with how you use it.

In cases where it was possible to change the definition of a transaction set to make it unambiguous, it was changed. Verify the changes before you use that transaction set. If a solution was not possible, without information on the data structure, the transaction set was left in its ambiguous state.

Note: If you do not use a transaction set that causes an analysis error, delete it from the schema. You can always copy it again from the original EDI schema if you begin to use it.

Transaction sets that cause analysis errors are detailed here:

Schema	Transaction Set	Analysis Error
ansi2003	#830	optional segments not distinguishable
ansi2040	#830	optional segments not distinguishable
ansi3010	#830	optional segments not distinguishable
ansi3020	#110	optional segments not distinguishable
	#838	data objects of same component not distinguishable
	#426	optional segments not distinguishable
ansi3030	#838	data objects of same component not distinguishable
	#861	optional loops not distinguishable
	#304	optional segments not distinguishable
	#404*	blocked loops not distinguishable
	#417*	blocked loops not distinguishable
ansi3060	#304	optional segments not distinguishable
ansi3070	#304	optional segments not distinguishable
ansi4010	#304	optional segments not distinguishable
ansi4020	#304	optional segments not distinguishable
ansi5040	#355	optional loops not distinguishable

\* The schemas were changed so these errors do not occur. Explanations of how the schemas were changed are found in the documentation provided here.

## X12 transaction sets that did not pass analysis

When the definition of a transaction set is in error, you receive one error for the inbound transaction and one for the outbound one.

For example, there are two errors in the ansi2003 schema that are related to the LoopLIN of the #830 transaction set, one for inbound and one for outbound.

The inbound and outbound errors are the same. Only the inbound errors are addressed here.

- **[Delete X12 transaction sets in error if not used](#)**

If you do not use a transaction that causes an analysis error, delete both occurrences of it, that way, when you analyze your schema, you do not get the errors. Deleting causes the analysis to run faster. You can delete the entire transaction set category under the Inbound category and the entire transaction set category under the Outbound category.

- **[ANSI2003 the #830 transaction set](#)**

The same error that occurred in the #830 transaction set in ANSI version 2003 also occurred in ANSI version 2040.

- **[ANSI3010 the #830 transaction](#)**

The same error that occurred in the #830 transaction set in ANSI version 2003 also occurred in ANSI version 3010.

- **[ANSI3020 the #110 transaction](#)**

The #110 transaction set causes two errors.

- **[ANSI3020 the #838 transaction](#)**

The ansi3020 analyze error L201 is different from the L199 error.

- **[ANSI3060, ANSI3070, ANSI4010, and ANSI4020 the #304 transaction](#)**

The L199 analyzer error occurs when the ansi3060, ansi3070, ansi4010, and the ansi4020 schemas are analyzed.

## Delete X12 transaction sets in error if not used

If you do not use a transaction that causes an analysis error, delete both occurrences of it, that way, when you analyze your schema, you do not get the errors. Deleting causes the analysis to run faster. You can delete the entire transaction set category under the Inbound category and the entire transaction set category under the Outbound category.

In addition, delete the Funct'IGroups, under Inbound and Outbound, that contain the deleted transaction. Then, analyze the schema again.

For example, the #838 transaction set in the ansi3030 schema causes an analysis error. If you are using ANSI version 3030, and you are not using the #838, you can delete the entire #838 category for the transaction set under Inbound and under Outbound.

Also, delete the Funct'IGroup type #838, under Inbound and under Outbound.

For information on customizing your own EDI type tree, see the Create industry subsets documentation.

If you do use a transaction set that causes an analysis error, refer to the explanation of the errors that follow. Then, determine how you want to fix it.

## ANSI2003 the #830 transaction set

After you analyze the ansi 2003 schema, the following analyzer message appears:

L199 - COMPONENT 4 is not distinguishable from COMPONENT 7 that may follow in TYPE 'LoopLIN #830 Inbound Partner Set V2003 ANSI EDI' (error)

In the #830 transaction set type, there is a LoopLIN type. Within the LoopLIN type, there is a LoopSLN type. LoopSLN ends with an optional PID Segment. However, there is also a PID Segment later in the component list of the LoopLIN. In between, the PO3 Segment and the CTP Segment are optional. This means that if a PID Segment appears in the data, it may be the one in the LoopSLN or the one in the LoopLIN.

Possible solutions for making the transaction set unambiguous include the following:

- Make at least one occurrence of the PO3 Segment or CTP Segment required, make its component range minimum at least 1.
- Remove one of the PID Segment components.

## ANSI2040 the #830 transaction

The same error that occurred in the #830 transaction set in ANSI version 2003 also occurred in ANSI version 2040.

See ANSI2003 the #830 transaction set documentation for more information.

## ANSI3010 the #830 transaction

The same error that occurred in the #830 transaction set in ANSI version 2003 also occurred in ANSI version 3010.

See the ANSI2003 the #830 transaction set documentation.

## ANSI3020 the #110 transaction

The #110 transaction set causes two errors.

The first analyze error defines indistinguishable components with optional components in between the SL1 Segments in the ansi3020 schema and might read as follows:  
L199 - COMPONENT 14 is not distinguishable from COMPONENT 17 that may follow in TYPE 'Transaction #110 Inbound Partner Set V3020 ANSI EDI' (error).

The 14th and 17th components of the #110 transaction set are the LoopLX and the SL1 Segment.

The problem is an ambiguous SL1 Segment; there is one in the actual transaction set. It might be confused with the one nested in the LoopLX within the LoopL5.

You must modify the definition according to your own specifications. Here is a possible solution for making the transaction set unambiguous:

- Remove one of the S1 Segment components.
- Make either the L4 Segment or L3 Segment components that are required by changing the component range minimum to at least 1.

The second analyze error for the ansi3020 schema #110 transaction set also identifies indistinguishable components:

The 14th and 18th components of the #110 transaction set are the LoopLX and the L10 Segment.

This problem is similar to the first error for this transaction. The L10 Segment in the actual transaction set and the one nested within the LoopLX are indistinguishable because optional components fall in between.

Modify the definition according to your own specifications. Here is a possible solution for making the transaction set unambiguous:

Remove one of the L10 Segment components.

- Make either the L3, L4, or SL1 components outside of LoopL5 and LoopL1 required.

## ANSI3020 the #838 transaction

The ansi3020 analyze error L201 is different from the L199 error.

For example, the following L201 message indicates that in the fourth component you cannot distinguish between one occurrence and the next occurrence: L201 - Different data objects of COMPONENT 4 are not distinguishable in TYPE 'LoopPLA #838 Inbound Partner Set V3020 ANSI EDI' (error). In this case, in the 4th component you cannot distinguish between one occurrence and the next occurrence.

In this case, the LoopN11 in the LoopPLA begins with an N1 Segment. Nested within it is another N1 Segment. The Nested N1 Segment is optional and all of the components that follow it are optional. If a second N1 Segment appears in the data, is it the beginning of another LoopN11? Or, is it the N1 Segment of the LoopTUD?

Note: If you use this transaction set, the best way to fix it is to contact your trading partner and ask how it is to be interpreted.

## ANSI3060, ANSI3070, ANSI4010, and ANSI4020 the #304 transaction

The L199 analyzer error occurs when the ansi3060, ansi3070, ansi4010, and the ansi4020 schemas are analyzed.

The #304 transaction set in ANSI version 3060 also occurs in ANSI version 3070, 4010, and 4020. The LoopPO42 contains an N9 Segment, which is indistinguishable from the N9 following the LoopPO42.

Modify the definition according to your own specifications. Remove one of the N9 Segment components or make one of the optional components between the indistinguishable N9 Segment segments required.

## Mapping purchase orders to invoices

An example map maps an ANSI X12 EDI transmission that contains purchase orders (#850 transaction sets) to an ANSI X12 EDI transmission that contains invoices (#810 transaction sets).

The example illustrates how to use the SDQ segment to split the purchase order data into the appropriate invoices.

The sdq.mms file installs in the following directory:

*install\_dir\supplychain\_edi\_vn.n.n\x12\examples\ansi\sdq*

The sdq file installs with the imported project.

- **By line item**  
An SDQ segment problem may occur when mapping from purchase orders by line item to invoices by store.
- **Purchase order**  
This example purchase order show how the various line items are handled.
- **Invoices to be received**  
The following example shows invoices to be received, one interchange for each store.
- **ByStore map**  
In the functional map ByStore, the #810 transaction set is produced by using another functional map, ByPO.
- **ByPO map**  
In the functional map ByPO, another functional map is called to produce the IT1 Loops, the line items of the invoice.
- **ByLine map**  
In the map ByLine, the quantity invoiced is found in the SDQ Segment of the line item in the PO.

## By line item

An SDQ segment problem may occur when mapping from purchase orders by line item to invoices by store.

You may have an input transmission that may contain multiple interchanges from your trading partner who sends you EDI purchase orders. A purchase order may be organized so that each line item identifies a set of stores that receive some quantity of the merchandise identified in that line item.

Your trading partner wants you to send an interchange for each store. The interchange must include one invoice for each inbound purchase order that references that store. Each invoice includes only the line items relevant to that particular store. You may want to receive invoices, one interchange for each store.

There are two inbound purchase orders that refer to store #0100, so the interchange for that store has two invoices. Each invoice for store #0100 references just those line items of the purchase order that had store #0100 identified in an SDQ Segment that was part of that line item.

The executable map, SDQ, has two inputs and two outputs. The inputs are an EDI transmission containing purchase orders, and a trading partner profile. The outputs are an EDI transmission containing invoices, and the updated trading partner profile.

## Purchase order

This example purchase order show how the various line items are handled.

The following example shows one purchase order:

The store number is indicated by the IDCd element of the N1\*ST\*0100 segment. In the example shown here, the store number is N1\*ST\*0100. The object is to generate an interchange for each store indicated in the data from your trading partner Wally. For example, if there are a total of three different stores in the data from your trading partner, you want to generate three interchanges.

To map each output interchange, the functional map ByStore is used.

The `UNIQUE` and `EXTRACT` functions are used to generate one Interchange for each unique value of the IDCd Element within the SDQ Segment. The second argument of ByStore is the entire input transmission. To map just the data from your trading partner, the `LOOKUP` function is used to look up the information in the trading partner profile. The last argument of ByStore is the `INDEX` of the current interchange being produced, which are used to generate the new ISA control number.

## ByStore map

In the functional map ByStore, the #810 transaction set is produced by using another functional map, ByPO.

Only the #850 transaction sets that have data for the store are sent to the functional map ByPO

## ByPO map

In the functional map ByPO, another functional map is called to produce the IT1 Loops, the line items of the invoice.

## ByLine map

In the map ByLine, the quantity invoiced is found in the SDQ Segment of the line item in the PO.

The SDQ map references the ByStore functional map. ByStore maps the data according to store number, and calls ByPO. ByPO maps the data according to PO, and calls ByLine. Finally, ByLine maps the data according to line item.

## Editbol map source file

The editbol map source file maps an EDI data file of ANSI X12 Motor Carrier Shipment Information (transaction #204) to an application file that contains bill of lading information.

The editbol.mms map source file installs in this directory:

*install\_dir\supplychain\_edi\_vn.n\X12\examples\ansi\editbol*

The editbol map source file installs with the project.

- [Mapping inbound EDI #204 transaction sets](#)

The input schema file is ANSI X12 Standard..

## Mapping inbound EDI #204 transaction sets

The input schema file is ANSI X12 Standard..

The schema file installs with the imported project.

The type\_tree is installed in this directory:

*install\_dir\packs\supplychain\_edi\_vn.n\X12\examples\ansi*

The output type tree file is bol.mtt, and is installed in this directory:

*install\_dir\packs\supplychain\_edi\_vn.n\X12\examples\ansi\editbol*

The input type of the executable map is Partner X12 Inbound Transmission.

The output type is File, which is your file that contains any number of bills of lading. Each bill of lading is composed of one header record and many detail records. Each header record has several fields, including repeating sets of name and address information. These sets are defined in the schema as a single object called NameSet, which is used three times. The detail record object contains five fields. These records are fixed-length records, where every field is mandatory and no delimiters are used. Header records are initiated by 01, and detail records by 02.

The output file is made up of BillOfLading(s). The EachBOL functional map maps each #204 transaction set to the output bill of lading.

- [EachBOL functional map](#)

In the EachBOL functional map, the output is a single bill of lading, which is made up of one header record and a series of detail records.

- [MakeNameSet functional map](#)

- [EachDetail functional map](#)

In the EachDetail map, the components of the output Detail Record are mapped from the LoopLX and the #204 transaction set.

## EachBOL functional map

In the EachBOL functional map, the output is a single bill of lading, which is made up of one header record and a series of detail records.

Each header record type is defined in the Type Designer with the initiator 01, and each detail record was defined as beginning with the initiator 02.

The header record is made up of ten components, three of which contain repeating patterns of name and address information. The rule for each component selects the necessary element from the appropriate segment from the inbound #204, or assigns a literal.

In the case of the repeating name and address section of the header record, **NameSet**, the correct occurrence of this loop must be selected to properly populate the user's file with either **ShipTo**, **BillTo**, or **Consignee** name and address data. This has been accomplished by using the **IF** function to test the **N1 Loop**, then calling a functional map to create each component of that **Name Set**. For example, the rule for **NameSet[1]** tests the **N1** segment for an **EntityIDC Element of CN**.

The rules of the three **NameSet** components reference three different **N1** loops: one for **Consignee**, one for **Ship To**, and one for **Bill To**.

## MakeNameSet functional map

The **MakeNameSet** functional map has the **N1 Loop** as the input.

Again, in the **EachBOL** map, the rule for the **Detail Record(s)** calls another functional map, **EachDetail**. This map is responsible for creating each individual **Detail Record** within a **BillOfLading**. The input arguments for this map are the **Transaction #204** and the **LoopLX**. From these two areas come the segments that make up the **DetailRecord**.

## EachDetail functional map

In the EachDetail map, the components of the output Detail Record are mapped from the LoopLX and the #204 transaction set.

## X12 schemas

The Pack for Supply Chain EDI contains X12 schemas. The X12 schemas are used to validate and ultimately transform data that conforms to the ANSI X12 standard, as described in the ANSI X12 specifications.

- [About the X12 Standard](#)  
The standards are maintained by the Accredited Standards Committee X12 (ASC X12) which is chartered by the American National Standards Institute (ANSI).
- [Installation](#)  
The X12 schemas are available for download from the ESD website. Your user ID and password are required to log in.
- [X12 schema details](#)  
Documentation that describes details about the X12 schemas including the ANSI, Interchange, and Transmission categories is provided here.
- [X12 examples](#)  
Example maps and schemas install with the Pack for Supply Chain EDI or within the Design Server imported project x12Examples.zip.

## About the X12 Standard

The standards are maintained by the Accredited Standards Committee X12 (ASC X12) which is chartered by the American National Standards Institute (ANSI).

Standards information and related data embedded in the [Licensee] Software, Outsourcing Services and Combined Software Solutions are protected by copyright and other the intellectual property of X12 Incorporated, a non-profit organization chartered by the American National Standards Institute to develop and maintain EDI standards and XML schemas. In order to provide and fund these activities in serving American industry, X12 is willing to grant to all end users of the Licensee Software, Outsourcing Services or Combined Software Solutions a license at a royalty of \$180 per year. IBM strongly recommends that you contact X12 at [Licensing Partner: IBM](#) to obtain a license to use and access X12 metadata, represented in, for example, more than 30 versions of more than 300 transaction sets and implementation guides, through X12's online viewer, Glass.

## Installation

The X12 schemas are available for download from the ESD website. Your user ID and password are required to log in.

## X12 schema details

Documentation that describes details about the X12 schemas including the ANSI, Interchange, and Transmission categories is provided here.

The schemas that are referenced in this documentation can be found in the Pack for Supply Chain EDI.

- [Overview](#)  
The root type of each ANSI X12 schema is called EDI.
- [ANSI category](#)  
The ANSI category has three subtypes: Control, Funct'lGroup,, and a V (*version*) category.
- [Interchange category](#)  
Double-click the X12 Inbound Interchange type to view the components of the interchange.
- [Transmission category](#)  
A transmission is made up of interchanges, so a Transmission type is made up of Interchange types.
- [Mapping ANSI data](#)  
When a map for mapping ANSI data is created, create an input or output card to represent the ANSI data.
- [Input card - receiving ANSI data from multiple partners](#)  
When the input consists of only one interchange, select an Interchange type that corresponds to the correct Transmission type.
- [Output card - sending ANSI data to multiple partners](#)  
When the output consists of only one interchange, select an Interchange type that corresponds to the Transmission type.

## Overview

The root type of each ANSI X12 schema is called EDI.

Each schema has an ANSI, Interchange, and Transmission category that stems from the EDI root type. For example, the following ansi4020 schema contains the ANSI X12 version 4020 and the ansi4030 schema contains the ANSI X12 version 4030.

- **ANSI**  
These types are subtypes of the ANSI category.
  - **Interchange**  
The Interchange type contains the data types for an interchange.
  - **Transmission**  
The Transmission type contains the data types for a transmission, made up of one or more interchanges.
- 

## ANSI

These types are subtypes of the ANSI category.

- Control type defines the ANSI control structure objects. The Control category is the same on each ANSI version schema.
  - Funct'lGroup type defines the functional groups for the version and the data objects for that particular version.
  - V category defines the version-specific data objects. For example, V4030 is the name of the category in the 4030-version schema (ansi4030).
- 

## Interchange

The Interchange type contains the data types for an interchange.

The Interchange category contains Inbound and Outbound partitioned group subtypes.

## Transmission

The Transmission type contains the data types for a transmission, made up of one or more interchanges.

The Transmission category contains Inbound and Outbound group subtypes.

The ANSI schemas include both inbound and outbound types, where appropriate. In addition, types that are called Partner define a generic trading partner.

## ANSI category

The ANSI category has three subtypes: Control, Funct'lGroup, and a V (*version*) category.

- **Control subtree**  
The subtypes of the Control category are the same in each ANSI schema.
  - **Funct'lGroup subtree**  
The types under the Funct'lGroup category represent functional groups in the X12 version.
  - **Version-specific subtree**  
The types specific to the ANSI version are found under the ANSI category.
- 

## Control subtree

The subtypes of the Control category are the same in each ANSI schema.

These types are used in ANSI envelope segments. Expand the Control category, under ANSI, to see the control types.

The following are subtypes of Control.

- Delimiter Items that are used to define syntax objects.
- Element Items that are used as envelope segment components.
- ISAPartnerInfo Components of the ISA segment.
- Segment Envelope segments.
- Variant Definitions of envelopes in other standards.
- **Segment group**  
The Segment group type in the Control category represents the envelope segments. Envelope segments are used:
- **ISA segment**  
The ISA segment is the first segment in an ANSI X12 Interchange.
- **Interchange acknowledgment**  
The TA1 segment is used as an interchange acknowledgment. It can be used in an interchange, just before the functional groups begin.
- **Interchange syntax extension**  
The ISX segment was introduced with the X12 version 7040 as an optional control segment. It can be used by the interchange sender to identify a release character and for character encoding.

- **Control elements**  
Elements under the Control category are the items that are used as components of the group types under the Control category.
- **Variant category**  
Envelope segments and elements for UCS (Uniform Communication Standard) are found under the Variant category.
- **Delimiter types**  
The Delimiter types are syntax items. They are used as element delimiters, composite delimiters, and terminator delimiters in the ANSI segments.

---

## Segment group

The Segment group type in the Control category represents the envelope segments. Envelope segments are used:

- To surround functional groups within an ANSI X12 interchange, the ISA, and IEA segments in X12.
- For interchange acknowledgments, the TA1 segment.
- To specify interchange delivery and handling requirements, the ISB, and ISE segments.

Each Segment envelope type begins with a set of letters that identifies the segment, for example IEA. These same sets of letters (IEA) are also used in the Properties window of the Type Designer to define the value of the initiator.

---

## ISA segment

The ISA segment is the first segment in an ANSI X12 Interchange.

The ISA segment contains data that identifies trading partners. This segment also specifies the delimiters and terminator within the interchange. The segment does not identify which X12 version data is contained in the interchange. This version information is in the GS segment, which is discussed in the [Funct'lGroup subtree](#) section.

The type ISA has an Inbound and an Outbound subtype, each of which has a Partner subtype. The Inbound ISA type is used as a component of the Inbound Interchange type. The Outbound ISA type is used as a component of the Outbound Interchange type.

The second component of ISA is the type ISAPartnerInfo, which has the following components:

- Auth'nInfoQual'r Element
- Auth'nInfo Element
- SecurityInfoQual'r Element
- SecurityInfo Element
- Sender InterchangeIDQual'r Element
- InterchangeSenderID Element
- Receiver InterchangeIDQual'r Element
- InterchangeRcv'rID Element
- InterchangeDate Element

This is an example of ISA segment data:

```
ISA*00*TSI *01*92511930 *01*ME *12*BRADLEY
*970815*1732*U*00201*000000050*0*T*
```

This ISA example wraps around on the page, but there is no CL/LF in the ISA segment.

In the data of an ISA segment, the first thing after the initiator ISA is the element delimiter, so the first component of the ISA type is Element Delimiter. The value of the delimiter can be any of a number of different values. In input data, after the delimiter value is found as the first component of the ISA. It is set as the delimiter value for the rest of segments in the entire interchange. Likewise, the Composite Delimiter is the third component of the ISA, and the terminator is defined as the last component of the ISA.

When mapping from EDI data, the syntax values can be mapped from the components of the ISA in the input. When you map to EDI data, you can set the syntax values by assigning values to the components of the ISA.

Note: The default value for the delimiter is an asterisk \*, and the default value for the terminator is a carriage return/linefeed <CR><LF>. If you want to test inbound data that does not contain the interchange envelope, the data must contain the default delimiter and terminator values, or the data is invalid. If the delimiter and terminator are different from the defaults, change the defaults in your schemas.

The IEA segment is the last segment in an interchange. The IEA segment has the same interchange control number that is in the ISA. The IEA segment also has a count of the functional groups within the interchange.

---

## Interchange acknowledgment

The TA1 segment is used as an interchange acknowledgment. It can be used in an interchange, just before the functional groups begin.

Typically used only by network providers, an interchange containing TA1s consists of the TA1s surrounded by the ISA and IEA segments; it does not typically contain any functional groups.

---

## Interchange syntax extension

The ISX segment was introduced with the X12 version 7040 as an optional control segment. It can be used by the interchange sender to identify a release character and for character encoding.

If the ISX appears in the data, the values that occur in the ISX set the active syntax values. If there is no ISX, the release character is assumed to be an exclamation point.

## Control elements

Elements under the Control category are the items that are used as components of the group types under the Control category.

For example, elements that appear in the ISA, ISB, and TA1 segments are defined here. Expand the Element category to view an alphabetical list of the elements.

Most of the definitions of the Element subtypes conform to the interchange standard, not the version standard. The main difference is the interpretation of the `NO` notation that is used in X12. The `NO` notation in the interchange standard refers to an unsigned integer. In the version standard, the `NO` notation refers to an integer, possibly preceded by a negative sign.

For example, the `InterchangeCtrl#` and `#InclFunct'lGroups` elements are part of the interchange standard and are defined in the schema as an unsigned integer. The `GroupCtrl#` Element, however, appears as part of a version standard, and is therefore defined as an ANSI implicit decimal with zero decimal places.

## Variant category

Envelope segments and elements for UCS (Uniform Communication Standard) are found under the Variant category.

The BG segment appears at the beginning of a UCS interchange, and the EG segment appears at the end. Elements that appear in the BG and EG segments are subtypes of the Element type.

## Delimiter types

The Delimiter types are syntax items. They are used as element delimiters, composite delimiters, and terminator delimiters in the ANSI segments.

The values of these syntax objects might be different in different interchanges. The Element Delimiter appears as the first component of the ISA. The Composite Delimiter appears as the third component of the ISA, following the ISAPartnerInfo data fields. The Terminator appears as the last component of the ISA. For X12 versions 7040 and later, the **Release Character** appears in the first component of the ISX segment and defaults to exclamation point if the ISX is not used. For information about delimiters that are specified as syntax items, see the Type Designer documentation.

After the values of the syntax objects are set by the ISA, they are used for the rest of the segments in that interchange. For example, the Element Delimiter value of the IEA segment is specified as the item Element Delimiter. The delimiter value that is found in the ISA is the same value in the IEA.

The following item window displays the Include restrictions list for the Element Delimiter type. They are the possible values of the delimiter between elements.

Note: If a trading partner uses a value that is not in the restriction list, you can add the new value to the list.

## Funct'lGroup subtree

The types under the Funct'lGroup category represent functional groups in the X12 version.

To allow for partner-specific definitions, the functional group types are organized under the category Partner, representing functional groups that are exchanged with a generic trading partner. Under Partner, the types are then organized by Inbound and Outbound. Subtypes of Inbound and Outbound are identical. Inbound and Outbound both have a subtype that is named F, followed by the X12 version. For example, F4030 is the name of the functional group type in the ansi4030 schema.

The first segment of a functional group is the GS segment. The GS segment includes information about trading partners, the X12 version of the data, and the types of transaction sets that are contained within the functional group.

Expand the Funct'lGroup category to see all the functional groups in the X12 version. Each functional group type is named according to the kinds of transaction sets that are contained within it. There are two possibilities for the type name of a functional group: name the type the transaction set number or name the type after the value of the element.

- If only one transaction set can appear within the functional group, its type name is the transaction set number. For example, in the functional group that contains purchase orders, the transaction set #850, can contain only purchase orders. It cannot contain any other transaction set. Therefore, the name of the functional group type is #850.

The following group window displays the components of the functional group #850 in the ansi4030 schema. Notice that the second component is a series of #850 transaction sets.

- If there can be more than one transaction set within a functional group, the type name of the functional group is the value of the FunctionalIDCd Element. For example, the CF functional group can contain both #844 and #849 transaction sets. The type name of the functional group, then, is the value of the FunctionalIDCd Element, which is CF. Each functional group has a unique value for the FunctionalIDCd Element.

Note: There is one exception to the naming convention. One functional group has a FunctionalIDCd Element whose value is IN. This functional group can contain Invoices, the #810, and Operating Expense Statements, the #819. Because IN is a reserved word in the Design Studio, the type name cannot be IN, so its name is IE.

As more industries join the EDI community, the list of functional groups gets longer. When you make your own schema from an ANSI schema, delete the functional groups that you have no interest in. For example, if you create your own schema from the ansi4030 schema, delete the functional group types under F4030, under Inbound, that you are not currently receiving. Then, do the same for the F4030 group under Outbound; delete the functional groups that you are not sending out. Remember you can always add them back later.

## Version-specific subtree

The types specific to the ANSI version are found under the ANSI category.

The name of the category where the types are organized begins with a V and is followed by the ANSI version. For example, the name of the type in the ansi4030 schema is V4030.

- **Elements**

The item subtypes of the Element category are the ANSI data elements.

- **XComposites and MComposites**

A composite is a set of related data elements.

- **Segments**

A segment is a logical unit of information, like a data record.

- **Sets - transactions sets, loops, and blocks**

The transaction sets and the loops for the ANSI version are under the Set category.

- **Transaction sets are organized under categories**

Each transaction set appears under a category with the same name.

- **Loops and blocks**

The loops and blocks within a transaction set appear under the same category where the transaction set definition itself is located.

## Elements

The item subtypes of the Element category are the ANSI data elements.

The names of these types are abbreviations of the element descriptions in the Data Interchange Standards Association (DISA) documentation of the ASC X12 standards.

To view an element's full description, perform the following steps:

1. Select the type in the schema.
2. Right-click and select Properties from the menu.

The description of the X12 data element is in the Value column of the Description property.

There are over 1000 element types in an ANSI schema. Although they are arranged alphabetically, you might want to use the **Find** command on the Edit menu to locate a particular element.

The following list summarizes how an ANSI schema corresponds to the ANSI EDI standards:

- Element codes are specified as item restrictions in an ANSI schema.
- Different elements with the same X12 description are named by appending the X12 data element reference number to the end of the type name.
- Some element types have subtypes. Element subtypes were added if the same element was used more than once as a component of the same segment. For example, if a segment has two Date Element components, one might be an Arrival Date Element and the other a Departure Date Element.

## XComposites and MComposites

A composite is a set of related data elements.

The ANSI standards incorporated the first composite in version 3030. In an ANSI X12 schema, the X12 composite data structures are found under the XComposite category, where the X stands for X12.

In addition, other sets of elements that ANSI does not define as composites are defined as composites. These are located under the MComposite category. MComposites were formed to identify repetitive patterns of data elements and to group elements that are logically related.

Defining the composites in this manner simplifies type definitions and mapping rules. In addition, it is easier to identify which elements are required when others are present (or absent, as the case might be). For example, the third component of the ACT segment is MComposite:

The ANSI X12 documentation states the following rule about two elements of the ACT segment:

**P0304 - If either ACT03 or ACT04 is present, then the other is required**

(where ACT03 is the IDCdQual'r Element and ACT04 is the IDCd Element).

If the data elements were defined as components of the ACT segment, a complex component rule, equivalent to the ANSI rule above, would be necessary. Instead, the two elements were defined as components of an IDCd MComposite:

The IDCd MComposite is then a component of the ACT segment, and is optional with a range of (0:1). This means that if an IDCd MComposite is in the data, both of its components must exist. In addition, if there is no IDCd MComposite in the data, neither component is there. Defining the data in this way meets the requirements of the ANSI standards and simplifies the type definition.

Another difference between XComposite types and MComposite types is their delimiters. The delimiter of an XComposite type is the Composite Delimiter, which appears as data in the ISA. The delimiter of an MComposite is the Element Delimiter.

## Segments

A segment is a logical unit of information, like a data record.

The Segment type is partitioned by initiator values. Each segment begins with a unique 2 or 3 character initiator, which identifies the segment. For example, the ACT segment begins with the initiator ACT.

Because an Element Delimiter must follow the segment initiator value and precede the first data element, each segment is defined as prefix delimited by the Element Delimiter and has a terminator of Terminator Delimiter.

Components of a segment might be Element types, MComposite types, and XComposite types. The segments are defined to comply with the rules specified in the X12 documentation.

## Sets - transactions sets, loops, and blocks

The transaction sets and the loops for the ANSI version are under the Set category.

To allow for partner-specific definitions, the transaction set types are organized under the category Partner. Partner subtypes are then organized by Inbound and Outbound; these categories are identical.

## Transaction sets are organized under categories

Each transaction set appears under a category with the same name.

The name of the category is the same as the name of the FunctlGroup type that contains that particular transaction set. For example, the #102 transaction set is a subtype of the #102 category, just as the FunctlGroup category that contains the #102 transaction set is called #102.

The #844 transaction set is contained in a functional group that can have both #844 and #849 transactions. The functional group type name is CF, so the actual transaction set #844 is found under the category named CF.

If there is only one transaction set under a category, the transaction set type name is simply Transaction. If there is more than one transaction set under a category, the type Transaction is partitioned and the separate transactions are subtypes of it. For example, the actual #844 transaction set has the name #844 and is a subtype of Transaction.

The ST Segment is the first component of each transaction, and is used as an identifier, the value of the TSIDC Element in the ST Segment tells what transaction it is, in this case, #844, or #849.

If a transaction set cannot be found by its transaction set number, use the **Find** command. For example, if you did not know that the #844 transaction set type was under the CF category, you might find it by choosing Find from the Edit menu, and entering #844 in the Find What field.

## Loops and blocks

The loops and blocks within a transaction set appear under the same category where the transaction set definition itself is located.

Loops are groups of two or more semantically related segments, though in an actual X12 transmission, a loop can appear as only the single loop that starts a segment. Loops can also contain other loops as components.

X12 defines two types of loops: unbounded and bounded. In unbounded loops, the first data segment in the loop appears once and only once in each loop occurrence (marking the start of an occurrence). Bounded loops are similar, but have no restriction on which data segment begins a loop occurrence and require a loop start (LS) segment before the first loop occurrence and a loop end (LE) segment after the last loop occurrence.

The type name of a loop is Loop followed by the identifier of the first segment in that loop and, if defined for the transaction set, the numeric Loop ID value that is specified by X12. For example, X12 version 4010 defines two different loops in transaction set #124, which begin with segment LM, loop IDs 3200 and 3320. These loops are named LoopLM3200 and LoopLM3320 respectively. If no numeric Loop ID values are specified for a transaction set and the same segment ID begins more than one loop, the sequential position of each loop within the transaction set is used to create unique loop names.

For example, version 4010, transaction set #151 has three different loops, which begin with segment PBI, named LoopPBI1, LoopPBI2, and LoopPBI3. Then there is more than one transaction set under a category, loop and block definitions for a specific transaction set are found under a category whose name begins with the functional group ID code, and is followed by the transaction set number. For example, the loops in transaction set #844 are subtypes of category CF844.

All bounded loop definitions for a transaction set appear under a group named Block. All bounded loops begin with an LS Segment, followed by the loop definition for the loop data segments and then an LE

## Interchange category

Double-click the X12 Inbound Interchange type to view the components of the interchange.

The following table lists and describes the components of the X12 Inbound Interchange.

Component	Description
ISA Segment	The first component of an interchange is the envelope header. The ISA segment identifies who sent the interchange or who you are sending one to. It also contains the objects that are used within the interchange for segment terminators, segment delimiters, and composite delimiters.
ISB Segment	Allows the sender to request more services from the service request handlers.
ISE Segment	Allows the sender to request more services from the service request handlers.

Component	Description
TA1 Segment	Optional and is typically used by network providers. TA1 is an interchange acknowledgment.
ISX Segment	Optional and is used to override the default release character and character encoding.
Funct'lGroup	Represents the functional groups that are sent or received.
IEA Segment	The interchange envelope trailer.

Note: The ISB and ISE segments are found only in ANSI versions 3050 and later. For example, the ISB and ISE segments are not shown as components of an interchange in the ansi3040 schema.

The X12 Outbound Interchange type is similar to the structure of the X12 Inbound Interchange type. The only difference is that Inbound is replaced with Outbound.

- [Restart attribute on functional group](#)  
The Funct'lGroup component of an interchange has the restart attribute.
- [Component rule on IEA segment](#)  
This documentation describes the component rule for the IEA segment.

## Restart attribute on functional group

The Funct'lGroup component of an interchange has the restart attribute.

If you receive functional groups from different departments within a trading partner, one department's good data will not be lost if another department's data is bad. You can remove this restart attribute if you would rather go directly to the next interchange if bad data occurs within any Inbound Funct'lGroup.

## Component rule on IEA segment

This documentation describes the component rule for the IEA segment.

The IEA Segment component of an interchange has the following component rule:

```
InterchangeCtrl# Element:$ =
InterchangeCtrl# Element:::Partner Inbound ISA Segment Control
ANSI & #InclFunct'lGroups Element:$-COUNTABS (Inbound Partner
Funct'lGroup ANSI)
```

The component rule states that the InterchangeCtrl# Element of the IEA Segment must be the same as the InterchangeCtrl# Element of the ISA Segment. If an Inbound Partner Funct'lGroup is invalid and a restart occurs, the component rule keeps different interchanges from being mixed up with one another.

## Transmission category

A transmission is made up of interchanges, so a Transmission type is made up of Interchange types.

An Inbound Transmission type is made up of Inbound Interchange types. For example, an X12 Inbound Transmission type is made up of X12 Inbound Interchange types and a Partner X12 Inbound Transmission type is made up of Partner X12 Inbound Interchange types.

The type Partner represents a generic trading partner. If you are trading with different partners who use different subsets of the X12 standards, you might want to rename the Partner type. You can then add new types to define the additional trading partners.

The components of Outbound Transmission types are similar to the components of the Inbound types.

- [Restart attribute on an interchange](#)  
The Interchange component of a Transmission type has the restart attribute.

## Restart attribute on an interchange

The Interchange component of a Transmission type has the restart attribute.

On input data, the restart attribute is intended to filter network noise and to detect invalid interchanges. If you receive an invalid interchange from one partner, the restart allows you to process good data in other interchanges in the same transmission.

When you receive network messages and you know where they appear in an inbound communication file, you might want to include them as a component of an Inbound Transmission type. If you do not include them as data, they are rejected as invalid interchanges if they are not recognized as part of a transmission. However, the processing time takes longer than if you included these network messages as data.

For EDI output data, restart is useful for auditing data. You can audit the output data to report when outbound interchanges within a transmission are invalid.

## Mapping ANSI data

When a map for mapping ANSI data is created, create an input or output card to represent the ANSI data.

When you specify the TypeName for the input card, you must specify a type under the Transmission category.

Select Inbound Transmission, or one of its subtypes, when your input is ANSI data. When you send ANSI data, select Outbound Transmission, or one of its subtypes.

## Input card - receiving ANSI data from multiple partners

When the input consists of only one interchange, select an Interchange type that corresponds to the correct Transmission type.

Select the Transmission type as shown in this table:

If you receive	Select this type
Multiple EDI standards	Inbound Transmission Note: Represents data from both ANSI and UCS
Only ANSI X12 data, and different trading partners in your schema are defined.	X12 Inbound Transmission
Only UCS data, and different trading partners in your schema are defined.	UCS Inbound Transmission
Only ANSI X12 data, and different trading partners in your schema are not defined.	Partner X12 Inbound Transmission
Only UCS data, and different trading partners in your schema are not defined.	Partner UCS Inbound Transmission

If you are familiar with Trading Partner PC, an Inbound Transmission (or one of its subtypes) defines the mail\_in\_new file. When you are mapping to EDI data, select an Outbound Transmission type for the output card. The type to choose depends on what you are sending.

## Output card - sending ANSI data to multiple partners

When the output consists of only one interchange, select an Interchange type that corresponds to the Transmission type.

This is shown in the following table:

If you are sending	Select this type
Multiple EDI standards.	Outbound Transmission Note: Represents data from both ANSI and UCS.
Only ANSI X12 data, and you define different trading partners in your schema	X12 Outbound Transmission
Only UCS data, and you define different trading partners in your schema	UCS Outbound Transmission
Only ANSI X12 data, and you have not defined different trading partners in your schema	Partner X12 Outbound Transmission
Only UCS data, and you have not defined different trading partners in your schema	Partner UCS Outbound Transmission

If you are familiar with Trading Partner PC, an Outbound Transmission type (or one of its subtypes) defines the mail\_out.new file.

## X12 examples

Example maps and schemas install with the Pack for Supply Chain EDI or within the Design Server imported project x12Examples.zip.

The X12 map and schema example files install in subdirectories under the following folder:

*install\_dir\supplychain\_edi\_vn.n.n\x12\examples*

The examples and example files are defined in the following table:

Example and associated files	Description
examples/ansi/asntoedi/ Example files: <ul style="list-style-type: none"><li>• asn856.txt - input record oriented data</li><li>• asn865.out - expected results X12 7040 856 transaction</li><li>• shipnotice - input schema</li><li>• sendasn - map source containing executable map sendasn</li></ul>	Creates an outbound EDI Advance Ship Notice (#856) with its nested hierarchical levels.
examples/ansi/editobol/ Example files: <ul style="list-style-type: none"><li>• Editobol.txt - input X12 7040 204 transaction</li><li>• bolout.txt - expected results record oriented data</li><li>• bol - input schema</li><li>• editobol - map source containing executable map bolading</li></ul>	Creates an outbound application record oriented file based on an inbound EDI Motor Carrier Shipment Information (#204).

Example and associated files	Description
examples/ansi/hlLoop/ Example files: <ul style="list-style-type: none"> <li>• asn856Test.input - input X12 7040 204 transaction</li> <li>• asn856Test.out - expected results record oriented data</li> <li>• ansi8020_856 - input schema</li> <li>• receiveasn - map source containing executable map receiveasn</li> </ul>	Creates an outbound application record oriented file based on an inbound EDI Advance Ship Notice (#856) with its nested hierarchical levels.
examples/ansi/sdq/ Example files: <ul style="list-style-type: none"> <li>• partner.txt - input partner file</li> <li>• wal850.new - input X12 850 (purchase orders).</li> <li>• Storeinfo.out - output temp file holding store information</li> <li>• wally.out - expected results of X12 810 invoices</li> <li>• profile - input schema for partner file</li> <li>• storeinfo - input schema for storeinfo file</li> <li>• sdq - map source containing executable map sqd</li> </ul>	Creates an outbound EDI invoice (#810) from an inbound EDI Order (#850). The turn-around mapping produces an interchange for each store number found in the inbound 850 SQD segment.
examples/ansi/xmlpo/ Example files: <ul style="list-style-type: none"> <li>• x12_850.in - input X12 7040 850 (purchase order)</li> <li>• orders.xml - input XML orders</li> <li>• xml_po_output.xml - expected output EDI to XML map</li> <li>• x12_po.out - expected output XML to EDI map</li> <li>• po_file - XML schema</li> <li>• xmlpo - map source that contains executable maps x12toxml and xmltox12</li> </ul>	Creates an outbound EDI 850 (purchase order) message, using XML input and an outbound XML Order using EDI 850 (purchase order) message input.

Run instructions for the asntoedi example.

## asntoedi example notes

Points to be aware of when using the asntoedi example.

The asntoedi example output is generated from input that contains fixed formatted header and detail records.

The LAST index generates the correct HierarchicalID Element, which must increment by one for each HL Segment in the hierarchy being built, as shown here:

```
ST*856*1
BSN*00*00000084*940111*1427
HL*1**S <- HierarchicalID Element of this shipment = 1,
 no parent
```

```

TD1*BOX*1
HL*2*1*I <- HierarchicalID Element of this item = 2,
 parent shipment is 1

HL*3*1*I <- HierarchicalID Element of this item = 3,
 parent shipment is 1

HL*4*1*I <- HierarchicalID Element of this item = 4,
 parent shipment is 1

HL*5**S <- HierarchicalID Element of this shipment = 5,
 no parent

TD1*BOX*1
HL*6*5*I <- HierarchicalID Element of this item = 6,
 parent shipment is 5

HL*7**S <- HierarchicalID Element of this shipment = 7,
 no parent

TD1*BOX*1
HL*8*7*I <- HierarchicalID Element of this item = 8,
 parent shipment is 7

HL*9*7*I <- HierarchicalID Element of this item = 9,
 parent shipment is 7

HL*10*7*I <- HierarchicalID Element of this item = 10,
 parent shipment is 7

CTT*7
SE*17*1

```

## How to run the asntoedi example

Run instructions for the asntoedi example.

### About this task

Follow these steps:

### Procedure

1. Open the x12\_examples project.
2. Navigate to schemas and open the X12\_7040 subset schema.
3. Analyze the schema. The schema should analyze with no errors.
4. Open the shipnotice schema and analyze the schema. The schema should analyze with no errors.
5. Navigate to maps and open the sendasn map.
6. Build the map and then run the map.
7. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
8. To download the file, go to Files and download the file, asn856.out.

## editobol example

Instructions for running the editobol example.

Review the example notes prior to running the example.

- [editobol example notes](#)  
Points to be aware of when using the editobol example
- [How to run the editobol example](#)  
Run instructions for the editobol example.

## editobol example notes

Points to be aware of when using the editobol example

- The input type of the executable map is Partner X12 Inbound Transmission. The output type is File, which is your file that contains any number of bills of lading. Each bill of lading is composed of one header record and many detail records. Each header record has several fields, including repeating sets of name and address information. These sets have been defined in the schema as a single object called NameSet, which is used three times. The detail record object contains five fields. These are fixed length records, where every field is mandatory and no delimiters are used. Header records are initiated by 01, and detail records by 02.
- The output file is made up of BillOfLading(s). The EachBOL functional map maps each #204 transaction set to the output bill of lading.

## How to run the editobol example

Run instructions for the editobol example.

## About this task

---

Follow these steps:

## Procedure

---

1. Open the x12\_examples project.
  2. Navigate to schemas and open the ansi7040 standard schema.
  3. Analyze the schema. The schema should analyze with no errors.
  4. Open the bol schema and analyze the schema. The schema should analyze with no errors.
  5. Navigate to maps and open the bolanding map.
  6. Build the map and then run the map.
  7. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
  8. To download the file, go to Files and download the file,.bolout.txt.
- 

## hlLoop example

The hlLoop example is an example of using a customized ITX standard for the X12 856 Ship Notice/Manifest or Advanced Ship Notice - ASN. The ITX standard has been customized to preserve the hierarchy during runtime parsing of the input data when a hierarchy is defined for the output for easier mapping.

Map source and executable: receiveasn.mms

Customized standard: ansi8020\_856.mtt

Input X12 856: asn856Test.input

Output X12 856: asn856Test.out

The REF segments in the output file identify, the functional map executions in the map source/executable along with the description from the input file of the loop levels. For example: REF\*ZZ\*forEachItem\*Item 1 & Pack 2 & S1Order 1

identifies functional map forEachItem execution

Item 1 with Pack 2 parent

Pack 2 parent is Order1

Order 1 parent is S1 (Shipment 1).

- [\*\*Understanding Hierarchical Loops\*\*](#)

Hierarchical loops defined in EDI transactions or messages are considered the most complex structures in the EDI processing environment. Hierarchical loops define different levels of data, which can be used in any sequence, and skipped if the information is not needed. This allows EDI messages to align the loop to the data.

- [\*\*Hierarchical Design Rules\*\*](#)

- [\*\*Example of Record Oriented Data\*\*](#)

- [\*\*Example Diagram of a Hierarchy\*\*](#)

- [\*\*Customizing ITX Standard for Hierarchical Loop level\*\*](#)

The instructions below reference the X12 856 Advanced Ship Notice transactions but can be used for similar hierarchical structures.

- [\*\*Mapping HL levels to the output\*\*](#)

At the point where you want to begin the shipping level, example command to be used. This will pass the Shipment HL Loop and all HL child loops to the functional map forEachShipment().

---

## Understanding Hierarchical Loops

Hierarchical loops defined in EDI transactions or messages are considered the most complex structures in the EDI processing environment. Hierarchical loops define different levels of data, which can be used in any sequence, and skipped if the information is not needed. This allows EDI messages to align the loop to the data.

A Hierarchical loop is simply a special kind of nested loop where the nesting is not physically defined in the EDI transaction, but rather in the data content of the hierarchy. Successive occurrences of a hierarchical show a parent - child relationship.

The X12 856 transaction set is used to describe a physical shipment as well as information relating to the shipment, such as order information, product description, physical characteristics, type of packaging, marking, carrier information, and configuration of goods within the transportation equipment.

The X12 856 HL segment is used to define the start of a hierarchical looping structure. The HL segment must be created for each node of the application data hierarchy.

---

## Hierarchical Design Rules

1. Define the hierarchical paths.
  - a. Create a diagram of the hierarchy.
  - b. Number the nodes top to bottom and left to right starting with the left most node.
    - Primary path is top to bottom.
    - Secondary path is left to right.
2. Identify the base nodes.
  - Base node is a level without a parent.

- Multiple hierarchical paths may indicate multiple base nodes.
  - Identify the hierarchical levels.
3. Identify the levels.
- Shipment = S
  - Order = O
  - Packs = P
  - Items = I
4. Identify the relationships.
- What are the parent/child relationships?
  - Is the parent/child relationship defined in the data?
  - Is the application dependent on the hierarchy?
    - May need to enforce hierarchy.
  - Is the mapping for the child dependent on the parent?
    - May need to enforce hierarchy.

If the hierarchy does not need to be enforced, then the HL loop could be mapped as a flat (not nested) loop. The ITX standard can be used as defined.

If the hierarchy needs to be enforced (application data definition contains nesting), then the HL loop may need to be customized to preserve the hierarchy and allow mapping to preserve the hierarchy.

## Example of Record Oriented Data

## Example Diagram of a Hierarchy

## Customizing ITX Standard for Hierarchical Loop level

The instructions below reference the X12 856 Advanced Ship Notice transactions but can be used for similar hierarchical structures.

### Procedure

1. Make a copy of the type tree to be customized. You can also trim/prune the type tree to remove components not used. There is a documented process for accomplishing this task.
2. Open the copy of the standard type tree to be used.
3. Navigate to ANSI V8020>Set>Partner>Inbound>856 transaction and expand.
4. Copy LoopHL to each HL Loop level needed in the hierarchy.  
For example, copy LoopHL to LoopHLShip, then again for LoopHLOrder, and again for LoopHLPack, and LoopHLPackItem.
5. Open LoopHLPack and add LoopHLItem (set range to min 0, max s). Open LoopHLOrder and add LoopHLPack (set range the same on all). Open LoopHLShip and add LoopHLOrder.
6. Open the transaction and edit the component LoopHL as follows:
  - a. Modify to LoopHLShip. Or drag and drop Loop HLShip and set range to be the same as LoopHL.
  - b. Remove the LoopHL component.
7. Enter the following mapping rule on LoopHLShip:

```
HierarchicalLevelCd Element:HL Segment:$ = "S"
& (ABSENT(HierarchicalParentIDNum Element:HL Segment:$)
 | MEMBER(HierarchicalParentIDNum Element:HL Segment:$, {"0", " "}))
```

8. Open LoopHLShip and move to the bottom and enter the following mapping rule on LoopHLOder:

```
HierarchicalLevelCd Element:HL Segment:$ = "O"
& HierarchicalParentIDNum Element:HL Segment:$ = HierarchicalIDNum Element:HL Segment
```

9. Open LoopHLPack and LoopHLItem and enter the following mapping rule:

```
HierarchicalLevelCd Element:HL Segment:$ = "P"
& HierarchicalParentIDNum Element:HL Segment:$ = HierarchicalIDNum Element:HL Segment
HierarchicalLevelCd Element:HL Segment:$ = "I"
& HierarchicalParentIDNum Element:HL Segment:$ = HierarchicalIDNum Element:HL Segment
```

10. Save and analyze the type tree.

## Results

---

The input should parse into each HL Loop depending on the HL Loop level code:

```
(HierarchicalLevelCd Element:HL Segment:$) and its parent id (HierarchicalParentIDNum Element:HL Segment:$ = HierarchicalIDNum Element:HL Segment)
```

## Mapping HL levels to the output

---

At the point where you want to begin the shipping level, example command to be used. This will pass the Shipment HL Loop and all HL child loops to the functional map `forEachShipment()`.

```
=forEachShipment(LoopHLShip:Input)
```

And inside the `forEachShipment()` map you can map the next level for Order and so on.

## sqd example

---

Instructions for running the sqd example.

Review the example notes prior to running the example.

- [sqd example notes](#)  
Points to be aware of when using the sqd example.
- [How to run the sqd example](#)  
Run instructions for the sqd example.

## sqd example notes

---

Points to be aware of when using the sqd example.

This example shows the following:

- The use of multiple series functions in the same mapping rule.
- Mapping element, composite and terminator syntax items used in X12, rather than using defaults.

This example shows how to re-organize input X12 EDI data consisting of multiple purchase orders (#850 transaction sets) to create multiple output X12 invoices (#810 transaction sets).

The input data is organized into #850 transaction sets. Within each #850 is a series of line items (LoopPO1). Nested within each line item is a series of SDQ segments. Each SDQ segment can contain up to 10 store identification codes. So, line item #1 could be associated with hundreds of stores, line item #2 could be associated with some of the same stores, and some different stores. The output must be re-organized to send one invoice for each store identified in the input data. Each invoice must have only the line items associated with the store specified in the invoice.

## How to run the sqd example

---

Run instructions for the sqd example.

## About this task

---

Follow these steps:

## Procedure

---

1. Open the x12\_examples project.
2. Navigate to schemas and open the ansi7040 schema.
3. Analyze the schema. The schema should analyze with no errors.
4. Open the schema profile and analyze the schema. The schema should analyze with no errors.
5. Open the schema storeinfo and analyze the schema. The schema should analyze with no errors.
6. Navigate to maps and open the storeinfo map.
7. Build the map and then run the map.
8. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.

9. To download the file, go to Files and download the file, wally.out..

## xmlpo example

Instructions for running the xmlpo example.

Review the example notes prior to running the example.

- [xmlpo example notes](#)

Points to be aware of when using the xplo example.

- [How to run the xmlpo example](#)

Run instructions for the xmlpo example.

## xmlpo example notes

Points to be aware of when using the xplo example.

- The schema for the input card for the x12toxml map and for the output card for the xmltox12 map is the ansi7040 schema.
- A trimmed schema can be used for improved performance.
- The native format of the orders.xsd schema is used directly in the mapping.
- The x12toxml map will only process a single interchange. One approach to using it with a transmission containing multiple interchanges would be to use a pre-process that split each interchange in the transmission into a file of its own. A Message Broker flow could be used that calls a map to split the file and then invokes the x12toxml map to transform each of these interchange files into an XML format.

## How to run the xmlpo example

Run instructions for the xmlpo example.

## About this task

Follow these steps:

## Procedure

1. Open the x12\_examples project.
2. Navigate to schemas and open the ansi7040 schema.
3. Analyze the schema. The schema should analyze with no errors.
4. Navigate to the maps and open the xmlto12 map.
5. Build the map, then run the map.
6. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
7. To download the file, go to Files and download the file,.x12\_po.out..
8. Repeat steps 6, 7, 8 and 9 of this procedure.

## EDIFACT schemas

The Pack for Supply Chain EDI contains EDIFACT standard schemas and example schemas.

EDIFACT schemas are used to validate and ultimately transform, data that conforms to the United Nation's (UN) EDIFACT standard, as described in the UN EDIFACT specifications.

- [About the EDIFACT standard](#)

The EDIFACT (Electronic Data Interchange For Administration, Commerce, and Transport) standard is primarily used in Europe.

- [Installation](#)

The EDIFACT schemas install with the Pack for Supply Chain EDI.

- [EDIFACT schema details](#)

Standard schemas and example schemas are contained in the Pack for Supply Chain EDI.

- [EDIFACT examples](#)

Example maps and schemas install with the Pack for Supply Chain EDI or within the Design Server imported project edifactExamples.zip and edifactExampleBlockChain.zip.

## About the EDIFACT standard

The EDIFACT (Electronic Data Interchange For Administration, Commerce, and Transport) standard is primarily used in Europe.

The standard is maintained by the UN and the specifications can be obtained from the United Nations Electronic Commission for Europe (UNECE) website:

[www.unece.org/trade/untdid/welcome.htm](http://www.unece.org/trade/untdid/welcome.htm)

This website contains links for the industry-specific, sub-standards.

ITX supports all of the modern **D** EDIFACT standard versions. Versions prior to that time are provided as parsing examples only. EDIFACT transitioned to using the **D** versions starting in the early 1990s. The **D** versioning system signifies that the release is a directory, updated twice a year, in a specific year.

#### Timeline of change:

- Before the Early 1990s  
EDIFACT versions were labeled with year identifiers such as **UN/EDIFACT 1988** or **UN/EDIFACT 1990**.
- Early 1990s onward  
EDIFACT started using the **D** versioning system. For example, **D.93A** refers to the directory released in the first half of 1993, while **D.93B** refers to the directory released in the second half of 1993.

#### Reason for the change:

The following are the reasons for the transition to the **D** versioning system:

- To standardize the release cycles  
The **D** versions provide a clear and systematic way to indicate the release cycle and year, making it easier to track updates and changes.
- To ensure consistency and predictability  
With biannual releases, users of EDIFACT standards can anticipate and prepare for updates more predictably, facilitating better planning and implementation.
- To improve the documentation and reference  
The **D** system simplifies the documentation and referencing, as each version is explicitly tied to a specific time period, reducing ambiguity.

#### How it works:

- D.XXA  
Indicates the first release of the year **XX**.

For example, **D.21A** refers to the first release of the year 2021.

- D.XXB  
Indicates the second release of the year **XX**.

For example, **D.21B** refers to the second release of the year 2021.

By using the **D** versioning system, EDIFACT ensures that the standards are regularly updated to keep pace with evolving business needs and technological advancements, while providing a clear and structured way to manage these updates.

---

## Installation

The EDIFACT schemas install with the Pack for Supply Chain EDI.

---

## EDIFACT schema details

Standard schemas and example schemas are contained in the Pack for Supply Chain EDI.

- [Overview](#)  
The root type of each EDIFACT schema is EDI.
- [EDIFACT category details](#)  
The EDIFACT category has four subtypes.
- [Interchange category](#)  
Double-click the Partner Inbound Interchange type to view the components of the interchange.
- [Transmission category](#)  
Transmission type is made up of Interchange types.
- [Mapping EDIFACT data](#)  
When creating a map for EDIFACT data, create an input or output card to represent the EDIFACT data.
- [Input card - EDIFACT data from multiple trading partners](#)  
Select an Interchange type that corresponds to a Transmission type.
- [Output card - sending EDIFACT data to multiple partners](#)  
When the output consists of only one interchange, select an Interchange type corresponding to the Transmission type

---

## Overview

The root type of each EDIFACT schema is EDI.

Each schema has EDIFACT, Interchange, and Transmission categories that stem from the EDI root type. For example, the edifd20a schema contains the EDIFACT version D, release 20A.

EDIFACT schemas are organized in the same way that ANSI X12 schemas are organized. If you trade by using both ANSI X12 and EDIFACT, you can easily design a schema to make it a multi-standard schema.

- [EDIFACT category](#)  
The EDIFACT category contains four subtypes.
  - [Interchange](#)  
The Interchange type contains the data types for an interchange.
  - [Transmission](#)  
The Transmission type contains the data types for a transmission. A data object is made up of one or more interchanges.
- 

## EDIFACT category

The EDIFACT category contains four subtypes.

The following are subtypes of the EDIFACT category:

- Control type defines the EDIFACT control structure objects. The Control category is the same on each EDIFACT version schema.
- Group type defines the functional groups for the version.
- Msg type defines the messages for the version.
- V category defines the message contents, segments, composites, and elements in that particular version.

The version-specific data objects can be found under the category whose name begins with a V followed by the version number. For example, VD20A is the name of the category in the edifd20a version schema.

For more information on these subtypes, see the ["EDIFACT Category"](#) section.

---

## Interchange

The Interchange type contains the data types for an interchange.

The Interchange category contains Inbound and Outbound partitioned group subtypes.

---

## Transmission

The Transmission type contains the data types for a transmission. A data object is made up of one or more interchanges.

The Transmission category contains Inbound and Outbound group subtypes.

Note: The EDIFACT schemas include both inbound and outbound types, where appropriate. In addition, types called Partner define a generic trading partner.

---

## EDIFACT category details

The EDIFACT category has four subtypes.

The subtypes are listed here: Control, Group, Msg, and a V (*version*) category.

- [Control subtree](#)  
The subtypes of the Control category are the same in each EDIFACT schema. These types are used in EDIFACT envelope segments.
  - [Group subtypes](#)  
The subtypes of the Group category represent functional groups in the given EDIFACT version.
  - [Msg subtype](#)  
The subtypes of the Msg category represent EDIFACT messages.
  - [Version specific subtype](#)  
The version specific category (for example, v93\_2) is a subtype of the EDIFACT category. The name of this category is determined by the EDIFACT version.
- 

## Control subtree

The subtypes of the Control category are the same in each EDIFACT schema. These types are used in EDIFACT envelope segments.

Expand the Control category to view the sub-schemas.

- [Envelope types](#)  
This documentation describes the ways in which envelope types are used.
- [UNA service string](#)  
The UNA type is an optional envelope control. It is used to specify syntax objects that appear within the EDIFACT interchange.
- [EDIFACT interchange envelope UNB and UNZ](#)  
An EDIFACT interchange begins with a UNB. It contains version release information, syntax information, and partner information. An interchange ends with a UNZ.
- [Functional group envelope UNG and UNE](#)  
A functional group begins with a UNG and ends with a UNE. Functional group envelopes in EDIFACT are optional.
- [Message envelopes - UNH and UNT](#)  
A message begins with a UNH and ends with a UNT.
- [Element category](#)

- **Delimiter category**  
The Delimiter types are syntax items.
- **Composite category**  
A composite is a group of related elements.

## Envelope types

This documentation describes the ways in which envelope types are used.

Envelope types are used for these reasons:

- To specify the syntax objects in the interchange that follows (the UNA).
- To surround messages or functional groups of an interchange (the UNB and UNZ).
- To surround a set of messages of the same type (the UNG and UNE).
- To surround the body of a message (the UNH and UNT).

Each Envelope type begins with a set of letters that identifies the segment, for example UNA. These same sets of letters (UNA) are also used in the Properties window of the Type Designer to define the value of the initiator.

## UNA service string

The UNA type is an optional envelope control. It is used to specify syntax objects that appear within the EDIFACT interchange.

The following are the components of the UNA type:

Component	Description
Composite Delimiter	A delimiter between components of a composite.
Element Delimiter	A delimiter between elements in an envelope or segment.
Decimal Delimiter	A separator between the integer and fractional part of EDIFACT decimal numbers.
ReleaseCharacter	A character used a release character.
Reserved Delimiter	Reserved for future use.
Terminator Delimiter	A terminator of an envelope or segment.

The Composite, Element, ReleaseCharacter and Terminator Delimiter types are all specified as syntax items. If a UNA appears in the data, the values that occur in the UNA set the active syntax values. If there is no UNA, the release character is assumed to be a question mark ? and the delimiter values are set to the values in the UNB.

## EDIFACT interchange envelope UNB and UNZ

An EDIFACT interchange begins with a UNB. It contains version release information, syntax information, and partner information. An interchange ends with a UNZ.

A UNB is defined as a prefix delimited type with the initiator UNB. Its delimiter is defined as Element Delimiter. The first component of the UNB type specifies the character set for text items, the Composite delimiter, and the version release.

Note: The default for the UNB delimiter is + and its default terminator is an apostrophe (') followed by a CR/LF. The default for the composite delimiter is set in the SyntaxID Composite type to a colon (:). You can change these defaults in the schemas, if necessary.

## Functional group envelope UNG and UNE

A functional group begins with a UNG and ends with a UNE. Functional group envelopes in EDIFACT are optional.

When functional group envelopes are used, the Functional Group Ref# Elements on both the UNG and the UNE must match. It is common not to use them because the version information is also in the message envelope.

## Message envelopes - UNH and UNT

A message begins with a UNH and ends with a UNT.

## Element category

The item subtypes of the **Element** category are used as components of **Envelope** types. For example, trading partner identification items are defined under the **Element** category.

## Delimiter category

The Delimiter types are syntax items.

They are used as composite delimiters, decimal separators, element delimiters, release characters, and terminators in the EDIFACT segments.

The values of these syntax objects can be different in different interchanges. Their values are determined in the UNA; each syntax object is a component of the UNA type. However, if the UNA is not present, the syntax values are found in the UNB. For example, the UNB type is defined as delimited, and the value of its delimiter is specified as the syntax item Element Delimiter. The value of the Find property is Yes. This value indicates that, in input data, the value in the UNB is found and used as the value for the delimiter for the rest of the segments in the interchange.

Double-click a subtype of Delimiter (for example, Element) to view its restrictions. The restrictions are the values that you can use for that syntax object.

## Composite category

A composite is a group of related elements.

The Composite group subtypes are used as components of Envelope types. A composite has its own delimiter, which is typically a colon :.

## Group subtypes

The subtypes of the Group category represent functional groups in the given EDIFACT version.

The type name of a functional group is F followed by the EDIFACT version. For example, the functional group type in the edifd20a schema is FD20A.

A functional group is made up of messages. A functional group begins with a UNG and ends with a UNE, which are optional.

## Msg subtype

The subtypes of the Msg category represent EDIFACT messages.

The sub-types of Fversion (for example, FD20A) are all the messages in the EDIFACT version. The name of each message is the value of the MsgType Element in the UNH.

A message begins with a UNH and ends with a UNT.

The middle component is the type that represents the actual contents of the message. These types are found under the version-specific category, for example, the VD20A category in the edid20a schemas.

Each message has a unique value for the MsgType Element. The value is specified by the component rule on the UNH component. For example, the component rule states that the MsgType Element of the UNH in the BAPLTE message is BAPLTE. Each message has a similar component rule.

## Version specific subtype

The version specific category (for example, v93\_2) is a subtype of the EDIFACT category. The name of this category is determined by the EDIFACT version.

- [Composite category](#)  
A composite is a set of related data elements.
- [Viewing the Element category's full description](#)  
The item subtypes of the Element category are the EDIFACT data elements.
- [Segment category](#)  
A segment is a logical unit of information, like a data record. The Segment type is partitioned by initiator value. Each segment begins with a unique initiator, which identifies the segment. For example, the BUS segment begins with the initiator BUS.
- [Set category](#)
- [Groups of segments](#)  
In EDIFACT, a repeating group of segments is called a group.

## Composite category

A composite is a set of related data elements.

Each composite is defined as infix delimited and its delimiter is the syntax item Composite Delimiter. For an interchange, the value of the Composite Delimiter is set in the UNA or the UNB. Typically, the composite delimiter is a colon :.

## Viewing the Element category's full description

The item subtypes of the Element category are the EDIFACT data elements.

## About this task

To see the full description of an element, view the type properties in the Map Designer.

To view an element's full description, perform these steps:

## Procedure

---

1. Select the type in the schema.
2. Right-click and select Properties from the menu. Or, click the Properties icon on the tool bar.  
The description is in the Value column of the Description property.

## Results

---

There are many element types in an EDIFACT schema. Although they are arranged alphabetically, you might want to use the **Find** command on the Edit menu to locate a particular element.

The following list summarizes how an EDIFACT schema corresponds to the EDIFACT documentation of the EDI standards:

- Element codes are specified as restrictions in an EDIFACT schema.
- Different elements with the same EDIFACT description are named by appending the reference number designator to the end of the subtype name.
- Some elements have subtypes of their own. These elements are not found as data elements in the EDIFACT documentation. Element subtypes were added if the same element was used more than once as a component of the same Segment. For example, if a Segment has two Date Element components, one might be an Arrival Date Element and the other a Departure Date Element.

---

## Segment category

A segment is a logical unit of information, like a data record. The Segment type is partitioned by initiator value. Each segment begins with a unique initiator, which identifies the segment. For example, the BUS segment begins with the initiator BUS.

Because an Element Delimiter must follow the segment initiator value and precede the first data element, each segment is defined as prefix delimited by the Element Delimiter, typically the plus sign + and has a terminator of Terminator Delimiter, typically the apostrophe ('). In addition, the release character is defined as Release Character Delimiter, typically the question mark (?).

Components of a segment can be Element types and Composite types. The segments were defined to comply with the rules specified in the EDIFACT documentation.

Note: For readability, the default Segment terminator is defined as an apostrophe ('), followed by a CR/LF. You can change the terminator as needed.

---

## Set category

Types are organized as subtypes of the Partner category: Inbound and Outbound. The subtypes of the Inbound and Outbound categories are identical.

Types defining message contents are organized under categories. Each type that defines the contents of a certain message appears under a certain category. The name of the category is the message name, which matches the type name under the Msg category. For example, the type that defines the contents of the BAPLTE message is found under the BAPLTE category.

The name of the type that defines the contents of a message is Message.

---

## Groups of segments

In EDIFACT, a repeating group of segments is called a group.

A BAPLTE group type can also contain other group types. The word Group is typically appended with a number, such as 1 (for Group1), to distinguish it from other groups. For example, the BAPLTE message type contains Group1, Group2, and Group3.

---

## Interchange category

Double-click the Partner Inbound Interchange type to view the components of the interchange.

The first component of the interchange, UNA, is sometimes called a "service string" in EDIFACT. It is optional. It specifies the syntax objects, such as delimiters, that appear in the rest of the interchange.

The second and fourth components collectively define the interchange envelope. The UNB is the envelope header. It specifies the trading partner information and syntactical information when the UNA is missing. The UNZ is the envelope trailer.

The third component defines the functional groups within the interchange. In EDIFACT data, the functional group envelopes are not required. Most often, EDIFACT data contains only a message envelope, which is inside the Inbound Partner Group.

The layout of components in the outbound interchange is similar to the layout in the inbound.

- [Restart attribute on functional group](#)

The Group component of an interchange has the restart attribute.

- [Component rule on UNZ segment](#)

The UNZ segment has a component rule that assures that the group of one interchange is not mixed up with the group of another interchange if a restart occurs.

## Restart attribute on functional group

The Group component of an interchange has the restart attribute.

When you receive different functional groups from different departments within a trading partner, one department's good data is not lost if another department's data is bad. You can remove this restart attribute if you would rather go directly to the next interchange if bad data occurs within any Inbound Group.

## Component rule on UNZ segment

The UNZ segment has a component rule that assures that the group of one interchange is not mixed up with the group of another interchange if a restart occurs.

The component rule is shown here:

```
InterchangeControlRef Element:$ = InterchangeControlRef Element:Partner Inbound UNB
Envelope Control EDIFACT Data
```

The rule states that the InterchangeControlRef Element of the UNZ must be equal to the InterchangeControlRef Element of the UNB. If an Inbound Partner Group is invalid and a restart occurs, the component rule keeps different interchanges from getting mixed up with one another.

## Transmission category

Transmission type is made up of Interchange types.

An Inbound Transmission type is made up of Inbound Interchange types. For example, an EDIFACT Inbound Transmission type is made up of EDIFACT Inbound Interchange types and a Partner EDIFACT Inbound Transmission type is made up of Partner EDIFACT Inbound Interchange types.

The Partner type represents a generic trading partner. If you are trading with different partners who use different subsets of the EDIFACT standards, you might want to rename the Partner type and add then add new types to define the additional trading partners.

The components of Outbound Transmission types are similar to those of Inbound.

The following group windows display the components of the Inbound and Outbound subtypes of Transmission. The Partner Inbound Transmission EDI group window illustrates that it is made up of Partner Inbound Interchange types and that the Partner Outbound Transmission EDI group window illustrates that it is made up of Partner Outbound Interchange types.

- [Restart attribute on an interchange](#)

The Interchange component of a Transmission type has the restart attribute. On input data, the restart attribute is intended to filter network noise and to detect invalid interchanges.

## Restart attribute on an interchange

The Interchange component of a Transmission type has the restart attribute. On input data, the restart attribute is intended to filter network noise and to detect invalid interchanges.

When you receive an invalid interchange from one partner, the restart attribute allows processing of valid data in other interchanges in the same transmission.

When you receive network messages and you know where they appear in an inbound communication file, you may want to include them as a component of an Inbound Transmission type. If you do not include them as data, they are not recognized as being part of a transmission and are rejected as invalid interchanges. However, the processing time is longer than if you included these network messages as data.

For EDI output data, the restart attribute is useful for auditing data. You can audit the output data to report when outbound interchanges within a transmission are invalid.

The following schema, EdifISO9735-4 conforms to ISO 9735 part 4.

## Mapping EDIFACT data

When creating a map for EDIFACT data, create an input or output card to represent the EDIFACT data.

When specifying the type of the card, select a subtype from the Transmission category.

When your input is EDIFACT data, select Inbound Transmission, or one of its subtypes. When sending EDIFACT data, select Outbound Transmission, or one of its subtypes.

## Input card - EDIFACT data from multiple trading partners

Select an Interchange type that corresponds to a Transmission type.

When the input consists of only one interchange, select an Interchange type that corresponds to the Transmission type, as shown in this table.

When You Receive	Select This Type
Multiple EDI standards	Inbound Transmission
Only EDIFACT data, and you have not defined different trading partners in your schema	Partner Inbound Transmission

When you map to EDI data, select an Outbound Transmission type for the output card. The type to choose depends on what is being sent.

## Output card - sending EDIFACT data to multiple partners

When the output consists of only one interchange, select an Interchange type corresponding to the Transmission type

The Interchange control type that corresponds to the Transmission type is shown in this table:

If You Are Sending	Select This Type
Multiple EDI standards	Outbound Transmission
Only EDIFACT data, and you have not defined different trading partners in your schema	Partner Outbound Transmission

## EDIFACT examples

Example maps and schemas install with the Pack for Supply Chain EDI or within the Design Server imported project edifactExamples.zip and edifactExampleBlockChain.zip.

The example map and schema example files install in subdirectories under the following folder:

*install\_dir\supplychain\_edi\_vn.n.n\edifact\examples*

The examples and example files are defined in the following table:

Example and associated files	Description
examples/arrival Example files: <ul style="list-style-type: none"><li>• arrival - map source containing arrival_notice executable map</li><li>• simonin - input schema</li><li>• child.txt</li><li>• master.txt</li><li>• arrival.out - expected output</li></ul>	Creates an outbound EDI Arrival notice message (IFTMAN), used for the exchange of cargo and transport related information. A lookup is performed in the master.txt input file using the track number field located in the child.txt input file.
examples/edf2xml Example files: <ul style="list-style-type: none"><li>• ordersedi_in.txt - input EDIFACT D17A purchase orders</li><li>• orders_in.xml - input XML purchase orders</li><li>• orders_out.xml - results EDI to XML executable map</li><li>• edifact_out.txt - results XML to EDI executable map</li><li>• orders - XML schema that defines the XML purchase order</li><li>• xmlpo - map source containing executable maps edifacttoxml and xmltoedifact</li></ul>	Creates an outbound EDI ORDER message, using XML input and an outbound XML Order using EDI ORDER message input.
examples/ediBlockChain Example files: <ul style="list-style-type: none"><li>• Multiple maps, schemas, files</li></ul>	Example of using traditional EDI with blockchain.

Example and associated files	Description
examples/packages Example files: <ul style="list-style-type: none"> <li>• Input_binPackage.txt - input binary data to attach</li> <li>• Input_ediPackage.txt - input edifact message to attach</li> <li>• Input_xmlPackage.xml - input non-binary data to attach</li> <li>• Output_edipkgAttach.txt - output from map edipkgAttach</li> <li>• Input_edipkgDetach1.txt - input for map edipkgDetach1</li> <li>• Input_edipkgDetach2.txt - input for map edipkgDetach2</li> <li>• packageTests - map source containing executable maps edipkgAttach, edipkgDetach1, edipkgDetach2</li> </ul>	Example using EDIFACT service segment definitions for packaging and security taking three different inputs to create EDIFACT packages.
examples/security Example files: <ul style="list-style-type: none"> <li>• Input_binPackage.txt - input binary data to attach</li> <li>• Input_ediPackage.txt - input edifact message to attach</li> <li>• Input_xmlPackage.xml - input non-binary data to attach</li> <li>• Output_edisecurity.txt - output from map edisecOut</li> <li>• Output_security.txt - output for map edisecIn</li> <li>• securityTests - map source containing executable maps edisecIn, edisecOut</li> </ul>	Example using EDIFACT service segment definitions for packaging and security taking three different inputs to create EDIFACT packages with security.
examples/vermas Example files: <ul style="list-style-type: none"> <li>• vermas_input.json - input JSON file representing vermas data</li> <li>• vermas_d17a.txt - results JSON to vermas executable map</li> <li>• vermas_template - JSON schema template for vermas message</li> <li>• jsonvermas - map source containing executable map json2vermas</li> </ul>	Creates an outbound EDI Verified gross mass message (VERMAS) message, which provides VGM information on transport equipment such as a seagoing container. The executable map issuing JSON as input.

Instructions for running the arrival example.

Review the example notes before you run the example.

- [arrival example notes](#)

Points to be aware of when using the arrival example.

- [How to run the arrival example](#)

Run instructions for the arrival example.

## arrival example notes

Points to be aware of when using the arrival example.

- In this map there are two input files which make up arrival notices. The master file contains headers. The child file contains sets of details, which correspond to the headers. These files are defined in the simonin schema.
- The output file is an EDIFACT EDI Interchange. It is defined in the edifd17a schema.
- In the map rule for the output IFTMAN, you will see the functional map toIFTMAN. This map generates one IFTMAN per functional map oIFTMAN. This map generates one IFTMAN per group of child records, and its corresponding master record.
- Within the map IFTMAN, the ChildToLoopGID functional map is referenced.
- Expected output can be found in the file, arrival.out.

---

## How to run the arrival example

Run instructions for the arrival example.

### About this task

Follow these instructions:

### Procedure

1. Open the edifact\_examples project.
2. Navigate to schemas and open the edfd17a standard schema.
3. Analyze the schema. The schema should analyze with no errors.
4. Open the simonin schema and analyze the schema. The schema should analyze with no errors.
5. Navigate to maps and open the arrival\_notice map.
6. Build the map and then run the map.
7. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
8. To download the file, go to Files and download the file, arrival.out.

---

## edf2xml example

Instructions for running the edf2xml example.

Review the example notes before you run the example.

- [edf2xml example notes](#)  
Points to be aware of when using the edf2xml example.
- [How to run the edf2xml example](#)  
Instructions for running the edf2xml example.

---

## edf2xml example notes

Points to be aware of when using the edf2xml example.

- The schema for the input card for the edifacttoxml map and for the output card for the xmltoedifact map is the edifd17a schema. A trimmed schema can be used for improved performance.
- The native format of the orders.xsd schema is used directly in the mapping.
- The edifacttoxml map will only process a single interchange. One approach to using it with a transmission containing multiple interchanges would be to use a pre-process that split each interchange in the transmission into a file of its own. A Message Broker flow could be used that calls a map to split the file and then invokes the edifacttoxml map to transform each of these interchange files into an XML format.

---

## How to run the edf2xml example

Instructions for running the edf2xml example.

### About this task

Follow these instructions:

### Procedure

1. Open the edifact\_examples project.
2. Navigate to schemas and open the edfd17a standard schema.
3. Analyze the schema. The schema should analyze with no errors.
4. Navigate to maps and open the xmltoedifact map.
5. Build the map and then run the map.
6. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
7. To download the file, go to Files and download the file, edifact\_out.txt.
8. Repeat steps 6, 7, 8 and 9 of this procedure.

## ediblockchain example

The ediblockchain example is an example of using traditional EDI with blockchain. The example is using EDIFACT EDI documents, but the block chain concept is not limited to EDIFACT or EDI documents.

With traditional EDI, participants are using multiple forms of data with their business processes for example:

- Legacy in-house applications
- ERP systems like SAP
- Public EDI standards like EDIFACT, X12, RAIL, HIPAA
- XML and JSON data
- Spreadsheets, email, and fax

Participants do business with their partners and handle these different forms of data multiple ways using transformation tools (ITX), vans, peer-to-peer connections, and portals.

They have some very complex maintenance and configuration with all these forms of data and they have tried to keep audit trails and business partner relationships along with maintenance of all this configuration and routing using as few tools as possible. Some Participants have moved some of the complex processing to a Service and so their transformations across all the forms of data is in one location.

This traditional EDI is 30+ years old and with these business processes, there are still gaps. It is difficult to share data with non-edi participants. Some participants are not known or not trusted. They want to expand their business relationships, but the configuration can be a complicated task. Some participants have manual data entry to handle email, fax and non-program readable data prone to errors. The audit trail is compromised or incomplete with some business processes required to keep the information for a designated period.

- **Understanding the ediBlockChain example**

The example identifies three EDI participants and three non-EDI participants. Each participant adds blocks to the order change by issuing requests to a block chain service. Execution begins with the Buyer having a json order which initiates EDI processes with the supplier. Next the supplier initiates EDI processes with the carrier and buyer. Last, the carrier books trucks for delivery to the buyer.

- **The structure of the example:**

- **What the ediblockchain folder contains**

The ediblockchain folder contains a script to compile all the maps in the example, compileall.bat

- **Quick execution steps:**

## Understanding the ediBlockChain example

The example identifies three EDI participants and three non-EDI participants. Each participant adds blocks to the order change by issuing requests to a block chain service. Execution begins with the Buyer having a json order which initiates EDI processes with the supplier. Next the supplier initiates EDI processes with the carrier and buyer. Last, the carrier books trucks for delivery to the buyer.

Each participant folder in the example contains maps for execution with a top-level map beginning with "a". The top-level maps contain the specific calls to the block chain service and shows document flows and execution order on the last output card with the name (mapControl).

The buyer creates an EDI ORDER, creates block chain order, adds participants for access to the chain and edi reference information as a block in the chain. The EDI ORDER contains block chain information in the RFF segment:

RFF+CBB:orderChain^12857654123450000134012345500004'

The supplier receives the EDI ORDER, creates an EDI ORDRESP, supplies the items in the order, initiates shipping via EDI IFTMBF (Carrier Booking), adds participants for access to the chain and edi reference information as a block in the chain. The EDI ORDRESP and EDI IFTMBF contains block chain information in the RFF segment:

RFF+CBB:orderChain^12857654123450000134012345500004'

The carrier receives the EDI IFTMBF, creates EDI IFTMBC (Carrier Booking Confirmation), adds participants for access to the chain and edi reference information as a block in the chain. The carrier adds non-EDI participants as Trucks and each truck will add temperature readings on the shipped items to the block chain.

Each participant will use a predefined control block interface and document definitions and call the block chain service map. The control block identifies the type of call being made and contains information for the block chain service map to process the request and add a block to the chain.

## The structure of the example:

```
ediblockchain
... blockchain
..... config
..... journal
..... maps
..... templates
... buyer
... carrier
```

... edifiles  
... supplier

---

## What the ediblockchain folder contains

The ediblockchain folder contains a script to compile all the maps in the example, compileall.bat

The blockchain folder contains the config folder, journal, maps, and templates. The config folder contains a configuration file which may be expanded in the future. The journal folder contains the json templates for the block chain information file and actual block chain file.

The journal folder also contains some control block definitions for the block chain service maps. The maps folder contains the map source for the block chain requests and processing. The templates folder contains some json document and control block definitions for the participants to use to make requests and pass documents to the block chain service. Viewing the templates will help understand the mapping and block chain service requests.

The edifiles folder contains the EDIFACT standard being used and will contain all the EDI documents communicated between each participant.

The buyer, carrier, and supplier folders identify an EDI participant and contain maps and data to create edi documents and make block chain requests. The map source in each participant folder contains a top-level map (aBuyerNewOrder, aSupplierNewOrder, aCarrierNewOrder). The last output card controls the block chain service requests, and triggers for the next participant.

The buyer folder is the main execution folder. The map source file is BuyerOrderMaps.mms and the top-level map aBuyerNewOrder will start the new order and trigger the other participants processing.

---

## Quick execution steps:

### Procedure

1. Compile all the maps in the example.
  - Using Design Studio, execute the script in folder .\ediblockchain\compileall.bat.
  - Using Design Server, the ediblockchain example is in the project edifactExampleBlockChain.zip. After importing, create a package for the project and build the package.
2. Execute the folder .\ediblockchain\buyer.
  - Using Design Studio, open the BuyerOrderMaps.mms and run the top level map aBuyerNewOrder
  - Using Design Server, open the aBuyerNewOrder map and run.

This executes all the block chain participants.

### Results

Execution flows from the buyer with a purchase order, to the supplier who communicates with the purchaser and the carrier for shipping, and the carrier who identifies the trucks used for delivery. Each block contains information relevant to the partner or participant.

Using Design Studio, folder .\ediblockchain\blockchain\journal contains example results:

- orderChain.dat contains the chain data.
- orderChainInfo.dat is the partner information and keys to chain data.

Using Design Server:

- Execute map aViewOrderChain and view the output to see the chain data.
- Execute map aViewOrderChainInfo and view the output to see the partner information and keys to the chain data.

## Packages example

The edfiso9735-41 type tree contains service segment definitions for packaging and security along with any updates to the CONTRL message.

The EDIFACT documentation identifies the UNO, Object, UNP as a package. The UNO/UNP should follow EDIFACT syntax with a segment terminator following the segment information. The documentation states that the data presented as an object shall not be governed by EDI syntax rules. This means the object cannot be validated as a typical EDI message. Although it is possible the object is encrypted data and when decrypted could be validated using the usual EDI syntax and the Supply Chain EDI compliance checking.

The documentation does not identify if the Object attached in the package should be terminated with a segment terminator or any other terminator.

Terminating the Object attachment would allow the UNO/UNP segments to be parsed and processed in the TX map using the edfiso9735-41 type tree and allow the Object to be detached without the UNO/UNP service segments. The edfiso9735-41 type tree defines the OBJECT group to allow this processing for both inbound and outbound for the Package Category.

If the Object is not terminated with a segment terminator, the UNO/UNP becomes part of the Object to be detached and must be processed outside the TX map used to detach the package which requires a user defined type tree and separate map. The edfiso9735-41 type tree defines the PACKAGE group to allow this processing for both inbound and outbound for the Package Category.

The input definition used for the example packages is defined as UTF-8 to ensure binary data is processed preserving the original data.

The output definition for the EDIFACT package object is defined as UTF-8.

- [What the map source of packages example contains](#)

## What the map source of packages example contains

The map Source packagetests.mms contains three executable maps:

- edipkgAttach - An example of taking three different inputs to create EDIFACT packages.
  - Three inputs:
    - Input\_xmlPackage.xml: Input 1 is xml
    - Input\_ediPackage.txt: Input 2 is EDIFACT EDI
    - Input\_binPackage.txt: Input 3 is binary
  - Output\_edipkgAttach.txt: Output is EDIFACT EDI containing packages.
- edipkgDetach1 - An example using one EDIFACT input containing multiple edi and xml packages to create raw data output. The output attempts to identify the UNO/Object/UNP parsing and mapping with and without a segment terminator for the Object.
  - Input\_edipkgDetach1.txt: Input 1 is EDIFACT EDI and multiple packages
  - Output\_edipkgDetach1.txt: Output is EDIFACT EDI containing packages
- edipkgDetach2 - An example using one EDIFACT input containing multiple edi, xml, binary packages to create raw data output. The input file was created with map execution of the edipkgAttach map and renamed. The output attempts to identify the UNO/Object/UNP parsing and mapping with and without a segment terminator for the Object.
  - Input\_edipkgDetach2.txt: Input 1 is EDIFACT EDI and multiple packages
  - Output\_edipkgDetach2.txt: Output is EDIFACT EDI containing packages

## Security example

The edfiso9735-41 type tree contains service segment definitions for packaging and security along with any updates to the CONTRL message.

The security segments provide EDIFACT structures with the security service of confidentiality for example encryption, compression, filter, digital signatures, etc. The message body or package is not governed by EDI message syntax rules and cannot be validated as a typical EDI message. Although it is possible to detach and decrypt the data which could be validated using the usual EDI syntax and the Supply Chain EDI compliance checking.

The input definition used for the example security also uses packages and is defined as UTF-8 to ensure binary data is processed preserving the original data.

The output definition for the EDIFACT package object is defined as UTF-8.

- [What the map source of security example contains](#)

## What the map source of security example contains

Map Source of securitytests.mms contains two executable maps:

- edisecOut - An example of taking three different inputs to create EDIFACT packages with security segments.
  - Three inputs:
    - Input\_xmlPackage.xml: Input 1 is xml
    - Input\_ediPackage.txt: Input 2 is EDIFACT EDI
    - Input\_binPackage.txt: Input 3 is binary
  - Output\_edisecurity.txt: Output is EDIFACT EDI containing packages and security segments.
- edisecIn - An example using one EDIFACT input containing multiple edi and xml packages with security segments to create raw data output. The output attempts to identify the UNO/Object/UNP parsing and mapping with and without a segment terminator for the Object.
  - Input\_ediSecurity.txt: Input 1 is EDIFACT EDI and multiple packages and security segments.
  - Output\_security.txt: Output is EDIFACT EDI containing packages.

## vermas example

Instructions for running the vermas example.

- [vermas example notes](#)  
Points to be aware of when using the vermas example.
- [How to run the vermas example](#)  
Run instructions for the vermas example.

## vermas example notes

Points to be aware of when using the vermas example.

- The vermas example creates an outbound EDI Verified gross mass message (VERMAS) message.
- The VERMAS message provides VGM information on transport equipment such as a seagoing container.
- The executable map uses a JSON document as input.
- The expected results can be found in vermas\_d17a.txt file.

# How to run the vermas example

Run instructions for the vermas example.

## About this task

Follow these instructions:

## Procedure

1. Open the edifact\_examples project.
2. Navigate to schemas and open the edfd17a standard schema.
3. Analyze the schema. The schema should analyze with no errors.
4. Navigate to maps and open the json2vermas map.
5. Build the map and then run the map.
6. View the output. Go to the map Diagram-Result, and hover the cursor over Target, then select View Data.
7. To download the file, go to Files and download the file, vermas\_d17a.txt.

## Compliance check Overview

The EDI Standard organizations publish formats for X12, RAIL, IATA, and EDIFACT documents so that they can be correctly translated by computers. Strict compliance with these standards is essential if EDI files are to be processed properly. Supply Chain EDI Compliance Check framework enforces these EDI standards by validating X12, RAIL, IATA, and EDIFACT EDI documents before translation occurs for your applications. Validation of newly created EDI documents ensures that the data you create conforms and does not create issues for your trading partners. As the trend in the industry is to consider fines for non-compliance, verifying that the data you create is compliant, and is of key importance.

Validation ensures more accurate EDI translation and a more robust automated process by detecting and rejecting EDI files with anomalies that might break the application and translation programs and interrupt production.

If there are errors present in the EDI data, the EDI Compliance Check framework produces acknowledgments that are ready for re-enveloping and transmittal back to the sending trading partner.

## Validation

Validation is performed at all levels of the EDIFACT, IATA, X12, or RAIL EDI message: the interchange, group and transaction envelopes, each segment, and each of the element components in each transaction.

The main maps for the EDI Compliance Checker are named ccx12 for X12, x12u for X12U, ccttx12 for X12 travel & transportation subset, ccrail for RAIL, ccapi for IATA-API, ccpnr for IATA-PNR, ccttedf for EDIFACT travel & transportation subset, and ccedf for EDIFACT. Each EDI Compliance Check map uses a framework that processes data through these steps.

- Collects and stores metadata information about the configuration and input data.
- Validates the Interchange envelope and optionally produces a TA1 acknowledgment for X12 and RAIL data.
- Validates the group and transaction data; collects error location and type information.
- Produces the acknowledgment for the interchange. If errors are found, an error log is produced for each transaction, group, or interchange error.
- Produces a JSON report based on interchange and group acknowledgment information.
- [X12 Validation considerations](#)  
The X12 EDI Compliance Check framework performs optional extended processing to be considered.
- [Validation overview](#)  
The EDI Compliance Check framework performs validation as follows:
- [Validation checklist](#)  
Validation involves ensuring the EDI data is syntactically correct as well as the message structure.

## X12 Validation considerations

The X12 EDI Compliance Check framework performs optional extended processing to be considered.

The Interchange Syntax Extension or ISX control segment was introduced with X12 version 7040 with release character delimiter and character encoding. X12 version 8010 was expanded to include override X12 version and Industry Identifier.

X12 members are advised to have trading partner agreements in place before using the ISX segment. When the data stream includes the ISX control segment, X12 compliance checking MUST be configured. At least one ISXcontrol setting must be present to continue compliance processing. These settings can be found in the x12cfg.xsd and XML configuration files for ccx12 execution or JSON configuration file for x12u execution.

```
<ISXcontrol>
 <IgnoreISX>F</IgnoreISX>
```

Any ISX control segment containing a character encoding value must use the new component x12u for compliance checking, or use ccx12 component with the XML configuration setting to `<IgnoreISX>T</IgnoreISX>`.

X12 validation processing for the release character must use ISA version 7040 or higher. Processing for the character encoding and code list override must use ISA version 8010 or higher. The ISX segment must be present in the input data stream.

The ISX control configuration settings identify processing control for the ISX segment.

```
<ISXcontrol>
 <IgnoreISX>F</IgnoreISX>
 <ReleaseCharacter>
 <DefaultReleaseCharacter></DefaultReleaseCharacter>
 <OverrideReleaseCharacter></OverrideReleaseCharacter>
 </ReleaseCharacter>
 <CharacterEncoding>
 <AllowEncoding>F</AllowEncoding>
 <DefaultSourceEncoding></DefaultSourceEncoding>
 <OverrideSourceEncoding></OverrideSourceEncoding>
 <DefaultTargetEncoding></DefaultTargetEncoding>
 <OverrideTargetEncoding></OverrideTargetEncoding>
 </CharacterEncoding>
 <CodeListVersionOverride>
 <AllowCodeListOverride>F</AllowCodeListOverride>
 <DefaultCodeListVersion></DefaultCodeListVersion>
 <OverrideCodeListVersion></OverrideCodeListVersion>
 </CodeListVersionOverride>
</ISXcontrol>
```

Default and override values for the release character, character encoding, and code list version override can be provided. Default values for Character Encoding (ISX02 element) and Code List Version Override (ISX03 element) can be used when these ISX elements do not contain the value. The exception being the Release Character Default, which will modify the value found in the ISX01 element. Override values can be used to override the values in the ISX. The values in the ISX will be used when no default or override values are configured.

The standards in the X12U component are defined with the UTF-8 universal character set and sized as character vs bytes. The standards provide validation and application mapping to preserve data values. For application maps it is recommended the target encoding configuration use UTF-8.

X12 standard defines valid values for the ISX character encoding element which can be expanded in future releases. Values that represent character sets can be implemented using the X12U component. For testing purposes, UTF-8 and UTF-16 TX codes have been added for X12 versions earlier than 00804. The supported character sets can be found in the x12codes.txt file.

```
ISX02=00803,1|US-ASCII,2|ibm-037,4|Latin1,5|Latin2,6|Cyrillic,7|Greek8,8|Latin3,9|Latin4,10|Arabic,11Hebrew,12|Latin5,13|Latin-9,T4|UTF-8,T5|UTF-16LE,T6|UTF-16BE
```

For example: ISX02 for ISA version 00803, value 1 represents the TX character set US-ASCII and ISX02 value 7 represents TX character set Greek8. The ISX02 values T4, T5, and T6 can be used for testing purposes. Example data in UTF-8 and UTF-16LE have also been included with the X12U component.

A set of maps are included in the X12U component in the map source file x12conv.mms to perform the character decoding and encoding as defined in the ISX and compliance check configuration using the X12U Standard schemas as the target or source for processing.

- **Character Encoding Processing**

The Supply Chain EDI component X12U must be used for character encoding processing. The ISX02 value identifies the character encoding beginning with the group envelope (GS/GE) for the rest of the interchange.

## Character Encoding Processing

The Supply Chain EDI component X12U must be used for character encoding processing. The ISX02 value identifies the character encoding beginning with the group envelope (GS/GE) for the rest of the interchange.

When the data stream is encoded with the ISX encoding value specified, the output or target data stream from the X12U processing will be encoded with the source encoding by default. The configuration settings are provided to override the target encoding. The TA1 does not contain the GS/GE structure and will not be encoded.

It is assumed that the ISX character encoding identification provides encoding at both element and package levels.

The Unicode Standard defines Universal character sets enabling data to be transmitted in single or multi-byte encodings to prevent the loss of data. The universal character sets such as UTF-16 and UTF-32 would indicate Package level encoding. With Package level encoding, the data stream beginning with the GS to the end of the interchange including the segment identification and code list values would be encoded. The segment identification and code list values as defined in the X12 standard would be preserved in single or multi-byte format.

The language specific character sets enable data to be transmitted in a specific language and applies to all the transaction text elements beyond the ISX. The language specific or non-universal character sets would indicate Element level encoding. With Element level encoding, the data stream beginning with the GS to the end of the interchange excluding segment identification and code list values would be encoded. The segment identification and code list values should remain as defined in the X12 standard. Only the text elements should contain the value in the character set as defined in the ISX character encoding identification.

## Validation overview

The EDI Compliance Check framework performs validation as follows:

- Envelope validation - The interchange, group, and transaction envelopes are checked for structure and configurable partner content restrictions. Segment, group and transaction counts are also validated.
  - An interchange that fails the envelope validation cannot continue in the process.
  - If the group envelope validation fails, the contents of the group cannot continue but other groups in the interchange continue.
  - If any transaction fails the envelope validation, only that transaction envelope is rejected, and all other transactions continue to be validated.

- Schema validation - the data in each transaction is compared to the pattern defined by the appropriate version of the standard EDI schema. If the data matches the pattern in the schema, it passes validation and no further processing is necessary.
- Segment structure validation - if data fails the schema validation step, it is passed through more validation. The transaction is checked for segment structure errors by using an external library to validate the order of the segments. This step checks for errors such as missing mandatory segments, or loops, too many repetitions of a segment or loop, or unrecognized segments.
- Segment detail validation - if no segment structure errors are found, the data is passed to a segment map to check for data element errors within the segments. This uses the audit log information to collect information about the location and reason for the error. Examples of errors that are detected by this step include the missing data elements, invalid data element values, and data elements that are too long or too short.
- The EDI Compliance Check framework collects all error information into a detailed error log and creates the acknowledgment. The error log and acknowledgment can report multiple errors if multiple errors are detected. However, there are some situations in which only the first error is reported. For example, if an error is found in the envelope, then detailed validation on the contained transactions is not performed. There are also some cases such as missing loops, or segments, where more error messages are suppressed because they would be misleading as they are the result of recovery attempts from the initial error. An optional JSON report component may also be created with configuration options for Accepted, Full, Never, and Rejected along with Interchange, Group, and Transaction header and trailer images from the inbound document.

Note: Incoming acknowledgments in the interchange are not validated or acknowledged.

## Validation checklist

Validation involves ensuring the EDI data is syntactically correct as well as the message structure.

The following is a list on syntax checks performed:

- Length - Both minimum and maximum lengths are checked.
- Data type - Data types are checked to ensure that numerical values, text values and date values are correctly represented.
- Qualifier restrictions - Qualifier restriction values are checked against restriction lists.
- Empty data elements - Empty data elements are checked to make certain there are no missing mandatory elements. For X12 and RAIL data, data elements that are marked as mandatory must have content if the segment is present. In the case of a composite data element, at least one component data element must have content if the composite is present.
- Relational conditions may exist between one or more data elements based on the presence or absence of those data elements. These conditions are verified.
- Unexpected elements/segments/loops - Loops and segments are checked to make sure that they occur in the data only where expected and do not occur where they are not expected. This error type can also be reported as a "missing mandatory" error and include the loop or segment that was expected at that position.
- Repetition - The number of times a loop, segment, or element is found in the data against the range that is specified by the standard.
- Duplicate control number checking (optional) - Optional validation is provided to check for duplicate control numbers within the group and transaction envelopes within the interchange. The compliance check maps work with one interchange at a time, so do not keep information about previous interchanges, and therefore, do not check for duplicate interchange control numbers. However, if duplicate interchange control numbers are checked outside of the compliance check maps, an input flag can be passed in, and an appropriate acknowledgment, reporting the duplicate interchange can be generated by the compliance check maps.

## Run the EDI compliance check maps

This section describes the basic steps to run the EDI compliance check maps by using the sample configuration and input data that is provided. These examples show how to run the maps using Design Studio and Design Server.

It is expected that Design Studio transformation extender projects have been defined and reference the Supply Chain EDI pack or Design Server compliance projects for EDIFACT, IATA, X12, or RAIL have been imported. Please review the ITX documentation for more information on defining and importing projects and review the IBM Transformation Extender Pack for Supply Chain EDI for download information.

Each compliance map, as shipped, executes with sample valid input data, which is also shipped. The expected output is valid data located in the respective output folders along with accepted outbound acknowledgments. Execution with sample invalid input data, also shipped, will result in output in the respective reject folders along with an error log and rejected outbound acknowledgments.

- [Run the X12/RAIL compliance check maps](#)

This section describes how to use the sample configuration and input data to run the X12 or RAIL compliance check maps using the Design Studio and Design Server. The X12 travel & transportation subset contains similar naming conventions.

- [Run the EDIFACT/IATA compliance check maps](#)

This section describes how to use the sample configuration and input data to run the EDIFACT compliance check maps using the Design Server.

## Run the X12/RAIL compliance check maps

This section describes how to use the sample configuration and input data to run the X12 or RAIL compliance check maps using the Design Studio and Design Server. The X12 travel & transportation subset contains similar naming conventions.

Compliance check maps are in three map source files: ccx12.mms, ccx12u.mms, x12segment.mms (contains a run map for each x12 version supported), and x12ttval.mms (contains a run map for each x12 version supported). For RAIL the source files are: ccrail.mms, railsegment.mms, and railttval.mms. Additional maps used for decoding and encoding are located in map source file x12conv.mms.

The sections below provide information related to X12 compliance checking but are applicable to both X12 and RAIL. X12 and RAIL processing is very much the same with slight differences.

There are several ways to build the maps including individual map selections using the Design Studio and Design Server, the Command Server, Deployment and Packages, Deployment and Build, etc.

- [To compile all the maps using Design Studio](#)
- [To compile all the maps using Design Server](#)

- [To compile select maps using Design Studio](#)
- [To compile select maps using Design Server](#)
- [Where is my output?](#)

The ccx12/rail maps ship with output destinations using FileOutputStream. This xml element in the configuration file (x12defaultconfig.xml or raildefaultconfig.xml), defines the path for output files.

- [Rest Container](#)

To design and compile ITX maps to be run by the Rest container, ITX Design Studio, or ITX Design Server must be used. The compiled maps then must be saved to the volume, or a host directory, bound to the /data/maps location in the container file system.

---

## To compile all the maps using Design Studio

### Procedure

1. Open Windows explorer.
2. Navigate to <supply chain pack install>  
  \x12\compliance\mapsandschemas
3. Execute the script compileallx12.bat
4. The script may be modified to compile for specific target platform using the -P option. For example:  
  mcompile ccx12.mms -A -O \*.mmc -P AIX

---

## To compile all the maps using Design Server

### Procedure

1. Open the Design Server.
2. Using the Deploy workspace select Packages.
3. Add a new package and select x12Compliance project.
4. Under the Maps section, check the checkbox beside Name.  
  This will select all the x12 compliance check maps.
5. Under the Files section, check the checkbox beside Name.  
  This will select all the x12 files.
6. Click the Add button.  
  This will create the package.
7. Click the Build icon in the top right corner.  
  Note: This will take a few minutes as there are many x12 standards supported. Once the maps are built there is no need to re-build the package unless changes have been applied.
8. Return to the Design Server Home page.
9. Using the Design workspace select Project x12compliance and open the ccx12 map.

---

## To compile select maps using Design Studio

### Procedure

1. Open the Design Studio and select or create a workspace.
2. Create or use an existing Extender project that contains the supply chain edi pack install.
3. Navigate to <supply chain pack install>  
  \x12\compliance\mapsandschemas
4. Open any of the map source files ccx12.mms, x12segment.mms or x12ttval.mms
5. Select the map to build and click the Build Map button at the top.

---

## To compile select maps using Design Server

### Procedure

1. Open the Design Server.
2. Using the Design workspace select x12Compliance project.
3. Search and select the ccx12 map.
4. In the Navigator, find and build the following maps: ccx12, putdatax, x12audit, ttv5010, seg5010. Selection can also be accomplished using Packages.
5. Return to the ccx12 map and open.
6. Select Run and you should see a successful run display.

---

## Where is my output?

The ccx12/rail maps ship with output destinations using FileOutputStream. This xml element in the configuration file (x12defaultconfig.xml or raildefaultconfig.xml), defines the path for output files.

The ccx12u maps use a JSON version of the xml configuration file (x12fullconfig.json.dat). A conversion utility to convert existing XML configuration files to JSON is located in x12\_data\_utilities.mms map source file. Verify the output is valid before JSON implementation.

## Design Studio

---

### File Output

```
<?xml version="1.0" encoding="UTF-8"?>
<Configuration>
 <VersionInfo>X12 10.1.0.0</VersionInfo>
 <RuntimeInfo>
 <FileOutput>
 <FileDirectory>./data/output</FileDirectory>
 </FileOutput>
```

The output file names are generated with a datetime stamp. This creates unique files with each execution of compliance. The unique files setting is defined on input card input card 2 as an echo literal value.

The default location defined in the configuration file is:

```
<supply chain pack install>\x12\compliance\data\output
```

The sub folders underneath contain the interchange and functional acknowledgment files, x12 valid and rejected data, and error log file.

## Design Server

---

### Card Output

```
<?xml version="1.0" encoding="UTF-8"?>
<Configuration>
 <VersionInfo>X12 10.1.0.0</VersionInfo>
 <RuntimeInfo>
 <CardOutput/>
```

When projects are imported using Design Server, example inputs and outputs are provided in the project under the Files tab. The output cards are defined as SINK or work files and can be viewed but not downloaded. Additional configurations are needed to download the output files created during Design Server execution. Please review the Configuration and Debug sections for more details.

One way to generate/download output from running the compliance example using Design Server is to define output destination files.

1. Open the x12Compliance project and the ccx12 map. Output cards are located under Structure.
2. Select the following example files as output cards. Custom files may also be created using the Files Add functions.
  - Output card ValidData  
Select Folder >> compliance/data/output/x12/cc\_x12.in
  - Output card InvalidData  
Select Folder >> compliance/data/output/x12/reject/cc\_x12.reject
  - Output card ErrorLog  
Select Folder >> compliance/data/output/x12/reject/cc\_x12.log
  - Output card AckOut  
Select Folder >> compliance/data/output/fa/outbound/cc\_ack.out
  - Output card TA1Out  
Select Folder >> compliance/data/output/ta1/outbound/cc\_ta1.out
3. Modify settings on each output card identified.  
Select connection >> file, click Next button.
4. Select the file using the dropdown list and click Next.
5. Click OK.
6. Save the ccx12 map.
7. Build the map.
8. Run the map.
9. Under Files, select the files created above and view or download.

To view the files created in the compliance/data/output/x12/reject folder, ccx12 compliance map must execute with invalid input.

1. Under Structure, select input card 1, x12data.
2. Expand Action Properties and select x12\_invalid.txt.
3. Save the map.
4. Build the map.
5. Run the map.
6. Repeat the steps for downloading files.

---

## Rest Container

To design and compile ITX maps to be run by the Rest container, ITX Design Studio, or ITX Design Server must be used. The compiled maps then must be saved to the volume, or a host directory, bound to the /data/maps location in the container file system.

Configuration files are located (relative to the map location) with the default output file location for the container file system defined. The map ccx12 input card ConfigInfo should be modified to use the x12rsconfig.xml file or the x12fullconfig.xml file. After modification of the map, deploy the package to the container file system.

The FileDirectory defined in the x12 configuration file should point to the container file system and mount location.

With container mount location /home/tx-rest/data and package name x12Compliance.

/home/tx-rest/data/maps/x12Compliance/compliance/data/x12rsconfig.xml

```
<FileOutput>
 <!-- This section will send output to files. Reference file x12rsconfig.sh -->
 <FileDirectory>/data/data/x12Compliance</FileDirectory>
</FileOutput>
```

The compliance check output folder structure must also be defined for the container file system and mount location /data/data.

A script file is located (relative to the map location) with the container package deployment to the rest container depending on the server definition in Design Server for deployment.

With container mount location /home/tx-rest/data

/home/tx-rest/data/maps/x12Compliance/compliance/data/x12rsconfig.sh

```
mkdir -p /home//tx-rest/data/x12Compliance/x12/reject
```

```
mkdir -p /home//tx-rest/data/x12Compliance/fa/inbound
```

```
mkdir -p /home//tx-rest/data/x12Compliance/fa/outbound
```

```
mkdir -p /home//tx-rest/data/x12Compliance/ta1/inbound
```

```
mkdir -p /home//tx-rest/data/x12Compliance/ta1/outbound
```

After deploying the package and modifications restart the container.

Please review the container documentation for more information.

---

## Run the EDIFACT/IATA compliance check maps

This section describes how to use the sample configuration and input data to run the EDIFACT compliance check maps using the Design Server.

Compliance check maps are in three map source files: ccedf.mms, edfsegment.mms (contains a run map for each EDIFACT version supported), and edftval.mms (contains a run map for each EDIFACT version supported). For EDIFACT subset for travel and transportation, the map source files are ccctedf.mms, ttedfsegment.mms (contains a run map for each EDIFACT version supported), and ttedftval.mms (contains a run map for each EDIFACT version supported). For IATA-API the map source files are ccapi.mms, apisegment.mms, and apitval.mms. For IATA-PNR the map source files are ccpnr.mms, pnsegment.mms, and prntval.mms.

There are several ways to build the maps including individual map selections using the Design Server, the Command Server, Deployment and Packages, Deployment and Build, etc.

- [To compile all the maps Design Studio](#)
- [To compile all the maps Design Server](#)
- [To compile select maps Design Studio](#)
- [To compile select maps Design Server](#)
- [Where is my output?](#)

The ccedf map ships with output destinations using FileOutput. This xml element in the configuration file (edfdefaultconfig.xml), defines the path for output files.

- [Rest Container](#)

To design and compile ITX maps to be run by the Rest container, ITX Design Studio, or ITX Design Server must be used. The compiled maps then must be saved to the volume, or a host directory, bound to the /data/maps location in the container file system.

---

## To compile all the maps Design Studio

### Procedure

1. Open Windows explorer.
2. Navigate to <supply chain pack install>  
 \edifact\compliance\mapsandschemas
3. Execute the script compilealldf.bat
4. The script may be modified to compile for specific target platform using the -P option. For example:  
 mcompile ccedf.mms -A -O \*.mmc -P AIX

---

## To compile all the maps Design Server

### Procedure

1. Open the Design Server.
  2. Using the Deploy workspace select Packages.
  3. Add a new package and select edifactCompliance project.
  4. Under the Maps section, check the checkbox beside Name.  
This will select all the edifact compliance check maps.
  5. Under the Files section, check the checkbox beside Name.  
This will select all the edifact files.
  6. Click the Add button.  
This will create the package.
  7. Click the Build icon in the top right corner.  
Note: This will take a few minutes as there are many edifact standards supported. Once the maps are built there is no need to re-build the package unless changes have been applied.
  8. Return to the Design Server Home page.
  9. Using the Design workspace select Project edifactcompliance and open the ccedf map.
- 

## To compile select maps Design Studio

### Procedure

1. Open the Design Studio and select or create a workspace.
  2. Create or use an existing Extender project that contains the supply chain edi pack install.
  3. Navigate to <supply chain pack install>\edifact\compliance\mapsandschemas
  4. Open any of the map source files ccedf.mms, edfsegment.mms or edftval.mms
  5. Select the map to build and click the Build Map button at the top.
- 

## To compile select maps Design Server

### Procedure

1. Open the Design Server.
  2. Using the Design workspace select edifactCompliance project.
  3. Search and select the ccedf map.
  4. In the Navigator, find and build the following maps: ccedf, putdatae, edfaudit, ttvd04a, segd04a. Selection can also be accomplished using Packages.
  5. Return to the ccedf map and open.
  6. Select Run and you should see a successful run display.
- 

## Where is my output?

The ccedf map ships with output destinations using FileOutputStream. This xml element in the configuration file (edfdefaultconfig.xml), defines the path for output files.

### Design Studio

#### File Output

```
<?xml version="1.0" encoding="UTF-8"?>
<Configuration>
 <VersionInfo>EDIFACT 10.1.0.0</VersionInfo>
 <RuntimeInfo>
 <FileOutput>
 <FileDirectory>../data/output</FileDirectory>
 </FileOutput>
 </RuntimeInfo>
 </Configuration>
```

The output file names are generated with a datetime stamp. This creates unique files with each execution of compliance. The unique files setting is defined on input card input card 2 as an echo literal value.

The default location defined in the configuration file is:

```
<supply chain pack install>\edifact\compliance\data\output
```

The sub folders underneath contain the interchange and functional acknowledgment files, EDIFACT valid and rejected data, and error log file.

### Design Server

#### Card Output

```
<?xml version="1.0" encoding="UTF-8"?>
<Configuration>
 <VersionInfo>EDIFACT 10.1.0.0</VersionInfo>
 <RuntimeInfo>
 <CardOutput/>
 </RuntimeInfo>
 </Configuration>
```

When projects are imported using Design Server, example inputs and outputs are provided in the project under the Files tab. The output cards are defined as SINK or work files and can be viewed but not downloaded. Additional configurations are needed to download the output files created during Design Server execution. Please review the Configuration and Debug sections for more details.

One way to generate/download output from running the compliance example using Design Server is to define output destination files.

1. Open the edifactCompliance project and the ccddf map. Output cards are located under Structure.
2. Select the following example files as output cards. Custom files may also be created using the Files Add functions.
  - Output card ValidData  
Select Folder >> compliance/data/output/edifact/cc\_edf.in
  - Output card InvalidData  
Select Folder >> compliance/data/output/edifact/reject/cc\_edf.reject
  - Output card ErrorLog  
Select Folder >> compliance/data/output/edifact/reject/cc\_edf.log
  - Output card AckOut  
Select Folder >> compliance/data/output/fa/outbound/cc\_ack.out
3. Modify settings on each output card identified.  
Select connection >> file, click Next button.
4. Select the file using the dropdown list and click Next.
5. Click OK.
6. Save the ccddf map.
7. Build the map.
8. Run the map.
9. Under Files, select the files created above and view or download.

To view the files created in the compliance/data/output/edifact/reject folder, ccddf compliance map must execute with invalid input.

1. Under Structure, select input card 1, edfdata.
2. Expand Action Properties and select edf\_invalid.txt.
3. Save the map.
4. Build the map.
5. Run the map.
6. Repeat the steps for downloading files.

---

## Rest Container

To design and compile ITX maps to be run by the Rest container, ITX Design Studio, or ITX Design Server must be used. The compiled maps then must be saved to the volume, or a host directory, bound to the /data/maps location in the container file system.

Configuration files are located (relative to the map location) with the default output file location for the container file system defined. The map ccddf input card ConfigInfo should be modified to use the edfrsconfig.xml file or the edffullconfig.xml file. After modification of the map, deploy the package to the container file system.

The FileDirectory defined in the EDIFACT configuration file should point to the container file system and mount location.

With container mount location /home/tx-rest/data and package name edifactCompliance.

/home/tx-rest/data/maps/edifactCompliance/compliance/data/edfrsconfig.xml

```
<FileOutput>
 <!-- This section will send output to files. Reference file edfrsconfig.sh -->
 <FileDirectory>/data/data/edifactCompliance</FileDirectory>
</FileOutput>
```

The compliance check output folder structure must also be defined for the container file system and mount location /data/data.

A script file is located (relative to the map location) with the container package deployment to the rest container depending on the server definition in Design Server for deployment.

With container mount location /home/tx-rest/data

/home/tx-rest/data/maps/edifactCompliance/compliance/data/edfrsconfig.sh

```
mkdir -p /home//tx-rest/data/edifactCompliance/edifact/reject
mkdir -p /home//tx-rest/data/edifactCompliance/fa/inbound
mkdir -p /home//tx-rest/data/edifactCompliance/fa/outbound
```

After deploying the package and modifications restart the container.

Please review the container documentation for more information.

---

## Configuration

In addition to the X12, RAIL, or EDIFACT interchange, the EDI compliance check maps require extra input cards.

These additional input cards define the settings that are listed here.

- Configuration settings that describe how the data is to be processed.
- Document-specific settings, such as adding a unique ID to identify the input interchange.
- Static table data that is used as part of the validation. This data is included with the compliance check maps.

These settings control whether certain types of validation are performed on the data, and the allowed values. They also control how, and if, acknowledgments are generated, and where data output is written.

- **Input card details**

The primary compliance check maps, cc12, ccrail, and ccedf take the input cards that are described in the following sections.

- **System information file**

The system information file, edicc.ini, defines certain system-specific information.

- **Configuration information details**

Configuration information is in XML format, and specified by the third input card. The configuration information is similar for X12, X12U, RAIL, IATA, and EDIFACT, but differs slightly because of standards-specific information.

---

## Input card details

The primary compliance check maps, cc12, ccrail, and ccedf take the input cards that are described in the following sections.

- **Card 1: EDI data**

This is the input X12, RAIL, or EDIFACT interchange that is to be validated. It must be a single X12, RAIL, or EDIFACT interchange. Multiple interchanges in a single input card are not permitted. If the input contains multiple interchanges, you get the message "Input valid but unknown data found", and only the first interchange is processed.

- **Card 2: unique ID**

This string value specifies a unique ID that identifies the input interchange. For file output, this ID is included as part of the output file names to help link the acknowledgments, output transactions, and error logs to the original interchange.

- **Card 3: configuration information**

This input card contains XML formatted data that describes processing options.

- **Card 4: duplicate interchange flag**

The duplicate interchange flag is a flag that can be passed to indicate that the interchange is a duplicate.

- **Card 5: table data**

This input card contains table data that is used to help validate restriction lists for X12, RAIL, and EDIFACT envelope segments.

- **Card 6: message code list**

This input card contains the text for error messages that are written to the log file.

- **Card 7: structure detail file**

This input file contains structure information about the expected order of the segments.

- **Card 8: system information file**

The system information file, edicc.ini, defines system information.

- **Card 9: trace flag**

If this is set to T or TU, the map writes an XML formatted trace file to the map directory.

---

## Card 1: EDI data

This is the input X12, RAIL, or EDIFACT interchange that is to be validated. It must be a single X12, RAIL, or EDIFACT interchange. Multiple interchanges in a single input card are not permitted. If the input contains multiple interchanges, you get the message "Input valid but unknown data found", and only the first interchange is processed.

The default for this is just a sample X12, RAIL, or EDIFACT file in the data directory, so this card is almost always overridden. To specify an input file, you might use the -IF1 option with Command Server, for example:

```
-IF1 \DataDir\MyEDIData.txt
```

---

## Card 2: unique ID

This string value specifies a unique ID that identifies the input interchange. For file output, this ID is included as part of the output file names to help link the acknowledgments, output transactions, and error logs to the original interchange.

This string value specifies a unique ID that identifies the input interchange. For file output, this ID is included as part of the output file names to help link the acknowledgments, output transactions, and error logs to the original interchange.

The default value for this is NoUniqueID. When this value is used, an ID is generated based on the current time stamp. You must then override the generated ID with your own unique ID so you can ensure that the ID is unique and link the output to other processes. To specify the unique ID, you can use the -IE2 option, for example:

```
-IE2 ID1234567890
```

---

## Card 3: configuration information

This input card contains XML formatted data that describes processing options.

The default value for this is a sample configuration in the data directory, so this card is normally overridden. To specify a configuration file, you can use the -IF3 option, for example:

## Card 4: duplicate interchange flag

The duplicate interchange flag is a flag that can be passed to indicate that the interchange is a duplicate.

The compliance check maps work only with a single interchange at a time, and do not track the interchanges that are processed before, or after the current interchange. You can, however, track other transactions, and use a preprocessing step to set this flag if the interchange is recognized as a duplicate. The value must be either `T` (interchange is a duplicate), or `F` (the default interchange is not a duplicate). If the flag is set to `T`, then the EDI compliance checking maps generate the appropriate logs and acknowledgment for the duplicate interchange. The default value for the flag is `F`. To set the flag to `T`, you can use the `-IE4` option, for example:

`-IE4 T`

## Card 5: table data

This input card contains table data that is used to help validate restriction lists for X12, RAIL, and EDIFACT envelope segments.

These files, `x12codes.txt` for X12, `railcodes.txt` for RAIL, and `edfcodes.txt` for EDIFACT, are included with the EDI pack. Changes to these files might require changes to the schemas, so do not change these files. Also, do not override the input card.

## Card 6: message code list

This input card contains the text for error messages that are written to the log file.

The error message can be translated to another language. Do not reformat the file or change or remove error code values.

Do not override this input card.

## Card 7: structure detail file

This input file contains structure information about the expected order of the segments.

This input file is used by an exit library that the map calls to check the transaction or message structure. You do not need to change this file, although in some cases you can improve performance by removing the structure information for versions and transactions that you do not use. If you modify this file, be sure to back up the original.

With the extensive list of EDI standard versions supported and the compliance checking process to validate the structure of the messages/transactions, the structure validation file has become large. Utilities in the EDIFACT and X12 components can be used to reduce the size of the structure validation file by selecting standard versions and message/transaction type being used to eliminate unused records.

The Utilities can be found in the utilities folder under the EDIFACT and X12 components.

In addition, a referenced structure file can be found in the `mapsandschemas` folder to be used with input card #7. This file contains a reference record for each message/transaction that identifies each standard version a particular structure record can be used with.

## Card 8: system information file

The system information file, `edicc.ini`, defines system information.

The system information that it defines includes the location of the exit library, which are used during system runtime executions for compliance checking. Do not override this input card.

The system information file, `edicc.ini`, defines certain system-specific information. You update this file when the EDI compliance checking maps are deployed to a system. After that time, the file does not need to be updated. The properties that this file includes are described here.

- **ismvs**

This setting is for z/os processing and should contain the value yes for z/os processing only. For all other platforms, the value should be no.

- **mvsrunmaplog**

This setting is for z/os processing and is used to suppress z/os run map logs during execution. The value `/NL` will be used with each run map call. This can improve performance with large files. For all other platforms, the value should be N/A.

- **exitlib**

The exitlib value should specify the path to the directory that contains the `edisvu` shared library. This can be either a relative path (relative to the map directory), or a fully qualified path name. For Unix systems, this would be path to `edisvu.so` or `edisvu.sl` file, and on Windows it will be the path to `edisvu.dll`.

## exitlib

The exitlib value should specify the path to the directory that contains the edisvu shared library. This can be either a relative path (relative to the map directory), or a fully qualified path name. For Unix systems, this would be path to edisvu.so or edisvu.sl file, and on Windows it will be the path to edisvu.dll.

The exit edisvu is installed with the Design Studio with the default setting below of ./.

The exit edisvu is installed with the Design Server with the default setting below of NA. Script files for replacing the exit are in the ediPlatformSupport project.

If the location of the edisvu exit has not changed, there are no updates needed for the edicc.ini file.

- Setting ./ is relative to map execution folder
- Setting N/A or NA (Not Applicable) identifies the ITX install folder
- Web UI Design Server execution must use N/A or NA

## Design Studio

---

The default setting for the exit module location is relative to the map execution folder and the exit library should be found at this location. The platform\_support folder contains the exit library for all operating systems.

For z/os the exit library should be in the JCL steplib.

## Design Server

---

The exit library must be in the ITX install folder and the exit module should be found at this location.

The ediPlatformSupport\* project zip files for the Design Server. This project also contains scripts to assist removal and placing the exit library to the correct location.

The exit library must be installed with the Windows Design Server and must be in the ITX install folder.

## Card 9: trace flag

---

If this is set to T or TU, the map writes an XML formatted trace file to the map directory.

The default value for this is None. To set this to T, or TU, you can use the -IE9 option, for example:

-IE9 T

## System information file

---

The system information file, edicc.ini, defines certain system-specific information.

## Configuration information details

---

Configuration information is in XML format, and specified by the third input card. The configuration information is similar for X12, X12U, RAIL, IATA, and EDIFACT, but differs slightly because of standards-specific information.

The XML formats are defined by the XML schema:

- x12cfg.xsd for X12
- x12cfg.json for X12U
- railcfg.xsd for RAIL
- edfcfg.xsd for EDIFACT and IATA

The configuration information can be in a static location, or it can be generated for each message by a preprocessing step based on some criteria such as trading partner information. Many settings have default values, so they do not need to be specified whether or not you want to use the default behavior.

This documentation describes the options that can be configured. Unless otherwise noted, the elements apply to X12, X12U, RAIL, IATA, and EDIFACT.

- **RuntimeInfo**  
The settings provided here contain information that is related, typically, to your runtime environment, rather than to specific trading partners.
- **CardOutput**  
If the CardOutput element is specified, output is written to map output cards, and the PUT calls are skipped.
- **FileOutput**  
If the FileOutput element grouping is specified, the compliance check maps write the output to files.
- **QueueOutput**  
If the QueueOutput element is specified, the compliance check maps write the output to MQ queues. This element also contains information that is needed by the MQ Adapter in order to write the data, and identifies to which queues the different types of output data should be written.
- **WireOutput**  
If the WireOutput element is specified, the compliance check maps write the output to wire terminals.
- **CreateRejectLog**  
The CreateRejectLog element specifies whether the compliance check maps are to create plain text error logs associated with any rejected transactions, groups, or interchanges.
- **JsonReport**  
The JsonReport element specifies whether the compliance check map should create JSON reports associated with any accepted/rejected transactions, groups, or interchanges. The default setting is N for Never.

- **[MaxNumErrors](#)**  
The MaxNumErrors element specifies whether the compliance check map report all errors or limit the number of errors generated. A value of zero indicates all errors will be generated.
- **[WorkSpace](#)**  
The WorkSpace element specifies whether the compliance check maps should set the workspace option to use memory or disk for runmap calls. The default setting is memory-based (-WM). A value (-WU) identifies workspace to use file-based options.
- **[SkipITValidation](#)**
- **[ISXcontrol - X12](#)**  
The ISXcontrol group specifies how the ISX control segment should be processed.
- **[PartnerInfo](#)**  
This element contains information that is based on trading partner relationships. For example, it includes validation and acknowledgment options.
- **[GenerateTA1 - X12, RAIL only](#)**  
The GenerateTA1 element specifies whether a TA1 interchange acknowledgment is generated when requested by the inbound interchange.
- **[AckInfo](#)**  
For X12, this documentation specifies whether 997/999 acknowledgments are generated, and how they are generated.
- **[CheckDuplicateGroupControl](#)**  
The CheckDuplicateGroupControl element specifies whether the compliance check maps are to check the interchange for duplicate groups.
- **[CheckDuplicateTrxControl](#)**  
The CheckDuplicateTrxControl element specifies whether the compliance check maps are to check each group for duplicate transactions and messages.
- **[Authority - X12, RAIL only](#)**  
This documentation specifies whether the Authorization information elements (ISA01 and ISA02) are to be checked for specific values, and if they are, what values they are to contain.
- **[Security - X12, RAIL only](#)**  
This element specifies whether the Security information elements (ISA03 and ISA04) are to be checked for specific values, and if so, what values they contain.
- **[RecipRef - EDIFACT only](#)**  
This documentation specifies whether the Recipient Reference composite, UNB06 is to be checked for specific values, and if so, what values it must contain. If this checking is requested, and the subelements do not contain the correct values, then the interchange is rejected and appropriate acknowledgments are generated.

## RuntimeInfo

The settings provided here contain information that is related, typically, to your runtime environment, rather than to specific trading partners.

This includes settings that describe where the output is to be written, and whether the error log is to be written.

One of the following element groupings is required:

- CardOutput - indicates that outputs are to be written to map output cards.
- FileOutput - indicates that output is to be written to files.
- QueueOutput - indicates that output is to be written to queues.
- WireOutput - indicates that output is to be written to wire terminals (used with IBM Sterling Transformation Extender Only).

## CardOutput

If the CardOutput element is specified, output is written to map output cards, and the PUT calls are skipped.

The following table describes which cards are used for each type output.

### Output

- Cards 1 - 4 continue to be used for internal processing, and output from these cards is not intended to be used by the map caller. These are used to gather information reported with the map trace Input card 9.
- By default, all the output cards in the following section are set to use the Sink adapter, so no physical output is generated for them. Although there is no physical output file to be downloaded with the Sink adapter, outputs may be viewed using the Design Server UI.

If you are using the CardOutput element, you must override the output cards that you use:

Card number	Card name	Description
5	ValidData	X12 interchange that contains all valid and accepted transactions. This output is only produced if one or more valid transaction sets are present in the input data that is to be validated.
6	InvalidData	X12 interchange that contains all invalid and rejected transactions and groups. This output is only produced if there are one or more invalid transaction sets or groups, or if the interchange header, or trailer errors are found in the input data that is validated.
7	Error log	Flat file that contains text descriptions of any errors that are detected, and where the errors are located.  This output is only produced if there are one or more invalid transaction sets, or groups, or if the interchange header, or trailer errors are found in the input data that is to be validated.  This information can also be parsed by use of a user application to reformat error information, if needed.
8	AckIn	X12 interchange that contains all inbound 997, or 999 transactions from the interchange. This output is only produced if the input data that is to be validated contains 997, or 999 acknowledgments.
9	AckOut	X12 Interchange containing generated 997 acknowledgments.  This output is only produced if functional acknowledgment (997) transactions are generated for the input data that is to be validated.
10	TA1In	X12 interchange that contains all inbound TA1 acknowledgments from the interchange. This output is only produced if the input data that is to be validated contains TA1 acknowledgments.

Card number	Card name	Description
11	TA1Out	X12 Interchange containing generated TA1 acknowledgments. This output is only produced if TA1 acknowledgments are generated for the input data that is to be validated.
12	FrameworkTrace	XML-formatted trace log for problem determination. This is only created if there are certain framework errors, or if the value T, or TU is specified for input card 9 (trace flag).
13	JsonLog	X12 JSON formatted report providing information related to the Interchange, Group, and Transaction errors and acknowledgments.

## FileOutput

If the FileOutput element grouping is specified, the compliance check maps write the output to files.

See [File naming conventions](#) for information about how the files are named, and the subdirectories to which they are written.

This element contains the FileDirectory element. The FileDirectory element specifies the top-level directory for the file output. The output is written to subdirectories within this directory.

The FileDirectory element is required if the FileOutput element is specified.

- [FileDirectory](#)

The FileDirectory element is required if the FileOutput element is specified.

## FileDirectory

The FileDirectory element is required if the FileOutput element is specified.

When you use file output, this directory, and the following sub-directories, must be created before the compliance check maps are run. Otherwise, the file adapter fails when it attempts to write the output files.

edifact	EDIFACT only
edifact/reject	EDIFACT only
fa	EDIFACT and X12
fa/inbound	EDIFACT and X12
fa/outbound	EDIFACT and X12
ta1	X12 only
ta1/inbound	X12 only
ta1/outbound	X12 only
x12	X12 only
x12/reject	X12 only

Note: The default directories are included with the pack compliance check installation. You can copy this directory structure to your output location.

Note: Eclipse does not copy empty folders when you import a project.

## QueueOutput

If the QueueOutput element is specified, the compliance check maps write the output to MQ queues. This element also contains information that is needed by the MQ Adapter in order to write the data, and identifies to which queues the different types of output data should be written.

This QueueOutput element contains the elements listed here.

- QueueServerClient
- QueueManagerName
- QueueNames
- [QueueServerClient](#)  
The QueueServerClient element indicates which WMQ mode the adapter is to use.
- [QueueManagerName](#)  
The QueueManagerName element applies to both X12, RAIL, and EDIFACT. It indicates which WMQ queue manager that the adapter must use. This value is required if the QueueOutput element is used.
- [QueueNames](#)  
The QueueNames element includes the queue names that are to be used.

## QueueServerClient

The QueueServerClient element indicates which WMQ mode the adapter is to use.

The allowed values are listed here.

- SERVER - The adapter uses WMQ server mode.
- CLIENT - The adapter uses WMQ client mode.

This value is required if the QueueOutput element is specified.

## QueueManagerName

The QueueManagerName element applies to both X12, RAIL, and EDIFACT. It indicates which WMQ queue manager that the adapter must use. This value is required if the QueueOutput element is used.

## QueueNames

The QueueNames element includes the queue names that are to be used.

This value is required if the QueueOutput element is specified.

For X12 data, the QueueNames element contains the following elements. All are required.

For EDIFACT data, the QueueNames element contains the following elements. All are required.

Scripts to create these queues are included in the compliance check data directories. The create\_x12\_queues.mqsc script creates the queues for X12, create\_rail\_queues.mqsc for RAIL, and the create\_edf\_queues.mqsc script creates the queues for EDIFACT. The runmqsc utility from MQ is used to run both scripts. Additional information is included in the comments at the beginning of the scripts.

These queues are not accessed until the compliance check maps are ready to write data to them. If you know that certain types of output are not to be generated, for example TA1 acknowledgments, you can specify a nonexistent queue name in the configuration such as "DUMMY\*". However, this can cause adapter errors if the output is later generated due to other configuration changes. A better solution is to route any unexpected output types to a special queue, such as EDI\_OTHER.

X12_TransactionQueue	Used for valid transaction output.
X12_RejectQueue	Used for rejected transactions, groups, and interchanges.
X12_RejectLogQueue	Used for error logs associated with the rejected transactions, groups, and interchanges.
FA_InboundQueue	Used for received, or inbound, 997 and 999 acknowledgments.
FA_OutboundQueue	Used for generated, or outbound 997 and 999 acknowledgments.
TA1_InboundQueue	Used for received, or inbound, TA1 acknowledgments.
TA1_OutboundQueue	Used for generated, or outbound, TA1 acknowledgments.
EDIFACT_TransactionQueue	Used for valid transaction output.
EDIFACT_RejectQueue	Used for rejected messages, groups, and Interchanges.
EDIFACT_RejectLogQueue	Used for error logs associated with the rejected messages, groups, and interchanges.
CONTRL_InboundQueue	Used for received, or inbound, CONTRL acknowledgments.
CONTRL_OutboundQueue	Used for generated, or outbound, CONTRL acknowledgments
X12_JsonOutQueue	Used for X12 JSON formatted report to provide information related to the Interchange Group, and Transaction and acknowledgments.
X12_JsonRejQueue	Used for X12 JSON formatted report to provide information related to the Interchange Group, and Transaction errors and acknowledgments.

## WireOutput

If the WireOutput element is specified, the compliance check maps write the output to wire terminals.

The WireOutput element can be used only with IBM Sterling Transformation Extender.

## CreateRejectLog

The CreateRejectLog element specifies whether the compliance check maps are to create plain text error logs associated with any rejected transactions, groups, or interchanges.

These values are allowed.

- T (True) - Create the plain text reject log.
- F (False) - Do not create the plain text reject log.

The default value is T (True).

## JsonReport

The JsonReport element specifies whether the compliance check map should create JSON reports associated with any accepted/rejected transactions, groups, or interchanges. The default setting is N for Never.

The valid values are:

- ( A )ccepted
- ( F )ull
- ( N )ever
- ( R )ejected

Full report indicates both accepted and rejected. The default is Never.

There are additional configuration settings to report the Interchange, Group, and Transaction images.

## MaxNumErrors

The MaxNumErrors element specifies whether the compliance check map report all errors or limit the number of errors generated. A value of zero indicates all errors will be generated.

Large files that contain thousands of errors, present performance issues related to memory usage. To address this issue, this value will restrict the number of errors to be generated. The default value is 0 (zero meaning there is no maximum). During processing if the maximum number of errors has been exceeded, the number of errors generated in the reject log and acknowledgment will be truncated and the following error E9004 will be logged.

E9004 The number of segment and element errors has exceeded the maximum (100). The error log and acknowledgment output has been truncated.

## WorkSpace

The WorkSpace element specifies whether the compliance check maps should set the workspace option to use memory or disk for runmap calls. The default setting is memory-based (-WM). A value (-WU) identifies workspace to use file-based options.

The default setting uses work files that are in memory, and is best for small to medium size transactions. The transaction size at which performance improves by using a work file on disk, depends upon the amount of memory available after other applications and services are taken into account.

The current framework is set up to handle small data as quickly as possible. If your large data is taking longer than expected to process, you can use this setting to use disk instead of memory with the value -WU.

The setting can also include page size, for example, -WM -P128:16.

## SkipTTValidation

There are three main processes performed during the compliance checking, as follows:

- Standard Type Tree validation
- Structure checking
- Segment checking

The Standard Type Tree validation uses the full standard to determine if the input file contains errors. If there are no errors, no further validation is needed. If there are errors, the second and third processes are executed. This first process can take a considerable amount of time depending on the standard and the message type.

The SKIPTTVALIDATION setting will skip the first process and always execute the structure checking and segment checking and eliminate the amount of data parsing and restarts. It also eliminates the ttval run map execution.

Valid values are T(rue) and F(alse). The default value is F(also) to identify execution of the three processes.

## ISXcontrol - X12

The ISXcontrol group specifies how the ISX control segment should be processed.

When present, the ISX segment can identify release character syntax, X12 code list version overrides, and the character encoding of the interchange following the ISX segment. Additional processing is required and will affect performance. These configuration settings override default processing and control how the data is processed when the ISX is present or absent. It is not required to define these controls unless you want to override the default processing. However, if the ISX is present in the input data stream, minimum configuration is required to avoid unexpected ISX between partners and requires the ISXcontrol group to be present in the configuration file.

IgnoreISX component must be set.

```
<ISXcontrol>
<IgnoreISX>F</IgnoreISX>
</ISXcontrol>
```

- **IgnoreISX**

The IgnoreISX component indicates whether to ignore the ISX overrides (ISX02, ISX03).

- **ReleaseCharacter**

The ReleaseCharacter group identifies optional configuration related to the ISX segment and the Release Character definition that will be used to indicate that the characters following it should be interpreted as the data value, not as a delimiter used for syntax and parsing.

- **CharacterEncoding**

The CharacterEncoding group identifies optional configuration related to additional processing required to perform inbound (source) and outbound (target) character encoding.

- **CodeListVersionOverride**

The CodeListVersionOverride group identifies optional configuration related additional processing required to perform code list validations using a different X12 standard version of the code list than is defined with the GS08.

---

## IgnoreISX

The IgnoreISX component indicates whether to ignore the ISX overrides (ISX02, ISX03).

Valid value are T and F. If not specified, the default is F.

---

## ReleaseCharacter

The ReleaseCharacter group identifies optional configuration related to the ISX segment and the Release Character definition that will be used to indicate that the characters following it should be interpreted as the data value, not as a delimiter used for syntax and parsing.

Specify the DefaultReleaseCharacter to define a release character syntax when the ISX01 value is missing and the X12 default syntax should not be used. Specify the OverrideReleaseCharacter to define a release character syntax to override the ISX01 value.

DefaultReleaseCharacter – default release character syntax

OverrideReleaseCharacter - default release character syntax ISX01

---

## CharacterEncoding

The CharacterEncoding group identifies optional configuration related to additional processing required to perform inbound (source) and outbound (target) character encoding.

The AllowEncoding value F is the default to not allow ISX02 and character encoding definitions. A value of T will enable any character encoding specifications. The AllowEncoding indicates whether to allow character encoding and perform additional decode/encode processing. If not specified, additional processing will be performed for the encoding identified (default to F).

Character encoding requires new processing found in component x12u and map ccx12u. The values below define a character encoding for inbound (source) or outbound (target). If specified, the value must be supported by both x12 and TX. This value will be used when the ISA version is 00704 or higher. Supported values can be found in the documentation and x12codes.txt file.

The DefaultSourceEncoding specifies a value to be used when the ISX02 value is absent.

The OverrideSourceEncoding specifies a value to be used to override the ISX02 value.

The DefaultTargetEncoding specifies a value to be used when the ISX02 is absent for all compliance checking outputs.

The OverrideTargetEncoding specifies a value to be used to override the ISX02 value. If encoding is not defined, the default encoding for ccx12 compliance checking is Western/Native and for ccx12u is Western/UTF-8.

---

## CodeListVersionOverride

The CodeListVersionOverride group identifies optional configuration related additional processing required to perform code list validations using a different X12 standard version of the code list than is defined with the GS08.

The AllowCodeListOverride value F is the default to not allow ISX02 and code list version overrides. A value of T will enable any code list version specifications. The AllowCodeListOverride indicates whether to allow code list version override and perform additional validations. If not specified, additional validations will be performed for the version identified (default to F). If specified, the value must be T or F. A value of F will ignore code list version override.

The values below define a code list version to be used for code list validation. If specified, the value must be supported by both x12 and TX. This default will be used when the ISA version is 00801 or higher.

The DefaultCodeListVersion specifies a value to be used when the ISX03 value is absent.

The OverrideCodeListVersion specifies a value to be used to override the ISX03 value.

---

## PartnerInfo

This element contains information that is based on trading partner relationships. For example, it includes validation and acknowledgment options.

This element is optional. If present it includes these elements:

- GenerateTA1 - X12, RAIL only
- AckInfo
- CheckDuplicateGroupControl
- CheckDuplicateTrxControl

- Authority - X12, RAIL only
  - Security - X12, RAIL only
  - RecipRef - EDIFACT only
- 

## GenerateTA1 - X12, RAIL only

The GenerateTA1 element specifies whether a TA1 interchange acknowledgment is generated when requested by the inbound interchange.

The allowed values for this element are listed here.

- R (Requested) - Generate TA1 if requested by ISA14 value. If the ISA14 value is "1", this setting always generates a TA1, even if the interchange envelope is valid.
- N (Never) - Never generate TA1, even if requested by ISA14 value.

The default value is R(Requested).

Note: TA1 acknowledgments are not generated if the data does not contain any transactions. This is to avoid a TA1 loop, per X12 standards.

---

## AckInfo

For X12, this documentation specifies whether 997/999 acknowledgments are generated, and how they are generated.

For EDIFACT, the element specifies whether CONTRL acknowledgments are to be generated, and how they are generated.

This element includes the AckType (X12 only), AckLevel and the AckVersion (X12, RAIL only) elements.

- **AckType**  
The Acktype element specifies 997 or 999 acknowledgments should be generated. The default is 997.
  - **AckLevel**  
This AckLevel element specifies whether acknowledgments are to be generated, and if so, at what level.
  - **ValidateContrl**
  - **AckVersion - X12, RAIL only**  
If acknowledgments are generated, the AckVersion element specifies which version is to be used. The version must be a valid X12, RAIL version such as "004010". If no value is specified, the default is to use the same version as the group that is being acknowledged.
- 

## AckType

The Acktype element specifies 997 or 999 acknowledgments should be generated. The default is 997.

---

## AckLevel

This AckLevel element specifies whether acknowledgments are to be generated, and if so, at what level.

The allowed values for the AckLevel element are described here.

- N (Never) - Do not generate 997/999 acknowledgments for X12, RAIL, or CONTRL acknowledgments for EDIFACT.
- T (Transaction) - Generate 997/999 or CONTRL acknowledgments at the transaction/message level. Explicitly acknowledge valid transactions by generating AK2/AK5, or UCM segments for each transaction/message, whether valid or invalid.

The default value for this element is T (Transaction).

---

## ValidateContrl

The ValidateContrl element specifies whether inbound EDIFACT **CONTRL** acknowledgments are to be checked for compliance. The value of T will validate the inbound **CONTRL** message and produce valid or invalid output with a reject log.

Valid values are (T)rue and (F)alse. The default value is (F)alse.

---

## AckVersion - X12, RAIL only

If acknowledgments are generated, the AckVersion element specifies which version is to be used. The version must be a valid X12, RAIL version such as "004010". If no value is specified, the default is to use the same version as the group that is being acknowledged.

For EDIFACT data, this element is not used, and the CONTRL acknowledgment is generated by using the same syntax version as the interchange that is acknowledged.

---

## CheckDuplicateGroupControl

The CheckDuplicateGroupControl element specifies whether the compliance check maps are to check the interchange for duplicate groups.

The allowed values for the CheckDuplicateGroupControl element are described here.

- T (True) - Check the interchange for duplicate groups. For X12 and RAIL, the CheckDuplicateGroupControl element checks for duplicate group control numbers. For EDIFACT, the CheckDuplicateGroupControl element checks the combination of application sender, application receiver, and group reference number.
- F (False) - Do not check the interchange for duplicate groups.

The default value is T (True).

## CheckDuplicateTrxControl

The CheckDuplicateTrxControl element specifies whether the compliance check maps are to check each group for duplicate transactions and messages.

The allowed values for the CheckDuplicateTrxControl are described here.

- T - (True) Check groups for duplicate transactions and messages. For X12 and RAIL, CheckDuplicateTrxControl checks for duplicate transaction control numbers. For EDIFACT, CheckDuplicateTrxControl checks the combination of message ID and message reference number.
- F - (False) Do not check groups for duplicate transactions and messages. Skipping the duplicate checking might save time for groups that contain many transactions.

The default value is T (True).

## Authority - X12, RAIL only

This documentation specifies whether the Authorization information elements (ISA01 and ISA02) are to be checked for specific values, and if they are, what values they are to contain.

If checking is requested, and the fields do not contain the correct values, the interchange is rejected and appropriate acknowledgments are generated.

These elements are described in this documentation.

- [Validate](#)  
The Validate element specifies whether the compliance check maps are to check the Authorization information values.
- [AuthSecInfo](#)  
If Authority information checking is requested, this element specifies the values.

## Validate

The Validate element specifies whether the compliance check maps are to check the Authorization information values.

The Validate element includes these values.

- T (True) - Verify that the Authorization information elements in the ISA match the values that are specified in the AuthSecInfo element.
- F (False) - Do not check the Authorization information elements.

The default value is F (False).

## AuthSecInfo

If Authority information checking is requested, this element specifies the values.

Authority information checking includes the qualifiers described here.

- Qualifier - The value that must be specified in the Authorization information qualifier (ISA01).
- AuthSecID - The value that must be specified in the Authorization information element (ISA02).

If authority validation is requested, both of these elements must be specified and must match the values in the ISA for the interchange to be accepted.

## Security - X12, RAIL only

This element specifies whether the Security information elements (ISA03 and ISA04) are to be checked for specific values, and if so, what values they contain.

If this checking is requested and the fields do not contain the correct values, then the interchange is rejected and appropriate acknowledgments are generated.

These elements are described here.

- [Validate](#)  
The Validate element specifies whether the compliance check maps are to check the Security Information values.
- [AuthSecInfo](#)  
If Security Information checking is requested, this element specifies the values.

## Validate

The Validate element specifies whether the compliance check maps are to check the Security Information values.

The allowed values for this element are described here.

- T (True) - Verify that the Security Information elements in the ISA match the values specified in the AuthSecInfo element.
- F (False) - Do not check the Security Information elements.

The default value is F (False).

## AuthSecInfo

If Security Information checking is requested, this element specifies the values.

Security Information checking includes these elements.

- Qualifier - The value that must be specified in the Security Information Qualifier (ISA03).
- AuthSecID - The value that must be specified in the Security Information element (ISA04).

If Security validation is requested, both of these elements must be specified and must match the values in the ISA for the interchange to be accepted.

## RecipRef - EDIFACT only

This documentation specifies whether the Recipient Reference composite, UNB06 is to be checked for specific values, and if so, what values it must contain. If this checking is requested, and the subelements do not contain the correct values, then the interchange is rejected and appropriate acknowledgments are generated.

These elements are described here.

- **Validate**  
This element specifies whether the compliance check maps are to check the Recipient Reference values.
- **RecipRefInfo**  
If Recipient Reference checking is requested, this element specifies the values.

## Validate

This element specifies whether the compliance check maps are to check the Recipient Reference values.

The allowed values for the Validate element are described here:

- T (True) - Verify that the Recipient Reference elements in the UNB match the values that are specified in the RecipRefInfo element.
- F (False) - Do not check the Recipient Reference values.

The default value is F (False).

## RecipRefInfo

If Recipient Reference checking is requested, this element specifies the values.

Recipient Reference checking includes the following elements:

- RecipRefInfo - The value that must be specified in the Recipient Reference element (UNB0601).
- RecipRefQual - The value that must be specified in the Recipient Reference Qualifier element (UNB0602).

If Recipient Reference validation is requested, both of these elements must match the values in the UNB, or be omitted from the configuration and from the UNB, for the interchange to be accepted.

## Deploy compliance check maps

Compile the maps for the target operating system, and then copy the compiled maps, the exit library, and other associated files to the target system. These steps are similar for both X12, RAIL, and EDIFACT.

- **Map deployment procedure**

For all operating systems, follow the steps provided here.

## Map deployment procedure

For all operating systems, follow the steps provided here.

## Procedure

---

### 1. Build the maps:

There are several ways to build the maps including individual map selections using the Design Studio or Design Server, the Command Server, Deployment and Packages, Deployment and Build, etc.

### 2. Copy the following files to the target system as binary and place the files in the same directory as the compiled maps:

- All compiled maps. If you are sure that certain versions of the standards are not going to be used again, you can skip the seg\* and ttv\* maps that correspond to those versions. As an example, If you are not going to use X12 version 002040 again, you do not need to upload the ttv2040 or seg2040 compiled maps. However, if these maps are not present and an X12 002040 transaction is encountered, the compliance check maps cannot process the transaction correctly.
- Configuration schema x12cfg.xsd (X12), railcfg.xsd (RAIL), or edfcfg.xsd (EDIFACT).
- The shared exit library, which is found under the platform\_support directory. Be sure to choose the operating system and bit type (32-bit or 64-bit) that matches your Transformation Extender installation.

### 3. Copy the following files to the target system as ascii, and then place the files in the same directory as the compiled maps:

Note: When you copy these files to UNIX systems, the CR characters (x0d) must be removed. If the process that you use to copy them (for example, FTP) does not remove them, then you must remove them manually.

- The file that contains error message text, errcodes.txt (X12, RAIL, and EDIFACT).
- Files with table data used by the compliance check maps: x12codes.txt and x12struct.txt (X12), railcodes.txt and railstruct.txt (RAIL), or edfcodes.txt and edfstruct.txt (EDIFACT).
- The system information file edicc.ini.

### 4. Edit the edicc.ini file on the target system, and set the exitlib value to point to the shared exit library that you uploaded in the earlier step.

- For Unix systems, this would be path to edisvu.so or edisvu.sl file, and on Windows it will be the path to edisvu.dll. (DO NOT INCLUDE FILE NAME IN PATH)
- Setting ./ is relative to map execution folder.
- Setting N/A or NA (Not Applicable) identifies the ITX install folder.

### 5. Set up your configuration file to point to the output location that you want to use. If you are using file output, you must create the following subdirectories under the output directory that you specify in your configuration:

edifact	EDIFACT only
edifact/reject	EDIFACT only
fa	EDIFACT, X12, and RAIL
fa/inbound	EDIFACT, X12, and RAIL
fa/outbound	EDIFACT, X12, and RAIL
ta1	X12, RAIL only
ta1/inbound	X12, RAIL only
ta1/outbound	X12, RAIL only
x12	X12 only
x12/reject	X12 only
rail	RAIL only
rail/reject	RAIL only

When the preceding steps are complete, the ccx12, ccrail, and ccedf maps are ready to run on the target system.

### [z/OS Implementation](#)

#### [Installing the shared exit library component on z/OS](#)

After installing the Supply Chain EDI Component on a Windows workstation, perform the following steps for each z/OS execution platform. This is done prior to porting and executing the Supply Chain X12 Compliance Check application on that platform.

#### [Installing the shared exit library component on UNIX](#)

After installing the Supply Chain EDI Component on a windows workstation, perform the following steps for each UNIX execution platform. This is done prior to porting and executing the Supply Chain X12 Compliance Check application on that platform.

---

## z/OS Implementation

### Batch Processing

The edicc.ini file contains system information for the runtime system.

- The exitlib value should be set to EDISVU.  
exitlib=EDISVU
- The ismvs value should be set to yes if IBM/TX is running in z/OS batch mode.  
ismvs=yes
- The mvsrunmaplog value should be set to no if run map logs should be suppressed.  
mvsrunmaplog=no

### CICS Processing

The edicc.ini file contains system information for the runtime system. Although the settings in edicc.ini file are not used during the CICS processing, the file is used as input card 8 for compliance checking.

With CICS processing, the EDISVU exitlib is defined with the CICS CSD definitions. The recommended CICS CSD definitions are as follows:

- DEFINE PROGRAM (EDISVU)
- GROUP (DTXCICS)
- DESCRIPTION (Packs Compliance)

- LANGUAGE (LE)
- CONCURRENCY (THREADSAFE)
- DATA (ANY)

Note: Refer to the following topics for more information related to the CICS CSD definitions:

- [Updating CICS CSD definitions and DFHRPL](#)
- [Using the EXIT function](#)

Additional changes may be needed depending on the pack version used. Verify the compliance check maps: ccedf, ccx12, etc to confirm the COMPLIANCE map function is being used.

- main map : Output Card 1

```
ExitDLLVersion DLLValidate Element:Runtime:SetupFramework
```

- map rule:

```
= VALID (COMPLIANCE ("X12", "GetHCIPVersion", "n/a", ExitDLL DLLValidate Element:Runtime:SetupFramework), "FAILED - GetHCIPVersion call: " + LASTERRORCODE() + "/" + LASTERRORMSG () + "<NL>Check the edicc.ini file to make sure that it correctly specifies the edisvu shared library")
```

- RunDLLSegCheck function map:

```
= RunDLLCompliance(
 Transaction,
 Structure_Detail_File,
 Runtime)
```

The Supply Chain EDI components for compliance using X12, RAIL, and EDIFACT contain XML configuration files that are processed using input card 3. The default setting on input card 3 is set to schema validation and there are two options for handling the schema validation:

- Modify the schema name in the metadata location on input card 3 to contain //DD:name, for example //DD:X12CFG which corresponds to the data set name in the execution JCL. The XML schema should be uploaded as binary to the dataset containing the maps.
- Modify the schema validation setting to Well Formed.

The Supply Chain EDI component for compliance X12U contains a JSON configuration file that is processed using input card 3. Input card 3 is using a JSON template for processing. The JSON template is not required for processing on z/OS.

Each Supply Chain EDI component contains an XML or JSON configuration file to control output to files. Output cards 2 and 3 are defined as SINK with ONSUCCESS APPEND. Output cards 2 and 3 will require an output data set to be defined and an execution parameter override for -OF2 and -OF3 to be identified in the execution JCL.

#### File Output:

The default setting is file output and the map putmvs\* in each component main execution map source file will be used to direct output for z/OS processing. With CICS execution, review the [z/OS CICS execution commands](#).

Pre-defined data set names will be used as follows:

Card number	Card name	Description
Output Card 5	DD:DATAIN	Contains valid data results.
Output Card 6	DD:REJECT	Contains rejected data results.
Output Card 7	DD:REJLOG	Contains validation error messages.
Output Card 8	DD:ACKIN	Contains 997 or 999 EDI found in the inbound EDI messages.
Output Card 9	DD:ACKOUT	Contains 997 or 999 outbound EDI messages.
Output Card 10	DD:TA1IN	Contains TA1 found in the inbound EDI message.
Output Card 11	DD:TA1OUT	Contains the TA1 outbound EDI message.
Output Card 12	DD:EDILOG	Fatal Error with framework.
Output Card 13	DD:JSONOUT	Optional JSON log report.x
	DD:JSONREJ	

#### Card Output:

Card output can be identified to override each output card which is defined as SINK.

```
<RuntimeInfo>
 <!-- This section will send output to map output cards -->
 <CardOutput/>
```

The z/OS JCL for a map execution provides output card overrides via the -OFx parameter. Any SINK output card may use the execution parameter override in the JCL.

## Installing the shared exit library component on z/OS

After installing the Supply Chain EDI Component on a Windows workstation, perform the following steps for each z/OS execution platform. This is done prior to porting and executing the Supply Chain X12 Compliance Check application on that platform.

## Procedure

1. Transfer the load library module file install\_dir/packs/supplychain\_edi\_vn.n.n/platform\_support/zos/edisvu.loadlib as binary to a z/OS dataset of 80-byte fixed length records named **my.exit.upload**.  
Note: There should be no ASCII to EBCDIC translation and no elimination of carriage return or line feed characters.
2. After the file is on z/OS, issue the TSO Receive command to create a load library. Perform the following steps:

- a. At the prompt, enter **ready**
  - b. Enter the following:
 

```
receive inda ('my.exit.upload')
receive inda ('userid.edisvu.upload')
```

The following messages or similar messages are displayed:

```
INMR901I Dataset EDISVU, UPLOAD from USER on NODENAME
INMR906A Enter restore parameters or 'DELETE' or 'END' +
```
  3. Enter the name of the load library to be created as follows:
 

```
da ('my.exit.loadlib')
da ('userid.edisvu.vxxx.loadlib')
```

Messages indicating that the load library is being created are displayed.
4. In the JCL, which is responsible for executing the Supply Chain X12 Compliance Check application, include a STEPLIB for the created load library that appears before the IBM Transformation Extender Core Install loadlib.
- Example**
- ```
//STEPLIB DD DSN=MY.exit.LOADLIB,DISP=SHR
// DD DSN=MY.ITX.INSTALL.LOADLIB,DISP=SHR
```

Installing the shared exit library component on UNIX

After installing the Supply Chain EDI Component on a windows workstation, perform the following steps for each UNIX execution platform. This is done prior to porting and executing the Supply Chain X12 Compliance Check application on that platform.

Procedure

1. Copy the UNIX shared library object edisvu.so or edisvu.sl for the Supply Chain X12 structure validation utility from `install_dir/packs/Supply Chain/platform_support/os`
- Where os indicates the operating system folder; e.g., aix, zos, etc. to the directory `install_dir/libs` on the target machine.
- Note: The read and execute permissions are set on the shared library.
2. If the setup script in the IBM Transformation Extender installation library is not run by the profile of the user, then the `edisvu.sl` or `edisvu.so` file should be copied to the location on the target machine that contains the compiled compliance check application maps.

File naming conventions

This section describes naming conventions that the X12, RAIL, and EDIFACT compliance check maps use to write the files when the file output option is configured.

In this documentation, some notations are used to represent values that are determined during map execution. The actual values are set as follows:

- `fileDirectory` the value from the *FileDirectory* element of the configuration
- `parentUid` the unique ID that identifies the interchange, from input card 2

The default setting is `NoUniqueID` which indicates date-time `parentUid`

The directories must be created before the map is run, or an error is returned by the File adapter.

- [X12 and RAIL file naming conventions](#)
The following show the file naming conventions for X12 and RAIL data.
- [EDIFACT file naming conventions](#)
The following show the file naming conventions for EDIFACT data.

X12 and RAIL file naming conventions

The following show the file naming conventions for X12 and RAIL data.

Note: In the following descriptions, UNIX style forward slashes (/) are used for the path separator in the Format description, and Windows style backslashes (\) are used in the examples. The map uses the appropriate path separator, based on platform.

- [Valid, accepted transactions](#)
The format and an example of valid, accepted transactions is shown here:
- [Invalid, rejected data](#)
The format and an example of invalid rejected data is shown here:
- [Generated, outbound, functional acknowledgments](#)
The format and an example of generated, outbound TA1 acknowledgments is shown here:
- [Generated, outbound, TA1 acknowledgments](#)
The format and an example of generated, outbound, received functional acknowledgments is shown here:
- [Inbound, received, functional acknowledgments](#)
The format and an example of inbound, received functional acknowledgments is shown here:
- [Inbound, received, TA1 acknowledgments](#)
The format of inbound, received TA1 acknowledgments is shown here:

Valid, accepted transactions

The format and an example of valid, accepted transactions is shown here:

| |
|---|
| Format: |
| <i>fileDirectory/x12/parentUid_x12.in</i> |
| <i>fileDirectory/rail/parentUid_rail.in</i> |
| Example: |
| c:\output\x12\1234567890_x12.in |
| c:\output\rail\20210226-154218_rail.in |

Invalid, rejected data

The format and an example of invalid rejected data is shown here:

| |
|--|
| Format for data file: |
| <i>fileDirectory/x12/reject/parentUid_x12.reject</i> |
| <i>fileDirectory/rail/reject/parentUid_rail.reject</i> |
| Format for error log file: |
| <i>fileDirectory/x12/reject/parentUid_x12.log</i> |
| <i>fileDirectory/rail/reject/parentUid_rail.log</i> |
| Example: |
| c:\output\x12\reject\20210226-154218_x12.reject |
| c:\output\x12\reject\20210226-154218_x12.log |
| c:\output\rail\reject\1234567890_rail.reject |
| c:\output\rail\reject\1234567890_rail.log |

Generated, outbound, functional acknowledgments

| |
|--|
| Format: |
| <i>fileDirectory/fa/outbound/parentUid_ack.out</i> |
| |
| Example: |
| c:\output\fa\outbound\20210226-154218_ack.out |
| |

Generated, outbound, TA1 acknowledgments

The format and an example of generated, outbound TA1 acknowledgments is shown here:

| |
|---|
| Format: |
| <i>fileDirectory/ta1/outbound/parentUid_ta1.out</i> |
| |
| Example: |
| c:\output\ta1\outbound\20210226-154218_ta1.out |
| |

Inbound, received, functional acknowledgments

The format and an example of inbound, received functional acknowledgments is shown here:

| |
|--|
| Format: |
| <i>fileDirectory/fa/inbound/parentUid_ack.in</i> |
| |
| Example: |
| c:\output\fa\inbound\20210226-154218_ack.in |
| |

Inbound, received, TA1 acknowledgments

The format of inbound, received TA1 acknowledgments is shown here:

| |
|---|
| Format: |
| <code>fileDirectory/ta1/inbound/parentUid_ta1.in</code> |
| |
| Example: |
| <code>c:\output\ta1\inbound\20210226-154218_ta1.in</code> |

EDIFACT file naming conventions

The following show the file naming conventions for EDIFACT data.

Note: In the following descriptions, the UNIX style forward slash (/) is used for the path separator in the Format description, and the Windows style backslash (\) is used in the examples. The map uses the appropriate path separator, based on platform.

- [Valid, accepted messages](#)
- [Invalid, rejected data](#)
- [Generated, outbound, CONTRL acknowledgments](#)
- [Inbound, received, CONTRL acknowledgments](#)

Valid, accepted messages

| |
|---|
| Format: |
| <code>fileDirectory/edifact/parentUid_edf.in</code> |
| |
| Example: |
| <code>c:\output\edifact\1234567890_edf.in</code> |

Invalid, rejected data

| |
|--|
| Format: |
| <code>fileDirectory/edifact/reject/parentUid_edf.reject</code> |
| |
| Format for error log file: |
| <code>fileDirectory/edifact/reject/parentUid_edf.log</code> |
| |
| Example: |
| <code>c:\output\edifact\reject\1234567890_edf.reject</code> |
| <code>c:\output\edifact\reject\1234567890_edf.log</code> |

Generated, outbound, CONTRL acknowledgments

| |
|--|
| Format: |
| <code>fileDirectory/fa/outbound/parentUid_ack.out</code> |
| |
| Example: |
| <code>c:\output\fa\outbound\1234567890_ack.out</code> |

Inbound, received, CONTRL acknowledgments

| |
|--|
| Format: |
| <code>fileDirectory/fa/inbound/parentUid_ack.in</code> |
| |
| Example: |
| <code>c:\output\fa\inbound\1234567890_ack.in</code> |

Performance tuning

Performance can be affected by many factors. The following information is related to map execution and may improve performance.

- Reduce the size of the structure validation file.
Review Card 7: structure detail file.
- With z/os processing, suppress the run map log.
Review Card 8: system information file.
- Skip the initial compliance processing step with SkipTTValidation setting.
Review the Configuration information details section.
- Workspace and page overrides.
Review the Configuration information details section and the following information.

The best configuration settings for the map RUN calls for the schema validation map, and the segment validation map, depend on the size of the transactions to be processed by the compliance check maps. The default setting uses work files that are in memory, and is best for small to medium size transactions. The transaction size at which performance improves by using a work file on disk, depends upon the amount of memory available after other applications and services are taken into account.

The recent compliance check maps use the setting in the configuration files without map modifications. You can review the **WorkSpace** configuration setting. However, older versions of the compliance check maps may not be using the configuration setting. Therefore, it may require the following map modifications.

- [Override schema validation maps](#)
- [Override segment detail validation maps](#)

Override schema validation maps

To override the setting for the schema validation maps, add the setting for map work files ("‐WU") to the rule where the schema validation maps are called:

- For X12 and RAIL data, update the ValidateTrxDetail functional map to add the setting in the rule defined for element
TTMapStatusTTValidate Element:TTValCheck:TrxDetailCheck
- For EDIFACT, update the ValidateMsgDetail functional map to add the setting to the rule defined for element
TTMapStatus TTValidate element:TTValCheck:MsgDetailCheck

The updated rule might look similar to the following rule shown here (the updated option is underlined):

```
= VALID(
RUN( TTMapName TTValidate Element:TTValCheck:TrxDetailCheck,
// pass data using ECHOIN if < 1 MB (approx), otherwise use HANDLEIN
IF (SIZE(TTMapData TTValidate Element:TTValCheck:TrxDetailCheck) < 1000000,
ECHOIN( 1, TTMapData TTValidate Element:TTValCheck:TrxDetailCheck ),
" -WU " + HANDLEIN( 1, TTMapData TTValidate Element:TTValCheck:TrxDetailCheck )
)
+ " -OE1"
),
"MAPFAIL|" +TTMapName TTValidate Element:TTValCheck:TrxDetailCheck + "|" +
LASTERRORCODE() + "/" + LASTERRORMSG() )
```

Override segment detail validation maps

To override the setting on the segment detail validation maps, change the following settings:

In the RunAuditEltCheck functional map, add the setting for running map work files: ‐WU in the Data_Audit_Result AuditLog Element:AuditEltCheck rule.

The updated rule looks similar to the following (updated option is underlined):

```
= VALID(
RUN ( SegMapName AuditLog Element:AuditEltCheck,
"-WU -ADM " +
ECHOIN ( 1 , SegMapData AuditLog Element:AuditEltCheck ),

"MAPFAIL|" +SegMapName AuditLog Element:AuditEltCheck + "|" +
LASTERRORCODE() + "/" + LASTERRORMSG()
)
```

Debugging

Logs are created by the compliance check maps to help with problem determination.

This section describes the logs and offers help to resolve some of the more common errors.

- [Compliance check logs](#)

The compliance check logs are written for any EDI interchanges that fail validation, and include information about any errors that were found. If there are no errors, then no compliance check logs are written.

- **Framework log**

If the compliance check maps are not providing the expected results, the primary problem determination tool is the framework log. This log is an XML-style log that is written to the map directory if certain severe errors occur, or if the trace input option is enabled. This log includes information about each step that was performed by the compliance check map. For large EDI interchanges, the framework log can become large.

- **Troubleshooting tips**

These troubleshooting tips are intended as suggestions to help resolve some of the more frequently encountered setup errors.

Compliance check logs

The compliance check logs are written for any EDI interchanges that fail validation, and include information about any errors that were found. If there are no errors, then no compliance check logs are written.

The compliance check logs are written to the following locations:

- File output – The x12/reject, rail/reject, or edifact/reject directory under the directory that is specified by the <FileDirectory> element in the configuration.
- Queue output – The queue that is specified by the <X12_RejectLogQueue>, <RAIL_RejectLogQueue>, or <EDIFACT_RejectLogQueue> element in the configuration.
- Wire output – The wire terminal that is specified by the <X12_RejectLogTerminal>, <RAIL_RejectLogTerminal>, or the <EDIFACT_RejectLogTerminal>.

The compliance check logs are intended to be read by humans. However, the format is also defined in the ccx12.mtt and ccedf.mtt schemas (type ErrorLog ErrorHandling EDI). You can use these schemas to create maps that convert the logs to other formats such as XML or HTML, or to do other automated processing with the logs.

If you do not want the compliance check log to be generated, you can set the configuration parameters to disable it. If the log is disabled, you must look at any generated acknowledgments to determine the errors. If the log is disabled, it can make it difficult to determine problems. For example, in cases where no acknowledgment is generated, no acknowledgment is requested or if the EDI data cannot be parsed.

Also, the compliance check log often includes additional information that is not included in the functional acknowledgment. To disable the creation of the compliance check log, set the CreateRejectLog element in the configuration to F (False). See [CreateRejectLog](#).

Framework log

If the compliance check maps are not providing the expected results, the primary problem determination tool is the framework log. This log is an XML-style log that is written to the map directory if certain severe errors occur, or if the trace input option is enabled. This log includes information about each step that was performed by the compliance check map. For large EDI interchanges, the framework log can become large.

To enable the trace option, set input card 9 to one of the following values:

- T – Trace log is written to file edilog.xml.
- TU – Trace log is written to a unique file, which is based on the unique id that is specified in input card 2. If no unique id is specified, an id is generated based on the current time stamp. The file name is in the format, edilog_uniqueid.xml

Note: If you specify the CardOutput element in your configuration, then the framework log is written to output card 12 instead of to the edilog.xml or edilog_uniqueid.xml file.

For example, to enable this trace you can specify the command line option:

-IE9 T

Note: Use caution when you use the TU option. The option can cause many log files to be generated, since a new log is created for each unique id. This log is intended to be read by a person, and in most cases an editor or viewer that can interpret XML data is useful to help read the log. However, in some cases this log might not be strictly well-formed XML - particularly if the EDI data contains XML control characters, such as, <, >, and &. To reduce complexity and processing overhead, these characters are not escaped, so there might be cases where XML processes do not handle these logs.

Troubleshooting tips

These troubleshooting tips are intended as suggestions to help resolve some of the more frequently encountered setup errors.

Issue: Map returns “One or more inputs was invalid” error

Troubleshooting: The compliance check maps never return the “One or more inputs was invalid” error for bad EDI data. If the EDI data is bad, the maps reject the data.

An error is then written to the compliance check log to indicate that it cannot be parsed, as X12, RAIL, or EDIFACT data.

The “One or more inputs was invalid” error typically indicates an error in one of the other input files. The error might be in the configuration file or one of the other text files that is used as input to the map.

Use the -TI option on the ccx12, ccrail or ccedf map to generate an input trace, which can help you identify which input is considered invalid.

Make sure that your configuration file is valid, and conforms to the XSD. See the sample configuration files in the data directory for valid examples.

If you are running on a system other than a Windows system, make sure that all files are copied correctly.

Issue: Map returns “Input valid but unknown data found” message

Troubleshooting: This issue can occur because there are multiple interchanges in the input EDI data (input card 1), or other data that follows the EDI interchange. The EDI compliance check maps support one interchange at a time in the input EDI data.

The first interchange of the input does get processed in this case. If there is only one interchange in your EDI input, use the -TI option on the ccx12, ccrail, or ccedf map to generate an input trace. Then, use the trace file to help you identify which input has unknown data at the end.

Issue: Map returns “FAIL function aborted map” error

Troubleshooting: This error occurs if there is a severe error – typically the map is not able to write to the file, queue, or wire terminal. When this type of failure occurs, a framework log edilog.xml is written to the map directory. For these failures, the log is written whether the trace was enabled or not.

Search the framework log for the string "<FrameworkErrorOccurred>". Immediately before this string there is usually some information about the error that occurred, such as an error writing to a specific file, queue, or wire terminal.

When you are writing to file output, the directories must already be created (and have write access) before you can run the map. The map does not create them. Also, be aware that path names are relative to the map directory, not necessarily to the directory you were in when you ran the command.

Issue: Schema validation map failed (E9002/E9003 error in compliance check log)

Troubleshooting: Make sure the schema validation map that is listed in the error message was compiled. If you are running on a system other than Windows, make sure that it was copied to the system as binary.

Issue: Segment detail validation map failed (E9015 error in compliance check log)

Troubleshooting: Make sure the segment detail validation map that is listed in the error message was compiled. If you are running on a system other than Windows, make sure that it was copied to the system as binary.

Issue: Exit/DLL call failed (E9010 error in compliance check log)

Troubleshooting: Make sure that the DLL/shared library used for the exit call is copied to the target system (as binary), and that the edicc.ini file has the correct path to the exit library and verify the exit library exists in the path. The default path using Design Studio is relative to the map location. The path using Design Server is the ITX install location. For z/os the exit library should be in the JCL steplib.

Pack for Supply Chain EDI samples

The Pack for Supply Chain EDI includes sample deenvelope and envelope tests for EDIFACT, and X12.

EDIFACT deenvelope and envelope tests

The EDIFACT sample tests are based on the batchfile.txt file that is in the *install_dir\examples\edi\edifact* directory.
The samples run these EDIFACT tests:

- A deenvelope test that uses good data input file, edifactin-multi.txt.
- A deenvelope test that uses bad data input file, edifactin-multi-bad.txt.
- An envelope test that uses good data input file poin-multi.txt.

The EDIFACT sample tests are based on the batchfile.txt file that installs with the imported project. The samples run these EDIFACT tests:

- A deenvelope test that uses good data input file, edifactin-multi.txt.
- A deenvelope test that uses bad data input file, edifactin-multi-bad.txt.
- An envelope test that uses good data input file poin-multi.txt.

X12 deenvelope and envelope tests

The X12 sample tests are based on the batchfile.txt file that is in the *install_dir\examples\edi\x12* directory.

The samples run these X12 tests:

- A deenvelope test that uses good data input file, x12in-multi.txt.
- A deenvelope test that uses bad data input file, x12in-multi-bad.txt.
- An envelope test that uses good data input file, poin-multi.txt.

The X12 sample tests are based on the batchfile.txt file that installs with the imported project. The samples run these X12 tests:

- A deenvelope test that uses good data input file, x12in-multi.txt
- A deenvelope test that uses bad data input file, x12in-multi-bad.txt
- An envelope test that uses good data input file, poin-multi.txt

Trading Manager Overview

Trading Manager is a Business to Business (B2B) management environment that uses the IBM WebSphere Transformation Extender to integrate trading partner transactions with enterprise applications.

Installation and Configuration

The documentation provided here describes how to install and configure Trading Manager.

Note the following before installing Trading Manager:

- the database associated with Trading Manager can reside on the same machine as the IBM WebSphere Transformation Extender Packs with Launcher, or on another machine that is network-accessible
 - the Design Studio must be installed prior to installing Trading Manager
- [**Overview**](#)
Trading Manager is a Business to Business (B2B) management environment that uses the IBM WebSphere Transformation Extender to integrate trading partner transactions with enterprise applications.
 - [**Installation requirements**](#)
 - [**Installing Trading Manager**](#)
 - [**Configuring Trading Manager**](#)
 - [**Installing and using Message Manager**](#)
 - [**Support for proprietary data types**](#)
 - [**Using alias files in maps**](#)
 - [**Checklists**](#)
 - [**Implementing custom X12 versions**](#)
 - [**TPEC to Trading Manager conversion**](#)

Overview

Trading Manager is a Business to Business (B2B) management environment that uses the IBM WebSphere Transformation Extender to integrate trading partner transactions with enterprise applications.

It includes two components: Partner Manager, a graphical administration component, and Message Manager, a runtime subsystem that uses trading profiles maintained by Partner Manager to automate document exchange among EDI partners. Electronic commerce data flows from external sources to internal destinations and from internal sources to external destinations, and possibly to other internal organizations.

- [**About the Trading Manager Environment**](#)
- [**IBM WebSphere Transformation Extender Packs for EDI**](#)
- [**IBM WebSphere Transformation Extender with Launcher**](#)

About the Trading Manager Environment

The Trading Manager B2B environment consists of the following components. Each component is described in detail in the following sections:

- Partner Manager
 - Message Manager
 - Design Studio
 - Integration Flow Designer
 - Launcher
 - Resource Adapters
- [**Partner Manager**](#)
 - [**Message Manager**](#)
 - [**Design Studio**](#)
 - [**Integration Flow Designer**](#)
 - [**Launcher**](#)
 - [**Resource Adapters**](#)

Partner Manager

Partner Manager is a graphical user interface (GUI) application used to create a comprehensive database of an organization's electronic commerce information and to manage its e-commerce activity. Partner Manager is used to define your trading relationships with your e-commerce partners. It also maintains the information for each trading partner including address information, contact persons, and the individual organizational entities with which you trade business information. Partner Manager allows for multiple databases to be used, or multiple copies may also access a single database.

Message Manager

Message Manager consists of a pre-defined system of maps specifically designed to process electronic commerce data. The executable maps are used for validation and routing of data.

Design Studio

The Design Studio is used to create maps that perform enterprise application integration by converting data from one form to another (typically to integrate e-commerce data with applications) and routing that information from its source to its target. The Design Studio features include the Integration Flow Designer, Map Designer, Type Designer, Metadata Type Importers for XML, EDI, and DBMS applications, and prebuilt adapters for messaging and transporting.

Integration Flow Designer

The Integration Flow Designer is used to define and organize maps into logical groups or comprehensive workflow systems. The Integration Flow Designer is used by a system analyst or system administrator responsible for linking internal applications with the Message Manager components provided as part of Trading Manager. Using the information defined in Partner Manager, the Integration Flow Designer is used to tailor the Message Manager for your organization's needs and to define run time settings for execution on the Launcher. It is a component of the Design Studio.

Launcher

The Launcher is used to execute the Message Manager maps. It is installed from the IBM WebSphere Transformation Extender. The Launcher can run on a single server or across multiple servers to distribute processing. Run-time event triggers are configured graphically using the Integration Flow Designer. During execution, there is seamless data flow between system components.

Resource Adapters

Resource Adapters provide connectivity to a wide array of types of data sources and targets, such as databases, messaging systems, FTP, or e-mail.

IBM WebSphere Transformation Extender Packs for EDI

The IBM WebSphere Transformation Extender Packs for EDI are collections of type trees representing the different versions of an EDI standard. Integration packages for the following EDI standards are available:

- X12
- EDIFACT
- TRADACOMS
- ODETTE
- EANCOM

IBM WebSphere Transformation Extender with Launcher

The IBM WebSphere Transformation Extended Edition provides the server with components to execute the IBM WebSphere Transformation Extender with Launcher. It includes the Launcher, the Management Tools (for Windows 7, Windows 2008, and Windows XP only), and the Command Server.

The Launcher must be installed before deploying Message Manager. The IBM WebSphere Transformation Extender Packs with Launcher helps you automate the execution of system maps. This map execution is based on time or source events, in contrast to the Command Server that executes maps according to commands that you supply involving only one map at a time.

Installation requirements

These instructions describe the requirements for installing Trading Manager. The database associated with Trading Manager can reside on the same machine as the IBM WebSphere Transformation Extender Packs with Launcher, or on another network-accessible machine.

The Design Studio must be installed prior to installing Trading Manager.

- [Minimum system requirements](#)
- [Prerequisites](#)
- [Installation checklists](#)
- [Launcher](#)

Minimum system requirements

The following documentation describes the requirements for Partner Manager, as well as the Windows 7, Windows 2008, Windows XP, UNIX, and Linux platforms.

- [System requirements for Partner Manager](#)

- [UNIX platform](#)

System requirements for Partner Manager

The minimum requirements to install and run Partner Manager are:

- Microsoft Windows 7, Windows 8, or Windows XP
- 512 MB RAM, however, 1 GB RAM is recommended

UNIX platform

The Launcher for UNIX (or Linux) is a multi-threaded daemon that runs on UNIX platforms.

The **cmsvu** shared libraries for each UNIX operating system are installed in the *install_dir\tmgr_vn.n\platform_support* directory. Before starting Message Manager on the server, ensure that the correct **cmsvu** file is copied to the **libs** directory located in the IBM install directory on the UNIX server.

Refer to the Launcher documentation for UNIX installation and configuration information.

Prerequisites

- **E-mail** - Ensure that connectivity and access to e-mail service and a user account for Message Manager is in place. Message Manager supports MS Mail, MS Exchange, Lotus CCMail, Lotus Notes and SMTP/POP3. Message Manager uses the e-mail service to send dynamic problem alerts to individuals responsible for managing the electronic commerce program.
- **Trading partner requirements** - To analyze your requirements, consider the following:
 - Number of trading partners to be supported.
 - Versions of standards and EDI documents (810, 850, 997, and others) to be exchanged.
 - Application format specifications for any internal applications interfacing with the EDI system.
 - Communication requirements for transporting data between application systems and the Trading Manager server. Requirements include the type of communications to use (e-mail, FTP, messaging product, and others), userids, passwords, naming conventions, and responsible parties.

Installation checklists

Before installing Trading Manager, please complete the installation checklist for your database software. See the Checklists documentation for more information.

Launcher

The Launcher is installed as part of the IBM WebSphere Transformation Extender. It should already be installed. If it is not installed, refer to the documentation for installation instructions.

Installing Trading Manager

About this task

These instructions describe the installation of the Trading Manager software components.

If you have an earlier version of Trading Manager installed, delete the **MessageManager.msl** file located in the *install_dir\systems* directory. If you do not delete this **.msl** file, the system will fail. The new default filename is **msg_mgr.msl**.

Refer to the Launcher documentation for installation information.

After the Launcher and Partner Manager are installed, you can configure the system as described in the documentation titled "[Configuring Trading Manager](#)".

Note: If you are a HIPAA customer, refer to: [Using Trading Manager with HIPAA](#).

Note: If you are converting from a prior release, refer to the readme file, **readme_tmgr.txt**, that is shipped with the Trading Manager application, for conversion instructions. This readme is located in the *install_dir* where *install_dir* represents the location of the core IBM WebSphere Transformation Extender product.

- [Determining the Trading Manager configuration](#)
- [Installation checklists](#)
- [Installing components](#)
- [Removing Trading Manager components](#)
- [Using Trading Manager with HIPAA](#)

Determining the Trading Manager configuration

Trading Manager enables you to manage your installation depending on your e-commerce processing needs. You can install all Trading Manager components on a single machine, or assign Trading Manager functions to different and dedicated machines.

- [Installing Trading Manager on a single workstation](#)
- [Installing Trading Manager on separate workstations](#)
- [Installing only Partner Manager](#)

On individual workstations using only Partner Manager to create information about trading and application partners, post offices, etc., only the Partner Manager application need be installed.

Installing Trading Manager on a single workstation

On a single workstation running all Trading Manager client/server components including the database, the following components must be installed:

- Server
- Partner Manager
- Message Manager
- Database Scripts

Note: Ensure that you have installed the Design Studio and IBM WebSphere Transformation Extender first.

Installing Trading Manager on separate workstations

If you are installing Trading Manager on separate workstations and servers in a client/server configuration, install these components:

- **Client workstation:** Partner Manager and Message Manager
- **Server machine where the Launcher is also installed:** this installation provides the Launcher and directory structure required for Message Manager map execution.
- **Database Server:** Database scripts

Installing only Partner Manager

On individual workstations using only Partner Manager to create information about trading and application partners, post offices, etc., only the Partner Manager application need be installed.

Installation checklists

Before installing the Trading Manager, please complete the installation checklist for your database software. See [Checklists](#).

Installing components

About this task

Before you begin installation, close any other programs running on your computer. Having other programs running may cause installation errors.

Before installing Trading Manager, the Design Studio must be already installed. If you have not done so already, perform this installation first by inserting the Design Studio CD into the CD-ROM drive and following the installation instructions.

You can optionally install the IBM WebSphere Transformation Extender for system execution on the local Windows 7, Windows 2008, or Windows XP client workstation using the Launcher. It is available on a separate IBM WebSphere Transformation Extender CD that installs the Launcher and related tools.

- [Installing Trading Manager on Windows](#)
- [Installing Message Manager components of Trading Manager on UNIX](#)

To install Trading Manager on HP-UX, Sun Solaris, or IBM RS/6000 AIX, Linux, or under UNIX System Services on z/OS, perform the following steps:

Installing Trading Manager on Windows

About this task

To install Trading Manager components on Windows, perform the following steps:

Procedure

1. Insert the Trading Manager CD into your CD-ROM drive.

2. If the program does not automatically start, go to the Start menu and select Run.
3. Enter **d:\install.exe** and click OK (where **d:** indicates the CD-ROM drive).
4. Follow the setup instructions to complete installation.

Installing Message Manager components of Trading Manager on UNIX

To install Trading Manager on HP-UX, Sun Solaris, or IBM RS/6000 AIX, Linux, or under UNIX System Services on z/OS, perform the following steps:

Procedure

1. Copy the **tmsinstall.ksh** file to the IBM WebSphere Transformation Extender install directory on the target machine.
2. Running in a korn shell, execute **tmsinstall.ksh** on the target machine.
Refer to the Launcher documentation for more information.
3. Navigate to the platform folder and copy the shared libraries to the **libs** directory under the IBM WebSphere Transformation Extender install directory on your UNIX machine.

Removing Trading Manager components

About this task

To remove Trading Manager components, perform the following steps:

Procedure

1. From the Start menu, select Settings > Control Panel > Add/Remove Programs.
2. Select the product component in the list provided.
3. Click Add/Remove.

Using Trading Manager with HIPAA

The **hipaa_x12_qualifier.dat** and **hipaa_x12_structure.dat** files must be imported into Trading Manager before any HIPAA trade links can be created. For a complete description of this activity, refer to the IBM WebSphere Transformation Extender Pack for HIPAA EDI documentation.

Configuring Trading Manager

These instructions describe how to configure Trading Manager with the databases, the and Partner Manager.

How you configure Trading Manager depends upon:

- The type of database your system is using: Microsoft Access, Microsoft SQL Server, Oracle, Sybase, or DB2
- Where the database is located
- Which applications interface with your system
- Whether you have a standalone or multi-machine configuration
- [Before you begin](#)
- [Creating the Trading Manager Database](#)
- [Determining the ODBC driver](#)
- [Defining an ODBC data source name](#)
- [Resolving ODBC difficulties](#)
- [Configuring Partner Manager](#)
- [Import structure validation](#)

Before you begin

Before configuring Trading Manager, ensure that:

- The database is created and ready for installation scripts
- Trading Manager components have been installed

You may then configure the Trading Manager database, Partner Manager settings, and Message Manager. The general configuration steps are:

- Create the Trading Manager database.
- Run the SQL scripts for IBM DB2, Microsoft SQL Server, Oracle, or Sybase to create the Trading Manager database objects.
- Configure Partner Manager to point to the Trading Manager database.

- Configure Message Manager to point to the Trading Manager database. These instructions describe how to change the database type in the *install_dir\tmgr_vn.n\mmgr\update.mdq* file to match the database type for your installation.
- [SQL scripts installed by Trading Manager](#)

SQL scripts installed by Trading Manager

Trading Manager installs the following SQL script files in the Trading Manager directory *install_dir\tmgr_vn.n\pmgr\sql*. The following descriptions apply to the scripts for Oracle, Microsoft SQL Server, Sybase, and IBM DB2.

- Installation script (***instnn.sql**): creates the tables, indexes, stored procedures, and views used by Partner Manager.
- Database load script (***loadnn.sql**): loads the database with data such as Folders, Version tables, Transaction Sets, and Functional IDs.
- Drop script (***dropnn.sql**): deletes all Partner Manager tables and data in the database.
- Update scripts (***update82to821.sql**): these upgrade your database from the 8.2 release. For customers converting from 7.8 and earlier, refer to the product readme for use of these files. These files are also used on a new customer installation of Trading Manager 8.2.1 and are described below.

| Database | Script |
|----------------------|--|
| Oracle | orainstnn.sql
oraloadnn.sql
oradropnn.sql |
| Microsoft SQL Server | sqlinstnn.sql
sqlloadnn.sql
sqldropnn.sql |
| Sybase | sybaseinstnn.sql
sybasedropnn.sql
sybaseloadnn.sql
sybaseloadnn_2.sql |
| IBM DB2 | db2instnn.sql
db2loadnn.sql
db2dropnn.sql |

Creating the Trading Manager Database

About this task

See the following topics to create a database.

- ["Using an Access Database"](#)
- ["Creating a Microsoft SQL Server Database"](#)
- ["Creating an Oracle Database"](#)
- ["Creating a Sybase Database"](#)
- ["Creating an IBM DB2 Database"](#)
- [Using an Access database](#)
- [Creating a Microsoft SQL Server Database](#)
- [Creating an Oracle Database](#)
- [Creating a Sybase Database](#)
- [Creating an IBM DB2 database](#)
- [IBM DB2 stored procedures](#)

The following procedures install eight Stored Procedures and one User Defined Function (UDF) into your database. These procedures should be performed by your DB2 DBA.

Using an Access database

An Access database (**tmgrnn.mdb**) is shipped with the Trading Manager client. The Access database is installed in the *install_dir\tmgr_vn.n\pmgr* directory. This database can be placed locally or on a server. If located on a server, it will be necessary to map a drive to that location before configuring the ODBC DSN Connection. See the documentation titled [Installing Trading Manager](#) for further information.

Due to performance reasons, it is recommended that you use the Access database for test or training purposes only; it should not be used in a production environment.

Creating a Microsoft SQL Server Database

About this task

When using Microsoft SQL Server, create the database data and log devices and then create the Trading Manager database using these devices. The name of the database you just created cannot contain spaces or special characters. Minimum disk space for the database data device is 100 MB and a recommended size is 500 MB. Minimum disk space for the database log device is 20 MB and a recommended size is 100 MB.

If any part of this procedure needs to be repeated, use **sqldropnn.sql** to delete all Partner Manager tables and data in the database.

Use caution: **sqldropnn.sql** cannot be reversed and should be used *only* if these steps must be repeated.

To run Microsoft SQL Server scripts:

Procedure

1. Start your **SQL Query** tool and connect to the Trading Manager database you just created.
2. See the Trading Manager release notes for the scripts to run.

What to do next

Note: These scripts do not contain a **COMMIT** statement. You must manually issue a commit if your database environment is not set to **auto-commit**.

Creating an Oracle Database

About this task

When using Oracle Server, use the default ORCL instance, or create an instance specifically for Trading Manager. The minimum disk space required for the instance is 100 MB. If you expect heavy transaction volume, use the auto-expand feature of Oracle.

If any part of this step needs to be repeated, use **oradropnn.sql** to delete all Partner Manager tables and data in the database. Use caution as **oradropnn.sql** cannot be reversed and should be used only if these steps must be repeated.

To run Oracle SQL scripts, perform the following steps:

Procedure

1. Log on to the desired Oracle instance in SQL*PLUS.
2. Create a spool output by entering the following (you can change this file name, or if available on your version of SQL*PLUS, use the File Spool option to set it):

```
spool C:\temp\inst.log
```

3. Process **orainst82.sql** (the path for the SQL files are in the directory where you installed Partner Manager, for example):

```
install_dir\mgr_vn.n\pmgr\sql\orainstnn.sql
```

4. Execute **oraupdate82to821.sql**.

5. When complete, shut off spooling with **spool off**, or use the File Spool option, if available.

6. Check the spool file created in Step 2 for errors. Resolve any errors before proceeding.

7. If there are no errors, enter **commit** in SQL*PLUS to save the changes.

8. Create another spool output by entering:

```
spool C:\temp\load.log
```

9. Process **oraloadnn.sql**:

```
install_dir\mgr_vn.n\pmgr\sql\oraloadnn.sql
```

10. When complete, shut off spooling with **spool off** or use the File Spool option, if available.

11. Check the spool file created in Step 8 for errors. Resolve any errors before proceeding.

12. If there are no errors, enter **commit** into SQL*PLUS to save the changes.

13. Exit SQL*PLUS.

Creating a Sybase Database

About this task

When using Sybase, create the database data and log devices and then create the Trading Manager database using these devices. The minimum disk space for the database data device is 100 MB. The minimum disk space for the database log device is 20 MB.

Note: If any part of this step needs to be repeated, a file named **sybasedropnn.sql** can drop all the tables created by **sybaseinstnn.sql**. Use caution, as the **sybasedropnn.sql** routine deletes all Partner Manager tables and data and cannot be reversed. It should only be used if these steps need to be repeated.

To create the Sybase Database, perform the following steps:

Procedure

1. Open the SQL editing tool.
2. Select **File > Open** and open the installation script from the default Trading Manager installation directory. If you changed the default directory during installation, use the correct directory for your install. Select the **sybaseinst82.sql** script.
3. Execute the **sybaseinst82.sql**.
4. Execute the installation script and wait for the last output message to be displayed. The message will read: **Install Complete**.
Note: On some versions of Sybase, you will receive the following warning: Row size could exceed row size limit, which is xxxx bytes (where xxxx can vary). Ignore this warning.
5. Check the output for errors; resolve any errors before proceeding.
6. Select **File > Open** and open the file **sqlupdate82to821.sql**.

7. Execute **sqlupdate82to821.sql** and wait for completion.
 8. Select File,>Open and open the file **sybaseunloadnn.sql**.
 9. Execute **sybaseunloadnn.sql** and wait for it to complete.
 10. Check the output for any errors.
 11. Select File,>Open and open the file **sybaseunloadnn_2.sql**.
 12. Execute **sybaseunloadnn_2.sql** and wait for it to complete.
 13. Check the output for errors.
- Note: These scripts do not contain a **COMMIT** statement. You must manually issue a commit if your database environment is not set to auto-commit.
-

Creating an IBM DB2 database

About this task

Construct the database using scripts loaded during the Trading Manager installation. The minimum disk space required is 200 MB.

To create the IBM DB2 Database, perform the following steps:

Procedure

1. Contact your Database Administrator (DBA) to get a database name, a user name, and a password.
 2. Verify with the DBA that the autocommit is on. If the autocommit is not on, either issue commits manually, or modify the **.sql** scripts to include the commits.
 3. Open the **db2inst82.sql** file in an editor. Change the first executable line to match your database name and user/password. For example, change **sample** and **db2admin** in the following executable line:
connect to sample user db2admin using db2admin
 4. Change the tablespace name (search and replace in **USERSPACE1**) as directed by your DBA. Trading Manager requires a DB2 tablespace page size of at least 8K; 32K is recommended. Ask your DBA to create such a tablespace, and replace **USERSPACE1** with the name of this tablespace
 5. Save the file.
 6. Using the DB2 Command Window, or the Command Line Processor, execute the new **db2instnn.sql** saved in step 5. Recommended usage is:
db2 -tvfs 'filepath\db2instnn.sql'>'filepath\logfilename'.
The Mainframe database tool '**SPUFI**' may also be used to execute scripts.
Note: Your DBA will instruct you on how to run SQL scripts. The scripts supplied are semi-colon delimited, plain text, SQL statements.
 7. After execution, review the results for errors.
 8. Open the **db2update82to821.sql** file in an editor. Change the first executable line to match your database name and user/password. For example, change **sample** and **db2admin** in the following executable line:
connect to sample user db2admin using db2admin
 9. Change the tablespace name (search and replace in **USERSPACE1**) as directed by your DBA. Trading Manager requires a DB2 tablespace page size of at least 8K; 32K is recommended. Ask your DBA to create such a tablespace, and replace **USERSPACE1** with the name of this tablespace
 10. Save the file.
 11. Using the DB2 Command Window, or the Command Line Processor, execute the new **db2update82to821.sql** saved above. Recommended usage is:
db2 -tvfs 'filepath\db2instnn.sql'>'filepath\logfilename'.
The Mainframe database tool '**SPUFI**' may also be used to execute scripts.
 12. After execution, review the results for errors.
 13. Open **db2loadnn.sql** in an editor and change the connect statement for the database, user name, and password and then save the file.
 14. Using the DB2 Command Window, or the Command Line Processor, execute the new **db2loadnn.sql** saved above.
 15. After execution, review the results for errors.
- If error free, the installation of **.sql** scripts is complete.
-

IBM DB2 stored procedures

The following procedures install eight Stored Procedures and one User Defined Function (UDF) into your database. These procedures should be performed by your DB2 DBA.

Note: DB2 Stored Procedures are supported on DB2 LUW (Linux, Unix and Windows) on versions 9.1 or greater.

Note: If multiple databases are used (for example, test and production databases), repeat these steps for each database.

If the stored procedures were previously installed with DB2 Data Studio, you may have stored procedures already defined, but named with a lowercase letter. If so, delete these stored procedures manually using the DB2 Control Center before continuing with this procedure. Delete the user defined function: **TMGR_TS_FMT**, as well as the following stored procedures:

```
eDF_INCREMENTMSG
eDF_INCREMENTNB
gETSTAMP_INCREMENTST
INCREMENTISA
INCREMENTGS_BY_TP
INCREMENTGS_BY_FID
INCREMENTGS_BY_AP
```

Preparation

Before you begin, make certain that you have the following software: DB2 Command Editor, DB2 Control Center (if required), and DB2 database, version 9.1 or greater. Make sure of the following conditions before installing stored procedures:

- Make certain that no Trading Manager activity is taking place during the installation process. It is suggested that you back up your database.

- Obtain the user id and password for the user that connects to the database in the Trading Manager maps. See [update.mdq](#). That user should be used to create these objects. If that user does not have create permission, it will require that GRANT EXECUTE statements be issued on all objects created here. Contact your DBA for assistance.
 - If the stored procedures and the User Defined Function already exist from a prior version or were created using Developer Workbench, delete them from the Control Center, or with the DROP statements defined later in this procedure.
- [**Installing DB2 stored procedures**](#)
The following procedure installs stored procedures and one User Defined Function (UDF) into your database. These procedures should be performed by your Database Administrator.

Installing DB2 stored procedures

The following procedure installs stored procedures and one User Defined Function (UDF) into your database. These procedures should be performed by your Database Administrator.

Procedure

1. Connect to the database using the Command Editor. Use the same user id and password specified in [update.mdq](#).
2. Set statement terminator to @ in Command Editor (at the bottom of the screen).
3. Set the Command Editor option to **Stop Execution on Error** (Tools > Tools Settings > Command Editor).
4. Open the SQL File, DB2V9TMSP.SQL in an editor and change the connect statement to the user id and password assigned in Trading Manager's [update.mdq](#), as described in the Preparation steps. DB2V9TMSP.SQL is located in the *install_dir/tmgr_dir/pmgr/sql* directory, where *install_dir* indicates the installation location of the core WebSphere Transformation Extender product and *tmgr_dir* indicates the location of Trading Manager.
5. Copy the changed SQL file and paste into the Command Editor and execute. If any errors are reported, contact your Database Administrator and/or IBM support.
6. The SQL file contains a suggested test call that can be run at this point.
7. To use the stored procedures in Trading Manager, set **Use Stored Procedures** in Partner Manager: Utilities > Message Manager Config > Database tab

- [**Copying drop statements**](#)

Copying drop statements

If drop statements are needed you can copy the following into Command Editor with an "@" statement terminator:

```
DROP PROCEDURE GETSTAMP
@
DROP PROCEDURE INCREMENTISA
@
DROP PROCEDURE INCREMENTGS_BY_TP
@
DROP PROCEDURE INCREMENTGS_BY_AP
@
DROP PROCEDURE INCREMENTGS_BY_FID
@
DROP PROCEDURE INCREMENTST
@
DROP PROCEDURE EDF_INCREMENTUNB
@
DROP PROCEDURE EDF_INCREMENTMSG
@
DROP FUNCTION TMGR_TS_FMT
@
```

Determining the ODBC driver

Before you use Partner Manager, you must configure an open database connectivity (ODBC) data source name (DSN) on each client machine that will run Partner Manager. The DSN associates an ODBC driver with your database type. Review the Database Requirements to determine the ODBC driver to select before defining your DSN. Ask your Database Administrator to assist you, then proceed with defining the DSN.

Defining an ODBC data source name

About this task

After you determine the ODBC driver to use, complete the following steps to define the DSN.

To define an ODBC DSN, perform the following steps:

Procedure

1. Select Settings...> Control Panel > Administrative Tools > Data Sources (ODBD) the ODBC Data Source Administrator displays.
2. Select the **System DSN** tab (not **User DSN**).
Selecting **System DSN** lets you create a DSN that is visible to all users; selecting **User DSN** creates a DSN that is only visible to the specified user on a particular machine.
3. Click **Add**.
The Create a New Data Source Name window opens.
4. Select the appropriate driver for your database from the list.
5. Click **Finish**.
The **ODBC Setup** window opens.
6. Enter the driver-specific setup parameters.
The name you assign in the Data Source Name window entry may be any name. However, IBM recommends that you use **Trading_Manager_TEST** (for testing) and **Trading_Manager_PROD** (for production) to simplify support and consulting consistency. The name entered will also be the selection for your DSN when you configure Partner Manager. You may enter an optional description in this window.
7. Complete the window as required by the driver provider.
8. Click **OK**.
9. The name you assigned appears in the **Name** list in the **ODBC Data Source Administrator**.
10. Click **OK**.

Resolving ODBC difficulties

About this task

If you experience difficulties with the ODBC connection when first installing or running Partner Manager, get the latest ODBC drivers from your database vendor. Ensure the driver is for your version of the database and client operating system.

Oracle users: ODBC driver version varied depending upon your Oracle configuration. See the Oracle Metalink article titled "Supported ODBC Configurations"; document ID 66403.1 for the proper Oracle driver number.

Contact your Database Administrator for a password to view this article.

http://metalink.oracle.com/metalink/plsql/ml2_documents.showDocument?p_database_id=NOT&p_id=66403.1

In the event this link is out of date, search MetaLink for "Supported ODBC Configurations".

Database vendors supply free ODBC drivers and they are available for download from their web sites.

Configuring Partner Manager

About this task

The first time that Partner Manager starts, it prompts for the DSN you configured in the documentation titled "[Installing Trading Manager](#)". To configure Partner Manager, perform the following steps:

Procedure

1. Start Partner Manager by selecting Start...>Programs>IBM WebSphere Transformation Extender n.n.>Trading Manager.>Partner Manager.
2. The first time Partner Manager starts, the Partner Manager Database Selection window opens.
3. Select a vendor from the **Database Vendor** drop-down list
4. Select the **Data Source Name** you created in "[Installing Trading Manager](#)" from the **DSN** drop-down list.
5. Enter **User ID** and **Password** (optional).
6. Enter an **Optional Description** if desired. This description appears on the title bar when Partner Manager is running.
7. Click **OK**.

Import structure validation

About this task

For all databases created other than Access, the X12 Structure Validation file must be imported. If you process EDIFACT transactions, the EDIFACT Structure Validation file must be imported as well.

The file need only be imported once per database created.

To import an X12 Structure Validation file

Procedure

1. Start Partner Manager with the DSN created in "[Configuring Partner Manager](#)".
2. Click the **Utilities** icon on the tool bar.
The **Utilities** navigator displays.
3. Click Standards.

4. In the Standards Maintenance window, select X12 Structure Validation: **Import** from the **X12 Standards** drop-down box.
5. Click the **Find File** button and select the **X12_StructureValidation.detl** file, which installed in the *install_dir\tmgr_vn.n\pmgr* directory.
6. Click the **Begin Import** button to import this data.
7. If you process EDIFACT data, repeat steps 4, 5 and 6 using the **EDF_StructureValidation.detl**: **Import** from the **EDIFACT Standards** drop-down box, using the **EDF_StructureValidation.detl** if you process EDIFACT data.

Installing and using Message Manager

These instructions describe how to install and use the Message Manager . The Message Manager is the business logic that provides the routing, archival, standards validation, audit, and alert functions within the Trading Manager. The Message Manager runs on the Launcher and is viewed, implemented, and configured using the Integration Flow Designer. The Message Manager provides a generic electronic commerce framework with EDI-specific functions.

- [Installing Message Manager](#)
- [General configuration and setup](#)
- [Starting Message Manager](#)
- [Message Manager deployment tasks](#)
- [Using Message Manager](#)
- [Message Manager subsystems](#)

Installing Message Manager

About this task

The Message Manager source files are installed as part of the Trading Manager. See "[Installing Trading Manager](#)" for installation instructions.

- [Where to install Message Manager](#)

Where to install Message Manager

About this task

The Message Manager can be installed onto a client workstation or the Trading Manager Launcher machine. The source Message Manager source maps and trees are installed within a valid Message Manager directory structure, such as *install_dir\tmgr_vn.n\mmgr*. There are advantages and disadvantages to each approach, which are discussed below.

- [Client workstation installation](#)
- [IBM WebSphere Transformation Extender Launcher installation](#)

Client workstation installation

Installing the Message Manager on a client workstation is the default option. This option requires connectivity to the IBM WebSphere Transformation Extender Launcher machine and the complete Design Studio environment. There are advantages and disadvantages to this type of installation.

As an advantage, this installation provides a single point of control for the Trading Manager operations. Also, better performance is achieved while running Design Studio as there is no network overhead.

As a disadvantage, it is difficult to share Message Manager responsibilities with other resources. Also, an extra step is required when adding new versions or transactions to the system.

IBM WebSphere Transformation Extender Launcher installation

Installing the Message Manager on the Trading Manager IBM WebSphere Transformation Extender Launcher machine (Windows 7, Windows 2008, or Windows XP platform) is also an alternative. It still requires connectivity between the client workstation of the individual administering the system and the server. This option also assumes the installation of the complete Design Studio environment on that administration client. It does not require the installation of the Design Studio components on the server. There are advantages and disadvantages to this installation.

An advantage of this installation is that it simplifies the sharing of Message Manager responsibilities due to centralized location of the source. It also eliminates the need for an extra copy step when building maps.

As a disadvantage, it may slow performance while running Design Studio clients due to network overhead. Another disadvantage is that standard drive mappings are required if multiple users are supported. For example, each client must map the server machine as Y.

General configuration and setup

About this task

You must complete the following activities before you can begin using Trading Manager:

- Install the Launcher Trading Manager components. See the documentation titled "[Installing Trading Manager](#)" for installation instructions.
 - Complete the configuration. See "[Configuring Trading Manager](#)".
 - Define trading partner information including trading relationships to the Partner Manager database using the Partner Manager client. See the Partner Manager documentation for more information.
-

Starting Message Manager

About this task

You start the Message Manager by opening the Message Manager system definition file **msg_mgr.msd** in the Integration Flow Designer, installed as part of the Design Studio.

To start the Message Manager:

- From the **Start** menu, select Programs->IBM WebSphere Transformation Extender->Trading Manager->Message Manager.

The Integration Flow Designer opens the **msg_mgr.msd** system definition file.

Message Manager deployment tasks

About this task

After you have completed the Trading Manager general configuration and setup steps, you are ready to prepare the Message Manager for deployment. Deploying Message Manager consists of the following activities:

- Define the server types in the **msg_mgr.msd** file.
 - Modify the **msg_mgr.msd** default pathname settings to match your physical environment
 - Deploy Message Manager on UNIX.
 - Modify the email alert settings to match your email environment.
 - Configure the Launcher service startup parameters.
 - Modify the Message Manager database query file for your database type.
 - Define Partners, Post Offices and Trade Links in Partner Manager.
 - Run the EDI Wizard.
 - Enable the **stampandsortFTP**, **stampandsortVAN**, and **stampandsortEmail** maps.
 - [Step 1. Define the server types in the msg_mgr.msd file](#)
 - [Step 2. Modify the msg_mgr.msd default path name settings](#)
 - [Step 3. Deploying Message Manager on UNIX](#)
If the target server is a UNIX based, build Message Manager maps and deploy to the UNIX server.
 - [Step 4. Create a configuration file](#)
 - [Step 5. Modify the E-mail alert settings](#)
 - [Step 6. Configure the Launcher service startup parameters](#)
 - [Step 7. Modify the Message Manager database/query file](#)
 - [Step 8. Identify the Trading Manager database](#)
 - [Step 9. Define Partners, Post Offices and Trade Links](#)
 - [Step 10. Run the EDI Wizard](#)
 - [Step 11. Enable stampandsortFTP, stampandsortVAN, and stampandsortEmail maps](#)
 - [Step 12. Modify Femail.mtt to support proprietary data](#)
 - [Step 13. Add application maps and link to Message Manager](#)
 - [Step 14. Use the deploy facility in the Integration Flow Designer](#)
 - [Step 15. Build and copy application and communication maps](#)
 - [Step 16. Start the Launcher service](#)
-

Step 1. Define the server types in the msg_mgr.msd file

About this task

In the following steps, use the Integration Flow Designer to define the server types in the **MessageManager** and **RunMaps** systems.

To define the server types, perform the following steps:

Procedure

1. From the Start menu, select Programs->IBM WebSphere Transformation Extender n.n->Trading Manager->Message Manager.
2. In the IFD navigator, click the Composition tab to show the **msg_mgr** system definition file.
3. Select **msg_mgr**.
4. From the Server menu, choose **New**.

The Add Server window opens.

5. Enter all values and click OK.

Step 2. Modify the msg_mgr.msd default path name settings

About this task

The Message Manager map and other components are configured assuming a default directory structure of:

C:\install_dir\tmgr_vn.n\mmgr

If you installed Message Manager to a different location, you need to update the Message Manager path names to reflect your environment.

To update the path names, follow the example steps to open the **msg_mgr.msd** system definition file in the Integration Flow Designer and use the **Replace** feature. The **Replace** feature enables you to change the Design-Time Paths and Run-Time Paths for **msg_mgr.msd**:

- **Design-Time Paths** are the directory paths for your system definition file and referenced source/compiled map components
- **Run-Time Paths** are the directory paths for input and output cards, audit log, trace and work files, and server map

The following example steps assume that you installed and will operate in the **d:\apps** directory and your client directory structure mirrors your server directory structure. After completing this step, your map components point to the correct path and file on your **d:\install_dir\tmgr_vn.n\mmgr** directory structure. You can verify this by trying to access any of the map components in Message Manager.

- [Changing design time, run time paths](#)

To change to design time, and run time paths:

1. From the Start menu, select Programs > IBM WebSphere Transformation Extender n.n > Trading Manager > Message Manager.
2. In the IFD navigator, click the Composition tab to show the **msg_mgr** system definition file.
3. Double-click MessageManager to show the **MessageManager** system.
4. From the **Edit** menu, choose **More Find/Replace**.
The Find/Replace window opens. Select the Replace tab.
5. Specify the **Find What** search criteria. To locate all path names that begin with C:, enter C: in the **Find What** field and select Path Names for the **Search Criteria**.
6. Click the **Settings** button to specify additional search parameters.
The Path Name Settings window opens.
7. Ensure that **Run-Time Paths** is disabled, and **Design-Time Paths** is enabled.
Note: Set the Design-Time settings before the Run-Time settings.
8. Click OK to save the settings and close the Path Name Settings window.
The Path Name Settings window closes and you are returned to the Find/Replace window.
9. With the Replace tab view selected, click Find.
A list of the run-time paths that match the search criteria is displayed in the list. In this case, the **C:\install_dir** directory structure is found.
10. In the **Replace** field, enter the path name you wish to replace: C:.
11. In the **With** field, specify the actual location of your **Run-Time Paths**; in this example, d:\apps.
12. Click Select All to select all entries in the list of paths matching the search criteria.
13. Click Replace.
14. Repeat steps 6 through 13; in step 7, enable **Run-Time Paths** and disable **Design-Time Paths**.
15. After performing this procedure for the **MessageManager** system, repeat all steps for the **RunMaps** systems.
Your map components now point to the correct path and file on your **D:\apps\IBM\tmgr_vn.n\mmgr** directory structure. You can verify this by trying to access any of the map components in Message Manager.

Changing the .mrn path names

To change the **.mrn** path names:

1. Open the **Resource Registry**.
2. Right-click on the **Resource Files** folder and choose **Open**.
3. Navigate to the **install_dir\tmgr_vn.n\mmgr** and open the **mmgr.mrn** file.
The file opens in the Resource Registry window.
4. Expand the **mmgr** file and expand the **Resources** folder.
5. Double-click each of the resources under the Resources folder (for example, **mmgr_share**).
The **EditResource** window opens.
6. In the **Resource Value** column, enter the new location of the share directory for the required server.
7. Repeat steps 5 and 6 of this procedure for each resource.

See the Resource Registry documentation for further information.

Step 3. Deploying Message Manager on UNIX

If the target server is a UNIX based, build Message Manager maps and deploy to the UNIX server.

About this task

To do this, the server location of all Message Manager maps, must be changed to reflect the deployment directory.

Message Manager maps use standard Windows directory nomenclature which must be changed to UNIX nomenclature (as an example, \ replaced by /).

Procedure

1. From the Start menu, select Programs->IBM WebSphere Transformation Extender n.n->Trading Manager->Message Manager.
2. In the IFD navigator, click the Composition tab to show the **msg_mgr** system definition file.
3. Double-click MessageManager to show the **MessageManager** system.
4. From the **Edit** menu, choose **More Find/Replace**.
- The Find window opens.
5. Click the Replace tab.
6. The Replace window opens.
7. Specify the **Find What** search criteria. To locate all path names that begin with C:, enter C: in the **Find What** field and select Path Names for the **Search Criteria**.
8. Click the **Settings** button to specify additional search parameters.
- The Path Name Settings window opens.
9. Disable the **Design Time Paths** checkbox.
10. Enable the **Run Time Paths** checkbox.
11. Disable all checkboxes in the **Run Time Paths** area of the window except the **Audit Log** and **Server Map Location** checkboxes.
12. Click OK.
- The Path Name Settings window closes and you are returned to the Find/Replace window.
13. In the **Find What** field, enter C:\install_dir.
14. Click Find.
15. Select all show entries.
16. In the **With** field enter the UNIX installation directory (excluding the **tmgr_vn.n/mmgr**).
17. Repeat steps 11 to 13, changing the FIND string to \, and the Replace string with /.

Step 4. Create a configuration file

Use the Resource Registry Tool to create a **.mrc** file. This file should point to the **mmgr.mrn** and to the **msg_mgr.msl** files that are created during deployment for the Launcher, Command Server and Global settings. Save this file as **mmgr.mrc**.

Step 5. Modify the E-mail alert settings

About this task

The Message Manager is configured with a default e-mail type of MAPI. If your mail system is other than a MAPI mail system (such as Microsoft Mail or Microsoft Exchange), modify a map rule to prepare the Message Manager for your environment.

To change the default email alert setting perform the following steps:

Procedure

1. Open the **Resource Registry**.
2. Open the **msg_mgr.msd** and **mmgr.mrc** files.
3. Select the relevant server. For example, **LocalServer**.
4. Select the **mmgr_e-mail_settings** Resource.
5. Select the **Resource Value** and enter the override settings.
6. Turn **Encryption On** or **Off**.
Note: If you use passwords, you will want to use the encryption feature.
7. Click OK.
8. Exit out by selecting Exit from the File menu.
9. Save changes.

Results

See the E-mail Adapter documentation for information regarding the e-mail adapter.

Step 6. Configure the Launcher service startup parameters

About this task

The following procedure is optional and is applicable to Windows 7, Windows 2008 and Windows XP only.

Some e-mail options supported by Trading Manager require a modification to the default Launcher service Startup parameters. MAPI mail systems such as Microsoft Mail and Microsoft Exchange require access to a user profile when receiving MAPI calls from a service. Configuration requires the creation of a user profile under an existing user account.

It is recommended that you create an **M4EC** user with appropriate permissions including the **User Rights Policy - Log on as a service**. This permission allows the Launcher Service to be accessed by the **M4EC** userid even if the server is running in unattended Automatic mode.

After the **M4EC** userid is established, create a **Mail** profile named **M4EC** that has permission to send mail to any appropriate parties. The **M4EC** mail profile does not need to receive mail to fulfill the alert functions. If you use the pager alert option, ensure that your mail administrator has given the profile sufficient permissions.

After you or your system administrator creates the **M4EC** userid and **M4EC** mail profile, modify the default **Startup** parameters for the Launcher Service.

To modify the default Launcher service startup parameters on Windows 7, Windows 2008 and Windows XP perform the following steps:

Procedure

1. From the Start menu, open the **Control Panel**.
2. Double-click **Administrative Tools**.
3. Double-click **Services**.
The Services window opens.
4. Double-click **Launcher**.
The service name may also include a version number.
5. On the General tab, select **Automatic** from the **Startup type** drop-down box.
6. Click the **LogOn** tab, enable the **This account** field and enter **M4EC**.
7. Enter the M4EC password in the **Password** and **Confirm password** fields.
8. Click **Apply** and then click **OK**.

Step 7. Modify the Message Manager database/query file

About this task

You need to change the database type in the *install_dir\tmgr_vn.n\mmgr\update.mdq* file to match the database type for your installation, for example Microsoft SQL Server or Oracle. Trading Manager is configured to use Microsoft Access as its database. If you have built your prototype environment using Microsoft Access, you must convert from Access to your database type in preparation for your production environment.

The Message Manager default database definition is an open database connectivity (ODBC) database for the Windows platform. See the Partner Manager documentation for more information.

Each Partner Manager client must have an ODBC System data source name (DSN) for both test and production servers.

To modify the **update.mdq** database/query file perform the following steps:

See the Database Interface Designer documentation for information on defining databases.

Procedure

1. Open the Database Interface Designer.
2. Open the **Update.mdq** file in *install_dir\tmgr_vn.n\mmgr*.
3. Expand **Update** to show the **TmrcMgrDB** database definition; select TmrcMgrDB.
4. From the Database menu, select **Edit**.
The **Database Definition** window opens.
5. Expand the **Adapter** setting.
6. From the **Type** drop-down list, select the appropriate database type.
The database-specific fields appear in the **Database Definition** window.
7. Specify the **Platform** from the drop-down list.
8. Enter the appropriate information for the selected database.
9. Click **OK** to set these database settings.
10. From the File menu, choose **Save** to save the database/query file.

Step 8. Identify the Trading Manager database

About this task

In this step, identify the ODBC Data Source Name for each Partner Manager client. Every client must have an ODBC System data source name (DSN) for both test and production servers.

- [Identify the Trading Manager database connection](#)

Identify the Trading Manager database connection

About this task

It is not necessary to define an ODBC Data Source Name (DSN) for your database because you are no longer using ODBC connectivity from the Message Manager server. However, Partner Manager requires an ODBC DSN definition on every client machine from which it will be used.

To identify the ODBC DSN for each client, perform the following steps:

Procedure

1. On the Trading Manager client machine, start Partner Manager.
2. From the File menu, choose **Database Settings** and enter the appropriate information into the fields in the Database Selection window.

Step 9. Define Partners, Post Offices and Trade Links

About this task

Using the Partner Manager, you must define at least one of each of the following to prepare for the remaining steps:

- Internal trading partner
- External trading partner
- **GET** post office
- **PUT** post office
- Trade link

See the Partner Manager documentation for information on defining trading relationships in Partner Manager.

Step 10. Run the EDI Wizard

About this task

After defining one or more trade links in Partner Manager, run the EDI Type Tree Wizard to create the **x12mail.mtt** type tree required by Message Manager. See the Partner Manager documentation for instructions.

Ensure that you create or copy the **X12mail.mtt** in the *install_dir\tmgr_vn.n\mmgr* directory. Message Manager uses this file for validation purposes.

Step 11. Enable stampandsortFTP, stampandsortVAN, and stampandsortEmail maps

About this task

Note: This step is optional.

Refer to "[stampandsortFTP/VAN/Email Maps](#)" for instructions to set up FTP, VAN, and e-mail communications in the **StampAndSort** subsystem.

Step 12. Modify Ecmail.mtt to support proprietary data

About this task

Note: This step is optional.

If you will be supporting non-EDI data types, modify the **Ecmail.mtt** type tree before building the Message Manager maps.

Step 13. Add application maps and link to Message Manager

About this task

Message Manager does not address your organization's specific application mapping requirements. It retrieves or sends data, validates, audits, and routes it to a directory for further action; it does not transform that data without a user-written map.

See the Integration Flow Designer documentation for information about creating **.msd** files and adding systems, subsystems, and map components.

- [Adding a Message Manager application map](#)
- [Configuring Launcher settings](#)

Adding a Message Manager application map

It is recommended that all application and communication maps are specified in a system definition file other than **msg_mgr.msd**. Having a separate file allows you to manage your version control and allows you to upgrade your Message Manager at any time without affecting your specific implementation.

To add an application map, perform the following steps:

1. Create a new system definition file named **AppMap**.
 - Select System Definition Files in the navigator.
 - From the File menu, choose New.
 - Right-click the new system file (**SystemFile1**) and save it as **AppMap**.
2. Add the user application map to the system and name it **P0toFlat**.
 - Enable the Toolbox by choosing **Toolbox** from the View menu.
 - Click the **AddSourceMap** tool on the Toolbox.
 - Click the **AppMap** system window.
 - In the **AddSourceMap** window, browse for the **.mms** map source file to add, name it **P0toFlat**, and click OK

Configuring Launcher settings

You configure the Launcher settings so that the **P0toFlat** map component executes (or triggers) when the EDI data arrives in your Put File post office. Here, configure the **P0toFlat** map component to have an Input Event trigger for the first input card with the File source defined as **d:\apps\IBM\tmgr_vn.n\mmgr\3050850*i.APP**

For this example, assume the following:

- The Put File PO Nickname is APP and its location is defined in Partner Manager as **d:\apps\IBM\tmgr_vn.n\mmgr\3050850**
- The EDI data is arriving from a VAN post office named **VAN**, which retrieves its data every hour
- As Message Manager gets the data from VAN, it passes through the **stampandsortfile**, **sortx12**, and **routex12** maps before being written to the Put File Post Office as
d:\apps\IBM\tmgr_vn.n\mmgr\3050850\VAN00001199809150001oi.APP
- In the **AppMap.msd** system window, ensure that the **Execution Mode** drop-down menu is set to Launcher.
- Click the execution settings button to display the Launcher Settings window.
- Click OK to save the Launcher settings.

Step 14. Use the deploy facility in the Integration Flow Designer

About this task

The Integration Flow Designer documentation describes the Deploy facility in more detail.

The Message Manager is delivered as a set of source maps. To complete the deployment tasks, you may build compiled map objects, transfer them to their appropriate server directory locations, and generate the Launcher control files (.msl) as separate procedures using the Integration Flow Designer (IFD).

However, the IFD Deploy facility automates these build, transfer, and generate steps that prepare systems to run on designated servers. The IFD includes four Deploy scripts to automate these three separate tasks. The Deploy scripts are **DeployMessageManager**, **BuildRunMaps**, **Deploy-MRN-Update** and **GenerateMSLonly**.

The following procedures enable you to:

- Build the MessageManager and RunMaps maps
- Generate the **msg_mgr.msl** Launcher control file
- Copy the compiled map files (.mmc) and Launchercontrol file (.msl) to the corresponding server directory (optional)
- [Using the IFD deploy facility](#)

Using the IFD deploy facility

To use the Deploy facility, perform the following steps:

1. In the IFD navigator, click the Composition tab to show the **msg_mgr** system definition file.
2. Expand **msg_mgr** to show the **MessageManager** and **RunMaps** systems.
3. Right-click **MessageManager** and select **Deploy...>Definitions**.
4. Select **Generate and Transfer Launcher Control File** and click Details.
5. In the window, select the path and filename to save the Launcher control file (.msl).
The default full path is **C:\install_dir\system\msg_mgr.msl**
6. Click Save and **Close**.
7. Right-click **MessageManager** and select **DeployMessageManager**.
The IFD builds the **MessageManager** maps and generates the **msg_mgr.msl** Launcher control file in the specified folder. It also copies compiled map objects (.mmc) to the server directory.
8. Click OK to view the specified deployment results.
9. Right-click **RunMaps** in the navigator and select **BuildRunMaps**.
The IFD builds the **RunMaps** maps.
10. Click OK to view the deployment results.

Step 15. Build and copy application and communication maps

About this task

The following steps can be performed in a deploy script you create. The Integration Flow Designer documentation describes the Deploy facility in more detail.

Build your application and communication maps as described in the following procedure; ensure that you select the application and communication map system definition file. All maps should compile without error. If any errors occur, those errors must be resolved before copying them to the server. Then copy the compiled map files to the corresponding server directory.

To build the application and communication system source map objects and copy the compiled map objects to the server, perform the following steps:

Procedure

1. Open the system definition file (**.msd**) in the Integration Flow Designer.
2. Display the System window for the system.
3. From the System menu, choose **Build Maps**.
4. Click Results to view a detailed summary of the build process and verify that all maps have been built successfully.
All maps should compile without error. If any errors occur, those errors must be resolved before continuing
5. Click OK.
6. Copy the compiled map objects (**.mmc**) to the corresponding server directory.
 - [Generate the Launcher control file for an application system](#)

Generate the Launcher control file for an application system

About this task

To generate the Launcher control file for an application system, perform the following steps:

Procedure

1. Open the application's system definition file in the Integration Flow Designer.
2. Display the System window for the system containing the application map components.
Always generate the Launcher control file **.msl** at the top level system. For instance, if **AppSysA** contains subsystem components **AppSys1** and **AppSys2**, generate the file for **AppSysA**.
3. From the System menu, choose **Generate**.
The Save As window opens to prompt you to enter the file name and location for the **.msl** file.
4. Enter the name and location for the **.msl** file:
 - Navigate to, and save, the **.msl** file to the **Systems** directory on the Trading Manager server.
5. Click Save to generate the file.

Step 16. Start the Launcher service

About this task

The final step in deploying the Message Manager is to start the Launcher Service. The Launcher documentation contains detailed information about configuring and starting the Launcher on both the Windows and UNIX platforms.

To start the Launcher service on Windows 7, Windows 2008, and Windows XP perform the following steps:

Procedure

1. From the Start menu, open the **Control Panel**.
2. Double-click **Administrative Tools**.
3. Double-click **Services**.
The Services window opens.
4. Select **Launcher**, right-click, and select **Start**. Or, click **(Start Service)** in the tool bar.
The service name may also include a version number.
5. When the Launcher is started, the **Status** column will display **Started**.

Results

See the Launcher documentation for Launcher starting information.

- [Launcher Manager tools](#)
-

Launcher Manager tools

About this task

The following are the Manager Tools for the Launcher:

- Launcher Administration
- Management Console
- Launcher Monitor
- Snapshot Viewer

You can use the Management Tools for status information and debugging. The Launcher management tools are described in the Launcher documentation. Use the Configuration file **mmgr.mrc** in the Launcher Administration setting.

Using Message Manager

The following topics are described here:

- The **MessageManager** system, which is defined in the **msg_mgr.msd** system definition file
- Inbound and outbound data flows
- Subsystems in **msg_mgr.msd**

As installed, the **MessageManager** system is a set of source maps. The system retrieves or sends data, then validates, audits, and routes it for further action. After adding your application map(s) according to your e-commerce configuration, you compile the maps and transfer them to their Trading Manager server locations before starting the Launcher. After you start the Launcher, event triggers execute the compiled maps and process your data.

The **MessageManager** system implements the logical functionality and EDI-specific features of the Trading Manager. It also provides a general framework for any data you choose to support in the system. The **MessageManager** system includes six major subsystems: **Archive**, **EDIFACT**, **StampAndSort**, **TRADACOMS**, **Update**, and **X12**. Each major subsystem contains maps or other subsystems.

In the top level view of the **MessageManager** system, the **StampAndSort** and **Update** subsystems provide a general data-handling framework. The **X12** subsystem is specific to ANSI X12 EDI functionality.

To fully deploy the Message Manager, you must add:

- Application maps
- Implementation-specific configuration settings
- Trading partner information supplied through the Partner Manager
- Actual data activity (that is, events on the Launcher)

Message Manager subsystems

The **msg_mgr.msd** system definition file has two executable systems: **MessageManager** and **RunMaps**. The **MessageManager** system has six subsystems: **Archive**, **EDIFACT**, **StampAndSort**, **TRADACOMS**, **Update**, and **X12**.

- [Archive subsystem](#)
- [EDIFACT subsystem](#)
- [EDIFACT inbound subsystem](#)
- [EDIFACT outbound subsystem](#)
- [StampAndSort subsystem](#)
- [TRADACOMS subsystem](#)
- [TRADACOMS inbound subsystem](#)
- [TRADACOMS outbound subsystem](#)
- [Value Added Tax \(VAT\) reports](#)
- [Update subsystem](#)
- [X12 subsystem](#)
- [X12 inbound subsystem](#)
- [X12 outbound subsystem](#)

Archive subsystem

The primary function of the Archive subsystem is to archive both inbound and outbound data. The Archive components archive files processed by the system and place them into the **archive\<process>\<process>_date.zip** file. Folder **stampfil** is used to archive all input data to Trading Manager, inbound or outbound. Folders **sendx12**, **sendedf**, and **sendtrc** are used to archive outbound files going out from Trading Manager.

You can selectively turn on/off the archiving process by going into the "Message Manager Configuration" options in Partner Manager. Options available are:

- Turn on/off archiving of Inbound files into Trading Manager.
- Turn on/off archiving of Outbound files into Trading Manager.

- Turn on/off archiving of Outbound files out from Trading Manager.
The **batchutil** component will perform batch archiving of online traffic information into the online archive. If is scheduled to run every night at 11:30 PM. Batch archiving is turned on/off and the corresponding options are specified through the "Message Manager Configuration" options in Partner Manager.

EDIFACT subsystem

The **EDIFACT** subsystem contains two subsystems: **EDIFACT Inbound** and **EDIFACT Outbound**.

- The **EDIFACT Inbound** subsystem provides sorting, validating, and routing functions for data flowing from external trading partners to internal trading partners.
- The **EDIFACT Outbound** system provides enveloping, validating, and routing functions for data flowing from internal trading partners to external trading partners.

EDIFACT inbound subsystem

The **EDIFACT Inbound** subsystem performs the validation and routing functions on inbound EDIFACT formatted data. The EDI data flows through three primary maps: **Process EDIFACT Inbound**, **edifact_in_alert**, and **EAudit_Inbound**.

- [edifact_in_alert map](#)

edifact_in_alert map

The **edifact_in_alert** map is a common map component used throughout the Message Manager. The **edifact_in_alert** map is configured to send alert notifications through e-mail or pager whenever data is rejected.

In the **EDIFACT Inbound** subsystem, the **edifact_in_alert** map is responsible for sending alert notifications when an error condition occurs in the **Process EDIFACT Inbound**, **edifact_in_alert**, or **EAudit_Inbound** maps. The rejected data is written to the *install_dir\tmgr_vn.n\mmgr\reject* directory and the appropriate form of notification is sent to the user-specified destination.

EDIFACT outbound subsystem

The **EDIFACT Outbound** subsystem performs the enveloping, validating, and routing functions on outbound EDIFACT formatted data. The EDI data flows through two primary maps: the **envedf** map and the **sendedf** map.

- [Send problem data alerts map](#)

Send problem data alerts map

The **Send Problem Data Alerts** map is configured to send alert notifications through e-mail or pager whenever data is rejected.

In the **EDIFACT Outbound** subsystem, the **Send Problem Data Alerts** map is responsible for sending alert notifications when an error condition occurs in the **envedf** or **sendedf** maps. The rejected data is written to the *install_dir\tmgr_vn.n\mmgr\reject* directory and the appropriate form of notification is sent to the user-specified destination.

StampAndSort subsystem

The purpose of the **StampAndSort** subsystem is to route different data types to their appropriate subsystem or map.

For example, if you retrieve a file from a customer's FTP server that contains ANSI X12 EDI data and proprietary flat file format, the **StampAndSort** subsystem regroups similar data types into a single file, then routes them to either the X12 subsystem or a user-defined map or subsystem designed to handle proprietary data.

The **StampAndSort** subsystem also includes the standard error-handling and alert mechanisms for unrecognizable data and an audit function for tracking purposes.

The **StampAndSort** subsystem serves as the entry and exit point for data flowing through Trading Manager.

The three primary functions of the **StampAndSort** subsystem are as follows:

- Send and receive data
 - Prepare the data for processing by assigning it a unique **ThreadID** as its filename
 - Identify databases (EDIFACT, TRADACOMS, and X12)
-
- [ThreadID definition](#)
 - [Inbound data archiving](#)
 - [stampandsortFTP/VAN/Email maps](#)
 - [Creating multiple stampandsortFTP maps](#)
 - [stampandsortfile map](#)
 - [Get file post office and put file post office](#)
 - [stampandsortack map](#)

- [Resend map](#)

ThreadID definition

The **ThreadID** contains the **TransmissionID**. The Trading Manager uses the **ThreadID** to track unique data objects as they pass through the system and to facilitate concurrent processing. The elements of the **ThreadID** are shown below. In this example we will use a typical **ThreadID** for illustrative purposes:

tes0000012000118oi.app

The elements of this **ThreadID** are defined in the following table:

| ThreadID element | Element name | Element description |
|------------------|--------------------------|--|
| tes | Get Post Office Nickname | These first three characters of the file name are the nickname of the Get post office from which the e-commerce data originated. |
| 0000001 | Mailbag Number | Number of different unique files received from a given post office per day. |
| 2000118 | Date received | Date the data goes through the StampAndSort subsystem (when ThreadID gets created). |
| o | Original | This value identifies whether this data is original data (o) going through the Trading Manager for the first time or is data that is being resent (r) through the Trading Manager. See the <i>Partner Manager Reference Guide</i> for information on resending data. |
| i | Direction | The last three characters following the period are the nickname of the Put post office where the e-commerce data is being placed. |
| app | Put Post Office Nickname | The last three characters following the period are the nickname of the Put post office where the e-commerce data is being placed. |

Inbound data archiving

As data is passed thru the Message Manager it is broken up into the respective Interchanges and archived in a specified directory.

To specify an archived directory

1. Click the **Server Directory Configuration** button on the Utilities window.
The Server Directory Configuration Maintenance window appears.
2. Type the desired archive directory in the **Archive** (contains 'in' and 'out' directories) field.
3. Click **Save**.
If you do not specify an archive directory, you will not be able to automatically archive your files. If you do create an archive, data can be edited and resent from the Interchange Traffic.

The archive directory you specify must include **in**, **out**, and **day** directories. For example, *install_dir\tmgr_vn.n\mmgr\archive*.

The archived filename will be **<thread_id>_<interchange_id>.<edi_standard>**.

Where **<thread_id>** is the internal **thread_id** of the transmission, **<interchange_id>** is the Interchange control number, and **<edi_standard>** will be EDIFACT or X12. For example, **0000010200106210000_635.X12**.

This data is used by the resend and editing functionality in Partner Manager and can be zipped or deleted from there. See the Partner Manager documentation for instructions on how to resend data.

stampandsortFTP/VAN/Email maps

The **stampandsortFTP**, **stampandsortVAN**, and **stampandsortEmail** maps are identical with the exception of the communication protocol. The configuration requirements for these three maps are described here, using the **stampandsortFTP** map as a specific example.

The **stampandsortFTP** map is designed to retrieve data using the FTP protocol and to submit that data to the Message Manager. The **stampandsortFTP** map performs the following four tasks:

- Gets data through the FTP resource adapter, using the FTP configuration information you supplied when you defined the **FTP Get** post office. An example FTP command line might be:

```
-URL ftp://ediuser:password@192.1.1.50/receive.txt?type=i
```

- Creates a unique **ThreadID** for the entire FTP transmission (the contents are concatenated as a single data stream if you use the FTP command **MGET**).
- Archives the data retrieved through FTP in the *install_dir\tmgr_vn.n\mmgr\archive\stampapp* directory with an archive name adhering to the archive naming convention requirements.
- Writes the data out to a file as *install_dir\tmgr_vn.n\mmgr\stampec*.mec*. The * represents the valid **ThreadID** assigned to the FTP transmission.

As delivered with the Message Manager, the **stampandsortFTP** map is *not* configured to run by default. The **stampandsortFTP** map does not have time or input event triggers defined. The following procedure describes how to activate the **stampandsortFTP** map.

To activate the stampandsortFTP map

Note: The following procedures assume you have experience with Partner Manager and the Design Studio.

1. Create an **FTP Get** post office in Partner Manager with a valid FTP command line.
(Create post offices using the Partner Manager Post Office navigator. In this navigator window, click Add
See the FTP Adapter documentation for information about valid FTP command lines.)

2. Open the **msg_mgr.msd** system in the Integration Flow Designer.
3. Select the **stampandsortFTP** map component in the **StampAndSort** subsystem.
4. Click the execution settings button on the **stampandsortFTP** map component to display the Launcher Settings window.
5. For the **TimeEvent** setting, add a time event trigger by setting the TimeEvent Switch to **ON** and specifying the Trigger Interval settings.
As discussed in the **export** map documentation, it is recommended that time events for FTP sessions be scheduled to start a few minutes after system startup to ensure the export process has completed before receiving data. You may also consider distributing FTP sessions over time if your systems are bandwidth-constrained.
6. Modify the **Input(s)** information for the #1 **POInfo** input card.
The GET source field for input card 1 (POInfo) of the stampandsort maps need to be updated with a string to indicate the Post Office nickname and the direction as follows **-PON EDI -DIR i**, where PON and DIR are keywords and are case-insensitive. The value for **dir** can be **i** (inbound), or **o** (outbound).
Note: The three-character **PO Nickname** must match the nickname created in Partner Manager. The Message Manager uses this three-letter nickname to create a valid and unique **ThreadID**.

Creating multiple stampandsortFTP maps

About this task

You will need an FTP session for each FTP **Get** post office that you define. You will probably need more than one FTP session to support your e-commerce needs. For each additional FTP location you want to support, create a copy of the **stampandsortFTP** map and repeat the steps in the previous procedure.

You do not need to copy the **stampandsortFTP** map into the **msg_mgr.msd** system definition file. It is recommended that you create a separate system definition file (**.msd**) for all communication maps. Having a separate file allows you to upgrade your core Message Manager at any time without affecting your specific implementation.

To create a copy of **stampandsortFTP** in the Message Manager, perform the following steps:

Procedure

1. Open the **msg_mgr.msd** system in the Integration Flow Designer.
2. Select the **stampandsortFTP** map component in the **StampAndSort** subsystem.
3. From the **Edit** menu, choose **Copy**.
4. From the **Edit** menu, choose **Paste**.
The **Copy** command creates a default map component named **stampandsortFTP(2)**. The **stampandsortFTP(2)** copy is pasted on top of the source **stampandsortFTP** map. Move the **stampandsortFTP(2)** map to view both the source and the duplicate map.
5. Rename the new **stampandsortFTP(2)** map component to uniquely identify this FTP session:
 - Right-click **stampandsortFTP(2)** and select **Edit Map Component**.
 - In the **Component Name** field, enter a new name for the map component.
 - Click **OK**.

Results

As a reminder, the **stampandsortFTP**, **stampandsortVAN** and **stampandsortEmail** maps are identical with the exception of the communication protocol they use. To configure the **stampandsortVAN** or **stampandsortEmail** maps, follow the same steps as outlined, replacing the FTP-specific information with VAN or e-mail equivalents.

stampandsortfile map

The **stampandsortfile** map is similar to the other **Stamp*** maps in that it is responsible for creating a **ThreadID**, archiving the data, and writing the data out for retrieval by the **stampandsortfile** map. The **stampandsortfile** map is unique, however, because it requires no configuration. **stampandsortfile** is pre-configured to trigger on any file event that occurs in the installed **mail** directory specified by the **mmgr_mail** resource name.

The only requirement for correctly implementing File Post Offices is the use of valid file names. Any e-commerce data object must have a valid **ThreadID** to successfully process inbound and outbound data objects. The creation of a valid **ThreadID** is done automatically for the application maps. For the **stampandsortfile** map, however, it is your responsibility to create a valid file-triggering name when writing the data to the **mail** directory. The precise file naming conventions for File Post Office files must be followed.

Get file post office and put file post office

The **stampandsortfile** map is only relevant for **Get** File Post Offices. **Put** File Post Offices are implemented directly within the Message Manager and use the Partner Manager post office definitions to route data.

It is usually a good idea to create multiple physical **Put** File Post Office directories, because they perform a "mailboxing" function as well as a triggering function. When Message Manager receives inbound data, that data is validated and routed to the **Put** post office specified in the trade link. This **Put** post office is usually defined as a File Post Office, although it can be any of the post office types (even VAN). User written application maps are then configured to trigger on the arrival of data in a particular **Put** File Post Office directory. Refer to [Step 13. Add application maps and link to Message Manager](#) for more information on the relationship between the **Put** location and triggering application maps.

When defining **Get** File Post Offices in Partner Manager, it is not necessary to create new physical directories for triggering files. You can define all **Get** File Post Offices to point to the existing folder *install_dir\mmgr_vn.n\mmgr\mail*. The role of the post office and its relationship to physical directory structures is explained in the ["StampAndSort Subsystem"](#) documentation.

There is no benefit to defining multiple physical **Get** File Post Office directories. Using the default *install_dir\tmgr_vn.n\mmgr\mail* directory simplifies your implementation if you are using this default directory for all File post offices. However, you can customize your implementation according to your needs.

stampandsortack map

The Trading Manager uses the **stampandsortack** map when generating Functional Acknowledgements. The **stampandsortack** map is configured to run and requires no user intervention. The **stampandsortack** map can also generate an alert message to the **stampandsortalert** map if the Message Manager should generate an invalid Functional Acknowledgement (**ack**) triggering name.

Resend map

The **resend** map works with the Resend feature in Partner Manager to retrieve previously archived data for resending through the Message Manager. The **resend** map has been configured to run correctly and should require no user intervention.

TRADACOMS subsystem

The **TRADACOMS** subsystem contains two subsystems: **TRADACOMS Inbound** and **TRADACOMS Outbound**.

- The **TRADACOMS Inbound** subsystem provides sorting, validating, and routing functions for data flowing from external trading partners to internal trading partners.
- The **TRADACOMS Outbound** system provides enveloping, validating, and routing functions for data flowing from internal trading partners to external trading partners.

It should be understood that the EDI wizard is not used for managing TRADACOMS standards in the Message Manager system.

TRADACOMS inbound subsystem

The **TRADACOMS Inbound** subsystem performs the validation and routing functions on inbound TRADACOMS formatted data. The EDI data flows through three primary maps: **TRADACOMS Inbound**, **TRADACOMS_in_alert_data**, and **TRADACOMS_Traffic_Inbound**.

- [**TRADACOMS_in_alert_data map**](#)
-

TRADACOMS_in_alert_data map

The **TRADACOMS_in_alert_data** map is a common map component used throughout the Message Manager. The **TRADACOMS_in_alert_data** map is configured to send alert notifications through e-mail or pager whenever data is rejected.

In the **TRADACOMS Inbound** subsystem, the **alert** map is responsible for sending alert notifications when an error condition occurs in the **TRADACOMS Inbound** map. The rejected data is written to the *install_dir\tmgr_vn.n\mmgr\reject* directory and the appropriate form of notification is sent to the user-specified destination.

TRADACOMS outbound subsystem

The **TRADACOMS Outbound** subsystem performs the enveloping, validating, and routing functions on outbound TRADACOMS formatted data. The EDI data flows through two primary maps: the **alert_data** map and the **TRADACOMS_Traffic_Outbound** map.

- [**alert_data map**](#)
-

alert_data map

The **alert_data** map is a common map component used throughout the Message Manager. The **alert_data** map is configured to send alert notifications through e-mail or pager whenever data is rejected.

In the **TRADACOMS Outbound** subsystem, the **alert_data** map is responsible for sending alert notifications when an error condition occurs in the **TRADACOMS_Outbound** map. The rejected data is written to the *install_dir\tmgr_vn.n\mmgr\reject* directory and the appropriate form of notification sent to the user-specified destination.

Value Added Tax (VAT) reports

About this task

The TRADACOMS subsystem (inbound and outbound) will create VAT reports for any invoice type messages. For example: INVOIC, CREDIT, and UTLBIL. The VAT report will automatically be created in the default **C:\install_dir\tmgr_vn.n\mmgr\VAT_Reports** directory.

If you wish to change the default directory, you can change the location in the **Edit Resource** window in the **Resource Registry**.

To change the default directory perform the following steps:

Procedure

1. Open the **Resource Registry**.
 2. Select Open from the File menu and navigate to the *install_dir\tmgr_vn.n\mmgr\mmgr.mrm*
 3. Expand the **mmgr** file.
 4. Expand the **Resources** file.
 5. Double-click the **mmgr_trc_VatReport** file.
The **Edit Resource** window opens.
 6. Edit the **Resource Value** to the desired location.
 7. Click OK.
-

Update subsystem

The **Update** subsystem provides the link between the Partner Manager database and the control files used by the Message Manager. The Partner Manager server database stores all the trading partner information needed to dynamically route, validate, envelope and monitor e-commerce data. This control information needs to be available to the Message Manager during run time to support dynamic routing, validation, and enveloping of data.

The **Update** functions can be scheduled to run as frequently as desired.

At user-defined intervals, configuration, routing and validation information is extracted from the Partner Manager database and made available to the Message Manager through a set of files with a **.tsv** file name extension. These **.tsv** files contain the configuration, routing, and validation information used as data flows through the Message Manager to dynamically route and transform the data for delivery to its final destination.

- **export map**
 - **dbalert map**
-

export map

The **export** map is responsible for extracting the data from the Partner Manager database and updating certain state information. The **export** map is triggered to run immediately each time the Launcher is restarted. The run time of the **export** map varies in duration based on the number of trading relationships defined.

As delivered with Message Manager, the **export** map is also triggered to run each night at approximately 12 AM. If you would like to run the **export** map more or less frequently, change the TimeEvent...Trigger settings in the Launcher Settings window for the **Trigger Every Night** map of the Update subsystem. This will allow you to apply immediate changes. Determining the ideal update frequency is a function of how often trading partners are added or updated. If you follow a process that introduces trading partner relationships once a day, the default setting running the **export** map once a day at midnight may be sufficient. If you require more frequent changes, you may want to run the **export** map every 30 minutes.

The **export** map must complete before you can begin processing data. It is recommended that you schedule any user maps with time event triggers to begin a few minutes after the Launcher startup to ensure the availability of the **.tsv** files.

You can trigger the export to run on demand from Partner Manager without cycling the Launcher. Every time the **export** map runs, any changes to trade link information are updated and made available to the **MessageManager** system. The **MessageManager** controls the transition from the old **.tsv** files to the new ones, so there is not a problem with information changing in the middle of a transaction.

It is not necessary to restart the Launcher when adding new trading relationships for existing version/document combinations. Those trading relationships will be active after the **export** map is run. You must restart the Launcher when adding new version/document combinations, as they require a rebuild of the **sortX12** and **sendX12** maps.

dbalert map

The **dbalert** map monitors the **export** map for error conditions. If an error condition occurs, the **dbalert** map sends an e-mail message with an explanation of the error to the e-mail recipient specified in the first output card. The **dbalert** map also saves a copy of the error information to the *install_dir\tmgr_vn.n\mmgr\reject\dberror.log* file.

You must configure the **dbalert** map with the appropriate mail type and recipient ID before running the **MessageManager** system. By default, the **Alert** output card is configured to write the message to: *install_dir\tmgr_vn.n\mmgr\share\Alert.tmp*. See ["Step 4. Modify the E-Mail Alert Settings"](#).

X12 subsystem

The **X12** subsystem contains two subsystems: **X12 Inbound** and **X12 Outbound**.

- The **X12 Inbound** subsystem provides sorting, validating, and routing functions for data flowing from external trading partners to internal trading partners.

- The **X12 Outbound** system provides enveloping, validating, and routing functions for data flowing from internal trading partners to external trading partners.

X12 inbound subsystem

The **X12 Inbound** subsystem performs the validation and routing functions on inbound ANSI X12 formatted data. The EDI data flows through the **sortx12 map**.

- [sortx12 map](#)
- [X12 FA inbound map](#)
- [X12_In_Alert_Data map](#)

sortx12 map

The **sortx12** map checks the ISA and GS control structures for valid trading partner information.

The **ISA** fields examined include:

- Interchange Sender ID Qualifier
- Interchange Sender ID
- Interchange Receiver ID Qualifier
- Interchange Receiver ID
- Test Indicator

The **GS** fields examined include:

- Functional ID Code
- Application Sender ID
- Application Receiver ID
- Version Release Indicator Code

These values are compared to trade links defined in Partner Manager based on the **Get** post office. If no match is found and an **Unknown Partner** link has not been defined, the data is rejected through the **alert** map.

X12 FA inbound map

The X12 FA Inbound map updates outbound traffic information with the status reflected in inbound Functional Acknowledgements.

X12_In_Alert_Data map

The **X12_In_Alert_Data** map is a common map component used throughout the Message Manager. The **X12_In_Alert_Data** map is configured to send alert notifications through e-mail or pager whenever data is rejected.

In the **X12Inbound** subsystem, the **X12_In_Alert_Data** map is responsible for sending alert notifications when an error condition occurs in the **sortx12** map. The rejected data is written to the *install_dir\tmgr_vn.n\mmgr\reject* directory and the appropriate form of notification is sent to the user-specified destination.

X12 outbound subsystem

The **X12 Outbound** subsystem performs the enveloping, validating, and routing functions on outbound ANSI X12 formatted data. The EDI data flows through the **sendx12** map.

- [x12_out_alert map](#)

x12_out_alert map

The **x12_out_alert** map is a common map component used throughout the Message Manager. The **x12_out_alert** map is configured to send alert notifications through e-mail or pager whenever data is rejected.

In the **X12 Outbound** subsystem, the **x12_out_alert** map is responsible for sending alert notifications when an error condition occurs in the **sendx12** map. The rejected data is written to the *install_dir\tmgr_vn.n\mmgr\reject* directory and the appropriate form of notification sent to the user-specified destination.

Support for proprietary data types

These instructions describe how to add proprietary data types to the Trading Manager, which supports EDI standard and proprietary data types. You can add other user-defined data types to the Trading Manager to take advantage of the Message Manager.

- [Inbound data flow](#)
 - [Adding proprietary data types](#)
-

Inbound data flow

The Message Manager consists of several subsystems that perform specific functions. The Message Manager maps represent a framework for handling e-commerce data. Any data type may enter the Message Manager through one of the resource adapters. Regardless of direction, the e-commerce data always passes through the **StampAndSort** system first. The **StampAndSort** system assigns a unique **ThreadID** to the e-commerce data object to facilitate multithreaded processing. The **ThreadID** also provides a way to track the e-commerce object through the rest of the system. For information on the Message Manager maps and systems, see the Message Manager subsystems documentation in ["Installing and Using Message Manager"](#).

After the **StampAndSort** subsystem processes the e-commerce data, the subsystem receives it for sorting. **StampAndSort** is based on the default **Ecmail.mtt** type tree and uses the partitioning concept to route e-commerce data dynamically based on its type.

The default **Ecmail.mtt** type tree supports ANSI X12, UN/EDIFACT, TRADACOMS and a Trading Manager proprietary data type. **StampAndSort** rejects any other data type as invalid and passes it into the reject handling system.

You may want to add other user-defined data types to Trading Manager to take advantage of the general e-commerce framework.

Adding proprietary data types

About this task

You only need to define enough of the proprietary data structure to make it distinguishable from the other partitioned subtypes.

To add support for a new data type

Procedure

1. Modify the type tree **Ecmail.mtt** to include a new data type **Test** under the partitioned object **M4EC**.
2. Analyze the **Ecmail.mtt** type tree to ensure your new data type is distinguishable.
3. Save the **Ecmail.mtt** type tree.
4. Build the **stampandsortfile** map component in **MessageManager** using the **Integration Flow Designer**.

The Message Manager is now configured to accept proprietary data. For inbound and outbound proprietary data, follow the same rules and naming conventions as you do with EDI data.

To add application processing for proprietary data

Procedure

1. Add your own map or system of maps designed to transform the proprietary data and pass it to an appropriate application.
2. Configure the map to trigger on: **C:\install_dir\tmgr_vn.n\mmgr\sortec*i.Test** (this configuration assumes inbound transmission).
Note: ***i.Test** represents the actual partition name with **Ecmail.mtt**. For instance, if a proprietary data type is added for **NACHA** data formats, the resulting filename from which to trigger would be ***.NACHA**.

Results

Your proprietary data will be processed like any data type in terms of audit trails and alerts. You will be able to track inbound and outbound transmissions in the Reports section of Partner Manager.

Using alias files in maps

Trading Manager maintains three additional pieces of user data when you define an application partner. This data is contained in the Alias Name, User Defined 1, and User Defined 2 fields and maintained in the Partner Manager database.

You may use this data in maps to reference application partner identification and EDI address information. To use this data:

- Define the alias or user defined fields
- Make the alias available to the application maps
- Choose the alias file to use
 - [Defining alias name and user defined fields](#)
 - [Making the alias data available to application maps](#)
 - [Choosing the alias file to use](#)
 - [Alias files type tree \(Alias.mtt\)](#)
 - [Creating user type trees](#)

Defining alias name and user defined fields

About this task

You define alias and user defined fields when you create or edit application trading partners.

For more information on how to specify an alias name and user defined fields for an application partner, see the Partner Manager documentation.

Making the alias data available to application maps

About this task

Every time the Message Manager **export** map runs, any changes to trade link information are updated and made available to the **Message Manager** system. It produces four files when it is run; each file contains information about each application partner, including:

- Alias Name
- User Defined 1
- User Defined 2

Each file contains the same data but the columns are ordered differently within the row and the rows are sorted differently within the file:

| Description | File Name | Row Sort Order |
|-------------------------------------|--------------|----------------------|
| Alias Information by Partner ID | AliasByP.tsv | By ISA Address (X12) |
| Alias Information by Alias Name | AliasByA.tsv | By Alias Name |
| Alias Information by User Defined 1 | AliasBy1.tsv | By User Defined 1 |
| Alias Information by User Defined 2 | AliasBy2.tsv | By User Defined 2 |

The alias files are written to the Message Manager .\tmgr_vn.n\mmgr\share directory.

The Message Manager does not use these files. They are provided to cross-reference information between your application's identification methods and the corresponding EDI addresses. For instance, you might use Alias Name to store your internal customer ID, account number, or client code. Using the appropriate alias files in your application maps, you could move easily between your internal coding systems and your EDI partner addresses.

Choosing the alias file to use

About this task

Because the four alias files are sorted differently, you can choose which file most efficiently finds the application coding value or EDI address value, based on your application needs and how you have defined the alias and user-defined fields in the Partner Manager.

For example, in an inbound EDI application map, you could use **AliasByP.tsv** (alias by partner ID) to get the appropriate alias name or user defined field for the external trading partner. For an outbound EDI application map where your application data contains the account number for each trading partner, use **AliasBy1.tsv** (alias by User Defined 1, if you have defined the User Defined 1 field to contain your account number).

Alias files type tree (Alias.mtt)

The **Alias.mtt** type tree describes the format of each alias file and is installed in the same directory as the Message Manager source maps and trees.

The **Alias.mtt** type tree contains definitions for each alias file:

| Type | Description |
|---------------------|----------------------------|
| AliasByAlias | By Alias Name |
| AliasByPartner | By ISA Address |
| AliasByUserDefined1 | By each User Defined field |
| AliasByUserDefined2 | By each User Defined field |

All four files use the same column definitions; the only difference between each Row definition is the sequence of the columns within the row. The first column corresponds to the sort order of the file.

This type tree can be used in your application maps where you want to use one or more of the alias files.

Creating user type trees

Overview

The User Type trees are created by the EDI Wizard located in Partner Manager. These type trees are for use in your application maps. If you have both X12 and EDIFACT data, two trees will be generated: **x12user.mtt** and **edifuser.mtt**. These trees are generated in the same directory as the mail trees used by Message Manager. The default

location for this is the Message Manager directory: **C:\install_dir\tmgr_vn.n\mmgr**. For information on how to use the EDI Wizard, see the Partner Manager documentation.

The EDI Wizard creates the type trees based on the X12 and EDIFACT inbound and outbound trade links defined in the Partner Manager. It automatically creates a type tree that contains the type definitions for all transaction sets for all versions that the internal trading partners and external trading partners exchange.

Checklists

The following checklists can be used as site preparation and installation checklists and may be reproduced in any form for use with Trading Manager systems.

Server Installation Checklists:

- [Server Installation Checklist for Microsoft SQL Server](#)
- [Server Installation Checklist for Oracle Database](#)
- [Server Installation Checklist for Sybase](#)
- [Server Installation Checklist for IBM DB2 Database](#)

Client Installation Checklists:

Server installation checklist for Microsoft SQL Server

The following checklist identifies the major installation steps required to install and configure Trading Manager for use with a Microsoft SQL Server database. During installation, fill in the specific information in the blanks provided in this list for future reference.

| | |
|------|---|
| ____ | System meets minimum requirements |
| ____ | Machine Name _____ |
| ____ | IP Address _____ |
| ____ | Modem Brand _____ |
| ____ | Modem Model _____ |
| ____ | Modem COM Port _____ |
| ____ | Microsoft SQL Server version 6.5, 7.0 (with Microsoft SQL Server Service Pack 3) or Microsoft SQL Server Version 2000 on the server |
| ____ | Database Device Name _____ |
| ____ | Log Device Name _____ |
| ____ | Database Name _____ |
| ____ | Userid _____ |
| ____ | Password _____ |
| ____ | Install the Launcher |
| ____ | Directory Path _____ |
| ____ | Install Trading Manager Server |
| ____ | Directory Path _____ |

Client installation checklist for Microsoft SQL Server

The following checklist identifies the major steps required to install and configure Trading Manager when connecting to a Microsoft SQL database server. During installation, fill in the specific information in the blanks provided in this list for future reference.

| | |
|------|---|
| ____ | System meets minimum requirements |
| ____ | Microsoft SQL Server database has been constructed on the server |
| ____ | Microsoft SQL Client Services have been installed on each Partner Manager |
| ____ | Check ODBC driver for SQL on each Partner Manager |
| ____ | Install Design Studio |
| ____ | Define ODBC DSN |
| ____ | Install Message Manager - Message Manager Client (either Application or Design) |
| ____ | Directory Path _____ |

Server installation checklist for Oracle database

The following checklist identifies the major installation steps required to install and configure Trading Manager for an Oracle database server. During installation, fill in the specific information in the blanks provided in this list for future reference.

| | |
|------|---|
| ____ | System meets minimum requirements |
| ____ | Machine Name _____ |
| ____ | IP Address _____ |
| ____ | Modem Brand _____ |
| ____ | Modem Model _____ |
| ____ | Modem COM Port _____ |
| ____ | Install Oracle version 7.x, Oracle8.x., Oracle9.x, or Oracle10x on the server |
| ____ | User Name _____ |
| ____ | Password _____ |
| ____ | Install the Launcher |
| ____ | Directory Path _____ |
| ____ | Install Trading Manager Server |
| ____ | Directory Path _____ |

Client installation checklist for Oracle Server

The following checklist identifies the major steps required to install and configure Trading Manager connecting to an Oracle database server. During installation, fill in the specific information in the blanks provided in this list for future reference.

| | |
|------|---|
| ____ | System meets minimum requirements |
| ____ | Oracle database version 7.x, Oracle8.x, or Oracle9.x installed |
| ____ | Oracle Client Utilities have been installed on each Partner Manager |
| ____ | Install ODBC driver for Oracle on each Partner Manager |
| ____ | Install Design Studio |
| ____ | Define ODBC DSN |
| ____ | Install Trading Manager Server |
| ____ | Directory Path _____ |

Server installation checklist for Sybase

The following checklist identifies the major installation steps required to install and configure Trading Manager for a Sybase. During installation, fill in the specific information in the blanks provided in this list for future reference.

| | |
|------|-----------------------------------|
| ____ | System meets minimum requirements |
| ____ | Machine Name _____ |
| ____ | IP Address _____ |
| ____ | Modem Brand _____ |
| ____ | Modem Model _____ |
| ____ | Modem COM _____ |
| ____ | Install Sybase on the server |
| ____ | User Name _____ |
| ____ | Password _____ |

| ----- | Install Trading Manager Server
Directory Path _____ |

Implementing custom X12 versions

This section describes how to implement custom X12 versions such as 004010VICS, 005010RAIL, and/or R2/8.

- [Overview](#)
- [Type trees](#)
- [Partner Manager](#)
- [Message Manager](#)
- [Creating structure records](#)

Overview

Trading Manager uses the **x12mail** Type Tree to validate X12 transactions, and Partner Manager Structure Records to identify segment and data element errors if the transaction fails validation by **x12mail**.

If a custom X12 version is a subset of an ANSI X12 version (for example, 4010VICS is a subset of 4010) Trading Manager will first attempt to use Type Tree and/or structure definitions for the specific subset. If these structure definitions are not found, Trading Manager will use the Type Tree and/or structure definitions for the related ANSI X12 version as long as there also are trade links specified for the functional group ids used in the custom X12 version that are using the ANSI X12 versions. When implementing custom X12 versions, create an **x12mail** Type Tree that includes all of the custom X12 versions to be processed.

You can bypass creating structure records but you should define acknowledgments (997s) to report on the group or transaction level only.

Type trees

For each custom X12 version, a Master Type Tree must be created that follows specific rules so that the EDI Wizard can generate the **x12mail** and **x12user** type trees. These rules are as follows:

- The overall organization of the Type Tree must conform to the organization of the X12 Type Trees contained in the IBM WebSphere Transformation Extender Packs for EDI (See the X12 type trees documentation.)
- Under **Inbound/Outbound Partner Funct'l Group ANSI EDI** the name of the custom group must be **F** followed by the custom version (excluding the leading zeroes). For example, to support 004010VICS the name of the group would be **F4010VICS**. Characters in the version name not supported by the Type Designer should be removed, for example, for **R2/8** the name of the group would be **FR28**.
- The component rule for the GS segment inside the custom group has to have the LEFT function removed and the literal must be the complete version string as it appears in the GS Segment. For example, for **4010VICS** the component rule must read: **VersionReleaseIndustryIDCd Element:\$ = "004010VICS"**
- Under **ANSI EDI** the category that contains the transactions for the custom group must be **V** followed by the custom version (excluding the leading zeroes). For example, to support 004010VICS the name of the category would be **V4010VICS**. Characters in the version name not supported by the Type Designer should be removed, for example, for **R2/8** the name of the category would be **VR28**.

Any changes to the transactions, segments, and/or elements inside the custom category will be picked up by the EDI Wizard and included in the resulting **x12mail** and **x12user** trees.

Versions that contain characters not supported (R2/8) must be manually added to the **x12mail** and **x12user** trees.

Partner Manager

About this task

To define tradelinks using custom X12 versions perform the following steps:

Procedure

1. Start Partner Manager and select **File > Utilities**.
The **Utilities** Navigator opens.
2. Select **Configuration > Standards**.
The Standards Maintenance window opens.
3. Select **X12 Versions** from the **X12 Standards** drop-down menu.
4. Enter the custom X12 version in the **Version** field as it shows in the GS Segment (excluding leading zeroes). For example: to support 004010VICS enter **4010VICS**.
5. Click **Save**.
6. Perform one of the following:
 - copy the Transactions and Functional ID's from any other X12 version
or
 - enter the Transactions and Functional ID's manually (see the Partner Manager documentation for more information).
If the custom version being implemented is a subset of an ANSI version (for example 4010VICS is a subset of 4010) then you do not need to create structure records. If it is not (for example R2/8), then create structure records and load them into Partner Manager. See "[Creating Structure Records](#)".
7. Create X12 tradelinks that use the custom X12 version.
8. Run the EDI Wizard and point to the Master Type Trees created previously.
Versions that contain characters not supported (R2/8) must be manually added to the **x12mail** and **x12 user** trees.

Message Manager

About this task

Once the EDI Wizard has been executed and an **x12mail** Type Tree created, the **RunMaps** system must be deployed. See "[Installing and Using Message Manager](#)."

Creating structure records

About this task

To create Partner Manager Structure Records:

Procedure

1. Locate the **StructureValidation.detl** file, in the **tmgr_vn.n\pmgr** folder and make a copy of it for the custom X12 version. Ensure that the filename extension is **.detl**.
2. Select a set of entries that most resemble the transactions under the custom X12 version you are implementing. Delete all other records.

3. In the records selected, change the first 10 characters in each row to represent the custom X12 version as it shows in the GS Segment (excluding leading zeroes). Ensure that the size of the field remains the same, for example: replace 4010_____ into 4010VICS__ (where _ represents spaces).
4. Ensure that columns 11 and 12 contain the string **T1** then save the updated file.
5. Start Partner Manager and select File> Utilities.
6. Select Configuration>Standards to open the **Standards Maintenance** window.
7. Choose **X12 Structure Validation: Import** from the **X12 Standards** drop-down menu.
8. Click Find File to browse to the directory where you placed the file that you created previously and select the file.
9. Click Begin Import to complete the process.

Results

Contact Trading Manager Support if more complex changes to the Partner Manager Structure Records for the custom X12 version are required.

TPEC to Trading Manager conversion

- [TPECAddressBook.xml file](#)
- [TPECPostOffices.xml file](#)
- [TPECTradelinks.xml file](#)
- [TPEC2CMConfig.txt file](#)
- [Running the TPEC to Trading Manager](#)
- [Setting up the TPEC2CM conversion map](#)
- [Running the "ConvertTPEC2CM" executable map](#)
- [TPEC control number conversion](#)
- [Running the Partner Manager XML Autoload Utility](#)
- [Warnings and error messages](#)
- [TPEC header trailer plug-in for Trading Manager](#)

If you are converting from TPEC, the instructions provided here describe the changes made to Message Manager to support header and trailer data. These changes are supplied as a plug-in to Trading Manager for handling the ability to maintain and wrap outbound messages with header and trailer information.

Overview

The Trading Partner E-Commerce (TPEC) to Trading Manager Conversion tool aids in the migration of X12 trading information from TPEC to Trading Manager. The tool automates the transfer of information related to partners and relationships and reduces the amount of tedious and error prone typing that you are required to do. This tool uses as input a file created using the TPEC Partner Extract and creates three files for Trading Manager XML Autoload. It also creates a report with warnings and errors found during the conversion.

After the tool is executed and the information is loaded into Trading Manager, some level of editing/customization will become necessary. The tool does provide for a configuration file that allows you to set parameters specific to your particular conversion.

TPECAddressBook.xml file

This file contains Partner definitions for Trading Manager. They are grouped into "external partners" (the sending partner of an inbound transaction) and "internal partners" (the receiving partner of an inbound transaction) each one with a unique ISA qualifier and ID combination. It is generated from the Relationship records in TPEC with the partner name from TPEC Partner records, ISA information from the TPEC Interchange records (if present, see the TPEC2CM Configuration File documentation), and GS information from the TPEC Relationship record. The conversion tool will generate as many Trading Manager partners as possible, even if they do not have any TPEC trading specifications defined. The TPEC alias records are not used by the conversion. Please note the following about internal and external partners.

- [Internal partners](#)
- [External partners](#)

Internal partners

- ISA definitions are defaulted since Trading Manager does not validate them.
- Partner names are built from the **ISACompanyPrefix** field in the TPEC2CM Configuration File and the ISA qualifier and ID.
- Application Partner names are built from the **GSCompanyPrefix** field in the **TPEC2CM** Configuration File and the GS ID.

External partners

- ISA definitions are migrated from the TPEC Interchange Records.
- Interchange Control Standard is hard coded to "U" for versions previous to 00402 and to the value specified by **DefaultRepetitionChar** in the TPEC2CM Configuration File for versions 00402 and higher.
- Partner Names are build from either the Corporate ID in the Partner Record or, if not found, from either the TPEC Interchange or TPEC Relationship record as specified by **DefaultPartnerNameFrom** in the TPEC2CM Configuration File. If there are duplicates the ISA Qualifier and ID are appended to the name.
- Application Partner names are built from the Relationship name. If there are duplicates the GS ID is appended to the name.

TPECPostOffices.xml file

This file contains Post Office definitions for Trading Manager. They represent logical inputs and outputs of data and there is no equivalent representation in TPEC. Since they are required, they are generated as follows:

- **Get Post Office:** A single post office is defined for all inbound and outbound data going into Trading Manager. Its nickname is hard coded to "EDI" and the path to the directory is defined in the TPEC2CM Configuration File.
- **Outbound Put Post Office:** A single post office is defined for all outbound data going out from Trading Manager to the external partners. Its nickname is hard coded to "EDO" and the path to the directory is defined in the TPEC2CM Configuration File.
- **Inbound Put Post Office:** One inbound put post office is defined for each unique combination of inbound Functional Group and Version/Release. This simplifies the implementation of the user maps need to convert inbound EDI data into the application format. The nickname is the two-character Functional Group ID plus one character representing an index for the Version/Releases found. These post offices are built from the TPEC Inbound Trading Specs. The conversion tool verifies that each Transaction and Version/Release combination is defined in Trading Manager.

TPECTradelinks.xml file

This file contains Tradelink definitions for Trading Manager. It describes the Functional Groups traded between the partners and has to be loaded last into Trading Manager since it requires CM Partner and Post Office records. It is loosely related to the TPEC Trading Specs records that represent Transactions traded between the Partners. Please note:

- [Inbound functional groups:](#)
- [Outbound functional groups](#)

Inbound functional groups:

- Both Test and Production Interchanges will be accepted and routed.
- Functional Acknowledgments will be configured based on the settings in TPEC. 999 Transaction Acknowledgments are not supported by the conversion tool and will be replaced by 997 Transactions.
- Functional Acknowledgments are configured to have the same GS Version/Release that the acknowledging inbound Functional Group have.
- HIPAA transactions are hard coded for Type 1 validation if the Acknowledge option is turned on in TPEC.
- Validation By is defaulted to Transaction.
- Tradelinks for Inbound Functional Acknowledgments are not generated (not required for CM Internal processing) unless the option is selected in the TPEC2CM Configuration File.
- All transactions in a Functional Group will be validated and routed.

Outbound functional groups

- Outbound Acknowledgements are generated only for those Inbound Tradelinks that have the Acknowledgment option turned on.
- ISA Control Number Scheme is set to "I" (by Interchange).
- GS Control Number Scheme is set to "T" (by Trading Partner).
- ST Control Number Scheme is set to "R" (Relative to the Functional Group).
- Application Format is set to "P" (Partial).
- Validate By is defaulted to "I" (Interchange).
- Last used Control Numbers are not converted from TPEC.

TPEC2CMConfig.txt file

The purpose of the TPEC2CM Configuration file is to allow the user to define parameters to drive the conversion. There are two types of parameters: site-specific constants and override values for fields in the ISA segment. Please note that the beginning and end of the file should not be changed, but entries and comments can be added in between.

Site-specific constants are required to complete the conversion process: they provide values need to successfully create the XML files for the Partner Manager XML Autoload utility. The following site-specific constants are available:

- ISACCompanyPrefix
 - Company Name Prefix for CM internal ISA Partners. Max length allowed is 15 characters.
- GSCompanyPrefix
 - Company Name Prefix for CM internal GS partners. Max length allowed is 15 characters.
- DefaultPartnerNameFrom
 - In TPEC Relationships are supposed to be linked with a Partner definition. In case one is not found the conversion program should default to Interchange (I) or Relationship (R) Records for the CM Partner Name.
- InboundPUTFolder
 - Single folder path for all Inbound PUT Post Offices. Make sure you include the last "\" (or "/" if Unix).
- OutboundPUTFolder
 - Single folder path for the EDO Outbound PUT Post Office. Make sure you include the last "\" (or "/" if Unix).
- GETFolder
 - Single folder path for all inputs into Trading Manager. Should match the StampAndSortFile input directory. Make sure you include the last "\" (or "/" if Unix).
- IgnoreInbound997
 - Inbound 997's are processed internally in Trading Manager. Tradelinks are only required if the user wants to process them into some application of their own. Values are Y/N
- DefaultRepetitionChar

- The ISA Control Standard is hard coded to "U" for ISA Control versions less than "00402". For "00402" and higher this Repetition Character will be hard coded. Character must be defined in ASCII HEX.

Override values are not required. The XML Autoload will verify that the old values for these parameters are valid in Trading Manager and fail if not. If they are not valid the user has the option of adding the failing values to Trading Manager or (by using these parameters) specifying replacement new values that are valid in Trading Manager. The following override values for fields in the ISA segment are available:

```
IchgQual:XX|YY
ElementSeparator:XX|XX
SubElementSeparator:XX|YY
SegmentTerminator:XX|YY
IchgCtrlVerNo:XXXXX|YYYYY
```

In the above values:

- X represents the old TPEC value; Y represents the new CM value.
- Old and New values are fixed length.
- All Old and New values have to be represented in ASCII HEX with the exception of IchgCtrlVerNo that has to be a text string.
- Old SegmentTerminator value is one character long. New value can be up to three characters long represented with a space in between. For example, a terminator of "~<CR><LF>" would be represented as: SegmentTerminator:0A|7E 0D 0A

Running the TPEC to Trading Manager

About this task

Creating the TPEC Partner Extract file

About this task

The conversion tool requires a specific file from TPEC. It can be generated by running the following JCL:

```
//USERIEXT JOB ()
//*****
//** TPJ - DATABASE EXTRACT
//*****
//*
//DBEXT EXEC PGM=TPBDRIVE,REGION=4M,
// PARM='DATABASE-EXTRACT,PROD'
//REPORT DD SYSOUT=*
//TPSVSRT DD SYSOUT=*
//SYSOUT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*
//SYSUDUMP DD SYSOUT=*
//TEPLIB DD DSN=TSI.TP31.GAI.XA.LOAD,DISP=SHR
//STEPLIB DD DSN=TSI.TP31.DEV.XA.LOAD,DISP=SHR
// DD DSN=TSI.TP31.DST.XA.LOAD,DISP=SHR
//TPFORM1 DD DSN=TSI.TP31.D3.DEV.TPFORM1,DISP=SHR
//TPDATA1 DD DSN=TSI.TP31.D3.DEV.TPDATA1,DISP=SHR
//TPFIL11 DD DSN=TSI.TP31.D3.DEV.TPFIL11,DISP=SHR
//TPFIL21 DD DSN=TSI.TP31.D3.DEV.TPFIL21,DISP=SHR
//TPFIL31 DD DSN=TSI.TP31.D3.DEV.TPFIL31,DISP=SHR
//TPSTWK01 DD UNIT=SYSDA,SPACE=(CYL,(10,1))
//----- *
// EBCDIC OUTPUT FILE USED BY THE TPEC2CM CONVERSION TOOL *
//----- *
//EXTRACT DD DSN=USER.TP31.EXTRACT,
```

```

// DISP=(NEW,CATLG),
// UNIT=SYSDA,
// SPACE=(TRK,(50,50),RLSE)
/* -----
/* ASCII OUTPUT FILE NOT USED *
/* -----
//DBXTBLE DD DSN=USER.TP31.DBXTBLE,
// DISP=(NEW,CATLG),
// UNIT=SYSDA,
// SPACE=(TRK,(50,50),RLSE)
//CONTROL DD *
EXTRACT PARTNERS
/*

```

Once the job completes FTP the file created by the EXTRACT DD name in ASCII mode and place it in the **C:\install_dir\tmgr_vn.n_beta\platform_support\tpec2cm** folder. Records are fixed length, make sure no trailing spaces are removed during the FTP.

Setting up the TPEC2CM conversion map

About this task

Before you build the maps that make up this tool please configure/verify:

- The tool uses "update.mdq" from the mmgr directory where the Message Manager source is installed. It provides access to a Trading Manager database that the tool requires. It needs to be configured to point to the target CM database for this conversion process. Due to expected amount of information in the extracted data, MS Access should *not* be used. A test database of the same type as the final target is recommended.
- The target database should not contain any entries in the Address Book, Post Offices, nor Tradelinks.
- The target database has to have the X12 Structure File loaded. If the TPEC system has HIPAA transactions the HIPAA Structure File should also be loaded into the target database before XML Autoload is executed.
- The tool also uses "cmsvc.dll", "m4ecmgmt.mtt", and "mmgr_library.mms" from the mmgr directory where the Message Manager source is installed. Output card 1 (ProcessCB) of executable map "ConvertTPEC2CM" has to point to the mmgr folder.

Running the "ConvertTPEC2CM" executable map

Procedure

- Open **tpec2cm.mms** and locate executable map: **ConvertTPEC2CM**
- Edit input card 1 and point to EXTRACT file FTP'ed from the Mainframe.
- Build ALL maps.
- Run the **ConvertTPEC2CM** executable map.

Results

The map will create three files for the XML Autoload:

- TPECAccountBook.xml**
- TPECPoOffices.xml**
- TPECTradelinks.xml**

The map will also create two log files with information about the conversion:

- TPEC to CM Conversion_xxxx_yyyy_session.xml]**
- ConvertTPEC2CM.log**

The following files are intermediate files useful for conversion debugging:

- PartnerReportFile.txt**
- CleanPartnerReportFile.txt**
- PostOfficeReportFile.txt**
- TradelinkReportFile.txt**
- CleanTradelinkReportFile.txt**

TPEC control number conversion

It is important to note that the TPEC conversion described here does not convert any existing control numbers into the Trading Manager database. The steps provided here describe how to convert those numbers.

It is also important to note that the Control Number Conversion is limited to only X12 Outbound ISA and GS control numbers. The procedure provided here does *not* convert X12 Inbound control numbers, or any EDIFACT/TRADACOMS control numbers. In addition, this procedure does not convert any ST control numbers.

WARNING: Running these steps more than once will overwrite any existing X12 Outbound Control Numbers.

WARNING: This program initializes all X12 Outbound Trade Links in the database to have a GS Scheme of **Increment by Application Partner**, which is the default value. All links are set in this way, even if no control numbers are found in the input **extract** file. Do not use this program if you use a different GS control number scheme.

To perform the conversion, perform the following steps:

1. Confirm the TPEC to Trading Manager conversion as previously described in this documentation has been accomplished successfully.
2. The control number update utility is **CtlNumUpdateForTPEC.exe**. This file is located in your **pmgr** directory. Locate and run this file.
3. Select the same extract file used in the TPEC to Trading Manager conversion as described previously in this documentation.
4. Select **Validation Run** the first time to check your entries. Select **Update** to actually perform the conversion on the database.
5. Enter the database connection information.
6. Select **Begin**.
7. When the program completes, you can print the report by selecting the **Print Report** button, or you can copy the report to your Windows Clipboard by using the context (typically right mouse click) menu on the report contents. Use the **Select All** and **Copy** in the context menu to copy the report to your clipboard. The report lists any records it cannot find, such as IT and RS records in the extract.

Running the Partner Manager XML Autoload Utility

About this task

The XML files created by the conversion map have to be loaded in the order they are listed above. Please note that you might have to run the conversion process several times before you get a clean run. Therefore is best to make a backup of your target database before loading any data. Perform the following steps for each file:

Procedure

1. Copy file **tm82.dtd** from **tmgr_vn.n\pmgr** to the **tpec2cm** folder.
2. Start program **PMAutoLoad.exe** in the **pmgr** folder.
3. Select the appropriate XML input file using the **Find** button.
4. Configure the destination database to match the one configured in the **tpec2cm.mdq** file.
5. Select Validate Only; Do not change Database, **Allow Add**, **Detailed Report**, and **Reject data that exceeds size**.
6. Click Begin.

Results

At this point the XML Autoload will validate the input file for format and content using the target database and any error are reported. Usually there are two types of errors:

- ISA field values that are not supported by Trading Manager. Either update the **TPEC2CMConfig.txt** file or, using the Standards option in Partner Manager, add the unsupported values to Trading Manager.
- Duplicate ISA Qual/ID combinations. This can happen when the new value for "IchgQual" in the TPEC2CM Configuration file is already used by some other partner. This can be resolved by either selecting a new value in the configuration file that is not used or changing the ISA information in TPEC for one of the duplicate partners.

Once the files are valid then proceed with the load by selecting "Run Load" in the XML Autoload. The most typical error during this step is:

- Missing structure files in Trading Manager. Either the structure files have not been loaded into the target database of the TPEC system is using non-standard transaction-version/release combinations. The user must either load or create and load structure files indicated by the errors.

Warnings and error messages

Warnings are created to log issues during processing for information purposes only. Error messages are shown in the following list in bold face type, with an explanation for each following it in regular face type.

- **ID="10001-W">>Relationship: GSSENDER Partner Name: 'ABC COMP' is a duplicate. Replaced with: 'ABC COMP ZZISASENDERID'**
 - In the process of creating external partner names two different ISA Qualifier/ID generated the same Partner Name for Trading Manager. The are made unique by adding the ISA Qual/ID to the name.
- **ID="10003-W">>Relationship: CONTROL Interchange: BENCH ISA Qualifier: AD is invalid. Replaced with: 19**
 - The conversion tool found a TPEC ISA Qualifier that matched an old value in the TPEC2CM Configuration file and replaced it with the indicated new value.
- **ID="10004-W">>Relationship: CONTROL Interchange: BENCH ISA Control Version: 00202 is invalid. Replaced with: 00200**
 - The conversion tool found a TPEC ISA Control Version that matched an old value in the TPEC2CM Configuration file and replaced it with the indicated new value.
- **ID="10005-W">>Relationship: BSS Interchange: BSS Sub Element Delimiter: D7 is invalid. Replaced with: 01**
 - The conversion tool found a TPEC Sub Element Delimiter that matched an old value in the TPEC2CM Configuration file and replaced it with the indicated new value.
- **ID="10006-W">>Relationship: CONTROL Interchange: BENCH Element Delimiter: D7 is invalid. Replaced with: 02**
 - The conversion tool found a TPEC Element Delimiter that matched an old value in the TPEC2CM Configuration file and replaced it with the indicated new value.
- **ID="10007-W">>Relationship: GAPFUNC Interchange: GAPTEST Segment Terminator: B9 is invalid. Replaced with: OD OA**

- The conversion tool found a TPEC Segment Terminator that matched an old value in the TPEC2CM Configuration file and replaced it with the indicated new value.
- **ID="10008-W">Relationship: GSGREG Could not find Partner records for Interchange: ABC. Using ABC**
 - The conversion tool found a Relationship in TPEC that had an associated Interchange record but could not find a Partner record. Usually happens when relationships are defined but no actual Trading Specs are associated to them. A CM Partner definition is still being created.
- **ID="10009-W">Relationship: CONTROL1 Found new GS ID: 'GSRECV'. Created new Application Partner called: 'CONTROL1 GSRECV'**
 - The conversion tool found multiple Relationship records that contain the same GS ID.
- **ID="10010-W">Relationship: KAYBGIN Interchange: KAYBGIN ISA ID: 'FDEX' is a duplicate of an External Partner. Replaced with: '13#FDEX'**
 - While creating internal partners it found ISA information that matches an already defined external partner. The tool created a dummy ISA ID to allow the load but this should be analyzed.
- **ID="10011-W">Relationship: KAYBGIN TradingSpec: 000071 Outbound FA: 999 not supported by this conversion tool. Replaced with 997**
 - The conversion tool does not support 999 Acknowledgments.
- **ID="10012-W">Relationship: HELEN TradingSpec: 000056 FA Relationship: HELEN FA to third party not supported by this conversion tool. Using current Relationship**
 - The conversion tool does not support acknowledgments to third parties. The tool used the current relationship to allow the load but this should be analyzed.
- **ID="20001-C">Relationship: KAYBGIN TradingSpec: 000071 Inbound Transaction: 875 Version/Release: 3020UCS not supported in Trading Manager**
 - Inbound Transaction-Version/Release not supported. No tradelink will be generated. Users have to add this Transaction-Version/Release to Trading Manager to migrate this Trading Spec.
- **ID="20002-C">Relationship: KAYBG TradingSpec: 000166 Outbound Transaction: 875 Version/Release: 3020UCS not supported in Trading Manager**
 - Outbound Transaction-Version/Release not supported. No tradelink will be generated. Users have to add this Transaction-Version/Release to Trading Manager to migrate this Trading Spec.
- **ID="20003-C">Relationship: ERISCO TradingSpec: 000045 Outbound FA: 997 Version/Release: 3032ERISCO not supported in Trading Manager**
 - Outbound Transaction-Version/Release not supported. No tradelink will be generated. Users have to add this Transaction-Version/Release to Trading Manager to migrate this Trading Spec.

TPEC header trailer plug-in for Trading Manager

If you are converting from TPEC, the instructions provided here describe the changes made to Message Manager to support header and trailer data. These changes are supplied as a plug-in to Trading Manager for handling the ability to maintain and wrap outbound messages with header and trailer information.

- [TPEC plug-in requirements](#)
- [Planning the conversion](#)
- [TPEC installation instructions](#)
- [Description of mailbox_bundle components](#)

The following documentation describes those components of the **mailbox_bundle**.

TPEC plug-in requirements

The following conditions are required prior to installing the TPEC plug-in:

- Trading Manager V8.2, or higher is installed
- A Personal Computer with the Trading Manager GUI's installed and running. The GUI's include:
 - Partner Manager
 - PM Copy
 - XML Autoload Utility
- Write/delete access on your Message Manager system
- Trading Manager connecting to either an Access or DB2 database
- The existing "Trading Partner EC to Trading Manager Conversion Tool" has been performed on the databases
- You must have the extract file that was used to perform the existing "Trading Partner EC to Trading Manager Conversion Tool" on the databases

Planning the conversion

The following components are essential to successful TPEC to Trading Manager conversion:

- Trading Partner EC to Trading Manager Conversion Tool – you must have first used this tool to create an XML Autoload file to populate the Trading Manager database. This step is included in the base related product and is not described in documentation provided here.
- Header and trailer conversion must be complete – new tables are populated with header and trailer information from the mailbox records in the TPEC extract used above. This program also creates new 'put' post offices in the Trading Manager database, one for each unique mailbox assigned to an existing trade link. This component of the plug-in is shipped

All components of the conversion can be run only once with the same extract file. If you attempt to run the Trading Partner EC to Trading Manager Conversion tool with the extract file more than once, all existing partners will be rejected in the XML Autoload step. Using the same extract with the header trailer conversion program will either delete and re-create the header trailer data or ignore it, depending on a setting of an on-screen option.

TPEC installation instructions

The procedures described in the following documentation must be performed in the order specified. If an error is returned in any step, do not continue. Contact IBM support. Follow these steps to perform TPEC installation:

1. Under your Trading Manager **mmgr** subdirectory, create the following two subdirectories:

- bundle
 - mailbox_bundle
2. Copy the following files from the **mmgr** directory to the newly created **mailbox_bundle** subdirectory:
- poheader.mdq
 - bundle.msd
 - bundle.mms
 - config.mtt
 - mailbox.conf
 - po_header.mtt
 - potree.mtt

The settings for the system are described as follows:

Description of **mailbox_bundle** components

The following documentation describes those components of the **mailbox_bundle**.

- **mailbox.conf**
This file contains 2 lines of code that indicate where the data to be appended (bundled) prior to header trailer wrapping is to be located, and where it will be located after it is wrapped.
- **config.mtt**
The **config.mtt** file is a type tree that describes the config.txt file derived from the **mailbox.conf**.
- **poheader.mdq**
The **poheader.mdq** is the component that specifies connection to the database where the mailbox information is located.
- **potree.mtt**
The potree.mtt file is the type tree that contains all of the different elements to be used throughout the conversion maps.

mailbox.conf

This file contains 2 lines of code that indicate where the data to be appended (bundled) prior to header trailer wrapping is to be located, and where it will be located after it is wrapped.

The value for both of these lines is:

install_dir\tnmgr_vn.n.n\mmgr\bundle

where *n.n.n* represents the current version of Trading Manager

Changes can be made to the code to point to a different directory structure, but other changes will need to be made in order to accommodate such a change. Also, it is restricted to a file-based destination.

config.mtt

The **config.mtt** file is a type tree that describes the config.txt file derived from the **mailbox.conf**.

poheader.mdq

The **poheader.mdq** is the component that specifies connection to the database where the mailbox information is located.

This should be the same as the **update.mdq** used for the Trading Manager system. A query is defined in this **mdq** file to obtain all of the post offices with header trailer information.

potree.mtt

The potree.mtt file is the type tree that contains all of the different elements to be used throughout the conversion maps.

Partner Manager

The documentation provided here describes Partner Manager, the graphical user interface component of Trading Manager. Partner Manager is used to create a comprehensive database of an organization's electronic commerce (e-commerce) information and to manage its e-commerce activity.

- **Overview**

Partner Manager is a data management system for defining and viewing e-commerce activity. Typically, an e-commerce administrator such as an EDI coordinator uses Partner Manager. As part of Trading Manager, Partner Manager is used to define your trading relationships with your e-commerce partners. Information is

maintained on each trading partner including address information, contact persons, and the individual organizational entities with which you trade business information.

- [Getting started](#)

- [Address books](#)

- [Post Offices](#)

- [Trade links](#)

Trade links contain the partner addresses, post offices used, standards information, control and tracking information, and current test or production status for each individual document that you exchange with that partner

- [Reports](#)

- [Resending E-commerce data](#)

Inbound and outbound data that has been processed by Trading Manager can be viewed and edited. Run the Interchange traffic report to resend the interchange immediately or edit/resend the interchange data.

- [Utilities](#)

- [EDI Wizard](#)

- [Database copy utility](#)

- [Managing traffic data](#)

Overview

Partner Manager is a data management system for defining and viewing e-commerce activity. Typically, an e-commerce administrator such as an EDI coordinator uses Partner Manager. As part of Trading Manager, Partner Manager is used to define your trading relationships with your e-commerce partners. Information is maintained on each trading partner including address information, contact persons, and the individual organizational entities with which you trade business information.

- [Uses for Partner Manager](#)

- [Theory of operation](#)

- [Trade Links and Partner Manager](#)

- [Partner Manager interface](#)

Uses for Partner Manager

Use Partner Manager to perform the following tasks:

- Define post offices; direct links using File Transfer Protocol (FTP), Value Added Networks (VANs), or e-mail to enable you to communicate with your partners
- Define the trading relationships with your EDI partners, including details such as the individual document level for its version, control numbering schemes, tracking, error handling, status, and post office used
- Provide audit and control information collected in the Trading Manager database, which you use to monitor your organization's ongoing inbound and outbound e-commerce transaction activity
- Be alerted to error conditions in e-commerce inbound or outbound processing

Theory of operation

Use Partner Manager to define:

- One or more internal trading partners
- One or more external trading partners
- Two or more post offices
- Trade links to associate internal trading partners with external trading partners
- Information the two trading partners exchange

The information from Partner Manager is shared with the Launcher component of Trading Manager for validating, tracking, and routing, e-commerce data. Information about this e-commerce activity is then incorporated into the Partner Manager database for monitoring and reporting.

Trade Links and Partner Manager

A primary Partner Manager function is the definition of trading relationships, also known as trade links. A trade link consists of four fundamental components:

| | |
|---------------------------------|--|
| Internal Trading Partner | An internal trading partner is defined in the Address Book navigator. This information identifies the EDI settings for an internal entity that sends and receives e-commerce data to and from another organization. Internal trading partners answer the question <i>Who are we?</i> |
| External Trading Partner | An external trading partner is also defined in the Address Book navigator. This information identifies the EDI settings for an entity with which internal trading partners exchange data. External trading partners answer the question <i>Who do we exchange data with?</i> |
| Post Office | A post office identifies where data to be processed by Trading Manager is located and the necessary configuration settings that Trading Manager needs to access that data. Post offices are defined from the Post Offices navigator. Post offices answer the question <i>Where is the data retrieved and routed when its processing is complete?</i> |
| Application | An application identifies the type of messages or documents that are exchanged between an internal and external trading partner. A minimum of one application is defined as part of the Link Wizard from the Trade Links navigator. Other applications can then be defined from the Trade Links navigator. Applications answer the question <i>What types of information do we exchange with a particular trading partner?</i> |

Partner Manager interface

The Partner Manager interface includes navigators, forms, the toolbar, the menu bar, command buttons, an Editor, reports, and right-click context menus.

Partner Manager functions are available from the main menu, right-click functionality, and toolbar.

- [Navigators](#)
- [Toolbar](#)
- [Form area](#)
- [Audit Info button](#)

Navigators

Partner Manager provides four navigators to help you define and view e-commerce information:

- **Address Book** navigator enables you to define trading and application partners. Use this navigator to store information about your internal organization's set of trading partners, your external trading partners, and their departments or application groups
- **Post Offices** navigator enables you to specify routing instructions for inbound data, outbound data, and error reporting. You can define the mail routes, FTP connections, e-mail addresses, or value added networks that you use to exchange data with your trading partners
- **Trade Links** navigator enables you to define trading partner relationships. Trade links connect a trading relationship with specific instructions for routing, error handling, and tracking. Partner Manager wizards help you construct and maintain trade links quickly and easily. Trade links connect you to your trading partner for each document that you trade with that partner.
- **Utilities** navigator contains utilities that allow you to make configuration changes, change database settings, organize trading partner subfolders and to modify security information.

Toolbar

The toolbar is a part of the Partner Manager window that provides you with quick access to various tools to invoke Partner Manager actions.

Form area

The form area displays dialog boxes and forms when you click a navigator folder. You enter trade and application partner, post office, trade link, and other information in the dialog boxes and forms that display here.

Audit Info button

About this task

Audit information is available throughout the Partner Manager; for example, when you edit trading or application partners, the edit dialog box includes an **Audit Info** button. The audit facility tracks the creation and creator of each entity by using a date, time stamp, and the user ID of the person that originally created the entry. This data is also stored in the database to provide an audit trail of all changes. All subsequent changes are logged in the audit database with the date, time, and user ID of the party making the change.

To view audit information:

Procedure

1. Click Audit Info on forms where the button is available.
The **Audit Information** dialog box appears.
2. View the information.
Click OK to close the **Audit Information** dialog box.

Getting started

Procedures described in this chapter enable you to:

- Start Partner Manager from the Start menu
- Start Partner Manager from the Windows desktop using a database-specific icon
- Select a database different from the default Partner Manager database
- Create, edit, and delete a database profile
- Merge and copy databases
- [Starting Partner Manager](#)
- [System requirements](#)

Starting Partner Manager

About this task

Note: Before you start Partner Manager, ensure that you are using the latest open database connectivity (ODBC) drivers from your database vendor. For example, if you are using the Microsoft ODBC Driver for Oracle, you must also install the Oracle Client on the client machine.

- You start the Partner Manager interface from the Windows Start menu or from an icon on your desktop.
- You can also customize the Partner Manager startup configuration to use different database profiles.
- [Starting Partner Manager from the Start menu](#)
- [Starting Partner Manager using a database-specific desktop icon](#)

Starting Partner Manager from the Start menu

About this task

The Partner Manager application may be started from the Start menu or a desktop icon.

To start Partner Manager from the Start menu:

Procedure

From the Start menu, select Programs > IBM WebSphere Transformation Extender n.n > Trading Manager > Partner Manager
Where n.n is the product version number.

Note: If user and group security are used, you must login with a valid user ID. See ["Utilities"](#).
The Partner Manager window opens.

Starting Partner Manager using a database-specific desktop icon

About this task

This technique is useful when you need to run multiple instances of Partner Manager or want to create an icon for each database you use. Information about the current profile in use is available by choosing **About** from the Help menu.

To start Partner Manager by using a database-specific desktop icon

Procedure

1. Create a new database profile.
2. Open Windows Explorer.
3. Select Desktop in the folder navigator.
4. From the File menu, select New > Shortcut.
5. Enter the following in the **Command Line** field of the **Create** Shortcut dialog box:

```
install_dir\tmgr_vn.n\pmgr\partnermanager.exe profile
```

where n.n represents the current Trading Manager version, and *profile* is the case-sensitive database profile you created. See ["Utilities"](#) more information.

6. Click Next and name the shortcut.
7. Click Finish.
8. To start Partner Manager, double-click the shortcut icon on the desktop.

Note: If the profile is incorrect or does not exist, the Partner Manager application uses the most recent valid database connection.

System requirements

The minimum requirements to install and run Partner Manager are:

- Design Studio is required to use the EDI Wizard
- System data source name
- [Database configuration](#)
- [System Data Source Name \(DSN\)](#)

Database configuration

A default Microsoft Access database named **tmgrnn.mdb** is installed in the *install_dir\tmgr_vnn\pmgr* folder as part of the Partner Manager installation program (where *nn* and *n.n* refer to the current Trading Manager version).

The Utilities enables you to select a different database. Other Partner Manager utility procedures enable you to:

- Create, edit, and delete a database profile
- Merge databases
- Copy databases

Note: When entering data in Partner Manager be aware that case sensitivity can vary by Database Vendor and even by database instance. For example, Microsoft Access considers "Acme" to equal "ACME"; most other databases consider these fields unequal. Consult your DBA to determine if your database is case sensitive and plan your database entries accordingly, especially if using Partner Manager's copy and merge functionality between database vendors.

System Data Source Name (DSN)

A system data source name (DSN) is a user-defined name that links a database driver to a database. You must configure a DSN to access the default *install_dir\tmgr_vn.n\pmgr\tmgrnn.mdb* database (where *n.n* and *nn* represent the current Trading Manager version number). The Trading Manager Installation documentation describes how to create and configure a system DSN.

The DSN enables direct access to the database using an application like Partner Manager. When configuring open database connectivity (ODBC) DSN, you must create a DSN for each database to which you connect.

Address books

The **Address Book** navigator is used to define the internal and external trading partners at the corporate, application, departmental, or divisional levels.

Procedures described in this chapter enable you to define:

- Trading partners in your organization
- Trading partners in organizations you do business with

From the **Address Book** navigator, you define trading partners internal and external to your organization. The **Address Book** navigator contains links for these trading partners. Internal links represent how your company is organized to manage your e-commerce relationships. Using these links, you define your company's internal partners, who represent your company as part of a trading partner relationship. External links enable you to define your trading partners in other companies or entities. These are the organizations that you do business with and represent the external trading partnerships that you establish.

- [Trading partner and application partner relationships](#)
- [Trading partners and application partners](#)
- [Configuring internal and external address books](#)
- [Application partners](#)
- [Managing Administrative Contacts](#)

Trading partner and application partner relationships

The trading partner and application partner relationships define how the trading partners and application partner associations are defined in Partner Manager.

- [One trading partner with one application partner](#)
- [Many trading partners with one or more application partners](#)
- [One trading partner with many application partners](#)

One trading partner with one application partner

Your organization may choose to have a single *window on the world* in terms of your EDI profile: that is, defining all EDI address envelopes with a single company EDI address. Typically, companies with a centralized e-commerce function that manages all relationships use this approach.

In Partner Manager, a single trading partner representing a company may be defined with one application partner that represents the entire organization.

Many trading partners with one or more application partners

You can maintain multiple relationships with external trading partners. For example, you may have autonomous divisions who wish to do business under their own name but still share a single EDI system administered by an e-commerce group. In this case, define a new trading partner for each internal entity that requires its own address.

In Partner Manager, a trading partner may be defined for each division of a company. For example, one for Domestic Operations and one for International Operations. One application partner is defined for each trading partner.

One trading partner with many application partners

You may also want to maintain a single company address for the corporate level and separate addresses for each department or division. Define a single internal trading partner name and use the application partner entries to enable you to connect a given department with its trading partners, yet have all mail processed through the corporate partner relationship first. For example, you can define specific trading relationships with your dealer/distributor chain, your suppliers, and your customers. You may also configure relationships for each major application: the Order Entry department as an entity receives all incoming orders; the Billing department processes invoices; and Human Resources handles healthcare enrollments and claims processing.

In this case, you configure a trading partner for the company and an application partner for each division.

Trading partners and application partners

The partners with which your organization exchanges e-commerce data can also be organized using the trading partner and application partner scenarios described in the previous sections.

- [Internal address book](#)
- [External address book](#)
- [Internal trading partner and application partner](#)

Internal address book

Use the **Internal Address Book** to specify address information for partners within your organization.

- **Admin** - contains information about administrative contact persons associated with your organization's e-commerce programs, particular applications or trading partners, Trading Manager, and so on.
- **EDIFACT** - contains the definition of entities within your organization that maintain relationships with external trading partners, based on the Electronic Data Interchange for Administration, Commerce, and Transport (EDIFACT) standard.
- **TRADACOMS** - contains the definition of the entities within your organization that maintain trading relationships with external trading partners, based on the TRADACOMS UN/TDI Standard.
- **X12** - contains the definition of the entities within your organization that maintain trading relationships with external trading partners, based on the ANSI ASC X12 standard.

The EDIFACT, TRADACOMS, and X12 folders can also contain information about contact persons within these internal trading partner organizations. You may add other subfolders to organize internal trading partners into logical groupings by choosing **Folder Utilities** from the Tools menu.

External address book

Use the **External Address Book** to specify address information for partners outside your organization. The **External** folder includes these subfolders:

- **EDIFACT** - contains the definition of entities outside your organization with which your organization maintains relationships, based on the EDIFACT standard. These entities are your trading partners. You may add other subfolders to organize external trading partners into logical groupings.
- **TRADACOMS** - contains the definition of entities outside your organization with which your organization maintains relationships, based on the TRADACOMS UN/TDI Standard. These entities are your trading partners. You may add other subfolders to organize external trading partners into logical groupings.
- **X12** - contains the definition of entities outside your organization with which your organization maintains trading relationships, based on the ANSI ASC X12 standard. These are your trading partners. You may add other subfolders to organize external trading partners into logical groupings.

Internal trading partner and application partner

Select the Internal, **EDIFACT**, **TRADACOMS**, or **X12** folder in the **Address Book** navigator. A dialog box opens.

The **Internal Address Book** is displayed with two list boxes. The **Trading Partner** list contains an entry for each trading partner within your organization. Select a trading partner in the list and the **Application Partner** list shows each application partner of the trading partner.

Trading partners that exchange e-commerce information can be organized for this exchange in several ways. How each trading partner is organized determines the trading partner and application partners that are defined in Partner Manager. The following paragraphs describe certain scenarios.

Configuring internal and external address books

The **Trading Partner** list in the **Address Book** form shows existing trading partners. The **Address Book** form enables you to add, edit, delete, or copy this partner information. You can also access contact information for your trading partners. Add or edit trading partners to define the trading partner EDI information for your company at the corporate level.

The **Application Partner** list in the **Address Book** form shows the application partners for the selected trading partner. The **Address Book** form enables you to add, edit, or delete this partner information. You can also access contact information. Use the **Application Partner** area of the form to add the information for the departments or responsible parties for particular applications. This information is used to create or validate the EDI data envelopes for the trading partner. Define an application partner for each unique address or qualifier within a given trading partner.

Note: An identical dialog box appears when you select the **Internal** or **External** folders for **EDIFACT**, **TRADACOMS**, or **X12**. The following instructions apply to maintaining internal and external trading partner information. Differences between internal and external trading partners are identified.

Adding X12 internal trading partners

About this task

Use the following instructions to add an X12 Internal Trading Partner:

Procedure

1. Select Address Book from the Partner Manager File menu.
2. Click Internal > X12.
The Address Book for Internal X12 window.
3. Click the **Add** button that is located to the right of the **Trading Partner** list box (upper panel).
The **Add X12 Trading/Application Partner In Internal Folder X12** window opens.

The window contains the tabs listed below. Refer to the following sections for a description of the fields displayed in each tab view:

- ["Trading Partner Tab"](#)
 - ["ISA Options Tab"](#)
 - ["Application Partner Tab"](#)
4. Complete all required fields, then complete any optional fields.
Note: The **Trading Partner Name** and **Interchange ID** field are required.
 5. Click Save.
The window closes and the new Trading Partner is added to the listbox in the Address Book for Internal X12 window.
- [Trading Partner tab](#)
 - [ISA Options tab](#)
 - [Application Partner tab](#)

Trading Partner tab

The following fields are contained in the Add X12 Trading/Application Partner In Internal Folder X12 window, with the Trading Partner tab view displayed:

| | |
|-----------------------------|--|
| Trading Partner Name | Enter a name for this trading partner. This name appears in the Trading Partner list, Trade Links dialog box, Traffic reports, and so on. This name must be unique for each trading partner defined, even if they are in different folders. |
| ISA Address | Select the unique two-character qualifier that identifies the coding structure used to define the Interchange ID. This field corresponds to ANSI ASC X12 data element I05. |
| Interchange ID | Enter the unique identification code for this trading partner to be used to route incoming and outgoing data. If the data is outbound from the trading partner, this is the ISA Sender ID. For data inbound to the trading partner, this is the ISA Receiver ID. This field corresponds to ANSI ASC X12 data elements I06 and I07. |

Note: The combination of the ISA address and Interchange ID must be unique across any implemented system of maps.

ISA Options tab

The following fields are contained in the Add X12 Trading/Application Partner In Internal Folder X12 window, with the **ISA Options** tab view displayed:

| Field | Description |
|---|--|
| Interchange Control Version ID | Select the version of the EDI standard that covers the interchange control segments. A default value of 00305 is provided. This field corresponds to ANSI ASC X12 data element I11.
You can add other versions using the X12 Standards Maintenance utility. |
| Interchange Standards ID or Repetition Character | This field takes on two meanings, depending upon the value selected in the Interchange Control Version ID field. If the value in the Interchange Control Version ID field is less than 00402, this field is called the Interchange Standards ID field. If the value is equal to, or greater than 00402, then it changes to become the Repetition Character field. Both field types are optional: the default value is "U" (caret Hex 5E) if the field denotes the Repetition Character; the default value is "U" for the Interchange Standards ID.
Note The dual meaning of this field resulted when the X12 committee stopped using the Interchange Standards ID and replaced it with the Repetition Character starting with Interchange Control version 00402. |

| Field | Description |
|-------------------|--|
| Separators | <p>Element - Select the delimiter used to separate data elements within a segment. A default value of * (asterisk) is provided.</p> <p>Sub Element - Select the delimiter used to separate component data elements within a composite data structure. A default value of : (colon) is provided. The value of this separator must be different than that of the element separator and segment terminator. This field corresponds to ANSI ASC X12 data element I15.</p> <p>Segment Terminator - Select the character used to terminate a segment. A default value of line feed is provided.</p> <p>You can add other separators to these lists using the X12 Standards Maintenance utility.</p> <p>The Separators delimiters provided as the Element, Sub Element, and Segment Terminator are used when generating outbound e-commerce data, including functional acknowledgements.</p> |

Application Partner tab

The following fields are contained in the Add X12 Trading/Application Partner In Internal Folder X12 window, with the **Application Partner** tab view displayed:

| Field | Description |
|----------------------------------|---|
| Application Partner Name | Enter a name for an application partner, such as a division, department or function within the trading partner. This name appears in the Application Partner List , Trade Links dialog box, Traffic reports, and so on. This name must be unique within a trading partner. |
| GS Address | Enter a code identifying the application partner, used to route data to and from it. If the data is outbound from the application partner, GS Address is the GS Sender ID. For data inbound to this application partner, GS Address is the GS Receiver ID. It corresponds to ANSI ASC X12 data elements 142 and 124. This address must be unique within a trading partner. |
| Alias Name | Enter an alias by which the application partner might be known, for instance an abbreviation of the application partner name, and so on. This alias is not used by Partner Manager or the Message Manager but is available for user application maps. Trading Manager validates this information to ensure that the alias name is unique. See the Trading Manager Installation documentation for more information about these files and the alias.mtt type tree. |
| User Defined 1
User Defined 2 | Enter any user-defined information for this application partner; for example, a department number, an internal customer number, and so on. Partner Manager or the Message Manager does not use this data but it is available for user application maps. See the Trading Manager Installation documentation for more information about these files and the alias.mtt type tree. |

Adding X12 external trading partners

About this task

Use the following instructions to add an X12 Internal Trading Partner:

Procedure

1. In the **Address Book** navigator, click External > X12.
The **Address Book for External X12** opens.
2. Click the **Add** button that is located to the right of the **Trading Partner** list box (upper panel).
The **Add X12 Trading/Application Partner In External Folder X12** window opens.

The window contains the tabs listed below. Refer to the following sections for a description of the fields displayed in each tab view:

- ["Trading Partner Tab - External X12"](#)
 - ["ISA Options Tab"](#)
 - ["TA1 Post Offices Tab"](#)
 - ["Authorization/Security Tab"](#)
 - ["Application Partner Tab"](#)
3. Complete all required fields, then complete any optional fields.
Note: The **Trading Partner Name** and **Interchange ID** field are required.
 4. Click Save.
The window closes and the new Trading Partner is added to the listbox in the Address Book for External X12 window.
- [Trading Partner tab - External X12](#)
 - [ISA Options tab](#)
 - [TA1 Post Offices tab](#)
 - [Authorization/Security tab](#)
 - [Application Partner tab](#)

Trading Partner tab - External X12

The following fields are contained in the Add X12 Trading Partner In External X12 window, **Trading Partner** tab view:

| Field | Description |
|----------------------|---|
| Trading Partner Name | Enter a name for this trading partner. This name appears in the Trading Partner list, Trade Links dialog box, Traffic reports, and so on. This name must be unique for each trading partner defined, even if they are in different folders. |

| Field | Description |
|--|--|
| ISA Address | Select the unique two-character qualifier that identifies the coding structure used to define the Interchange ID. This field corresponds to ANSI ASC X12 data element I05. |
| Interchange ID | Enter the unique identification code for this trading partner to be used to route data to and from it. If the data is outbound from the trading partner, this is the ISA Sender ID. For data inbound to this trading partner, this is the ISA Receiver ID. This field corresponds to ANSI ASC X12 data elements I06 and I07. The combination of the ISA address and Interchange ID must be unique across any system of maps you implement. |
| Interchange | When checked, enables checking of duplicate interchange control numbers for this Trading Partner. If a duplicate interchange is found it is rejected. |
| Functional Group within an Interchange | When checked enables checking of duplicate Functional Group control numbers within the interchange for this partner. If a duplicate functional group is found it is then rejected. |
| Transaction within a Functional Group | When checked, enables checking of duplicate transaction control numbers within the functional group for this partner. If a duplicate transaction is found it is then rejected. |
| Last Interchange Control # | Resets the Interchange control number. |

ISA Options tab

The fields in the Add X12 Trading Partner In External X12 window, **ISA Options** tab view are described in ["ISA Options Tab"](#).

TA1 Post Offices tab

The following fields are contained in the Add X12 Trading Partner In External X12 window, **TA1 Post Offices** tab view::

Get

Allows override of the TA1 Get Post Office that was set in Message Manager Configuration. Get Post Office fields can be disabled depending on the setting in the Message Manager configuration.

Put

Allows override of the TA1 Put Post Office that was set in Message Manager Configuration.

Authorization/Security tab

The fields in the Add X12 Trading Partner In External X12 window, **Authorization/Security** tab view are described in the following table:

| Field | Description |
|--|--|
| Authorization Qualifier (Inbound and Outbound) | Enter the two-character qualifier that identifies the coding structure used to define the inbound or outbound Authorization ID. The default value is 00, indicating no authorization information present. This field corresponds to ANSI/ASC/X12 data element I01. |
| Authorization ID (Inbound and Outbound) | Enter the inbound or outbound authorization information for this trading partner to be used for additional identification or authorization of data sent by this trading partner. By default, no authorization information is defined. This field corresponds to ANSI ASC X12 data element I02. |
| Security Qualifier (Inbound and Outbound) | Select the two-character qualifier that identifies the type of information in the Security ID. The default value is 00, indicating there is no security information present. This field corresponds to ANSI ASC X12 data element I03. |
| Password (Inbound and Outbound) | Enter a password if you selected 01 in the inbound or outbound Security Qualifier field. |
| Validate Authorization | Indicates whether or not ISA Authorization information is validated against the Partner Manager database. |
| Validate Security | Indicates whether or not security elements are validated against the Partner Manager database. |

Application Partner tab

The following fields are contained in the Add X12 Trading Partner In External X12 window, **Application Partner** tab view:

| Field | Description |
|--------------------------|---|
| Application Partner Name | Enter a name for an application partner, such as a division, department or function within the trading partner. This name appears in the Application Partner List, Trade Links dialog box, Traffic reports, and so on. This name must be unique within a trading partner. |
| GS Address | Enter a code identifying the application partner, used to route data to and from it. If the data is outbound from the application partner, GS Address is the GS Sender ID. For data inbound to this application partner, GS Address is the GS Receiver ID. It corresponds to ANSI ASC X12 data elements 142 and 124. This address must be unique within a trading partner. |
| Alias Name | Enter an alias by which the application partner might be known, for instance an abbreviation of the application partner name, and so on. This alias is not used by Partner Manager or the Message Manager but is available for user application maps. Trading Manager validates this information to ensure that the alias name is unique. See the Trading Manager Installation documentation for more information about these files and the alias.mtt type tree. |

| Field | Description |
|--------------------------|---|
| User Defined 1 | Enter any user-defined information for this application partner; for example, a department number, an internal customer number, and so on. Partner Manager or the Message Manager does not use this data but it is available for user application maps. See the Trading Manager Installation documentation for more information about these files and the alias.mtt type tree. |
| User Defined 2 | |
| HIPAA Type 7 Institution | Allows selection of HIPAA Institution. |

Adding Internal EDIFACT Trading Partners

About this task

Use the following instructions to add an internal EDIFACT Trading Partner:

Procedure

- In the **Address Book** navigator, click Internal > EDIFACT.
The **Address Book for Internal EDIFACT** opens.
- Click the **Add** button that is located to the right of the **Trading Partner** list box (upper panel).
The **Add EDIFACT Trading/Application Partner In Internal Folder EDIFACT** window opens.

The window contains the tabs listed below. Refer to the following sections for a description of the fields displayed in each tab view:

- [Identification Tab](#)
 - [Syntax/Separators Tab](#)
 - [Application Partner Tab](#)
- Complete all required fields, then complete any optional fields.
Note: The **Trading Partner Name** and **Interchange ID** field are required.
 - Click Save.
The window closes and the new Trading Partner is added to the listbox in the Address Book for Internal EDIFACT window.
- [Identification tab](#)
 - [Syntax/Separators tab](#)
 - [Application Partner tab](#)

Identification tab

The following fields are contained in the Add EDIFACT Trading Partner In Internal EDIFACT window, in the **Identification** tab view:

| Field | Description |
|---|--|
| Trading Partner Name | Enter a name for this trading partner. This name appears in the Trading Partner list, Trade Links dialog box, Traffic reports, and so on. This name must be unique for each trading partner defined, even if they are in different folders. |
| Interchange ID | Enter the unique identification code for this trading partner to be used to route data to and from it. If the data is outbound from the trading partner, this is the Sender ID. For data inbound to this trading partner, this is the Receiver ID. The combination of the Partner Code ID Qualifier and Interchange ID must be unique across any system of maps you implement. |
| Partner ID Code Qualifier | Select the unique two-character qualifier that identifies the coding structure used to define the Interchange ID. |
| Routing Address | Enter a code identifying the application partner, used to route data to and from it. |
| Comm Agreement ID | Enter a code identifying the commercial agreement ID. |
| Enveloping Option (these buttons only appear when you are adding internal partners) | Identify the format of the data that is provided by the application maps that is sent to this trading partner.
Partially Enveloped - the version type and other information have limited information and are to be completed by Trading Manager before routing the EDI data to the trading partner.
Fully Enveloped - The fully enveloped option is provided to support legacy translator support. It allows the user to use existing translators in order to preserve existing interface code, while using Trading Manager for communications and audit purposes. |

Syntax/Separators tab

The following fields are contained in the Add EDIFACT Trading Partner In Internal EDIFACT window, in the **Syntax/Separators** tab view:

| Field | Description |
|------------------------|--|
| Use UNA Segment | Check box if you use the UNA Segment for this Trading Partner. |
| Syntax ID | Select the Syntax ID used for this Trading Partner. Values are: UNOA; UNOB; UNOC; UNOD; UNOE; UNOF; UNOG; UNOH |
| Syntax Version | Enter a number greater than zero and less than 10 denoting the EDIFACT version syntax in use with this Trading Partner. The default is 1. |
| Component Data Element | Select the delimiter used to separate component data elements within a composite data structure. A default value of : (colon) is provided. |
| Data Element | Select a delimiter used to separate data elements within a segment. |
| Segment Terminator | Select the character used to terminate a segment. A default value of line feed is provided. You can add other separators to these lists using the Standards Maintenance utility. |
| Release Indicator | Select the character used to restore separator and terminator signs within the interchange. A default value of ? (question mark) is provided. |
| Decimal Notation | Select the character used for the decimal point within the interchange. A default value of , (comma) is provided. |

| Field | Description |
|--------------------|--|
| Reserved Character | Spare character reserved for future use. A space is provided as the default. |

Application Partner tab

The following fields are contained in the **Add EDIFACT Trading Partner In Internal EDIFACT** window, in the **Application Partner** tab view:

| Field | Description |
|---------------------------------------|---|
| Application Partner Name | [Optional] Enter a name for an application partner, such as a division, department or function within the trading partner. This name appears in the Application Partner List , Trade Links dialog box, Traffic reports, and so on. This name must be unique within a trading partner. |
| UNG Application ID | Enter a UNG segment header application ID identifying the application partner. |
| Application Partner ID Code Qualifier | [Optional] Identify the format of the data that is provided by the application maps that is sent to this trading partner. |
| Alias Name | [Optional] Enter an alias by which the application partner might be known. For example, an abbreviation of the application partner name, and so on. This alias is not used by Partner Manager or the Message Manager but is available for user application maps. Trading Manager validates this information to ensure that the alias name is unique. |
| User Defined 1 | [Optional] Enter any user-defined information for this application partner; for example, a department number, an internal customer number, and so on. Partner Manager or the Message Manager does not use this data but it is available for user application maps. |
| User Defined 2 | |

Adding External EDIFACT Trading Partners

About this task

Use the following instructions to add an external EDIFACT Trading Partner:

Procedure

- In the **Address Book** navigator, click External EDIFACT. The **Address Book for External EDIFACT** opens.
- Click the **Add** button that is located to the right of the **Trading Partner** list box (upper panel). The **Add EDIFACT Trading/Application Partner In External Folder EDIFACT** window opens.

The window contains the tabs listed below. Refer to the following sections for a description of the fields displayed in each tab view:

- [Identification Tab](#)
 - [Syntax/Separators Tab](#)
 - [Application Partner Tab](#)
- Complete all required fields, then complete any optional fields.
Note: The **Trading Partner Name** and **Interchange ID** field are required.
 - Click Save.
The window closes and the new Trading Partner is added to the listbox in the Address Book for External EDIFACT window.
- [Identification tab](#)
 - [Syntax/Separators tab](#)
 - [Application Partner tab](#)

Identification tab

The following fields are contained in the Add EDIFACT Trading/Application Partner In External Folder EDIFACT window in the **Identification** tab view:

| Field | Description |
|---------------------------|--|
| Trading Partner Name | Enter a name for this trading partner. This name appears in the Trading Partner list, Trade Links dialog box, Traffic reports, and so on. This name must be unique for each trading partner defined, even if they are in different folders. |
| Interchange ID | Enter the unique identification code for this trading partner to be used to route data to and from it. If the data is outbound from the trading partner, this is the Sender ID. For data inbound to this trading partner, this is the Receiver ID. The combination of the Partner Code ID Qualifier and Interchange ID must be unique across any system of maps you implement. |
| Partner ID Code Qualifier | Select the unique two-character qualifier that identifies the coding structure used to define the Interchange ID. |
| Routing Address | Enter a code identifying the application partner, used to route data to and from it. |
| Comm Agreement ID | Enter a code identifying the commercial agreement ID. |
| Password | Allows you to enter a password for the Trading Partner. |
| Password Qualifier | Allows you to select a two character qualifier for the password. |
| Duplicate Control | Allows you to select either None , for no duplicate control, or Interchange in order to have duplicate control conducted at the Interchange level. |

| Field | Description |
|--------------------|--|
| Last UNB Control # | Resets the last UNB Control number to a new value. |

Syntax/Separators tab

The following fields are contained in the **Add X12 Trading/Application Partner In External Folder EDIFACT, Syntax/Separators** tab view:

| Field | Description |
|------------------------|--|
| Use UNA Segment | Check box if you use the UNA Segment for this Trading Partner. |
| Syntax ID | Select the Syntax ID used for this Trading Partner. Values are: UNOA; UNOB; UNOC; UNOD; UNOE; UNOF; UNOG; UNOH |
| Syntax Version | Enter a number greater than zero and less than 10 denoting the EDIFACT version syntax in use with this Trading Partner. The default is 1. |
| Component Data Element | Select the delimiter used to separate component data elements within a composite data structure. A default value of : (colon) is provided. |
| Data Element | Select a delimiter used to separate data elements within a segment. |

| Reserved Character | Spare character reserved for future use. A space is provided as the default. |

Application Partner tab

The following fields are contained in the **Add X12 Trading/Application Partner In External Folder EDIFACT, Application Partner** tab view:

| Field | Description |
|---------------------------------------|---|
| Application Partner Name | [Optional] Enter a name for an application partner, such as a division, department or function within the trading partner. This name appears in the, Application Partner List Trade Links dialog box, Traffic reports, and so on. This name must be unique within a trading partner. |
| UNG Application ID | Enter a UNG segment header application ID identifying the application partner. |
| Application Partner ID Code Qualifier | [Optional] Identify the format of the data that is provided by the application maps that is sent to this trading partner. |
| Alias Name | [Optional] Enter an alias by which the application partner might be known. For example, an abbreviation of the application partner name, and so on. This alias is not used by Partner Manager or the Message Manager but is available for user application maps. Trading Manager validates this information to ensure that the alias name is unique. |
| User Defined 1
User Defined 2 | [Optional] Enter any user-defined information for this application partner; for example, a department number, an internal customer number, and so on. Partner Manager or the Message Manager does not use this data but it is available for user application maps. |
| Password | Allows you to enter a password for the Application Partner. |

Adding Internal TRADACOMS Trading Partners

About this task

Use the following instructions to add an internal TRADACOMS Trading Partner:

Procedure

- In the **Address Book** navigator, click Internal > **TRADACOMS**.
The **Address Book for Internal TRADACOMS** opens.
- Click the **Add** button that is located to the right of the **Trading Partner** list box (upper panel).
The **Add TRADACOMS Trading Partner In Internal Folder TRADACOMS** window opens.

The window contains the tabs listed below. Refer to the following sections for a description of the fields displayed in each tab view:

- ["Trading Partner Tab"](#)
 - ["Application Partner Tab"](#)
- Complete all required fields, then complete any optional fields.
Note: The **Trading Partner Name** and **Trading Partner ID** fields are required.
 - Click Save.
The window closes and the new Trading Partner is added to the listbox in the Address Book for Internal TRADACOMS window.
- [Trading Partner tab](#)
 - [Application Partner tab](#)

Trading Partner tab

The following fields are contained in the **Add X12 Trading Partner In Internal Folder TRADACOMS** window in the **Trading Partner** tab view:

| Field | Description |
|----------------------|---|
| Trading Partner Name | Enter a name for this trading partner. This name appears in the Trading Partner list, Trade Links dialog box, Traffic reports, and so on. This name must be unique for each trading partner defined, even if they are in different folders. |
| Trading Partner ID | Enter the unique identification code for this trading partner to be used to route data to and from it. If the data is outbound from the trading partner, this is the Sender Reference or Name. For data inbound to this trading partner, this is the Receiver Reference or Sender Name. |

Application Partner tab

The following fields are contained in the **Add X12 Trading Partner In Internal Folder TRADACOMS** window in the **Application Partner** tab:

| Field | Description |
|----------------------------------|---|
| Application Partner Name | Enter a name for an application partner, such as a division, department, or function within the trading partner. This name appears in the Application Partner List, Trade Links dialog box, Traffic reports, and so on. This name must be unique for each trading partner defined, even if they are in different folders. |
| Application Partner ID | Determined form the SDT (supplier ID composite) and CDT (customer ID composite). |
| Alias Name | Enter an alias by which the application partner might be known. For example, an abbreviation of the application partner name, and so on. This alias is not used by Partner Manager or the Message Manager but is available for user application maps. Trading Manager validates this information to ensure that the alias name is unique. |
| User Defined 1
User Defined 2 | Enter any user-defined information for this application partner; for example, a department number, an internal customer number, and so on. Partner Manager or the Message Manager does not use this data but it is available for user application maps. |

Adding External TRADACOMS Trading Partners

About this task

Use the following instructions to add an external TRADACOMS Trading Partner:

Procedure

1. In the **Address Book** navigator, click External > **TRADACOMS**.
The **Address Book for External TRADACOMS** opens.
2. Click the **Add** button that is located to the right of the **Trading Partner** list box (upper panel).
The **Add TRADACOMS Trading Partner In External Folder TRADACOMS** window opens.

The window contains the tabs listed below. Refer to the following sections for a description of the fields displayed in each tab view:

- ["Trading Partner Tab"](#)
 - ["Application Partner Tab"](#)
3. Complete all required fields, then complete any optional fields.
Note: The **Trading Partner Name** and **Trading Partner ID** field are required.
 4. Click Save.
The window closes and the new Trading Partner is added to the listbox in the Address Book for External TRADACOMS window.

- ["Trading Partner tab"](#)

Trading Partner tab

The following fields are contained in the **Add TRADACOMS Trading Partner In External Folder TRADACOMS** window in the **Trading Partner** tab view:

| Field | Description |
|----------------------|---|
| Trading Partner Name | Enter a name for this trading partner. This name appears in the Trading Partner list, Trade Links dialog box, Traffic reports, and so on. This name must be unique for each trading partner defined, even if they are in different folders |
| Trading Partner ID | Enter the unique identification code for this trading partner to be used to route data to and from it. If the data is outbound from the trading partner, this is the Sender Reference or Name. For data inbound to this trading partner, this is the Receiver Reference or Sender Name. |
| Duplicate Control | Allow duplicate control checking to be set to None , or to be set to Interchange when duplicate control checking is to be performed at the interchange level. |

Editing a Trading Partner

About this task

The Edit Trading Partner window enables you to edit the EDIFACT, TRADACOMS, and X12 fields.

To edit a trading partner

Procedure

1. In the **Address Book** navigator, click Internal > *folder* or External > *folder* to display the **Address Book** form, where *folder* is **EDIFACT**, **TRADACOMS**, or **X12**.
2. Select a trading partner from the **Trading Partner** list.
3. Click **Edit**.
Note: You can also double-click the trading partner name to display the Edit Trading Partner dialog box.
The Edit Trading Partner dialog box appears.
4. Edit any field for a trading partner.
5. Click **Save**.

Copying a Trading Partner

You can copy existing trading partner information to a new trading partner.

Enable the **Copy Application Partners** check box to copy associated application partners information to the new trading partner.

The following information is not copied:

- Application partner **Alias Name**; this record is unique to each application partner
- Contact information associated with the trading and application partners
- Trade links associated with the trading and application partners

To copy a trading partner

1. In the **Address Book** navigator, click **Internal** > *folder* or **External** > *folder* to display the **Address Book** form, where *folder* is **EDIFACT**, **TRADACOMS** or **X12**.
2. Select a trading partner from the **Trading Partner** list.
3. Click **copy**.
The **Copy Trading Partner** window opens.
4. Enter a new trading partner name in the **Trading Partner Name** field. The other required fields vary depending upon whether you are copying X12, EDIFACT or TRADACOMS.
 - For X12 - You must select the new ISA Address
 - For EDIFACT - You must change either the Interchange ID or the Routing Address
 - For TRADACOMS - You must change the Trading Partner ID
5. Change any information in the remaining fields, if required.
6. Enable the **Copy Application Partners** check box if you want the existing application partner information copied to the new trading partner.
7. Click **Save**.
The information is copied to a new trading partner and appears in the Address Book.

Deleting a Trading Partner

About this task

The following procedures describe how to delete a trading partner.

To delete a trading partner

Procedure

1. In the **Address Book** navigator, click Internal > *folder* or External > *folder* to display the **Address Book** form, where *folder* is **EDIFACT**, **TRADACOMS**, or **X12**.
 2. Select a trading partner from the **Trading Partner** list.
 3. Click **Delete**.
The **Trading Partner Delete** form displays.
- Note: This function may delete many records from the database and should be used with care. The **Trading Partner Delete** form displays the impact of this deletion, and after accepted, deletes all records associated with the Trading Partner.
4. Click **Delete** to confirm the removal of the records.
A confirmation appears that asks if it is okay to remove the Trading Partner.
 5. Click **OK**.
A message box opens that tells you the delete was performed successfully.
 6. Click **OK** to close the message box.
The Trading Partner has been successfully deleted and is removed from the Address Book.

Application partners

Application partners are associated with a particular trading partner or application, such as the Billing department. Application partners provide a means of grouping transactions by functional area within an organization.

You can add, edit, and delete application partners.

Application partners are managed in the Internal and External address book for the data type (EDIFACT, TRADACOMS, or X12).

For all application partner management, select the data type (EDIFACT, TRADACOMS, or X12) in the Internal or External address book.

Note: Application partners are required for X12 but are optional for EDIFACT and TRADACOMS.

- [Adding an EDIFACT Application Partner](#)
- [Adding TRADACOMS Application Partners](#)
- [Editing an Application Partner](#)
- [Deleting an Application Partner](#)

Adding an X12 Application Partner

About this task

Use the following instructions to add an internal or external X12 Application Partner

Procedure

1. In the **Address Book** navigator:
 - Click Internal...X12 to add an Application Partner to an Internal Trading Partner.
 - Click External...X12 to add an Application Partner to an Internal Trading Partner.
2. Select a Trading Partner in the **Trading Partner** list box (upper panel).
3. Click the **Add** button that is located to the right of the **Application Partner** list box (lower panel).
The **Add Internal Application Partner for Trading Partner** window opens.
4. Enter information in the fields of this window. See the next section, "[Add X12 Application Partner Window Fields](#)" for field descriptions.
Note: The **GS Address** must be unique within the associated trading partner.
Note: The **Application Partner Name** and **GS Address** fields are required.
5. Click Save.
The new application partner is added and appears in the Application Partner list in the Address Book.

- [Add X12 Application Partner Window fields](#)

Add X12 Application Partner Window fields

The following fields are contained in the X12 Add Internal Application Partner for Trading Partner window:

| Header | Header |
|----------------------------------|---|
| Application Partner Name | Enter a name for an application partner, such as a division, department or function within the trading partner. This name appears in the, Application Partner List , Trade Links dialog box, Traffic reports, and so on. This name must be unique within a trading partner. |
| GS Address | Enter a code identifying the application partner, used to route data to and from it. If the data is outbound from the application partner, GS Address is the GS Sender ID. For data inbound to this application partner, GS Address is the GS Receiver ID. It corresponds to ANSI ASC X12 data elements 142 and 124. This address must be unique within a trading partner. |
| Alias Name | Enter an alias by which the application partner might be known, for instance an abbreviation of the application partner name, and so on. This alias is not used by Partner Manager or the Message Manager but is available for user application maps. Trading Manager validates this information to ensure that the alias name is unique. See the Trading Manager Installation documentation for more information about these files and the alias.mtt type tree. |
| User Defined 1
User Defined 2 | Enter any user-defined information for this application partner; for example, a department number, an internal customer number, and so on. Partner Manager or the Message Manager does not use this data but it is available for user application maps. See the Trading Manager Installation documentation for more information about these files and the alias.mtt type tree. |
| HIPAA Type 7
Institution | Note: This field only appears when you are adding an Application Partner to an X12 External Trading Partner. Allows you to select a type of Healthcare Institution to associate with the Application Partner (for example Medicare). |

Adding an EDIFACT Application Partner

About this task

Use the following instructions to add an internal or external EDIFACT Application Partner

Procedure

1. In the **Address Book** navigator:
 - Click Internal...EDIFACT to add an Application Partner to an Internal Trading Partner.
 - Click External...EDIFACT to add an Application Partner to an Internal Trading Partner.

- Select a Trading Partner in the **Trading Partner** list box (upper panel).
 - Click the **Add** button that is located to the right of the **Application Partner** list box (lower panel).
The **Add Internal Application Partner for Trading Partner** window opens.
 - Enter information in the fields of this window. See the next section, "[Add EDIFACT Application Partner Window Fields](#)" for field descriptions.
Note: The **Application Partner Name** and **UNG Application ID** fields are required.
 - Click Save.
The new application partner is added and appears in the Application Partner list in the Address Book.
- [Add EDIFACT Application Partner window fields](#)

Add EDIFACT Application Partner window fields

The following fields are contained in the Add Internal Application for Trading Partner EDIFACT window in the **Application Partner** tab view:

| Field | Description |
|---------------------------------------|---|
| Application Partner Name | Enter a name for an application partner, such as a division, department or function within the trading partner. This name appears in the , Application Partner List Trade, Links dialog box, Traffic reports, and so on. This name must be unique within a trading partner. |
| UNG Application ID | Enter a UNG segment header application ID identifying the application partner. |
| Application Partner ID Code Qualifier | Identify the format of the data that is provided by the application maps that is sent to this trading partner. |
| Alias Name | Enter an alias by which the application partner might be known. For example, an abbreviation of the application partner name, and so on. This alias is not used by Partner Manager or the Message Manager but is available for user application maps. Trading Manager validates this information to ensure that the alias name is unique. |
| User Defined 1
User Defined 2 | Enter any user-defined information for this application partner; for example, a department number, an internal customer number, and so on. Partner Manager or the Message Manager does not use this data but it is available for user application maps. |
| Password (external EDIFACT only) | This field appears only when you are adding an Application Partner to an external EDIFACT Trading Partner. Allows you to enter a password for the Application Partner. |

Adding TRADACOMS Application Partners

About this task

Use the following instructions to add an internal or external EDIFACT Application Partner

Procedure

- In the **Address Book** navigator:
 - Click **Internal...TRADACOMS** to add an Application Partner to an Internal Trading Partner.
 - Click **External...TRADACOMS** to add an Application Partner to an External Trading Partner.
 - Select a Trading Partner in the **Trading Partner** list box (upper panel).
 - Click the **Add** button that is located to the right of the **Application Partner** list box (lower panel).
The Add Internal Application Partner for Trading Partner window opens.
 - Enter information in the fields of this window. See the next section, "[Add TRADACOMS Application Partner Window Fields](#)" for field descriptions.
 - Click Save.
The new application partner is added and appears in the Application Partner list in the Address Book.
- [Add TRADACOMS Application Partner window fields](#)

Add TRADACOMS Application Partner window fields

The following fields are contained in the Add Internal Application for Trading Partner TRADACOMS window in the **Application Partner** tab view:

| Field | Description |
|----------------------------------|---|
| Application Partner Name | Enter a name for an application partner, such as a division, department, or function within the trading partner. This name appears in the Application Partner List Trade Links dialog box, Traffic reports, and so on. This name must be unique for each trading partner defined, even if they are in different folders. |
| Application Partner ID | Determined from the SDT (supplier ID composite) and CDT (customer ID composite). |
| Alias Name | Enter an alias by which the application partner might be known. For example, an abbreviation of the application partner name, and so on. This alias is not used by Partner Manager or the Message Manager but is available for user application maps. Trading Manager validates this information to ensure that the alias name is unique. |
| User Defined 1
User Defined 2 | Enter any user-defined information for this application partner; for example, a department number, an internal customer number, and so on. Partner Manager or the Message Manager does not use this data but it is available for user application maps. |

Editing an Application Partner

About this task

You can edit application partner definitions.

To edit an application partner

Procedure

1. In the **Address Book** navigator, click Internal > *folder* or External > *folder* to display the **Address Book** form, where *folder* is **EDIFACT**, **TRADACOMS**, or **X12**.
2. Select a trading partner in the **Trading Partner** list to view the associated application partners.
3. Select an application partner in the **Application Partner** list.
4. Next to the **Application Partner** list, click the **Edit** button.
The Edit Application Partner dialog box appears.
5. Edit any field for the application partner.
6. Click Save.

Deleting an Application Partner

About this task

Note: Associated trade links must be deleted from the trading partner **Address Book** before the application partner can be deleted.

To delete an application partner

Procedure

1. In the **Address Book** navigator, click Internal > *folder* or External > *folder* to display the **Address Book** form, where *folder* is **EDIFACT**, **TRADACOMS**, or **X12**.
2. Select a trading partner from the **Trading Partner** list.
3. Select the application partner from the **Application Partner** list.
4. Click Delete and confirm the delete action when prompted.

Managing Administrative Contacts

About this task

Use the **Address Book** to define contacts that are associated with a particular trading partner or particular application partner. You can also define administrative contacts that are not associated with a trading partner. Contact information is useful for defining the person to contact in your organization or your trading partner's organization about issues involving EDI traffic.

Contact information includes identifying individuals or groups of individuals and how to reach them. Providing contact information allows Trading Manager to send error notifications.

These contact types are not associated with a trading or application partner; therefore, the **Alert Options** are not available. Typically, they are people in your organization to contact.

You can add, edit, and delete administrative contacts in the **Admin** address book.

- [Adding a Contact](#)
- [Editing a Contact](#)
- [Deleting a Contact](#)

To add an administrative contact

Procedure

1. In the **Address Book** navigator, select the Internal > Admin folder.
The Contacts for Administration dialog box appears, listing any defined administrative contacts.
2. Click Add.
The Add a Contact dialog box appears.
3. Enter the contact information.
4. Click Save.

To edit an administrative contact

Procedure

1. In the **Address Book** navigator, click the Internal > Admin folder.
2. Select the contact from the **Contacts** list.
3. Click Edit in the Contact List dialog box. The **Edit a Contact** dialog box appears.
4. Edit the contact information.
5. When your contact information is complete, click Save.

To delete an administrative contact

Procedure

1. In the **Address Book** navigator, click the **Internal** Admin folder.
2. Select the contact from the list.
3. Click Delete.
A message box opens that prompts you to confirm the delete.
4. Click Yes.
The contact is deleted.

Adding a Contact

About this task

Use the following procedures to define contacts that are associated with a particular trading partner or particular application partner. You can also define administrative contacts that are not associated with a trading partner.

This information is defined for your convenience and may be used to format e-mail message headers, compose letters using your default word processor, or route data to appropriate people when Alert conditions are detected.

To add a contact

Procedure

1. In the **Address Book** navigator, click Internal > *folder* or External > *folder* to display the **Address Book** form, where *folder* is **EDIFACT**, **TRADACOMS**, or **X12**.
2. Select a partner from the **Trading Partner** list or **Application Partner** list.
3. Click Contacts in the area for the partner selected.
The **Contact List** appears, listing any contacts defined for the selected partner.
4. Click Add in the Contact List dialog box.
The **Add a Contact** dialog box appears.
5. Enter the contact information.
6. Select an alert option from the **Alert Options** group box. (This option is only available for contacts associated with internal trading/application partners).
7. Click OK.
8. Click Save.
 - [E-Mail Check box and Field](#)
 - [Monitor Directory Check box and Field](#)

E-Mail Check box and Field

About this task

If the alert is to be sent by e-mail, enable the **E-Mail** check box and specify the e-mail address to which the alert is to be sent. If you specified an e-mail address on the **Contact** dialog box, that information is automatically displayed in this field.

Monitor Directory Check box and Field

About this task

If the alert is to be sent to a directory location, enable **Monitor Directory**, and specify the directory to which the alert is to be written.

Editing a Contact

About this task

Note: Alert Options are only available when editing information for a contact associated with an internal trading or application partner.
To edit a contact

Procedure

1. In the **Address Book** navigator, click Internal > *folder* or External > *folder* to display the **Address Book** form, where *folder* is **EDIFACT**, **TRADACOMS**, or **X12**.
 2. Select a partner from the **Trading Partner** list or **Application Partner** list.
 3. Click Contacts in the area for the partner selected.
The trading or application partner **Contact** form appears, listing the contacts defined for the selected partner.
 4. Select a contact in the contact list.
 5. Click Edit in the Contacts dialog box.
The Edit Contact dialog box appears.
 6. Edit the contact information including **Alert Options**.
 7. Click Save.
-

Deleting a Contact

About this task

Use the following procedure to delete a contact for a trading or application partner.

To delete a contact

Procedure

1. In the **Address Book** navigator, click Internal > *folder* or External > *folder* to display the **Address Book** form, where *folder* is **EDIFACT**, **TRADACOMS**, or **X12**.
2. Select a partner from the **Trading Partner** list or **Application Partner** list.
3. Click Contacts in the area for the partner selected.
The trading or application partner **Contacts** form appears, listing the contacts defined for the selected partner.
4. Select the contact from the **Contacts** list.

Results

Click Delete and confirm the delete action when prompted

Post Offices

Use the **Post Offices** navigator to define and maintain the routing instructions for inbound and outbound data for Trading Manager. The **Post Offices** navigator is used to define post offices that represent sources and destinations for data flowing to and from Trading Manager.

- [Overview](#)
 - [Viewing Post Offices](#)
 - [Adding Post Offices](#)
 - [Copying Post Offices](#)
 - [Editing Post Offices](#)
 - [Deleting Post Offices](#)
 - [VAN Post Offices Overview](#)
-

Overview

This chapter describes the **Post Offices** navigator and provides instructions for creating and modifying post office information.

Procedures described in this chapter enable you to define:

- Where data from trading partner relationships is transferred
- How data is transferred to and from Trading Manager

A **Get** post office is the source for data that is processed by the Message Manager. A **Put** post office is the destination for data from the Message Manager.

- A **Get** post office is always used to pick up data coming into the Message Manager
 - A **Put** post office is always used to drop off data coming out of the Message Manager
- [File Post Offices](#)
 - [E-Mail post offices](#)
 - [FTP Post Offices](#)
 - [VAN post offices](#)
 - [HTTP post offices](#)
 - [JMS post offices](#)
 - [MessageQ client post offices](#)
 - [MessageQ server post offices](#)
 - [MQSeries client post offices](#)
 - [MQSeries server post offices](#)

- [MSMQ post offices](#)
 - [OracleAQ post offices](#)
-

File Post Offices

Use a File Post Office when data is transferred to or from local directory structures. Configuring a file route post office requires only that you identify a local directory where e-commerce data is **Get** or **Put** without specifying how the file is physically transferred.

- **Get Post Offices** - The Message Manager is configured to execute automatically based on new files created or existing files changed in the directory defined for the File Post Office. This creation or change is known as a file event. Unless Message Manager has been customized, there is only one Get File Directory: the one specified in **mmgr_mail** value. For example, in Windows this is: `install_dir\tmgr_vn.n\mmgr\mail`. Any other get file directory is ignored unless the Launcher and **stampandsortfile** systems have been customized. See the Trading Manager documentation for further information about **stampandsortfile** map systems.
Note: Get post office fields may be disabled depending upon the setting in the Message Manager configuration.
 - **Put Post Offices** - The data resulting from Message Manager processing is written to files in the directory defined for the File Post Office.
-

E-Mail post offices

Use an E-mail Post Office when the source of or destination for e-commerce data is an e-mail message using a MAPI, cc:Mail, Lotus Notes, or Internet mail system. When you define an e-mail post office, Trading Manager uses the e-mail adapter to route mail into or out of the Message Manager. For more information about the E-mail adapter, see the E-mail Adapter documentation.

- **Put Post Offices** - The data resulting from Message Manager processing is routed using the e-mail adapters and the settings defined for the e-mail post office.
-

FTP Post Offices

Use File Transfer Protocol (FTP) Post Offices to get and put files in remote directories using the Internet's FTP communications support. Trading Manager uses the FTP adapter to route files using FTP. For more information about the FTP adapter, see the FTP Adapter documentation.

- **Get Post Offices** - The Message Manager is configured to execute at particular time intervals to retrieve any available data from the remote directories using the FTP adapters and the settings defined for the FTP post office.
Note: Get Post Office fields may be disabled depending upon the setting in Message Manager configuration.
 - **Put Post Offices** - The data resulting from Message Manager processing is routed to the remote location using the FTP adapters and the settings defined for the FTP post office.
 - [Examples of FTP commands](#)
The following are examples of typical FTP commands. In these examples, replace `company` with your company name.
-

Examples of FTP commands

The following are examples of typical FTP commands. In these examples, replace `company` with your company name.

```
-t -URL FTP://abfed1:adiabf@ftp2.company.com/outgoing/$thread$.xxx  
-t -URL FTP://abfed1:adiabf@ftp2.company.com/outgoing/$thread$.Internal_test  
-t -URL FTP://abfed1:adiabf@ftp2.company.com/outgoing/$thread$_internal_test.xxx  
-t -URL FTP://abfed1:adiabf@ftp2.company.com/outgoing/Test_$thread$_somevalue.xxx  
-t -URL FTP://abfed1:adiabf@ftp2.company.com/outgoing/abc.xxx
```

In the first example in the above list, xxx indicates the specific Post Office nickname. In the last example in the list, any file for this Post Office will have the unique name abc.txt and will override any previous one.

VAN post offices

Use VAN Post Offices to send and receive mail asynchronously through a commercial Value Added Network (VAN). VAN adapters must be used to send or receive mail from a Value Added Network by using a scripted session. For more information about the VAN adapter, see the VAN Adapter documentation.

- **Put Post Offices** - The data resulting from Message Manager processing is routed to the remote VAN using the VAN adapters and the settings defined for the VAN post office.
-

HTTP post offices

Use HTTP Post Offices when e-commerce data is being transferred to and from an HTTP(S) web server. If you have a Command Server, a Launcher, or Platform API on one platform, you can use the HTTP adapter to transfer data to an HTTP(S) web server on another platform. For more information about the HTTP adapter, see the HTTP Adapter documentation.

JMS post offices

Use JMS Post Offices when e-commerce data is being transferred to a Java Messaging Service (JMS) compliant system provider. JMS is part of the Java 2 Platform Enterprise Edition (J2EE) standards and defines a standard API for accessing enterprise-messaging systems. Trading Manager uses the Java Message Service Adapter to transfer data to and from JMS systems. For more information about the JMS adapter, see the Java Message Service Adapter documentation.

MessageQ client post offices

Use MessageQ Client Post Offices when BEA MessageQ adapters are used to perform message transformation in the MessageQ environment, including the translation of data between different formats. The BEA MessageQ adapters also control the flow of messages between MessageQ applications. For more information about the BEA MessageQ adapter, see the BEA MessageQ Adapter documentation.

MessageQ server post offices

Use Message Q Server Post Offices when BEA MessageQ adapters are used to perform message transformation in the MessageQ environment, including the translation of data between different formats. The BEA MessageQ adapters also control the flow of messages between MessageQ applications. For more information about the BEA MessageQ adapter, see the BEA MessageQ Adapter documentation.

MQSeries client post offices

Use MQSeries Client Post Offices when transferring e-commerce data between applications using IBM WebSphere applications. IBM WebSphere MQ can move data in heterogeneous computer networks, allowing systems of dissimilar computers to move data to and from each other. The IBM WebSphere MQ client adapter controls the data. For more information about the IBM WebSphere MQ Adapter, see the IBM WebSphere MQ Adapter documentation.

MQSeries server post offices

Use MQ Series Server Post Offices when transferring e-commerce data between applications using IBM WebSphere applications. IBM WebSphere MQ can move data in heterogeneous computer networks, allowing systems of dissimilar computers to move data to and from each other. The IBM WebSphere MQ client adapter controls the data. For more information about the IBM WebSphere MQ Adapter, see the IBM WebSphere MQ Adapter documentation.

MSMQ post offices

Use MSMQ Post Offices when transferring e-commerce data to and from Microsoft Message Queue (MSMQ) servers. For more information about the MSMQ Adapter see the MSMQ Adapter documentation.

OracleAQ post offices

Use OracleAQ Post Offices when e-commerce data is being transferred to and from an Oracle database. See the OracleAQ Adapter documentation.

Viewing Post Offices

About this task

When you select a post office view from the **Post Offices** navigator, you can add, copy, edit, and delete post offices of that type.

To view all post offices

Procedure

1. Open Partner Manager.
2. From the File menu, select Post Offices.
The **Post Offices** navigator opens.
3. Click All Post Offices in the navigator.
The All Post Offices dialog box appears with both **Get** and **Put** post offices displayed.
4. View **Get** or **Put** post offices only by clicking the associated option button in **Post Office Type**.

To view specific post offices

Procedure

Select one of the post office types displayed in the navigator.

For example, when you select E-Mail from the navigator, a list showing only the e-mail post offices opens.

Adding Post Offices

About this task

The following steps describe how to add a post office.

Note: The following instructions are not applicable to File and VAN post offices. If you are adding a File post office, see "[Adding a File Post Office](#)". For VAN post offices see the [Adding a VAN Post Office](#).

To add post offices

Procedure

1. Select one of the post office types displayed in the navigator.

The list of post offices for that adapter is displayed.

2. Click Add.

The **Add Post Office** dialog box appears.

3. Enter the following information:

- a. **Name** - Name for the post office; for example, X12 Data for Processing. The name displays in the Post Offices list and in the drop-down list boxes when maintaining trade links.
- b. **Nickname** - A three-character nickname. A valid, unique nickname is automatically generated based on the **Name** entry. You may use this nickname or assign one of your own. The nickname is used to identify this post office throughout the Trading Manager system.
- c. **Adapter Type** - Select an adapter type.
- d. **Get/Put Indicator** - Select the post office type option.
- e. **Adapter Command String** - Enter an adapter command string; for example:
-PR MAPI -U mzipper -P srhwec9 -TO pbure -RCPT

4. Click Save.

The new post office appears in the **Post Offices** list.

- [Adding a File Post Office](#)
-

Adding a File Post Office

About this task

To add a file post office

Procedure

1. Click File in the **Post Offices** navigator.

The File Post Offices dialog opens.

2. Click Add.

The Add Post Office dialog box opens.

3. Select File from the **Adapter Type** drop-down menu.

4. The Add Post Office dialog box for **File** adapters opens.

Enter information in this dialog box as described in the following table.

| Field | Information to enter or select |
|-------------------|---|
| Name | Name of the file route post office; for example, X12 Data For Processing. The name displays in the Post Offices list and in the Get File Post Office and Put File Post Office lists in the Trade Links navigator. |
| Nickname | A three-character nickname. A valid, unique nickname is automatically generated based on the Name entry. You may use this nickname or assign one of your own. The nickname is used to identify this post office throughout the Trading Manager system. |
| Get/Put Indicator | Select the post office type option. |
| Directory | Enter the path of the directory or folder where files for the file post office are located. Specify a path relative to the directory where the Launcher is installed. It is recommended that you use the default directory (<i>install_dir\tnmgr_n.n\mmgr\file</i>) for all Get file post offices to simplify Message Manager configuration and processing, instead of creating different physical directories for each file route post office. For Put file post offices, however, you may specify different physical directories. |

5. Click Save.

The new post office appears in the **Post Offices** list.

Copying Post Offices

About this task

You can copy post offices.

To copy a post office

Procedure

1. From the File menu, select Post Offices.
The list of all post offices appears.
2. Select a post office from the **Post Offices** list.
3. Click Copy. The Copy Post Office dialog box appears.
4. Specify a new **Name** and **Nickname** for the copy of the existing post office.
5. Edit the other File post office settings as needed.
6. Click Save.
The additional post office appears in the **Post Offices** list.

Editing Post Offices

About this task

You can edit post offices.

To edit a post office

Procedure

1. Select one of the Post Office types displayed in the navigator.
The list of Post Offices for that adapter is displayed.
 2. Select a post office from the list.
 3. Click Edit.
The Edit Post Office dialog box opens.
- Note: When editing the File Post Office, be aware that changing the nickname may cause a conflict with associated trade links. Also, if you change the physical directory, you need to verify that all files have been moved to the new directory.
4. Specify a new **Name** and **Nickname** for the copy of the existing post office.
 5. Edit the other File post office settings as needed.
 6. Click Save.
The additional post office appears in the **Post Offices** list.

Deleting Post Offices

About this task

Note: You cannot delete a post office that is associated with any trade links. You must change the post office for each affected trade link prior to deleting the post office.

To delete a post office

Procedure

1. Select one of the Post Office types displayed in the navigator.
The list of Post Offices for that adapter is displayed.
2. Select the post office that you want to delete from the list.
3. Click Delete and confirm the delete action when prompted.
The post office is removed from the **Post Offices** list.

VAN Post Offices Overview

This section describes how to configure the VAN adapter as well as how to specify options for the Monitor file, as well as how to add, copy, edit, and delete VAN Post Offices.

- [Supported VAN Types](#)
- [Adding a VAN Post Office](#)

Supported VAN Types

The following is a list of supported VAN types:

| | |
|---------------------------------|-------------------------|
| • Advantis (IBM) | • Kleinschmidt |
| • Advantis (Sears) | • EDINet |
| • AT&T | • Sprint |
| • Commerce | • Transettlements |
| • Compuserve | • User-defined networks |
| • GE Information Systems (GEIS) | |

Adding a VAN Post Office

About this task

For more information about the VAN adapter, see the VAN Adapter documentation.

To add a VAN post office

Procedure

1. Select VAN from the list of Post Office types displayed in the navigator.
The VAN Post Offices dialog box opens with all Post Offices associated with the VAN adapter displayed.
2. Click Add.
The **Add Post Office** form appears.
3. Select VAN from the **Adapter Type** drop-down menu.
The Add Post Office dialog box for the **VAN** adapter type opens.
4. Enter information in this dialog box as described in the following table.

| VAN Post Office Field | Information to Enter or Select |
|------------------------|--|
| Name | Name for the post office; for example, X12 Data For Processing . The name displays in the Post Office list and in the Get Mail Post Office and Put Mail Post Office drop-down list box in the Trade Links navigator. |
| Nickname | A three-character nickname. Partner Manager automatically generates a valid, unique nickname based on the Name entry. You may use this nickname or assign one of your own. The nickname is used to identify this post office throughout the Trading Manager system. |
| Adapter Type | Select the VAN adapter type. |
| Get/Put Indicator | Enable the option button for Get Post Office or Put Post Office . |
| Adapter Command String | The command string specified in the VAN configuration setting automatically displays here. |

5. At this point you can either save the Post Office without configuring it, or configure the Post Office before you save it.
 - To save the Post Office without configuring it, click the **Save** button. A confirmation box will open which will ask you to confirm your save. Click OK to close this box and add the Post Office to the scroll list in the VAN Post Offices dialog box.
 - If you want to configure the Post Office, see the next section *Configuring a VAN Post Office*.
- [Configuring a VAN Post Office](#)
- [VAN source configuration](#)
- [Specifying options for the Monitor File](#)
- [Other VAN source configuration options](#)

Configuring a VAN Post Office

About this task

These steps describe how to configure a VAN Post Office.

To configure a VAN Post Office

Procedure

1. Add a VAN Post Office and complete all fields as described in "[Adding a VAN Post Office](#)".
2. Click Configure.
The **VAN Source Configuration** dialog box appears.

Note: All VANs include the **VAN Name**, **Phone**, **User ID**, **Password**, and **Script** fields; some VANs have additional fields to configure.

3. Select the **VAN Name**.

Each supported VAN destination is configured according to VAN requirements. After you select the **VAN Name** from the drop-down list, the configuration dialog box and required fields are customized for each VAN.

4. Enter a numeric **Phone** number for the modem to dial to connect to the VAN.

The numeric phone number cannot contain any spaces, dashes, or parentheses.

5. Enter the **User ID** for the specific VAN account.

6. Enter the **Password** associated with the **User ID**.

7. Enter the **Script** file name or click **Browse** to navigate your file system and select the **Script** file.

The script file contains all the commands and responses to send to the VAN to satisfy the logon requirements of the specific network. You may want to add your own script, create it, and save the file with a **.job** file name extension.

Scripts used as sources for input map cards have a ***_g.job** designation (indicating a **GET**). Scripts used as targets (destinations) for output map cards have a ***_p.job** designation (indicating a **PUT**).

8. Click **OK**.

The VAN adapter command string is built from the information in the VAN Source Configuration dialog box and appears in the **Adapter Command String** field.

9. Click **Save**.

The new VAN Post Office appears in the **Post Offices** list.

VAN source configuration

In addition to defining VAN source information, you can define configuration files, trace file creation, and monitor options.

Click a tab on the VAN Source Configuration dialog box to define:

- **Options** to specify a configuration file other than the default **aplus.cfg**. Leave this field blank.
- **Trace** to specify a trace file name and append option for a trace file containing diagnostic information.
- **Diagnostics** to specify a modem monitor file and overwrite options.

Specifying options for the Monitor File

About this task

You can specify options for the monitor file that override the default settings. The monitor file name is based on the prefix of the associated data file and the **.mon** file extension.

To specify the options for the monitor file

Procedure

1. Add a VAN Post Office as described in ["Adding a VAN Post Office"](#) and click the **Configure** button.
2. Complete all required fields in Connection tab on the VAN Source Connection dialog box as described in ["VAN Source Configuration"](#).
3. Select the **Diagnostics** tab.
4. Select a **Monitor Mode**:
 - a. **NONE** - no monitor file is produced
 - b. **APPEND** - information is added to the existing monitor file each time the adapter is run
 - c. **OVERWRITE** - any existing monitor file is overwritten each time the adapter is run
- 5.
6. Click **OK**.
7. Click **Save**.

Other VAN source configuration options

Two other tabs on the VAN Source Configuration dialog box allow you to set the following options:

- **Options** - allows you to specify a configuration file other than the default **aplus.cfg**. Leave this field blank.
- **Trace** - allows you to specify a trace file name and append option for a trace file containing diagnostic information.

Trade links

Trade links contain the partner addresses, post offices used, standards information, control and tracking information, and current test or production status for each individual document that you exchange with that partner

• [Trade Links Overview](#)

Trade Links Overview

Use the **Trade Links** navigator to define and maintain trading relationships.

The **Trade Links** navigator enables you to coordinate the trading partners, post offices, and additional information to define a trading relationship. The navigator contains **Inbound** and **Outbound** trade links.

This chapter describes how to use the **Trade Links** navigator to define EDIFACT, TRADACOMS, and X12 trade links.

- [Establishing trade links](#)
Establishing trade links is automated by two wizards that guide you through the process, to ensure that the resulting link provides a logical connection.
 - [Exporting trade links](#)
Trade links may be exported into an XML file. Such exports are useful when communicating issues with support, or for your own information extraction needs.
-

Establishing trade links

Establishing trade links is automated by two wizards that guide you through the process, to ensure that the resulting link provides a logical connection.

The **Trade Link Add Wizard** helps you define the trade link in the database. The **EDI Wizard** is used for X12 and EDIFACT trade links. This wizard operates on messages that you define, to produce the correct type tree for the correct version and release of the standard for the Message Manager. The **EDI Wizard** produces two copies of the e-commerce type tree: one tree used by the Message Manager and another tree that is available for your use in application maps.

Exporting trade links

Trade links may be exported into an XML file. Such exports are useful when communicating issues with support, or for your own information extraction needs.

However, due to the complexity of trade links, importing is not currently supported, except by IBM Support using IBM tools. Exporting a trade link will also export to the opposite direction (inbound vs. outbound) trade link if one exists, so that any acknowledgement link is also included. In addition to the trade links, the current configuration settings, post offices, and applicable standards data are included in the XML file so that it reports a current snapshot of your trade link. For more information about the format of the XML generated by the export process, see the XML Autoload Utilities documentation.

To export a trade link:

1. Display any type of trade link desired.
2. Click the **Export** button.
3. Click **OK**.

Note: Export files can be appended to, if desired. If the file selected already exists, you will be given the option to overwrite, or append.

The following objects are not exported during this process:

- Security information, such as user names or passwords
 - Display options
 - Field defaults
 - Traffic
 - Server directory configuration data, such as FTP accounts/passwords
-

Inbound trade links

Inbound indicates that your company (also known as an internal trading partner) is receiving data from another entity (also known as an external trading partner). A basic inbound trade link consists of the following information:

- The external trading partner from which you receive the data.
- Which internal trading partner receives the data.
- Where Trading Manager gets its data (Get post office) and puts its data (Put post office).
- What type(s) of information the two trading partners are exchanging.

-

Adding an X12 Inbound Trade Link

About this task

An inbound trade link is defined as one in which your (external) partner is sending data to you (the internal partner). You are the receiver of the incoming data.

To add an X12 inbound trade link

Procedure

1. From the File menu, select **Trade Links**.
The **Trade Links** navigator appears.
 2. Click Inbound > **X12** in the **Trade Links** navigator.
The X12 Inbound Trade Links window opens.
 3. Click Add Link.
The **X12 Inbound Trade Links Add Wizard** opens.
 4. Follow the on-screen instructions in the Wizard to add an X12 Trade Link.
 5. When you click Finish to complete adding an inbound trade link using the Wizard, the X12 Trade Link: Add Application window opens.
 6. Select a version and functional ID.
 7. Click OK.
You are returned to the X12 Inbound Trade Links window.
 8. Select either the **Test** or **Production** check box to activate the associated **Test Post Office** or **Production Post Office** field.
 9. Select a post office from the drop-down menu on the selected field.
Note: The **Test Post Office** field, and the **Production Post Office** field are mandatory depending upon which Test/Production check boxes are enabled. One of these fields must be completed before you can save the Trade Link.
 10. If you want to make changes to any of the fields in the window related to acknowledgements and validation, click the Acknowledgements/Validate By tab to display those fields.
 11. If you are adding a HIPAA X12 document, click the HIPAA Validation Types tab to display the HIPAA fields.
Note: In the preceding screen, it should be noted that the fields in the **HIPAA Validation Types** area are active only when a HIPAA Version and a Functional ID Code other than FA is selected. These fields display when the HIPAA Validation Types tab is selected. These fields are described in "[Editing a HIPAA X12 Document](#)".
 12. Click Save.
The Trade Link is saved.
-

Editing an X12 Inbound Trade Link

About this task

The following instructions describe how to edit existing trade links.

To edit an inbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, expand **Inbound > X12**.
3. Find the desired trade link by using the search buttons at the top of the window. See "[Searching for an X12 Trade Link](#)" for additional search information.
After making your selection, the Search dialog closes and you are returned to the X12 Inbound Trade Links window.
4. Make your changes.

5. Click Save.
A message box opens that informs you that your updates have been made.

6. Click OK.
The Trade Link is updated.

Copying an X12 Inbound Trade Link

About this task

The following instructions describe how to copy existing trade links.

To copy an inbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, expand **Inbound > X12**.
The **X12 Inbound** Trade Links window opens.
3. Click the **Copy** button in the trading partner area of the window. The Copy X12 Inbound Trade Link window opens.
4. Click **Find All** in the **New 'From' Trading Partner** area to open the X12 Partner Lookup window, or click **Search** for a more refined search.
5. Highlight a trading partner and click **Select**.
6. Click **Find All** in the **New 'To' Trading Partner** area, or click **Search** for a more refined search.
7. Highlight a partner and click **Select**.
8. Click **Begin Copy**.
9. If the link being copied has no acknowledgement partners, a message box opens that informs you that the copy was successful.
10. If the selected link contains an acknowledgement partner, the **Select Acknowledgement Partner** dialog opens.

You have the following options:

- **Set to Same as 'From' Partner** - you can use the same Acknowledgement partner as the new From partner
- **Select a New Acknowledgement Partner** - you select a different Acknowledgement partner; the Partner Lookup dialog box appears if you click this button
- **Set This Application to 'No Acknowledgement'** - you can set the application so that it has no acknowledgement

11. Make your selection and click **OK**.
A message box opens that informs you that the copy was successful.
12. Click **OK** to close the message box.
The Trade Link is copied.

Deleting an X12 Inbound Trade Link

About this task

The following instructions describe how to delete existing trade links.

Note: Deleting a link deletes all applications and transactions associated with the trade link. The delete operation cannot be reversed.

To delete an X12 inbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, expand **Inbound** and **X12**.
3. Find the trade link that you want to delete by using the search buttons at the top of the window. See "[Searching for an X12 Trade Link](#)" for additional search information.
4. Highlight a link.
5. Click **Select**.
6. Click **Delete**.
The **Trade Link Confirmation** message box opens to ask if you really want to delete the trade link.
7. Click **Yes** to delete the trade link, including all applications and transaction sets associated with it.
A message box opens that informs you that the trade link was successfully deleted.
8. Click **OK** to close the message box.

EDIFACT Inbound Trade Links

The section describes how to add, edit, copy, and delete EDIFACT Inbound Trade Links.

- [Adding an EDIFACT Inbound Trade Link](#)
- [Editing an EDIFACT Inbound Trade Link](#)
- [Copying an EDIFACT Inbound Trade Link](#)

- [Deleting an EDIFACT Inbound Trade Link](#)

Adding an EDIFACT Inbound Trade Link

About this task

An inbound trade link is defined as one in which your (external) partner is sending data to you (the internal partner). You are the receiver of the incoming data. To add an EDIFACT inbound trade link, you use the **Link Wizard**.

To add an EDIFACT Inbound Trade Link

Procedure

1. From the File menu, select Trade Links.
The **Trade Links** navigator opens.
2. Click Inbound > **EDIFACT** in the **Trade Links** navigator.
The EDIFACT Inbound Trade Links window opens.
3. Click Add Link.
The **EDIFACT Inbound Trade Links Add Wizard** opens.
4. Follow the on-screen instruction in the Wizard to add an EDIFACT Trade Link. If the EDIFACT trading partners have an application partner, you will be allowed to define whether a UNG should be absent, required, or optional, the default no longer being NO UNG.
5. When you click Finish to complete adding an inbound trade link using the Wizard, the EDIFACT Trade Link: Add Application window opens.
6. Add applications defining the message types you receive from the external trading partner.
7. The **Version/Message Type** group box includes the four components of the EDIFACT version that you defined for the EDIFACT Standard Version.
 - Click Find Version/Message Types to select an existing EDIFACT version, or
 - Select the components from the **Version/Message Type** lists that define the version or message type.
8. Click OK. The EDIFACT Inbound Trade Links window is displayed with the newly added trade link displayed.
9. Click Save.
The EDIFACT Trading Partner is added.

Editing an EDIFACT Inbound Trade Link

About this task

The following instructions describe how to edit existing EDIFACT inbound trade links.

To edit an EDIFACT inbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, expand **Inbound** and select **EDIFACT**.
3. Find the desired trade link by using the search buttons at the top of the window. See ["Searching for an EDIFACT Trade Link"](#) for additional search information.
After you have selected the trading partner that you want to edit, it appears in the EDIFACT Inbound Trade Links window.
4. Make your changes.
5. Click Save.
A message box opens that informs you that your updates have been made.
6. Click OK.
The Trade Link is updated.

Copying an EDIFACT Inbound Trade Link

About this task

The following instructions describe how to copy existing trade links.

To copy an inbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, expand **Inbound** > **EDIFACT**.
3. Click the **Copy** button in the trading partner area of the window. The Copy EDIFACT Inbound Trade Link window opens.
4. Click Find All in the **New 'From' Trading Partner** area to open the EDIFACT Partner Lookup window, or click Search for a more refined search
5. Highlight a trading partner and click Select.

6. Click Find All in the **New 'To' Trading Partner** area, or click Search for a more refined search.
7. Highlight a partner and click Select.
8. Click Begin Copy.
A message box will open to inform you that your copy was successful.
9. Click OK.
The EDIFACT Trading Partner is copied.

Deleting an EDIFACT Inbound Trade Link

About this task

The following instructions describe how to delete existing trade links.

Note: Deleting a link deletes all applications and transactions associated with the trade link. The delete operation cannot be reversed.

To delete an EDIFACT inbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, select **Inbound > EDIFACT**.
The EDIFACT Inbound Trade Link window opens.
3. Find the trade link to be deleted by using the search buttons at the top of the window. See "[Searching for an EDIFACT Trade Link](#)" for additional search information.
After you select the link, the search window closes and you are returned to the EDIFACT Inbound Trade Link window with the selected link displayed.
4. Click **Delete**.
The **Trade Link Confirmation** message box opens to ask if you really want to delete the trade link.
5. Click **Yes** to delete the trade link, including all applications and transaction sets associated with it.
A message box opens that informs you that the trade link was successfully deleted.
6. Click **OK** to close the message box.

TRADACOMS Inbound Trade Links

The section describes how to add, edit, copy, and delete TRADACOMS Inbound Trade Links:

- To add a TRADACOMS Inbound Trade Links, see "[Adding a TRADACOMS Inbound Trade Link](#)".
- To edit a TRADACOMS Inbound Trade Links, see "[Editing TRADACOMS Inbound Trade Links](#)".
- To copy a TRADACOMS Inbound Trade Links, see "[Editing TRADACOMS Inbound Trade Links](#)".
- To delete a TRADACOMS Inbound Trade Links, see "[Deleting TRADACOMS Inbound Trade Links](#)".
- [Adding a TRADACOMS Inbound Trade Link](#)
- [Editing TRADACOMS Inbound Trade Links](#)
- [Copying TRADACOMS Inbound Trade Links](#)
- [Deleting TRADACOMS Inbound Trade Links](#)

Adding a TRADACOMS Inbound Trade Link

About this task

An inbound trade link is defined as one in which your (external) partner is sending data to you (the internal partner). You are the receiver of the incoming data. The procedure uses the **Link Wizard**.

Note: Because application partners are optional in TRADACOMS, if SDT/CDT segments are expected, select the trading partner that also has an application partner associated with it.

To add a TRADACOMS inbound trade link

Procedure

1. From the File menu, select **Trade Links**.
The **Trade Links** navigator opens.
2. Click **Inbound > TRADACOMS** in the **Trade Links** navigator.
The TRADACOMS Inbound Trade Links window opens.
3. Click **Add Link**.
The **TRADACOMS Inbound Trade Links Add Wizard** opens.
4. Follow the on-screen instruction in the Wizard to add a TRADACOMS Trade Link.
5. When you click **Finish** to complete adding an inbound trade link using the Wizard, the TRADACOMS Trade Link: Add Application window opens.

6. Select a Document Type by selecting a type from the **Document Type** field drop-down menu.
You can access a list of all TRADACOMS document types by clicking the **Find** button.
7. Click OK.
The TRADACOMS Trade Link: Add Application window closes and you are returned to the TRADACOMS Inbound Trade Links window with the Application tab displayed.
8. Select a Get Post Office using the **Get Post Office** field drop-down menu.
Note: The **Get Post Office** field is mandatory and must be entered before the Trade Link can be saved.
9. Select a Put Post Office.
If the **Test** check box is enabled, you must enter a Post Office in the **Test Put Post Office** field

If the **Production** check box is enabled, you must enter a Post Office in the **Production Put Post Office** field.

Note: The **Get Post Office** and **Production Put Post Office** fields are mandatory depending upon which Test/Production check boxes are enabled. One of these fields must be completed before you can save the Trade Link.
10. If you want to make changes to customer or supplier details, click the SDT/CDT & VAT tab.
11. Click Save.
The **Trade Link Saved** message box opens to inform you that the trade link is saved.
12. Click OK.
The message box closes and the Trade Link is saved.

Editing TRADACOMS Inbound Trade Links

About this task

The following instructions describe how to edit existing EDIFACT inbound trade links.

To edit a TRADACOMS inbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator select **Inbound >TRADACOMS**.
3. Find the trade link to be edited by using the search buttons at the top of the window. See "[Searching for a TRADACOMS Trade Link](#)" for additional search information.
After you have selected the trading partner that you want to edit, it appears in the TRADACOMS Inbound Trade Links window.
4. Make your changes.
5. Click Save.
A message box opens that informs you that your updates have been made.
6. Click OK.
The Trade Link is updated.

Copying TRADACOMS Inbound Trade Links

About this task

The following instructions describe how to copy existing trade links.

To copy a TRADACOMS inbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, expand **Inbound > TRADACOMS**.
The TRADACOMS Inbound Trade Link window opens.
3. Click the **Copy** button in the trading partner area of the window.
The Copy TRADACOMS Inbound Trade Link window opens.
4. Click Find All in the **New 'From' Trading Partner** area to open the TRADACOMS Partner Lookup window, or click Search for a more refined search
5. Highlight a trading partner and click Select.
6. Click Find All in the **New 'To' Trading Partner** area, or click Search for a more refined search).
7. Highlight a partner and click Select.
8. Click Begin Copy.
A message box will open to inform you that your copy was successful.
9. Click OK.
The TRADACOMS Trade Link is copied.

Deleting TRADACOMS Inbound Trade Links

About this task

The following instructions describe how to delete existing trade links.

Note: Deleting a link deletes all applications and transactions associated with the trade link. The delete operation cannot be reversed.

To delete a TRADACOMS inbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, select **Inbound > TRADACOMS**.
3. Find the desired trade link by using the search buttons at the top of the window. See "[Searching for a TRADACOMS Trade Link](#)" for additional search information.
After you have selected the trade link to be deleted, the search window closes and you are returned to the TRADACOMS Inbound Trade Link window with the selected trade link displayed.
4. Click **Delete**.
The **Trade Link Confirmation** message box opens to ask if you really want to delete the trade link.
5. Click **Yes** to delete the trade link, including all applications and transaction sets associated with it.
A message box opens that informs you that the trade link was successfully deleted.
6. Click **OK** to close the message box.

Inbound trade link applications

One or more business documents are exchanged between an internal and external trading partner, with each business document defined as an application within the trading relationship. The initial applications are added when you run the **Inbound Trade Links Wizard**. You can add more applications for a given external and internal trading partner from the Inbound Trade Links: Partner View dialog box.

- [X12 Inbound Trade Link Applications](#)
- [EDIFACT Inbound Trade Link Applications](#)
- [TRADACOMS Inbound Trade Link Applications](#)

Refer to the following procedures to add, edit, and delete TRADACOMS Inbound Trade Link Applications.

X12 Inbound Trade Link Applications

Refer to the following procedures to add, edit, and delete X12 Inbound Trade Link Applications.

- [Adding an X12 Inbound Trade Link Application](#)
- [Editing an X12 Inbound Trade Link Application](#)
- [Editing a HIPAA X12 document](#)
- [Deleting an X12 Inbound Trade Link Application](#)

Adding an X12 Inbound Trade Link Application

About this task

One or more business documents are exchanged between an internal and external trading partner, with each business document defined as an application within the trading relationship.

The initial applications are added when you run the **Inbound Trade Links Wizard**. You can add more applications for a given external and internal trading partner from the Inbound Trade Links: Partner View dialog box.

Use the following instructions to add a new X12 application for a trade link.

To add a new X12 inbound trade link application

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator select **Inbound > X12**.
The X12 Inbound Trade Links window opens.
3. Click the Applications tab.
The Applications tab view opens.
4. Click Add Application.
The X12 Trade Link: Add Application window opens.

5. Select a Version and Functional ID then click OK.
 6. Specify the data state to be exchanged. At least one of the two check boxes must be checked
 - Enable **Test**, if exchanging test data
 - Enable **Production**, if exchanging production data
 7. If you enabled the **Test** or **Production** indicators, choose the **Put Post Office** where the application-ready EDI data received in Test or Production mode is placed.
 8. If desired you can click the Acknowledgements/Validate By tab and enter any information. Refer to the X12 Functional Acknowledgement table following these procedures for a description of the X12 FAs.
 9. If you are adding a HIPAA Inbound Trade Link Application, click the HIPAA Validation Types tab and set the fields as desired. Refer to "[Editing a HIPAA X12 Document](#)" for more information.
 10. If you do not want to perform data validation, but you want to route the data, check the **Route Only; No Validation** check box. See [Route only option](#), for more information.
 11. Click Save.
- The X12 Inbound Trade Links window displays the new trade link application in the list.
- [Route only option](#)
- The route only option does not ignore all possible errors in the data file.

Levels of X12 Functional Acknowledgement (FA)

About this task

The following are levels of X12 functional acknowledgements:

| Level | Description |
|------------------------|--|
| No Acknowledgement | No FA is sent |
| Functional Group Level | An FA is sent acknowledging receipt of the functional group, providing details of the inbound data to only the functional group (AK1) level. |
| Transaction Set Level | An FA is sent acknowledging receipt of the functional group, providing details of the inbound data to the transaction set (AK2) level. |
| Segment Level | An FA is sent acknowledging receipt of the functional group, providing details of the inbound data to the segment (AK3) level. |
| Data Element Level | An FA is sent acknowledging receipt of the functional group, providing details of the inbound data to the data element (AK4) level. |

If you select an FA to be sent, specify the receiving external trading partner. By default, functional acknowledgements are sent to the X12 external trading partner in the trade link.

To send acknowledgements to an address other than the external trading partner

Procedure

1. In the X12 Inbound Trade Link window Application tab view
 2. Click the **Find Ack To** button
 3. The X12 Partner Lookup in Folder window opens.
 4. Enter search criteria in the window, then click Execute to display partners.
 5. Click Select to close the Lookup window.
- The X12 Inbound Trade Links window displays the new application.

Route only option

The route only option does not ignore all possible errors in the data file.

Tradelink errors, envelope errors, and structural errors that do not allow data to be recognized as valid recognizable data are *not* handled by the **Route only** option. These errors are captured in the **stampandsort** map. The function of this map is to create a tradelink, validate the envelope recognized supported type of data to be processed by Trading Manager (X12; EDIFACT; TRADACOMS), and to create the temporary files that the remaining Trading Manager validation process uses.

During each tradelink validation process (maps **sendxx** or **sortxx**), the logic determines if the flag for Route Only was set 'up'. If not, the logic continues to validate each transaction segment to report validation results within the acknowledgement and/or rejection files. If the Route Only option is turned 'on', the acknowledgments/rejects will not get created if there are errors in the data within transaction segments.

A typical example of this scenario would be the presence of BIN segments. A BIN segment consists of two elements, BIN01 and BIN02. BIN01 is a numeric value that should indicate the size of element BIN02 so that it is known where this element ends. The reason is that the BIN02 is a binary element, and it might contain characters that match any of the delimiters or other segment initiators. If the BIN01 element is incorrect, the parsing of this segment will result in a structurally invalid X12 file, thus the data will fail to be recognized during the initial process where the ROUTE only option is still not in effect.

Editing an X12 Inbound Trade Link Application

About this task

To edit an inbound X12 inbound trade link application

Procedure

1. From the File menu, select **Trade Links**.
 2. In the **Trade Links** navigator select **Inbound > X12**.
- The X12 Inbound Trade Links window opens.
3. Click the Applications tab.
 4. Select a trade link application from the list.

5. Make changes to any of the fields in **Post Offices/Routing: Acknowledgements/Validate By**; and **HIPAA Validation Types** (HIPAA users only) tab views.
6. When the information is complete, click **Save**.
The **Trade Link Saved** message box will open to tell you that your changes have been saved.
7. Click **OK** to close the message box.

Results

The following are **Validate By** group box options:

Interchange

If the transaction is bad, the whole interchange will be removed.

Message

EDIFACT only. If a transaction is bad, only that transaction will be removed. All remaining good data will be processed.

Transaction

X12 only. If a transaction is bad, only that transaction will be removed. All remaining good data will be processed.

Functional Group

If a transaction is bad, the functional group that contained the bad transaction will be removed and the remaining good data will be processed.

Editing a HIPAA X12 document

The selections that you make in the **HIPAA Validation Types** area of the Edit X12 Inbound Trade Link window are used by Message Manager to determine the validation level of incoming HIPAA data.

Note: These fields are enabled *only* when the Inbound Group is for a HIPAA Version with a Functional ID code other than FA. Additionally, to enable these drop-down menus, at least one Structure Validation record must be imported, or manually added for levels 1 and 2 and at least one HIPAA Type Qualifiers Import (**hipaa_x12_4010_qualifier.dat**), or maintenance must be performed for levels 3; 4; 6; and 7, with one exception. In this exception, type 5 will be enabled if type 2, 3, or 4 is enabled and a HIPAA Type Qualifiers Import was run. For details related to the HIPAA Type Qualifiers Import, see the Chapter 3 of the *Trading Manager Installation and User Guide*.

You may select one of the following values for these fields:

- Type 1: **Disabled; Enabled; or Reported in 997**
- Type 2: **Disabled; Enabled; Enabled, Reported in 997; or Enabled, Reported in 999**
- Type 3: **Disabled; Enabled; Enabled; Reported in 824; Enabled; Reported in 999; or Enabled, Execute Map**
Note: If **Enabled, Execute Map** is specified in Type 3, the Type 3 Map field must contain a value.
- Type 4: **Disabled; Enabled; Enabled, Reported in 824; Enabled, Reported in 999**
- Type 5: **Disabled; Enabled; Enabled, Reported in 997; Enabled, Reported in 999**
- Type 6: **Disabled; Enabled; Enabled, Reported in 824; Enabled, Reported in 999**
- Type 7: **Disabled; Enabled; Enabled, Reported in 824; Enabled, Reported in 999**

You can only specify Type 7 if the External Application Partner for this link has a "HIPAA Institution" set.

If any 824 reporting was selected, a box will be enabled to allow you to specify the version for the 824 transaction. The default version is 4050, but it can be changed to a value in the drop down list (currently versions 4050 and 4010 are available).

For tradelinks for HIPAA version V4050X151 and functional ID "PI", if a type 4 824 or 999 report was selected, another check box in the HIPAA validation window is enabled to allow you to define how to perform validation for the BIN segments that might be present in those transactions. The default value is to perform no validation (Value=NEVER), but you can also specify the values "X" to perform only format validation, or "S" to perform validation against a Schema for both version and content. It is important in the last two cases to have the required schema file located in the same directory as the Message Manager maps.

Deleting an X12 Inbound Trade Link Application

About this task

The following instructions describe how to delete an existing X12 trade link application.

To delete an X12 inbound trade link application

Procedure

1. From the File menu, choose **Trade Links**.
2. In the **Trade Links** navigator select Inbound > **X12**.
The X12 Inbound Trade Links window opens.
3. Click the Applications tab.
4. Select a trade link application from the list.
5. Click the **Delete Application** button.
The **Trade Links Application Removal Confirmation** box opens. The box tells you that you must **Save** after closing the box to complete removal.
6. Click **OK**.
The message box closes.
7. Click **Save**.
The trade link application is deleted.

EDIFACT Inbound Trade Link Applications

Refer to the following procedures to add, edit and delete EDIFACT Inbound Trade Link Applications

- [Adding an EDIFACT Inbound Trade Link Application](#)
- [Editing an EDIFACT Inbound Trade Link Application](#)
- [Deleting an EDIFACT Inbound Trade Link Application](#)

Adding an EDIFACT Inbound Trade Link Application

About this task

One or more business documents are exchanged between an internal and external trading partner, with each business document defined as an application within the trading relationship.

The initial applications are added when you run the **Inbound Trade Links Wizard**. You can add more applications for a given external and internal trading partner from the Inbound Trade Links: Partner View dialog box.

Use the following instructions to add a new EDIFACT application for a trade link.

To add a new EDIFACT inbound trade link application

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator select **Inbound > EDIFACT**.
The EDIFACT Inbound Trade Links window opens.
3. Click the Applications tab.
4. Click the **Add Application** button.
The EDIFACT Trade Link: Add Application window opens. If the No UNG option is set, the two fields in the **Application Partners** area will be grayed out.
5. If this is an optional or mandatory UNG link, and an UNG segment is expected for this application, select the Application Partners associated with this UNG segment in the drop-down list.
6. Complete the **Msg Version No**, **Msg Release No**, and **Controlling Agency** fields.
7. Click the **Find Version Message Types** button to open the **Find All EDIFACT Functional ID Message Types** list box and select a message type from the list.
8. Click OK.
9. With the Post Offices tab displayed select test or production data by enabling one or both **Test** and/or **Production** check boxes.
10. Select a Test Post Office and/or Production Post Office. You must select a test or production Post Office in order to save the trade link application.
11. If data is not to be validated, but is to be routed to the Post Office, enable the **Route Only; No Validation** check box. See [Route only option](#) for details.
12. If validation is desired, click the Acknowledgements/Validate By tab and make changes to any fields in this view.
13. Click Save.
The new Inbound Trade Link Application is now created.

Levels of EDIFACT Acknowledgement (CONTRL)

About this task

The following list identifies the levels of EDIFACT functional acknowledgements. Please note that CONTRL, as used in this section, is *not* a typographical error.

| Acknowledgment | Description |
|------------------------|---|
| No Acknowledgment | No CONTRL is sent |
| Interchange Level | A CONTRL is sent acknowledging receipt, providing details of the inbound data to only the interchange (UCI) level. |
| Functional Group Level | This option is only available if this is a UNG level document, that is, application partners are specified. A CONTRL is sent acknowledging receipt, providing details of the inbound data to only the functional group (UCF) level. |
| Message Level | A CONTRL is sent acknowledging receipt, providing details of the inbound data to the message (UCM) level. |
| Segment Level | A CONTRL is sent acknowledging receipt, providing details of the inbound data to the segment (UCS) level. |
| Data Element Level | A CONTRL is sent acknowledging receipt, providing details of the inbound data to the data element (UCD) level. |

Editing an EDIFACT Inbound Trade Link Application

About this task

To edit an inbound EDIFACT trade link application

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator select Inbound > **EDIFACT**.
The EDIFACT Inbound Trade Links window opens.
3. Click the Applications tab.
4. Select a trade link application from the list.
5. Make changes to any of the fields in **Post Offices/Routing; Acknowledgements/Validate By**; and Application Partners tab views.
6. When the information is complete, click **Save**.
The **Trade Link Saved** message box will open to tell you that your changes have been saved.
7. Click **OK** to close the message box.

Deleting an EDIFACT Inbound Trade Link Application

About this task

The following instructions describe how to delete an existing EDIFACT trade link application.

To delete an EDIFACT inbound trade link application

Procedure

1. From the File menu, choose **Trade Links**.
2. In the **Trade Links** navigator select Inbound > **EDIFACT**.
The EDIFACT Inbound Trade Links window opens.
3. Click the Applications tab.
4. Select a trade link application from the list.
5. Click the **Delete Application** button.
The **Trade Links Application Removal Confirmation** box opens. The box tells you that you must **Save** after closing the box to complete removal.
6. Click **OK**.
The message box closes.
7. Click **Save**.
The trade link application is deleted.

TRADACOMS Inbound Trade Link Applications

Refer to the following procedures to add, edit, and delete TRADACOMS Inbound Trade Link Applications.

The **Trade Links Application Removal Confirmation** box opens. The box tells you that you must **Save** after closing the box to complete removal.
6. Click **OK**.
The message box closes.
7. Click **Save**.
The trade link application is deleted.

Outbound trade links

When you define **Outbound Trade Links**, outbound indicates that your company (also known as an internal trading partner) is sending data to another entity (also known as an external trading partner). A basic outbound trade link consists of the following information:

- Which internal trading partner is sending the data
- Which external trading partner is receiving the data
- Where Trading Manager gets its data (Get post office) and puts its data (Put post office)
- What type(s) of information the two trading partners are exchanging
- **X12 Outbound Trade Links**
X12 Outbound Trade Links can be added, edited, copied, and deleted.
- **EDIFACT Outbound Trade Links**
EDIFACT Outbound Trade Links can be added, edited, copied, and deleted.
- **EDIFACT Outbound Trade Links Applications**
You can add, edit, and delete EDIFACT Outbound Trade Link Applications.

X12 Outbound Trade Links

X12 Outbound Trade Links can be added, edited, copied, and deleted.

- [Adding an X12 Outbound Trade Link](#)
- [Editing an X12 Outbound Trade Link](#)
- [Copying an X12 Outbound Trade Link](#)
- [Deleting an X12 Outbound Trade Link](#)

Adding an X12 Outbound Trade Link

About this task

To add an X12 outbound trade link requires the following steps:

- Select the external and internal trading partners with associated application partners.
- Select the **Get** and **Put** post offices:
- The **Get** post office is where Message Manager retrieves the EDI data.
- The **Put** post office provides the routing instructions for the EDI data produced by Message Manager (or how Message Manager sends the data).
- Select the interchange control (ISA) and functional group (GS) numbering schemes.
- Add applications defining the message types you receive from the external trading partner.

To select external and internal X12 trading partners

Procedure

1. From the File menu, select Trade Links.
2. In the **Trade Links** navigator select Outbound > X12.
3. Click Add Link.
The **Add an X12 Outbound Link Wizard** opens.
4. Follow the on-screen instructions in the Wizard to add an X12 Trade Link.
5. When you click Finish to complete adding an inbound trade link using the Wizard, the X12 Trade Link: Add Application window opens.
6. Select a version and functional ID for the application partner.
7. Select a version and functional ID for this outbound link. Click OK to return to the X12 Outbound Trade Links window.
8. If you want to add another application click the **Add Application** button.
9. When you are finished adding applications, select a Put Post Office for the selected version and functional group (FG). At least one Put Post Office is required per version and FG. You may select a Test and/or Production Post Office. Message manager will route the data to this post office based on the Test/Production indicator in the X12 data. You may also specify if this application should be Route Only. Setting Route Only bypasses all validation for the selected version and functional group. See [Route only option](#) for details.
10. In the X12 Outbound Trade Links window, in the Application tab, and click the Format, GS/ST Control tab.
This tab view contains the **Application Format** options and the **GS Time Stamp Options**.

You can choose one of the following Application Format enveloping options by selecting the associated button:

- **Fully Enveloped** - This option indicates that the data passed to Trading Manager for outbound processing is already fully enveloped with terminators/delimiters, ISA envelope information, and Control numbers. Trading Manager makes no updates, leaving this enveloping information as is.
 - **Control Number Enveloped** - This option indicates that terminator/ delimiter enveloping is set in the data, but Trading Manager should generate a proper control number at the Interchange, Functional Group, and Transaction level.
 - **Partially Enveloped** - Trading Manager envelopes data with terminators/delimiters as specified in Partner Manager, and generates a proper control number at the Interchange level, Functional Group level, and Transaction level. ISA control fields are also set based on information in Partner Manager.
- You can change the **GS Time Stamp Option** by selecting one of the following buttons. **HHMM**; **HHMMSS**; **HHMMSSD**; **HHMMSSDD**.

Time is expressed in 24-hour clock time as follows: HHMM, or HHMMSS, or HHMMSSD, or HHMMSSDD, where H = hours (00-23), M = minutes (00- 59), S = integer seconds (00-59) and DD = decimal seconds; decimal seconds are expressed as follows: D = tenths (0-9) and DD = hundredths (00-99)

The **GS Control By Application** fields may be changed if the **GS Group Control # Schema** is set to Increment By Application. This scheme is set in the main tab labeled **GS Control**.

11. You can select the Format tab view and the Transactions tab view and modify any of the default settings of fields in these tab views.
12. Select the **Identification**, **GS Control**, **ISA Control** and Applications tab and make any desired changes to any of the fields.
13. Click Save.

Editing an X12 Outbound Trade Link

About this task

The following instructions describe how to edit existing X12 Outbound trade links.

To edit an X12 outbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, expand **Outbound** and **X12**.
3. Find the desired trade link by using the search buttons at the top of the window. See ["Searching for an X12 Trade Link"](#) for additional search information.

After making your selection, the search window closes and you are returned to the X12 Outbound Trade Links window.

4. Make any desired changes to the fields in the Edit windows, and click Save when you are finished.
You are returned to the X12 Outbound Trade Links window.
5. Click any of the tab views in this window to modify any fields.
6. When you are satisfied that all of your changes have been made, click Save.
The **Trade Link Saved** message box opens to inform you that your changes were successfully saved.
7. Click OK.
8. The message box closes and the edit is complete

Copying an X12 Outbound Trade Link

About this task

The following instructions explain how to copy an X12 outbound trade link.

To copy an X12 Outbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, select **Outbound > X12**.
3. Click **Copy Link** in the trading partner area of the window. The Copy X12 Outbound Trade Link dialog box appears.
4. Click **Find All** in the **New 'From' Trading Partner** area (or click Advanced Find for a more refined search).
5. Highlight a partner and click **Select**.
6. Click **Find All** in the **New 'To' Trading Partner** area (or click Advanced Find for a more refined search).
7. Highlight a partner and click **Select**.
8. Click **Begin Copy**.
9. Click **OK** to confirm.

The trade link copied will appear in the **X12 Outbound Trade Links** window.

Deleting an X12 Outbound Trade Link

About this task

Note: Deleting a link deletes all partner relationships, applications, and transactions associated with the trade link. The delete operation cannot be reversed.

To delete an X12 outbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, select **Outbound > X12**.
The X12 Outbound Trade Links window opens.
3. Find the trade link to be deleted by using the search buttons at the top of the window. See "[Searching for an X12 Trade Link](#)" for additional search information.
After making your selection, the search window closes and you are returned to the X12 Outbound Trade Links window.
4. Click **Delete**.
5. When the confirmation dialog box appears, click **Yes** to delete the trade link, including all applications and transaction sets associated with it.

Adding an EDIFACT Outbound Trade Link

About this task

Refer to the following procedures to add an EDIFACT Outbound Trade Link

To add an EDIFACT outbound trade link

Procedure

1. From the File menu, select Trade Links.
The **Trade Links** navigator opens.
2. Click Outbound > **EDIFACT** in the **Trade Links** navigator.
The EDIFACT Outbound Trade Links window opens.
3. Click Add Link.
The **EDIFACT Outbound Trade Links Add Wizard** opens.
4. Follow the on-screen instruction in the Wizard to add an EDIFACT Trade Link.
5. When you click Finish to complete adding an inbound trade link using the Wizard, the EDIFACT Trade Link: Add Application window opens.
6. Add applications defining the message types you receive from the external trading partner.
7. The **Version/Message Type** group box includes the four components of the EDIFACT version that you defined for the EDIFACT Standard Version.
 - Click Find Version/Message Types to select an existing EDIFACT version, or
 - Select the components from the **Version/Message Type** lists that define the version or message type.
8. Click OK.
The EDIFACT Outbound Trade Links window is displayed with the newly added trade link displayed.
9. In the Post Offices tab view, select the **Test** or **Production** check box. You can also select both.
10. Select a **Test Put Post Office** and/or a **Production Put Post Office** (depending upon which check boxes that you selected in the **Test/Production Indicators** area).
11. If validation is not desired, enable the **Route Only; no Validation** check box. See [Route only option](#) for details.
12. Click Save.
The EDIFACT Trading Partner is added.

Editing an EDIFACT Outbound Trade Link

About this task

The following instructions describe how to edit an existing EDIFACT outbound trade link.

To edit an EDIFACT inbound trade link

Procedure

1. From the File menu, select Trade Links.
2. In the **Trade Links** navigator, expand **Outbound** and select **EDIFACT**.
3. Click the **Edit From TP** button.
The Edit EDIFACT Trading Partner window opens.
4. Make changes to the fields in this window as desired.
5. Select the Syntax/Separators tab and make any desired changes.
6. Click Save.
The Edit EDIFACT window closes and you are returned to the EDIFACT Inbound Trade Links window.
7. Click the **Edit To TP** button.
The Edit EDIFACT Trading Partner in Internal folder EDIFACT window opens.
8. Make changes to the fields in this window as desired.
9. Select the Syntax/Separators tab and make any desired changes.
10. Click Save.
The Edit EDIFACT window closes and you are returned to the EDIFACT Outbound Trade Links window.
11. Click Save.
A message box opens that informs you that your updates have been made.
12. Click OK.
The EDIFACT Trade Link is updated.

Copying an EDIFACT Trade Link

About this task

The following instructions describe how to copy existing trade links.

To copy an EDIFACT outbound trade link

Procedure

1. From the File menu, select Trade **Links**.
2. In the **Trade Links** navigator, expand **Outbound > EDIFACT**.
3. Find the desired trade link by using the search buttons at the top of the window. See "[Searching for an EDIFACT Trade Link](#)" for additional search information.
Highlight a link and click Select.
4. Click the **Copy** button in the trading partner area of the window. The Copy EDIFACT Outbound Trade Link window opens.
5. Click Find All in the **New 'From' Trading Partner** area to open the EDIFACT Partner Lookup window, or click Search for a more refined search
6. Highlight a trading partner and click Select.
7. Click Find All in the **New 'To' Trading Partner** area, or click Search for a more refined search).
8. Highlight a partner and click Select.
9. Click Begin Copy.
A message box will open to inform you that your copy was successful.
10. Click OK.
The EDIFACT Trading Partner is copied.

Deleting an EDIFACT Outbound Trade Link

About this task

The following instructions describe how to delete existing trade links.

Note: Deleting a link deletes all applications and transactions associated with the trade link. The delete operation cannot be reversed.

To delete an EDIFACT outbound trade link

Procedure

1. From the File menu, select Trade **Links**.
2. In the **Trade Links** navigator, select Outbound > **EDIFACT**.
3. Find the desired trade link by using the search buttons at the top of the window. See "[Searching for an EDIFACT Trade Link](#)" for additional search information.
Highlight a link and click Select.
The selected trade link is displayed in the EDIFACT Outbound Trade Links window.
4. Click Delete.
The **Trade Link Confirmation** message box opens to ask if you really want to delete the trade link.
5. Click Yes to delete the trade link, including all applications and transaction sets associated with it.
A message box opens that informs you that the trade link was successfully deleted.
6. Click OK to close the message box.

Adding a TRADACOMS Outbound Trade Link

About this task

An inbound trade link is defined as one in which your (external) partner is sending data to you (the internal partner). You are the receiver of the incoming data. The procedure uses the **Link Wizard**.

Note: Because application partners are optional in TRADACOMS, if SDT/CDT segments are expected, select the trading partner that also has an application partner associated with it.

To add a TRADACOMS outbound trade link

Procedure

1. From the File menu, select Trade Links.
The **Trade Links** navigator opens.
2. Click Inbound > **TRADACOMS** in the **Trade Links** navigator.
3. Click Add Link.
The **TRADACOMS Outbound Trade Links Add Wizard** opens.
4. Follow the on-screen instruction in the Wizard to add a TRADACOMS Trade Link.
5. When you click Finish to complete adding an inbound trade link using the Wizard, the TRADACOMS Trade Link: Add Application window opens.
6. Select a Document Type by selecting a type from the **Document Type** field drop-down menu.
You can access a list of all TRADACOMS document types by clicking the **Find** button.
7. Click OK.
The TRADACOMS Trade Link: Add Application window closes and you are returned to the TRADACOMS Inbound Trade Links window with the Application tab displayed.
8. Select a Get Post Office using the **Get Post Office** field drop-down menu.
Note: The **Get Post Office** field is mandatory and must be entered before the Trade Link can be saved.
9. Select a Put Post Office.

If the **Test** check box is enabled, you must enter a Post Office in the **Test Put Post Office** field.

If the **Production** check box is enabled, you must enter a Post Office in the **Production Put Post Office** field.

Note: The **Get Post Office** and **Production Put Post** Office fields are mandatory depending upon which Test/Production check boxes are enabled. One of these fields must be completed before you can save the Trade Link.

10. If you want to make changes to customer or supplier details, click the SDT/CDT & VAT tab.

11. Click Save.

The **Trade Link Saved** message box opens to inform you that the trade link is saved.

12. Click OK.

The message box closes and the Trade Link is saved.

Editing TRADACOMS Outbound Trade Links

About this task

The following instructions describe how to edit existing EDIFACT inbound trade links.

To edit a TRADACOMS outbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, expand **Outbound** and select **TRADACOMS**.
3. Find the desired trade link by using the search buttons at the top of the window. See "[Searching for a TRADACOMS Trade Link](#)" for additional search information.
Highlight a link and click Select.
After you have selected the trading partner that you want to edit, it appears in the TRADACOMS Inbound Trade Links window.
4. Click the **Edit From TP** button to edit "From" Trading Partner fields, or click the **Edit From AP** button to edit "From" Application Partner fields.
The **Edit TRADACOMS Trading Partner** window opens.
5. Make changes to the fields in this window as desired.
6. When your changes are complete, click Save.
You are returned to the TRADACOMS Inbound Trade Links window.
7. Click the **Edit To TP** button to edit "To" Trading Partner fields, or click the **Edit To AP** button to edit "To" Application Partner fields.
8. Make any desired changes to the fields in these window(s) and save your changes.
9. From the TRADACOMS Inbound Trade Links window, click the Applications tab and make any desired changes to the Get Post Office, Test Post Office, and/or Production Post Office by selecting the Edit button located to the right of each field.
10. Select the STD/CDT & VAT tab and make any desired changes.
11. When your edits are complete, click Save.
12. A message box opens that informs you that your updates have been made.
13. Click OK.
The TRADACOMS Trade Link is updated.

Copying TRADACOMS Outbound Trade Links

About this task

The following instructions describe how to copy existing trade links.

To copy a TRADACOMS outbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, expand **Outbound > TRADACOMS**.
3. Find the desired trade link by using the search buttons at the top of the window. See "[Searching for a TRADACOMS Trade Link](#)" for additional search information.
After you select a link it is displayed in the TRADACOMS Outbound Trade Links window.
4. Click the **Copy** button in the trading partner area of the window. The Copy TRADACOMS Outbound Trade Link window opens.
5. Click Find All in the **New 'From' Trading Partner** area to open the TRADACOMS Partner Lookup window, or click Search for a more refined search.
6. Highlight a trading partner and click Select.
7. Click Find All in the **New 'To' Trading Partner** area, or click Search for a more refined search).
8. Highlight a partner and click Select.
9. Click Begin Copy.
A message box will open to inform you that your copy was successful.
10. Click OK.
The TRADACOMS Trade Link is copied.

Deleting TRADACOMS Trade Links

About this task

The following instructions describe how to delete existing trade links.

Note: Deleting a link deletes all applications and transactions associated with the trade link. The delete operation cannot be reversed.

To delete a TRADACOMS outbound trade link

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator, select Inbound or **Outbound > TRADACOMS**.
3. Find the desired trade link by using the search buttons at the top of the window. See "[Searching for a TRADACOMS Trade Link](#)" for additional search information.
Highlight a link and click **Select**.
You are returned to the TRADACOMS Outbound Trade Links window with the link that you selected displayed.
4. Click **Delete**.
The **Trade Link Confirmation** message box opens to ask if you really want to delete the trade link.
5. Click **Yes** to delete the trade link, including all applications and transaction sets associated with it.
A message box opens that informs you that the trade link was successfully deleted.
6. Click **OK** to close the message box.

Adding an X12 Outbound Trade Links Application

About this task

To add a new outbound X12 trade link application

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator select **Outbound > X12**.
The X12 Outbound Trade Links window opens.
3. Click the Applications tab.
The Applications tab view opens.
4. Click **Add Application**.
The X12 Trade Link: Add Application window opens.
5. Select a Put Post Office.
6. Add details about the Application by selecting the Format, GS/ST Control tab and the Transactions tab views.
7. Click **Save**.
The **Trade Link Saved** message box opens.
8. Click **OK** to close the message box.
The X12 Outbound Trade Link Application is saved.

Editing an X12 Outbound Trade Link Application

About this task

To edit an X12 outbound trade link application

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator select **Outbound > X12**.
The X12 Outbound Trade Links window opens.
3. Click the Applications tab.
4. Select a trade link application from the list.
5. Make changes to any of the fields in **PO/Validation/Ack**; **Format GS**; and Transactions tab views.
6. When the information is complete, click **Save**.
The **Trade Link Saved** message box will open to tell you that your changes have been saved.
7. Click **OK** to close the message box.

Deleting an X12 Outbound Trade Link Application

About this task

To delete an X12 outbound trade link application

Procedure

1. From the File menu, choose **Trade Links**.
2. In the **Trade Links** navigator select Outbound > **X12**.
The X12 Outbound Trade Links window opens.
3. Click the Applications tab.
4. Select a trade link application from the list.
5. Click the **Delete Application** button.
The **Trade Links Application Removal Confirmation** box opens. The box tells you that you must **Save** after closing the box to complete removal.
6. Click OK.
The message box closes.
7. Click Save.
The trade link application is deleted.

EDIFACT Outbound Trade Links Applications

You can add, edit, and delete EDIFACT Outbound Trade Link Applications.

- [Adding an EDIFACT Outbound Trade Links Application](#)
- [Editing an EDIFACT Outbound Trade Link Application](#)
- [Deleting an EDIFACT Outbound Trade Link Application](#)
- [TRADACOMS Outbound Trade Link Applications](#)

You can add, edit, and delete TRADACOMS Trade Link Applications.

Adding an EDIFACT Outbound Trade Links Application

About this task

Use the following instructions to add an EDIFACT Outbound Trade Links Application.

To add an EDIFACT outbound trade links application

From the File menu, select **Trade Links**.

Procedure

1. In the **Trade Links** navigator select Outbound > **EDIFACT**.
The EDIFACT Outbound Trade Links window opens.
2. Click the Applications tab.
3. Click the **Add Application** button.
The EDIFACT Trade Link: Add Application window opens. If the No UNG option is set, the two fields in the **Application Partners** area will be grayed out.
4. If this is an optional or mandatory UNG link, and an UNG segment is expected for this application, select the Application Partners associated with this UNG segment in the drop-down list.
5. Complete the **Msg Version No**, **Msg Release No**, and **Controlling Agency** fields.
6. Click the **Find Version Message Types** button to open the **Find All EDIFACT Functional ID Message Types** list box and select a message type from the list.
7. Click OK.
8. With the Post Offices tab displayed, select test or production data by enabling one or both **Test** and/or **Production** check boxes.
9. Select a Test Post Office and/or Production Post Office. You must select a test or production Post Office in order to save the trade link application.
10. Click the **Msg Control No/Version Info** and Application Partners tab and make any changes to any fields in these views.
The Acknowledgements are set in the **Ack Level** field. See [Adding an EDIFACT Inbound Trade Link Application](#).
11. Click Save.
The new Outbound Trade Link Application is now created.

Editing an EDIFACT Outbound Trade Link Application

About this task

To edit an inbound EDIFACT outbound trade link application

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator select Outbound > **EDIFACT**.
The EDIFACT Outbound Trade Links window opens.
3. Click the Applications tab.
4. Select a trade link application from the list.
5. Make changes to any of the fields in **Msg Control No/Version Info**, **Post Offices** and Application Partners tab views.
6. When your updates are complete click **Save**.
The **Trade Link Saved** message box will open to tell you that your changes have been saved.
7. Click OK to close the message box.

Deleting an EDIFACT Outbound Trade Link Application

About this task

To delete an EDIFACT outbound trade link application

Procedure

1. From the File menu, choose **Trade Links**.
2. In the **Trade Links** navigator select Inbound > **EDIFACT**.
The EDIFACT Inbound Trade Links window opens.
3. Click the Applications tab.
4. Select a trade link application from the list.
5. Click the **Delete Application** button.
The **Trade Links Application Removal Confirmation** box opens. The box tells you that you must **Save** after closing the box to complete removal.
6. Click OK.
The message box closes.
7. Click **Save**.
The trade link application is deleted.

TRADACOMS Outbound Trade Link Applications

You can add, edit, and delete TRADACOMS Trade Link Applications.

Adding a TRADACOMS Outbound Trade Link Application

About this task

To add a new TRADACOMS outbound trade link application

Procedure

1. From the File menu, select **Trade Links**.
2. In the **Trade Links** navigator select Outbound > **TRADACOMS**.
The TRADACOMS Outbound Trade Links window opens.
3. Click the Application tab.
4. Click the **Add Application** button.
The TRADACOMS Trade Link: Add Application window opens.
5. Select a Document Type.
6. Click OK.
7. Add data as desired in the fields in the SDT/CDT Control No VAT RSG tab view.
8. With the Post Offices tab displayed, select test or production data by enabling one or both **Test** and/or **Production** check boxes.
9. Select a **Test Post Office** and/or **Production Post Office**.
10. Click **Save**.

Editing a TRADACOMS Outbound Trade Link Application

About this task

To edit an outbound TRADACOMS trade link application

Procedure

1. From the File menu, select **Trade Links**.
2. In the Trade Links navigator select Outbound > **TRADACOMS**.
The **TRADACOMS Outbound Trade Links** window opens
3. Click the Applications tab.
4. Select a trade link application from the list.
5. Make changes to any of the fields in **Post Offices** and SDT/CDT Control No VAT RSG tab views.
6. When the information is complete, click **Save**.
7. The **Trade Link Saved** message box will open to tell you that your changes have been saved.
8. Click **OK** to close the message box.

Deleting a TRADACOMS Outbound Trade Link Application

About this task

To delete a TRADACOMS outbound trade link application

Procedure

1. From the File menu, choose **Trade Links**.
2. In the **Trade Links** navigator select Outbound > **TRADACOMS**.
The TRADACOMS Outbound Trade Links window opens.
3. Click the Applications tab.
4. Select a trade link application from the list.
5. Click the **Delete Application** button.
The **Trade Links Application Removal Confirmation** box opens. The box tells you that you must **Save** after closing the box to complete removal.
6. Click **OK**.
The message box closes.
7. Click **Save**.
The TRADACOMS Outbound Trade Link Application is deleted.

ISA and GS Numbering Schemes

The functional group control number reset does not occur until after the next refresh (the next time the Message Manager's **Export** map is executed). See the Trading Manager documentation for information on scheduling the execution of the **Export** map.

The following list defines the ISA and GS Numbering Schemes.

Increment

This numbering scheme is the default. A perpetually-incrementing interchange control number is used.

The first interchange sent for this relationship has a control number of 1, the second has a control number of 2, and so on.

If you select Increment, you can also reset the number to your preference by enabling **Reset** and specifying a control number.

User Defined

Use a user-defined numbering scheme. Enter the full name and path to a compiled map file (.mmc) that provides this custom control number.

The compiled map file is required when you select this option. The full file name and path of the compiled map file must be specified relative to the path of the Launcher.

You can also reset the number to your preference by enabling **Reset** and specifying a control number.

Increment by Trading Partner

A perpetually incrementing GS number within this partner link (internal application partner to external trading partner) is used.

The first interchange sent for this relationship has a control number of 1 the second has a control number of 2, and so on.

You can also reset the number to your preference by enabling **Reset** and specifying a control number.

Increment by Application Partner

A perpetually incrementing functional group control number within this partner link (application partner and application partner) is used.

The first functional group sent for this application partner within this trading partner has a control number of 1, the second has a control number of 2, and so on.

You can also reset the number to your preference by enabling **Reset** and specifying a control number.

Increment by Functional ID Code

A perpetually incrementing functional group control number within the functional ID code, regardless of trading partner is used.

The first PO functional group sent has a control number of 1; the second has a control number of 2 (regardless of its partner link), and so on.

Relative

This selection is the default.

A functional group control number that is relative to the functional group's sequence within its interchange.

The first functional group in the first interchange has a control number of 1, the second has a control number of 2, the first functional group in the second interchange has a control number of 1, and so on.

Searching for a trade link

When entering search criteria, case sensitivity for the search depends on the database. By default, Microsoft Access and Microsoft SQL Server are not case sensitive (for example, Acme is the same as ACME), while Oracle is case sensitive. For more information, contact your database administrator to determine if SQL LIKE searches are case sensitive.

Searching for an X12 Trade Link

About this task

Refer to the following steps to search for an X12 Trade Link.

To search all X12 trade links

Procedure

1. Click the File menu and select Trade Links.
The **Trade Links** navigator opens.
2. Select Inbound or **Outbound > X12**.
The **Inbound** or Outbound X12 Trade Links window opens. The Search buttons are located at the top of the window. These buttons allow you to search for Trade Links based upon various search criteria.
3. To search all available trade links, click the **All Links** button.
The X12 Inbound Trade Link Lookup: All Links window opens.
4. Sort the names in the list box by selecting one of two **Display** buttons.
 - Select Names to sort the list by Trading Partner name. This causes names to be sorted in alphanumeric order.
 - Select ISA/GS to sort in ISA order:
5. Select the desired Trade Link from the list and click Select.

To search X12 trade links by partner

Procedure

1. Click the File menu and select Trade Links.
The **Trade Links** navigator opens.
2. Select Inbound or **Outbound > X12**.
3. Click the **Search by Partner** button at the top of the window.
The X12 Inbound Trade Link Lookup: Search By Partner window opens.
4. Define your search criteria by enabling or disabling (checking or unchecking) the check boxes in the Search the following window area and by selecting and deselecting a button in the ISA/GS Search (Exact) window area.
5. When you are satisfied that your search criteria are properly defined, click the **Begin Search** button to populate the list box with trade links that match your search criteria
6. Select the desired trade link from the list box and click Select.

To select an X12 trade link by document type

Procedure

1. Click the File menu and select Trade Links.
2. Select Inbound or **Outbound > X12**.
3. Click the **Search by Document** button at the top of the window.
The X12 Inbound Trade Link Document Search window opens.
4. Select a document from the top list box. When you click on the document, the trade links associated with that document display in the bottom list box.
5. Click on the desired trade link then click Select.

Searching for an EDIFACT Trade Link

About this task

Refer to the following steps to search for an EDIFACT Trade Link.

To search all EDIFACT trade links

Procedure

1. Click the File menu and select Trade Links.
2. Select Inbound or **Outbound > EDIFACT**
3. Click the **Search All** button at the top of the window.
The EDIFACT Inbound or Outbound Trade Link Lookup: All Files window opens.
4. Scroll through the files in the list until you locate the desired file.
5. Click Select.

To select EDIFACT trade links by partner

Procedure

1. From the File menu select Trade Links.
2. Select Inbound or **Outbound > EDIFACT**
3. Click the **Search By Partner** button at the top of the window.
The EDIFACT Inbound or Outbound Trade Link Lookup: Search By Partner window opens.
4. Define your search criteria by enabling or disabling (checking or unchecking) the check boxes in the Search the following window area and by selecting and deselecting a button in the Interchange ID Search (Exact) window area.
 - Search for a specific Folder or Trading Partner by entering specific data into the **Search For** field.
 - Search for a specific Interchange ID by entering specific data into the **Interchange ID** field.
5. When you are satisfied that your search criteria are properly defined, click the **Begin Search** button to populate the list box with trade links that match your search criteria
6. Select the desired trade link from the list box and click Select

To select an EDIFACT trade link by document

Procedure

1. From the File menu select Trade Links.
2. Select Inbound or **Outbound > EDIFACT**
3. Click the **Search by Document** button at the top of the window.
The EDIFACT Inbound or Outbound Trade Link Document Search window opens.
4. Select a document from the top list box. When you click on the document, the trade links associated with that document display in the bottom list box.
5. Click on the desired trade link then click Select.

Searching for a TRADACOMS Trade Link

About this task

Refer to the following steps to search for an EDIFACT Trade Link.

To search all TRADACOMS trade links

Procedure

1. Click the File menu and select Trade Links.
2. Select Inbound or **Outbound > TRADACOMS**
3. Click the **Search All** button at the top of the window.
4. The **TRADACOMS Inbound** or Outbound Trade Link Lookup: All Files window opens.
5. Sort the files in the list by selecting one of two buttons in the Display area at the top of the window.
 - Select the **Names** button to sort the list by Trading Partner name.
 - Select **ID** to sort by Trading Partner ID.
6. Click Select.

To select TRADACOMS trade links by partner

Procedure

1. From the File menu select Trade Links.

2. Select Inbound or **Outbound > TRADACOMS**
3. Click the **Search By Partner** button at the top of the window.
The **TRADACOMS Inbound** or Outbound Trade Link Lookup: Search by Partner window opens.
4. Define your search criteria by entering starting letters for a trading partner, application partner or from application partner ID in the fields in the Enter Starting Letters window area. You can also select whether or not you want to sort using names, or IDs by selecting one of the two **Display** buttons.
5. When you are satisfied that your search criteria are properly defined, click the **Begin Search** button to populate the list box with trade links that match your search criteria
6. Select the desired trade link from the list box and click Select.

To select a TRADACOMS trade link by document

Procedure

1. From the File menu select Trade Links.
2. Select Inbound or **Outbound > TRADACOMS**
3. Click the **Search by Document** button at the top of the window.
The **TRADACOMS Inbound** or Outbound Trade Link Document Search window opens.
4. Select a document from the top list box. When you click on the document, the trade links associated with that document display in the bottom list box.
5. Click on the desired trade link then click Select.

Automatic acknowledgement creation

Partner Manager will display the **Automatic Acknowledgement Creation** dialog if the trade link for that acknowledgement does not already exist and an acknowledgement is expected from your external trading partner, or you are creating an acknowledgement.

This may occur when you:

- add a trade link
- copy a trade link
- add an application to an existing trade link

This dialog will create or modify the trade link for the opposite direction so that you do not have to manually make those changes. The dialog may display multiple times if there are more than version/functional group on the trade link.

The instructions presented at the top of the dialog will show the version and transaction set that will be created. Follow the instructions carefully as they will change when multiple versions are being processed.

Outbound CONTRL trade link

Please note that CONTRL, as used in this section, is *not* a typographical error.

Partner Manager displays the Automatic Outbound CONTRL Creation dialog box when you:

- Add a trade link
 - Copy a trade link
 - Add an application to an existing trade link
 - The trading partner link requires an outbound CONTRL acknowledgement (an outbound acknowledgement does not already exist for that trading/application partner and version)
- The Automatic Outbound CONTRL Creation dialog box appears only when you are creating EDIFACT trade links.

If you select No Acknowledgement in the **Ack Level** drop-down list, this dialog box does not appear.

If you want to create an outbound CONTRL acknowledgement, select the **Put and Get Post Offices** from the drop-down list and click Create. This dialog box may appear more than once if the link contains multiple versions and/or acknowledgement partners. In this case, the version appears in the dialog box.

The Control Message Type will default to : Version=4, Release=1, Controlling Agency=UN; the sole CONTRL Message Type provided by IBM in the EDIFACT Standards (see Utilities > Standards). This section of the form will remain disabled until you create additional CONTRL Message Types in the EDIFACT Standards definitions. At such a time, this section will be enabled and you can select which CONTRL Message Type to use.

The UNG Options (No UNG vs. Mandatory UNG) is disabled if an Outbound Trade Link already exists for this CONTRL creation, or if the Inbound Trade Link does not contain an UNG-level definition. If an Outbound Trade Link already exists, the UNG Option of that link will be used for the CONTRL document. Note Optional UNG CONTRL Trade Links are not supported.

Note: The Automatic CONTRL form will not be displayed if an Outbound Trade Link already exists, and contains a CONTRL Message Type.

Creating a control number map

Trading Manager supports user-defined numbering schemes in maps for interchange, functional group, and transaction set control numbers. This section describes the requirements for your maps that provide a number and are executed from the Message Manager using the RUN function.

- [Exchanging information with Message Manager](#)

You implement user-defined control numbering schemes through control number maps. When building envelopes for those application partners that provide

- partially wrapped X12 data, the compiled map providing the control number level and specified in the Partner Manager is executed by the `RUN` function.
- [Map requirements and features](#)

Exchanging information with Message Manager

You implement user-defined control numbering schemes through control number maps. When building envelopes for those application partners that provide partially wrapped X12 data, the compiled map providing the control number level and specified in the Partner Manager is executed by the `RUN` function.

The Message Manager passes input card 1 to the control number map the last used control number for this particular trading partner, application partner, or transaction set. The control number map returns the control number value to be used as output card 1 to the Message Manager; this value is placed in the appropriate EDI envelope.

This control number returned by the control number map is used to update the last used control number within the Message Manager for the appropriate trading partner, application partner, and transaction set.

Map requirements and features

The control number map must have at least one input card and one output card. You must define input card 1 and output card 1 to accommodate a control number character size of 1-9 characters. For example, define a text or number item with a minimum length of 1 and a maximum length of 9.

Alternately, you could define a control number Group in a type tree with Items that recognize component parts of the one- to nine-character control number. Include an Item where the control number is defined as `YYMMDD`.

Note: Although the string that is transferred to and from the control number map can be defined as text, the interchange and functional group control numbers must be numeric.

- [Example: increments other than 1](#)
- [Example of transaction set control number by date](#)

Example: increments other than 1

The map may include other input cards and output cards as needed. For example, you may have established an increment other than one for the ISA control number that you exchange with your partner:

- Input card 1 represents the most recently used control number (`LastUsedControl Number`)
- Input card 2 represents data from a Customer Master Database (`CustomerMasterDB`)
- Output card 1 contains a rule with the `SEARCHUP` function to find the increment for the ABC Rock customer; the increment is added to the most recently used control number and the result is returned to the Message Manager. The map rule is:

```
=LastUsedControlNumber + SEARCHUP ( Increment Column:::CustomerMasterDB ,  
CustID Column:::CustomerMasterDB , "ABC Rock" )
```

Example of transaction set control number by date

For example, a map may concatenate a sequence number with other information such as the current date:

- Input card 1 represents the most recently used control number (`LastUsedControl Number`)
- Output card 1 contains a rule with the `CURRENTDATE` function. In this example, the first six characters of the control number are the current date in YYMMDD format. The last three characters represent the sequence number of the current data set. If the date from the most recently used control number is the same date as the current date, the sequence number is incremented by one. If the date is not the same as the current date, the sequence number is reset to 1. The map rule is:

```
=IF Shift 9 =( RENTDATE() = YYMMDD:LastUsedControlNumber ,  
SeqNum:LastUsedControlNumber +1 , 1 )
```

Reports

About this task

Use the Reports window to view Message Manager transmission and audit report information. The Reports window enables you to view and generate detailed information about transmissions and transactions.

To access the Reports window

Procedure

Click on Reports the toolbar. Or, select Reports from the File menu.
The Reports window displays.

Results

The following four types of reports are available from the **Report Type** drop-down box:

- ["Traffic Reports"](#)
- ["Alerts Report"](#)
- ["Additional Reports Overview"](#)
- ["Partner Manager Log Report"](#)

You can run Partner Manager reports on the current or archive database. After reports are run, they can be printed or exported.

Reports are presented in views, which provide different levels of detail and enable resend interchange capability. Each report has a default view.

Note: If you do not have any traffic for a data type, that data type will not be displayed in the data type's drop-down box. For example, if you do not have X12 traffic, **X12** will not be listed in the data type's drop-down box.

- [Traffic reports](#)
 - [Additional reports overview](#)
 - [Printing Partner Manager reports](#)
 - [Exporting reports](#)
 - [Value Added Tax \(VAT\) reports](#)
 - [Partner Manager editor](#)
-

Traffic reports

Traffic reports contain information on transmissions that have been processed by the Message Manager system in the specified date range.

- Traffic reports can be refreshed at any time.
- The default date selection for traffic reports is configured in the Display Options utility.
- Traffic reports can be run on inbound and outbound directions on a selected report level.
- Traffic reports can be exported to file formats for viewing and printing.
- Traffic reports allow you to edit and resend interchanges.
- Traffic Reports allow you to optionally view X12 997 content, and to jump between X12 997 transmissions and the corresponding Functional Group.
- Traffic Reports allow you to review your X12 Acknowledgement activity. For example, displaying Overdue Acknowledgements, All Unacknowledged, Acknowledged Only, or manually Acknowledged traffic.

Navigate in traffic reports with right-click command access or by clicking the buttons on the toolbar.

- [Drill down for details](#)
 - [Report specific search](#)
 - [Specify a date range](#)
 - [Report status icon colors and codes](#)
 - [Partner Manager log report](#)
 - [Alerts report](#)
 - [Resend requests](#)
 - [Transmission report](#)
 - [Interchange report](#)
 - [Functional group report](#)
 - [Message/transaction report](#)
 - [X12 TA1 status reports](#)
-

Drill down for details

You can "drill down" to view finer levels of detail from the default report view in traffic reports. The "drill down" options include:

| View Type | Drill Down To |
|------------------|---|
| All | Display Detail |
| Transmission | Display Data Type |
| Data Type | View Interchanges |
| Interchange | View Functional Groups
Resend the interchange immediately
Edit/Resend the interchange |
| Functional Group | Display Transactions |
| Transaction | Display Segment Errors |

Icon colors in the reports provide visual status indicators for each transmission.

For EDIFACT reporting, the drill down may skip functional group views if there are no functional groups in the data.

- [View Interchanges in Reports](#)
- [View Functional Groups in Reports](#)
- [Display detail in reports](#)
- [Display Transactions in Reports](#)
- [Display Segment Errors in Reports](#)
- [Display Data Types](#)

View Interchanges in Reports

About this task

In a data type report view, you can view interchanges for the selected transmission.

To view interchanges

Procedure

1. In a report, select a single transmission.
2. Click the **Interchanges** button.
The **Interchanges View** appears.

Results

From the **Interchanges View**, you can view Functional Groups, resend that interchange immediately, and edit/resend the interchange. If X12 TA1 records exist, a drill-down from **Interchange** to **Functional Groups** will also display those X12 TA1 records in a separate window.

View Functional Groups in Reports

About this task

In an interchange report view, you can view functional groups for the selected interchange.

To view functional groups of a specific interchange

Procedure

1. In a report, select a single functional group.
2. Click the **Functional Groups** button.
The Functional Groups View appears.

Display detail in reports

For each report view, the **Display Detail** screen provides detailed information on the selected interchange, transmission, functional group, transaction, alert, or log.

Display Transactions in Reports

About this task

In a functional group view report, you can view transaction details.

To view transaction details

Procedure

1. Select a single transmission.
2. Click the **Display Transactions** button.
The **Transactions View** of that transaction is displayed.

Display Segment Errors in Reports

About this task

For each transmission in a transactions view report, you can display segment errors if they exist.

To view segment errors of a transmission

Procedure

1. Select a single transmission in a transaction view of a report.

2. If segment errors exist for the selected transmission, click the **Display Segment Errors** button.

Note: The **Display Segment Errors** button is available only if the selected transmission contains segment errors. If no segment errors exist, the button is not available.

Display Data Types

About this task

In a report **Transmission View**, you can view data type details in the **Interchanges View**.

To view data type details

Procedure

1. Select a single transmission.
2. Click the **Display Data Type View** button.

Results

Double-click a transmission in the **Data Type View** to display functional group details, and then transaction details.

Report specific search

The **Report Specific Search** field is specific to each report level.

Report levels in traffic reports include:

| | |
|--------------------|-----------------------|
| • Transmission | • Message/Transaction |
| • Interchange | • Traffic Alert |
| • Functional Group | • Partner Manager Log |

Specify a date range

For traffic reports, the **Date Range** can be adjusted as required. Click the option button to choose your date range.

| Option | Header |
|------------|---|
| All dates | All dates are reported |
| Date Range | When enabled, the From Date and To Date fields can be populated. Click Calendar to choose the From Date and To Date. For Traffic Alerts, the From Time and To Time can be entered in HHMM format. |
| Today | Data with current (today's) date reported. |

Report status icon colors and codes

The colors of the icons in the Partner Manager traffic reports provide visual indicators of status. The status description, **Red**, **Yellow**, **Green** or **Blue** can also be included in the exported traffic reports by enabling the **Include Traffic Status Color** check box).

| Color | Description |
|---------------------------|---|
| Red | Indicates an error in transmission at that level |
| Red (TA1 reports only) | Rejected |
| Yellow | Error at a level below displayed transmission level |
| Green | Transmission completed without errors |
| Green/Yellow | X12 Functional Acknowledgement is in error |
| Green (TA1 reports only) | Accepted |
| Yellow (TA1 reports only) | Partially accepted |
| Blue | In process |

The following table describes each code and its icon color.

| Code | Description | Icon Color |
|------|--|------------|
| 2 | Syntax version or level not supported | Red |
| 7 | Interchange recipient not actual recipient | Red |
| 12 | Invalid value | Red |
| 13 | Missing | Red |
| 14 | Value not supported in this position | Red |

| Code | Description | Icon Color |
|-------------|---|-------------------|
| 15 | Not supported in this position | Red |
| 16 | Too many constituents | Red |
| 17 | No agreement | Red |
| 18 | Unspecified error | Red |
| 20 | Character invalid as service indicator | Red |
| 21 | Service character(s) | Red |
| 22 | Invalid service character(s) | Red |
| 23 | Unknown Interchange sender | Red |
| 24 | Too old | Red |
| 25 | Test indicator not supported | Red |
| 26 | Duplicate detected | Red |
| 28 | References do not match | Red |
| 29 | Control count does not match number of instances received | Red |
| 30 | Groups and messages/packages mixed | Red |
| 32 | Lower level empty | Red |
| 33 | Invalid occurrence outside message, package, or group | Red |
| 35 | Too many data element or segment repetitions | Red |
| 36 | Too many segment group repetitions | Red |
| 37 | Invalid type of character(s) | Red |
| 39 | Data element too long | Red |
| 40 | Data element too short | Red |
| 45 | Trailing separator | Red |
| 46 | Character set not supported | Red |
| 47 | Envelope functionality not supported | Red |
| 48 | Dependency condition violated | Red |
| D01 | Mandatory element missing | Red |
| D02 | Data element has incorrect size | Red |
| D03 | Invalid code for identifier | Red |
| D04 | Invalid date format | Red |
| D05 | Invalid time format | Red |
| E00 | Unknown data element | Red |
| E01 | Code list error | Red |
| E02 | Data element has incorrect format | Red |
| E03 | Data element has incorrect size | Red |
| E04 | Missing segment | Red |
| E05 | Missing segment terminator | Red |
| E06 | Mandatory element missing | Red |
| E07 | Error in data | Red |
| E08 | Unknown element found | Red |
| E09 | Failed business rule | Red |
| E10 | Missing element | Red |
| E11 | ISA/IEA format or content error | Red |
| E12 | GS/GE format or content error | Red |
| E13 | Invalid because of errors elsewhere | Red |
| E14 | Missing tradelink | Red |
| E15 | Unknown transaction/Version release | Red |
| E16 | Failed to route to PUT post office | Red |
| E17 | Valid but not delivered because of errors elsewhere | Red |
| E18 | Functional group does not contain any transaction | Red |
| E19 | Contains transaction(s) that do not belong in this functional group | Red |

| V09 | Failed Interchange Security Check | Red |

Partner Manager log report

Access to the Partner Manager Log report is granted or denied in the **Security Groups** utility. The Partner Manager Log report identifies error messages and reports Resend requests/processing. In addition, if Partner Manager security is enabled and then later disabled, a warning will appear in the log. This report is run for a specified date range. You can export the report. For information on how to purge the log, see the "Purge" section in Chapter 8.

Click an options button in the **Reports Options** to dynamically populate the report for **All Messages, Errors Only, Warnings Only, and Information Only**.

Information in the Partner Manager Log report includes:

| Field | Description |
|-----------|--|
| Source | Source of the log message. |
| User | The current User ID if Security Groups are being used. If Partner Manager security is not used, User defaults to the database user name that user or the current user. |
| Date Time | The date and time of the log event in the YYYYMMDD HH:MM:SS format. |
| Message | Log message that describes the log event. |

Note: The Partner Manager Log report replaces the Resend Requests report.

- [Source of Partner Manager log message](#)

Source of Partner Manager log message

The source of the log message includes incident type and status level.

Possible log message sources include:

| Log Message Type | Description | Status Type | Icon |
|------------------|---|-------------|--------|
| Program Error | Run-time errors generated by the Partner Manager application. | Error | Red |
| SQL Errors | Errors generated by the database system you are using. | Error | Red |
| User Maintenance | In the event security is disabled (by deleting the last user). | Warning | Yellow |
| Login | In the event the user with the password overwrote the database-version check. | Warning | Yellow |
| Resend | When a resend request is made. Also when the resend item is processed by Message Manager. | Information | Green |

Program and SQL errors are useful for communicating with IBM Software Customer Support if problems arise.

Alerts report

The Alert report shows a history of e-mail traffic alert notifications of rejected data for the specified date range and database (current or archive). The dates specified are for the Message Manager map execution dates (when traffic occurs in Partner Manager).

You can specify reporting on traffic alerts that match the following selection requirements:

- Specified Date Range
- Specified Database (Current or Archive)
All traffic in the Message Manager system is reported, regardless of data type.

Information in the Traffic Alert report includes:

| Field | Description |
|-----------------|---|
| PO Nickname | Post office nickname as defined in Partner Manager. |
| Transmission ID | Unique Transmission ID assigned by Message Manager to the interchange. |
| Data Type | EDIFACT, X12, or TRADACOMS. |
| Contact | The e-mail address specified in the Address Book for the trading partner. |
| Start Time | Time when the traffic alert was sent. |

Resend requests

The **Resend Requests** report has been replaced with the Partner Manager Log Report, which logs resend requests.

Transmission report

The **Transmission** report is a standard-independent report that displays a summary of inbound or outbound transmissions.

Note: All transmissions are reported (EDIFACT, TRADACOMS, X12, and any other standards).
You can specify reporting on transmissions that match the specified selection requirements.

Information is displayed for the specified transmission direction (inbound or outbound). The information displayed includes:

| Field | Description |
|-----------------------|---|
| Transmission ID | A component of the ThreadID assigned by Message Manager system to the transmission. |
| Date | Date when the Message Manager transmission processing began. |
| Time | Time when the Message Manager transmission processing began. |
| Size | Size (in bytes) of the transmission data. |
| Return Code | Report status code. |
| O/R | Original or Resend indicator. An O indicates an original transmission. An R indicates a resent transmission. |
| Input Thread | Source of the transmission data. If the data source is a file, this column shows the file name. Otherwise, it shows the resource adapter (FTP, E-mail, VAN) command string. |
| Original Transmission | If this is a resent transmission, the Original Transmission ID is displayed. Blank if this is not a resent transmission. |
| PO Nickname | Post Office associated with the transmission. |

Note: Double-click a transmission, or select a single transmission and click the **Data Type View** button, to the display the **Data Type View**.

Interchange report

The Interchange report displays trading partner interchange information for the specified interchange date range.

The **Inbound or Outbound Interchanges View** displays information for interchanges and allows you to:

- Resend that interchange immediately
- Edit/Resend the interchange

You can specify reporting on interchanges that match the following selection requirements:

- Data Type** (select EDIFACT, TRADACOMS, or X12, or other standard from the drop-down list)
- Specific Post Office Nickname
- Specified Date Range
- Direction (Inbound or Outbound)
- Database (Current or Archive)
- Record **Status of All Records, No Errors**, records with **Errors Only**, or a Specific Status Code
- A specific Trading Partner
- A Report Specific Search (enter a Control Number)

The information displayed includes:

| Field | Description |
|-----------------------|--|
| Transmission ID | Unique Transmission ID assigned by Message Manager to the interchange. |
| Sender Ichg ID/ Qual | ISA Sender ID qualifier and address of the trading partner that sent the interchange. |
| Sender Name | Trading partner name as defined in the Address Book . |
| Receiver Ichg ID/Qual | ISA Receiver ID qualifier and address of the trading partner that received the interchange. |
| IC Ctrl No. | ISA Control number of the interchange. |
| IC Date | YYYYMMDD format of the date the interchange was created by the sender. (UNB/ISA Envelope) |
| IC Time | HHMM format of the time the interchange was created by the sender. (UNB/ISA Envelope) |

- [Drill down tips](#)
- [Specific trading partner for the interchange report](#)
- [Specific status codes for the interchange report](#)
- [Edit and/or resend an interchange](#)
- [Resend an interchange Immediately](#)

Drill down tips

About this task

- Double-click a transmission in the interchange view-to-view functional group information.
- Double-click a transmission in the functional group view to display transaction information.
- Double-click a transmission in the transaction view to display segment errors (if any).

Specific trading partner for the interchange report

About this task

In the Interchange report, you can specify a specific trading partner.

To specify a specific trading partner

Procedure

1. In the **Trading Partner** area, enable the **Sending** or **Receiving** option button.
2. Click the **Find** button.
The specified data type Trading Partners dialog box appears.
3. Select a trading partner.
4. Click **Select**.
The selected trading partner appears in the **Name** field.

Specific status codes for the interchange report

About this task

In the Interchange report, you can specify a specific status code.

Procedure

1. To specify a specific status code
2. For the **Specific Status Code** field, enter the status code.
Or click the **Status Codes** button and select a status code from the **Find All Status Codes** dialog box. Click **Select**.
3. Click the **Run Report** button to run the Interchange report for the specific status code.

Edit and/or resend an interchange

About this task

In the Interchange report, you can select a single interchange and edit and resend that interchange immediately.

Note: The Display Options,>Editor/Viewer setting controls which text editor is used to edit the interchange.

To edit and resend an interchange

Procedure

1. Select a single interchange in the Interchange report.
2. Click the **Edit/Resend Interchange** button in the toolbar.
The Partner Manager Editor window appears.
3. Edit the interchange as desired.
4. If using a text editor other than the Partner Manager Editor:
 - Save the file and close that editor.
 - Click Revert on the Partner Manager Editor toolbar to view the interchange in the Partner Manager Editor window.
5. Click Resend on the Partner Manager Editor toolbar.
A confirmation dialog box appears.
6. Click OK to resend the data as displayed.
A resend status confirmation dialog box appears. The location of the resend data and the interchange file name is displayed.

Results

The resend, user, date and time stamp, and message appear in the Partner Manager Log report.

Note: The Security Group Maintenance,>Transmission Data setting controls edit and resend capability.

Resend an interchange Immediately

About this task

In the Interchange report, you can select a single interchange and resend that interchange immediately.

To resend an interchange immediately

Procedure

1. Select a single interchange.
2. Click Resend Interchange Immediately button on the toolbar.
A resend confirmation dialog box appears.
3. Click OK to send the interchange.
A sent confirmation dialog box appears.
4. Click OK.

Results

The resend, user, date and time stamp, and message appear in the Partner Manager Log report.

Note: The Security Group Maintenance > Transmission Data setting controls edit and resend capability.

Functional group report

The **Functional Group** report displays a summary of functional groups received (**Direction = Inbound**) or sent (**Direction = Outbound**) for sending or receiving trading partners.

For a complete description of all fields in the report display, see the section "[Functional Group View](#)".

- [Jumping to X12 997](#)
- [X12 acknowledgement reporting options](#)
- [Manual override of acknowledgement settings](#)
- [Functional group view](#)

Jumping to X12 997

About this task

The **X12 Functional Group** Report allows you to jump directly to the corresponding 997 from a functional group.

To jump to a X12 997

Procedure

1. Select a functional group.
2. Click the **Jump to Corresponding 997 group** icon in the toolbar.
The display "jumps" to the corresponding 997 from the functional group.
3. Use the report's **Back** button to return to the original report.
Note: Two conditions must exist for this function to be available. The selected functional group must have had its Functional Acknowledgment Received (that is, the FG Reconciliation has processed this record), and if user security is in force, the user's Security Group setting for "X12 997 Data: View Data" must be checked.

X12 acknowledgement reporting options

When an **Outbound X12 Functional Group** report is selected in the Reports dialog box, five options become available in the **Report Specific Search** area on the **Acknowledgement Reporting** drop-down menu:

| Option | Description |
|--------------------------|---|
| All Records | The default; displays all data regardless of Acknowledgement Status. |
| Overdue Acknowledgements | Only functional groups that have not been acknowledged within the time frame specified on the trade link will be included. See "Specifying Acknowledgement Timeframe". This time calculation is based on the number of hours specified on the trade link, the map execution date and time, and current date and time of the PC running Partner Manager. |
| All Unacknowledged | Only Unacknowledged Functions Groups will be included. |
| Acknowledged Only | Opposite of "All Unacknowledged"; only those functional groups that have been acknowledged will be included. |
| Manual Acknowledged Only | Only those functional groups that have been manually acknowledged will be included. See Manual Override of Acknowledgement Settings for additional information. |

Note: Functional groups that have a Functional Acknowledgement in Error will display a green and yellow arrow pointing right in this report. This arrow and unique color is used to distinguish between a good functional group (green circle), a Functional Group containing an error at a lower level (yellow diamond), and a Bad Functional Group (red stop sign).

Manual override of acknowledgement settings

About this task

The **X12 Outbound Functional Group** report allows you to manually set the acknowledgement flag. Normally, the maps set this acknowledgement flag automatically during functional group reconciliation when the 997 is received. However, there may be times where you want to set this flag yourself, perhaps after manual intervention with your trading partner.

To manually set the Acknowledgement flag

Procedure

1. Select the functional group record you wish to change in this report.

2. Click the **Manual Acknowledgement Override** icon in the toolbar.

The Manual Acknowledgement Override dialog box appears.

The Manual Acknowledgement Override dialog box displays a summary of the Functional Group you selected and two areas:

- **FA Received.** Select Yes or No

- **FA Status Code.** Select one of the four options presented from the **FA Status Code** drop-down menu Accepted, Partial, Rejected, or Error.

3. Click the **Save** button to save your changes, or click Cancel to bypass.

Changes are recorded in the **Partner Manager Log** report for auditing purposes. Additionally, the last manual override change is displayed in the **Acknowledgements** section of the **X12 Functional Group Detail** report.

Note: Partner Manager Security can be used to restrict access to the manual override function. The **Allow Override** check box in the Manual FA Override parameter in Security Groups controls this function. See ["Utilities"](#) for more information.

Functional group view

About this task

The **Functional Group View** displays information about functional groups that meet the specified report selection requirements. The information displayed includes:

| Field | Description |
|------------------|---|
| Transmission ID | A component of the ThreadID assigned by Message Manager system to the transmission. |
| Func'l ID Code | Functional ID code for the functional group from the GS. |
| GS Sender ID | GS address of the trading partner that sent the functional group. |
| Sender TP Name | Name of sending trading partner. |
| Sender AP Name | Name of sending application partner. |
| GS Receiver ID | GS address of the trading partner that received the functional group. |
| Receiver TP Name | Name of receiving trading partner. |
| Receiver AP Name | Name of receiving application partner. |
| FG Control No. | GS Control number of the functional group. |
| FG Version | Functional group version number. |
| FG Date | YYYYMMDD format of the date the functional group was created by the sender. (GS/UNG Envelope) |
| FG Time | HHMMSS format of the time the functional group was created by the sender. (GS/UNG Envelope) |
| Ack Status Cd | Functional acknowledgement status code. |
| Ack Recvd Flag | Flag that indicates receipt (Y or N) of a functional acknowledgement for the functional group sent. |

Procedure

1. To report on functional acknowledgements

2. Specify a **Functional Group Code of FA** in the **Report Specific Search** field.

Message/transaction report

The Message/Transaction report displays information on transactions. You can specify reporting on messages or transactions that match the following selection requirements:

- **Data Type** (select EDIFACT, **TRADACOMS**, or **X12**, or other standard from the drop-down list)
- Specific Post Office Nickname
- Specified Date Range
- Direction (Inbound or Outbound)
- Database (Current or Archive)
- Record **Status of All Records, No Errors**, records with **Errors Only**, or a Specific Status Code
- A Report Specific Search (enter a Message/Transaction Number)

The information displayed includes:

| Field | Description |
|-----------------|--|
| Transmission ID | A component of the ThreadID assigned by Message Manager system to the transmission. |
| TS ID | Transaction set code of the transaction. |
| TS Control No | ST control number of the transaction. |

| Field | Description |
|------------------|---|
| Status | Status code of the transaction set: V indicates Valid, E indicates Error. |
| Sender TP Name | Name of sending trading partner. |
| Sender AP Name | Name of sending application partner. |
| Receiver TP Name | Name of receiving trading partner. |
| Receiver AP Name | Name of receiving application partner. |

The information displayed for TRADACOMS includes:

| Field | Description |
|-------------------|--|
| Transmission ID | A component of the ThreadID assigned by the Message Manager system to the transmission. |
| Message Type | The name of the message in this document, for example INVHD . |
| Doc Body Index | The index of the body in this document. |
| STX Sender Info | The identifier specified in this message for the STX Sender. |
| STX Sender Name | The STX Sender's name, as found in Trading Manager database via the STX Sender Info field, above. |
| STX Receiver Info | The identifier specified in this message for the STX Receiver. |
| STX Receiver Name | The STX Receiver name, as found in Trading Manager database via the STX Receiver Info field, above. |
| SDT Info | The identifier specified in this message for the SDT Partner. |
| SDT Name | The SDT name, as found in Trading Manager database by way of the SDT Info field, above. |
| CDT Info | The identifier specified in this message for the CDT Partner. |
| CDT Name | The CDT name, as found in Trading Manager database by way of the CDT Info field, above. |
| Body Ref | The index of the body in this interchange. |
| Doc Type | The Document Type of this message, for example INVOIC . |
| Map Date | The date the map created this traffic record. |

- [Viewing 997 content](#)
- [Jumping to a functional group](#)

Viewing 997 content

About this task

The **X12 Transaction Report** allows you to view the content of the selected 997 transaction. This is useful to see how your partner responded to your transmission.

To view 997 content

Procedure

1. Select a 997 transaction.
2. Click on the **Display Report Detail** icon on the toolbar.

Results

If 997 content exists, it will be displayed in the right hand side of the **X12 Transaction Detail** window.

Note: The following conditions must be true in order to view 997 content. If user security is in force, the user's Security Group setting for **X12 997 Data: View Data** must be checked. Additionally, to have 997 content written to a database so it can be viewed here, the **Store 997 Content in Database** check box, found in Utilities>Message Manager Configuration, must be enabled.

Jumping to a functional group

About this task

The **X12 Transaction** report allows you to jump directly to the corresponding Functional Group from a 997 transaction.

To jump to a functional group from a 997 transaction

Procedure

1. Select a 997 transaction.
2. Click on the **Jump to Corresponding Functional Group** icon on the toolbar.
The display "jumps" to the functional group from the 997 transaction.
3. Use the report's **Back** button to return to the original report.
Note: Any traffic data converted from releases prior to Trading Manager V7.0 will not have this option available.

X12 TA1 status reports

The X12 TA1 Status reports TA1 status information for the specified date range.

The information displayed includes:

| Field | Description |
|-----------------------|--|
| Transmission ID | A component of the ThreadID assigned by the Message Manager system to the transmission. |
| Sender Ichg ID/Qual | ISA sender ID qualifier and address of the trading partner that sent the interchange. |
| Receiver Ichg ID/Qual | ISA sender ID qualifier and address of the trading partner that received the interchange. |
| Orig IC Ctrl No | Original ISA control number |
| Original IC Time | Original HHMM format of the time the interchange was created by the sender |
| IC Ack Code | ISA control number acknowledgement code. |
| IC Note Code | ISA control number note code |

Additional reports overview

The **Additional Reports** view enables you to generate detailed reports that you can print or export.

Additional reports include:

- Application Partner Detail Report
- EDIFACT Inbound Trade Link Application Report
- EDIFACT Outbound Trade Link Application Report
- Post Office Report
- TRADACOMS Inbound Trade Link
- TRADACOMS Outbound Trade Link
- Trading Partner Detail Report
- X12 Inbound Trade Link Application Report
- X12 Outbound Trade Link Application Report
- Post Office Where Used Report
- [Running additional reports](#)

Running additional reports

About this task

Additional reports are selected from the **File** menu.

To run additional reports

Procedure

1. Click on the **Reports** button on the toolbar.
The Reports window displays.
2. Select Additional Reports from the **Report Type** drop-down box.
3. Select a report from the **Reports** drop-down box.
4. Click the **Run Report** button.
The report-specific form appears.
5. Make your selections.
6. Click the **Run Report** button.

Printing Partner Manager reports

Traffic reports must be exported to xml, html, or text formats prior to being printed. You can then print the exported file from a browser, the Partner Manager Editor, or any text editor.

Exporting reports

Traffic reports use the Traffic Report Export feature.

Additional reports use the export feature.

- [Exporting traffic reports](#)

Exporting traffic reports

About this task

The **Traffic Report Export** feature enables you to export traffic reports to html, xml, and plain text formats.

You can specify the action to take place after the export is completed:

| Action | Description |
|-----------------------------|--|
| Launch Browser | The default browser is launched. |
| Launch Editor | The Partner Manager editor or the user-specified editor (defined in the Display Options utility) is launched. |
| Exit without Launching File | No editor or browser is launched. |

You can specify the number of rows to export and whether to include the traffic status color in the exported file.

If reports are exported to an existing file, the existing file is overwritten.

Note: The file that was overwritten is moved to the recycle bin.

To export a traffic report

Procedure

1. Click the **Export** button.
The Traffic Report Export dialog box appears.
 2. In the **Report Column**, select the columns to export.
 3. Select the **Export Method**.
 4. Select the **After Export Completes** action.
 5. Select the **Number of Rows to Export**.
 6. Enter the full path and filename of the export file or click **Browse** to navigate your file system to **Select/Enter Export File Destination**.
The **File name** defaults to the *reportview.reporttype* name.
 7. Specify the **File name**.
 8. Click **Save**.
If the export file already exists, an overwrite confirmation dialog box appears. Files that are overwritten are moved to the recycle bin.
 9. Click **Begin Export**.
The report is exported.
- [Default traffic report export settings](#)

Default traffic report export settings

About this task

- All report columns are selected for export by default.
- Where applicable, the **Include Traffic Status Color** check box is enabled by default.
- The default export method is **HTML Page**.
- The default behavior to occur after export is **Launch Browser**.
- The default number of Rows to Export is **All**.

Value Added Tax (VAT) reports

About this task

The TRADACOMS subsystem (inbound and outbound) will create VAT reports for any invoice type messages. For example: INVOIC, CREDIT, and UTLBIL. The VAT report will automatically be created in the default *install_dir\tnmgr_vn.n\mmgr\VAT_Reports* directory.

If you wish to change the default directory, you can change the location in the **Edit** Resource dialog box in the **Resource Registry**.

To change the default directory

Procedure

1. Open the **Resource Registry**.
2. Select **Open** from the File menu and navigate to the *install_dir\tnmgr_vn.n\mmgr\mmgr.mrm*
3. Expand the **mmgr** file.
4. Expand the **Resources** file.
5. Double-click the **mmgr_trc_VatReport** file.
The **Edit** Resource dialog box appears.
6. Edit the **Resource Value** to the desired location.
7. Click **OK**.

Partner Manager editor

This editor extracts data from the archives and presents the data to enable access to the original EDI data as presented to Trading Manager.

The Partner Manager Editor is used to:

- Edit and resend interchanges
- View reports exported in html or xml format.
- The Editor can be used to print the exported reports. Other features of the Editor enable you to:
 - Save the exported file
 - Save the exported file in a different format
 - Revert to the saved file (brings in the user-specified editor changes)
 - Launch a user specified editor
 - Find/Replace/Highlight text in the exported file
 - Format the exported file

Note: If you use the **Find/Replace/Highlight** feature and then resize the Editor window, the color changes are not saved.

Note: Use care when using the Editor as the user-specified editor may have multiple files open.

Resending E-commerce data

Inbound and outbound data that has been processed by Trading Manager can be viewed and edited. Run the Interchange traffic report to resend the interchange immediately or edit/resend the interchange data.

The resend interchange data feature extracts data from the Message Manager **archive** folder.

- The resend immediately feature allows you to resend a message immediately, without viewing or editing the original e-commerce data, inbound or outbound.
- The edit/resend interchange feature allows you to edit the interchange, and then resend it.

You must run the Interchange traffic report to access these features.

Note: The Security Group Maintenance, Transmission Data setting controls view, edit, and resend capability.

The ability to resend inbound or outbound data allows you to resubmit e-commerce data that had previously been transformed correctly, but may have encountered transmission errors during processing by the receiving application.

You can view and edit the original e-commerce data prior to resending to your trading partner or internal application. This allows you to update a code that did not pass EDI validation, or create a file containing only a single transaction set that for resubmission.

The **Message Manager** picks up and reprocesses the file that was resent. A new ThreadID reflects this resend activity.

The Server Directory Configuration Maintenance utility configures the location of the archived transmission data and the location where resent data is placed.

Note: For more information on the **Update** and **Resend** components of the Message Manager, see the Trading Manager documentation.

- [**Resend ThreadID**](#)

The **Message Manager System Resend** map creates a new **ThreadID** for the data, changing the origin indicator from original (**o**) to resend (**r**).

Resend ThreadID

The **Message Manager System Resend** map creates a new **ThreadID** for the data, changing the origin indicator from original (**o**) to resend (**r**).

For example:

- Original **ThreadID** - edi00001199809150001**o**.app
- Resent **ThreadID** - edi**00002**199809150001**r**.app

Partner Manager maintains a complete audit trail of the resent data based on its new **ThreadID**.

Utilities

This chapter describes Partner Manager options that are set using the Utilities navigator.

The navigator can be opened by clicking the **Utilities** icon on the Partner Manager toolbar, or by selecting Utilities from the File menu.

Options that can be set using the **Utilities** navigator include the following:

- Configuration
- Database Utilities
- Folders
- Security
- [**Configuration**](#)
- [**Field defaults**](#)

To speed data entry, use this form to enter default values for many of the fields seen in Partner Manager.
- [**Database utilities**](#)

- [Folders](#)
 - [Security](#)
-

Configuration

The **Configuration** utilities contains the following:

- Database Settings
 - Display Options
 - Message Manager Configuration
 - Post Office Search and Replace
 - Post Office Types
 - Server Directory Configuration
 - Standards
 - Field defaults
 - [Database settings](#)
 - [Display options](#)
 - [Message Manager configuration maintenance](#)
 - [Post Office search and replace](#)
 - [Post Office types](#)
 - [Server directory configuration](#)
 - [Standards](#)
 - [Adding and deleting TRADACOMS standards](#)
-

Database settings

In the **Database Settings** utility, you can:

- Change the database you are currently using; see "[Importing a Database Profile](#)"
 - Create a new database profile; see "[Creating a New Database Profile](#)"
 - Import a database profile; see "[Importing a Database Profile](#)"
 - Export a database profile; see "[Exporting a Database Profile](#)"
 - Edit an existing profile; see "[Editing an Existing Database Profile](#)"
 - Delete an existing profile; see "[Deleting an Existing Database Profile](#)"
 - [Database selection](#)
 - [Creating a new database profile](#)
 - [Importing a database profile](#)
 - [Exporting a database profile](#)
 - [Editing an existing database profile](#)
 - [Deleting an existing database profile](#)
 - [Selecting a different database profile](#)
-

Database selection

About this task

Partner Manager lets you change the current database through the Database Selection dialog box.

To change the current database

Procedure

1. From the File menu, select Database **Settings**.
The Partner Manager Database Selection window opens:
2. Select the database vendor from the drop-down menu.
3. Select the Data Source Name (**DSN**) from the drop-down menu.
Note: You create DSNs from the **ODBC** applet in the Windows **Control Panel**.
4. Enter a user ID and password, if required.
5. Enter the database file name.
Note: For Access and Oracle databases, you can leave the **Database** field blank. For all other database types, enter the name of the database, as it exists on the server.
6. (Optional) Enter a description of the database (as it will appear in the title bar).
7. Click **Test Connection**.
The **Connection Test OK** message box opens to inform you that the test has been satisfactorily completed.
8. Click **OK**.
The **Text Connection** message box closes.
9. Click **OK** in the Partner Manager Database Selection window.

A message box opens that informs you that Partner Manager parameters are being updated.

10. Click OK.
Partner Manager closes.
11. Restart Partner Manager to use the new database.

Creating a new database profile

About this task

To create a new database profile

Procedure

1. From the File menu, select Database **Settings**.
The Partner Manager Database Selection dialog box appears.
2. Click Profile Maintenance.
The Back-End Profile Maintenance dialog box opens.
3. Enter a name for the new profile and press **Tab** or **Enter**.
A dialog box appears asking you to confirm the creation of the new profile.
4. Click Yes to create the new database profile.
5. (Optional) Enter a description for the profile.
6. Select the Data Source Name (**DSN**) from the drop-down menu.
7. Enter a user name and password, if required.
8. Enter the database file name.
For Access and Oracle databases, leave the **Database** field blank. For all other database types, enter the name of the database, as it exists on the server.
9. Select a database vendor from the drop-down list.
10. Click **Test Connection** to confirm the database connection.
11. Click **Save** and **OK** to confirm the new profile.
12. Click **Cancel** to close the dialog box.

Results

You can now select the profile from the **Profile** drop-down list.

Importing a database profile

About this task

To import a database profile

Procedure

1. Open the Back-End Profile Maintenance window as described in "[Creating a New Database Profile](#)".
2. Click the **Import** button.
The Profile Import window opens.
3. Select an Import Source:
 - If you are importing from a file, click the **Browse** button and navigate to the file that you want to import. The path will be displayed in the **File to import** field.
 - If you are pasting XML from an existing file, select the **Paste from Clipboard** button to activate the **Paste Export File Here** text entry box. Click in the **Paste Export File Here** field and use the windows copy feature to copy the XML from the clipboard.
4. Select an Import Option:
 - If you want over-write the existing profile, select the **Over-write Existing** button.
 - If you do not want to over-write the existing profile (skip it), select the **Skip Existing** button.
5. Click the **Import** button.

Exporting a database profile

About this task

To export a database profile

Procedure

1. Open the Back-End Profile Maintenance window as described in "[Creating a New Database Profile](#)".
2. Click the **Export** button.
The **Profile Export** window opens.
3. Select a Profile ID by placing a check beside the desired profile in the list, or if you want to select all of the profiles, click the **Select All** button.
4. Choose the export method:
 - If you want to export the profile to a file, click the Export to File checkbox, then use the **Browse** button to navigate to the file you want.
 - If you want to export to clipboard, check the Export to Clipboard checkbox.
5. Click the **Export** button.
 - If you selected Export to File, the profile is copied to the file that you selected.
 - If you selected Export to Clipboard, the profile is copied to the clipboard.

Editing an existing database profile

About this task

To edit an existing database profile.

Procedure

1. From the File menu, select Database **Settings**.
The Partner Manager Database Selection dialog box appears.
2. Click Profile Maintenance.
The Back-End Profile Maintenance dialog box appears.
3. Select an existing profile from the **Profile** drop-down list.
4. Edit the settings.
Note: For Access and Oracle databases, leave the **Database** field blank. For all other database types, enter the name of the database, as it exists on the server.
5. Click Test **Connection** to confirm the database connection.
6. Click Save.
A dialog box opens that confirms successful database connection.
7. Click OK.
8. Close Partner Manager.
9. Restart Partner Manager.

Deleting an existing database profile

About this task

To delete an existing database profile

Procedure

1. From the File menu, select Database **Settings**.
2. The **Partner Manager Database** Selection dialog box appears.
3. Click Profile Maintenance.
The Back-End Profile Maintenance dialog box appears.
4. Select a profile from the **Profile** drop-down list.
5. Click Delete.
A confirmation box opens that asks you to confirm the delete.
6. Click Yes to delete the profile.
7. Click Cancel to close the Back-End Profile Maintenance dialog box.
8. Click OK to close the Partner Manager.
9. Restart Partner Manager.

Selecting a different database profile

About this task

To select a different database profile

Procedure

1. From the File menu, select Database **Settings**.
2. The **Partner Manager Database** Selection dialog box appears.

3. Select an existing profile from the **Profile** drop-down list.
 4. Click OK to close the Partner Manager.
 5. Restart Partner Manager.
-

Display options

About this task

The **Display Options** utility allows you to modify the display according to your personal preferences. Display options are set using the Display Options dialog.

Opening the Display Options dialog

Procedure

1. From the Tools menu, select Display Options.
The Display Options dialog box opens.
 2. Refer to the following sections to specify display options.
 - [Specifying processing options](#)
 - [Specifying transmission data options](#)
 - [Change the look and feel of the display](#)
-

Specifying processing options

About this task

The following procedures describe how to set processing options for your display.

To specify processing options

Procedure

1. Open the Display Options dialog as described in the Display Options section. Make certain that the Processing Options tab is selected.
 2. Select the most recently used trade links to display when you open Partner Manager by enabling or disabling the **Display Last Inbound Trade Link** check box, and/or the **Display Last Outbound Trade Link** check box.
 3. Specify the default date selection for all traffic reports. Select Today, or **All Dates**.
 4. Select Standards (**X12**, **EDIFACT** or **TRADACOM**).
Note: The **Standards** check boxes allow you to restrict display of EDI Standard-Specific options. For example, if your company does not use EDIFACT or TRADACOMS, you can disable these options and the screens specific to these two standards will not appear. You can always restore access to these standards by enabling the check box. This setting only applies to the PC running Partner Manager; it does not affect other users
 5. When you are satisfied with your selections, click Save.
-

Specifying transmission data options

About this task

The following procedures describe how to specify the editor and temporary directory to be used for viewing and editing transmission data in the traffic reports and during the traffic export.

To specify the default editor/viewer

Procedure

1. Open the Display Options dialog as described in the Display Options section.
2. Select the Transmission Options tab.
3. For the **Editor/Viewer**, enable an option button:
Default to Built-in Editor or
Default to User-Specified Editor
 4. If you choose to default to a user-specified editor, enter the full path of that editor application executable program file in the **User Specified Editor** field.
(For example, **C:\WINNT\Notepad.exe**).
Note: The user-specified editor must accept a file name as a parameter. The user-specified editor can be launched by default or launched from the Partner Manager Editor.
 5. Specify the **Temporary Directory**.
Note: While an interchange is being edited, it is placed in this temporary directory until the editing/resend operation is complete.
6. When you are satisfied with your selections, click Save.

Change the look and feel of the display

About this task

The following procedures describe how to make changes to the look and feel of the display based upon your personal viewing preferences.

To make changes to the Display

Procedure

1. Open the Display Options dialog as described in the Display Options section.
2. Select the Look and Feel tab.
3. If you want to hide the IBM banner that appears at the top of the Partner Manager application, disable the **Display IBM Banner** check box.

4. Select Startup Options:

If you want Partner Manager Windows to display in standard Windows default mode, enable the **Windows Default** check box.

If you would prefer the active window always be displayed on top of all others, enable the **Display at Top** check box.

Note: You may find that the Display at Top mode of operation is useful if you are using a lower resolution screen display (for example 800 x 600).

5. When you are satisfied with your selections, click Save.

Message Manager configuration maintenance

About this task

The Message Manager Configuration Maintenance window is used to specify the run-time parameters used by the system of maps in the Message Manager portion of Trading Manager.

These settings apply to all users of the current database (the current database is displayed in **Help > About**). If you have multiple Trading Manager databases (for example, Test or Production), you may want to set these parameters to all of them.

To specify Message Manager parameters

Procedure

1. From the Tools menu, select Message Manager Configuration.
The Message Manager Configuration Maintenance window opens.

2. Make changes to the fields in this window by selecting one of six tab views.

For a detailed description of fields contained in the tab views, refer to the tab view discussed in the following sections:

- ["Optimization Tab"](#)
- ["Mapping Options Tab"](#)
- ["Database Tab"](#)
- ["X12 Acknowledgements Tab"](#)
- ["Archive Options Tab"](#)
- ["Traffic Batch Archiving Tab"](#)
- ["Alerts tab"](#)
- ["Post Office Options tab"](#)

3. Click Save.

The information that you have entered using this form is saved.

- [Optimization tab](#)
- [Mapping Options tab](#)
- [Database tab](#)
- [Acknowledgements tab](#)
- [Archive Options tab](#)
- [Traffic batch archiving tab](#)
- [Alerts tab](#)
- [Post Office Options tab](#)

Optimization tab

Open the Message Manager Configuration Maintenance window with the Optimization tab selected.

Optimization Tab Field Descriptions

The Message Manager Configuration Maintenance window displays the fields described in the following table when the Optimization tab is selected:

| Field | Description |
|-------|-------------|
|-------|-------------|

| Field | Description |
|--|--|
| Maximum X12 FG Validation Size | The value entered represents the maximum size of a functional group that will be validated in a single pass. If a functional group is larger than this size, then each transaction will be validated individually. Best performance is achieved when validating the functional group in a single pass, but it will consume that much more memory and might exceed the capacity of the server and cause Trading Manager to fail. Setting this value allows for smaller functional groups to be processed as fast as possible while larger functional groups will not cause undue crashes or performance degradation. |
| Work File Options | The options available from this drop-down menu are used by Message Manager to determine the work file setting for all RUN maps used in the system. These options are:
-WM - places all work files in memory, which increases performance, but uses memory.
-W - places work files as physical files on the disk, using default work file names, which results in slower performance but reduces memory usage.
Note This option should only be used in specific debugging cases as it forces all RUN maps to be single threaded. If work files on disk are desired, use option -WU (see below).
-WD - indicates default work files on disk, delete when done.
-WU - indicates uniquely named work files on disk, delete when done. |
| One File per Put PO | For outbound files, creates one file containing all the interchanges destined for that specific put Post Office. This eliminates the need to develop a custom system to append all the data into a single file for delivery. |
| One File per Put PO per Interchange | For outbound files, this option allows this version of Trading Manager to run as it did in previous versions and creates one output file for each interchange. |
| X12 Inbound Data Containing Multiple Functional Groups | Check this box to route one file for each functional group. Uncheck to route one file consolidating all functional groups. |

Mapping Options tab

Open the Message Manager Configuration Maintenance window with the Mapping Options tab. Open the window as described previously. Refer to the following table for field descriptions.

Mapping Options Tab Field Descriptions

Open the Message Manager Configuration Maintenance window. The following fields are displayed when the Mapping Options tab is selected.

| Field | Description |
|---------------------------------|--|
| Maximum Reject File Size | This text entry field allows you to enter a value that restricts the amount of EDI data that can be shown in the reject cards. The Message Manager subsystems produce error reports for any EDI data content that fails validation. If the size of the reject data is greater than the value shown, then data will not be present in the error report. The data will still be archived and can be re-sent. A value of '0' means that the Reject data will always be shown in the Error Report. |
| Minimum Reject Data Size | This text entry field allows you to set a value that will cause Message Manager to ignore meaningless EDI data between interchanges or attached at the end, such as extra "new line" characters or messages from a VAN. The value should be set to less than the smallest size of an interchange, or data in general, that you expect to receive. |
| Optional X12/EDIFACT Validation | When enabled, this check box performs: For X12: IEA/GE segment count comparisons; IEA/ISA and GE/GS control number comparison and ST01/GS01 Validation. For EDIFACT: UNB/UNZ and UNG/UNE control number comparison and segment count comparison. |

Database tab

Open the Message Manager Configuration Maintenance window with the **Database** tab selected. Open the window as described previously in this section. Refer to the following table for field descriptions.

This tab view also provides the **Run Export** button. For details see the [Run Export](#).

Database Tab Field Descriptions

The Message Manager Configuration Maintenance window displays the fields described in the following table when the Database tab is selected.

| Field | Description |
|-------------------------------|--|
| Use Stored Procedures | When checked, stored procedures will be used for outbound control number generation and thread id generation on Oracle, SQL Server, Sybase, and DB2 (Non-z/OS). Not applicable for Access or DB2 running on z/OS. |
| Sort TSV Files During Extract | If this check box is enabled, Message Manager will re-sort the tables as they are being created in the export process. This is required when non-alphanumeric or lower/uppercase characters are used to uniquely identify Trading or Application Partners, and your database sort order does not match IBM's sort order. |
| Current DB Vendor | This is a read-only field used by Message Manager to generate SQL statements when they are database dependent. |

Run Export

The **Run Export** button allows you to trigger the Export process on demand, without having to cycle the Launcher. By default, Trading Manager is configured to run Export to synchronize the tsv files with the database at Launcher startup and every day at midnight. You can use the **Run Export** button if you want the tsv files to be synchronized immediately without having to wait for the scheduled time.

Note: Running unnecessary Exports adds overhead to Message Manager and can interfere with the processing of EDI data. You can review the results of a successful export by viewing the Partner Manager log file.

Acknowledgements tab

Open the Message Manager Configuration Maintenance window with the **X12 Acknowledgements** tab selected. Open the window as described previously. Refer to the following table for field descriptions.

Acknowledgements tab field descriptions

The Message Manager Configuration Maintenance window displays the fields described in the following table when the **Acknowledgements** tab is selected.

| Field | Description |
|---|--|
| Store 997 Content in Database | When enabled, this check box allows the content of all 997's received to be stored in the database so they can be viewed in traffic reports. Storing 997 data in the database increases the size of the database and can have an impact on Message Manager performance. |
| Ignore Missing Trade Links for Inbound X12 997's and EDIFACT CONTRL | If you do not want to custom process inbound 997/CONTRL, you can skip entering Trade Links for them and thus prevent Message Manager from generating Trade Link errors. Message Manager will still reconcile these acknowledgements against the outbound transactions recorded in the Partner Manager database regardless of this setting. |
| Create one FG for each 997 Transaction | By default Trading Manager will wrap as many 997 transactions in a single functional group as possible. When enabled, this option forces each 997 transaction to be wrapped in its own functional group. |
| No TA1s | Disables Trading Manager TA1 processing. |
| Create TA1 in TA1 Folder | Enables creating error TA1s and places them in the x12\TA1 folder. |
| Create TA1 and Route to Partner | Enables creating error TA1s and routes them to the external partner. |
| Create TA1 in TA1 Folder and Route to Partner | Enables creating error TA1s and places them in the x12\TA1 folder and also routes them to the external partner. |
| Create 000 TA1's | When enabled, this check box allows Message Manager to build TA1s for interchanges that do not fail the TA1 envelope check., as Message Manager, by default, only creates TA1s for interchanges that fail the check. These TA1s have a code of 000. |
| Default TA1 Post Offices | If TA1 routing is selected, these options have to be entered to properly route TA1. They define the default GET and PUT PO for any TA1 created. These default POs can be overridden for each partner in the Address Book. |

Archive Options tab

Open the Message Manager Configuration Maintenance window with the Archive Options tab selected. Open the window as described previously. Refer to the following table for field descriptions.

Archive Options tab field descriptions

The Message Manager Configuration Maintenance window displays the fields described in the following table when the **Archive Options** tab is selected.

| Field | Description |
|---|--|
| Inbound Transmission as delivered to Trading Manager (zip/tar) | Archive all inbound transmissions into Trading Manager in a zip or tar format. The archived files are located in <code>install_dir\tmgr_n.n\mmgr\archive\stampfil</code> folder and are not used by Trading Manager. Users that already have archiving processes somewhere else can disable this feature for better performance. |
| Outbound Transmission as delivered to Trading Manager (zip/tar) | Archive all outbound transmissions into Trading Manager in a zip or tar format. The archived files are located in <code>install_dir\tmgr_n.n\mmgr\archive\stampfil</code> folder and are not used by Trading Manager. Users that already have archiving processes somewhere else can disable this feature for better performance. |
| Inbound Interchange (Text) | Archives all inbound interchanges in text format. These files are used by Partner Manager's edit/resend feature. Feature can be disabled if Edit/Resend is not used. |
| Outbound Interchange before Trading Manager re-enveloping (Text) | Archives all outbound interchanges before re-enveloping in text format. These files are used by Partner Manager's edit/resend feature. Feature can be disabled if the Edit/Resend features are not used or not required. |
| Outbound Interchange after Trading Manager re-enveloping (Text) | Archives all outbound interchanges after re-enveloping in text format. These files are used by Partner Manager's edit/resend feature. Feature can be disabled if the Edit/Resend features are not used or not required. |
| Outbound Transmission after Trading Manager re-enveloping (zip/tar) | Archive all outbound transmissions out from Trading Manager in a zip or tar format. The archived files are located in the <code>install_dir\tmgr_n.n\mmgr\archive\sendx12</code> , <code>install_dir\tmgr_n.n\mmgr\archive\senddef</code> , or <code>install_dir\tmgr_n.n\mmgr\archive\sendtrc</code> folder (based on the data format) and are not used by Trading Manager. Users that already have archiving processes somewhere else can disable this feature for better performance. |

Traffic batch archiving tab

The Traffic Batch Archiving option automatically moves traffic to the on-line archive using Message Manager. Data will be kept for the number of days specified. The results of this archiving is reported in the Partner Manager log.

Open the Message Manager Configuration Maintenance window with the **Traffic Batch Archiving** tab selected. Open the window as described previously. Refer to the following table for field descriptions.

Traffic batch archiving tab field descriptions

The Message Manager Configuration Maintenance window displays the fields described in the following table when the **Traffic Batch Archiving** tab is selected.

| Field | Description |
|--------------------------------|--|
| Enable Batch Traffic Archiving | This flag enables the batch traffic archiving. |
| Days to Keep | Specifies how many days worth of traffic is to be left in the traffic tables. If you enter a 0 in this field, all traffic will be moved to the online archive. |

If you enable this option, any control numbers currently used for duplicate interchange control number checking are removed at the point that traffic is being archived, not at the point the option is enabled. The utility displays a warning to notify you of this before the setting is saved.

Alerts tab

When an alert is created by Message Manager, it is usually sent to the alert email address associated with the trading partner. There are cases, however, where an alert is generated before the trading partner can be determined. Set the fields on this tab to send an alert in such cases. You may also attach the data causing the alert using the checkbox Attach Data.

Post Office Options tab

The Post Office options tab contains a checkbox that allows you to enable the Fixed Post Office. If you check the **Use One GET Post Office per Standard** checkbox to disable all Get post office functionality in Partner Manager and the XML Autoload, and in its place use 3 Get post offices, one for each standard.

The Post Office options tab contains a checkbox that allows you to enable the Fixed Post Office. If you check the **Use One GET Post Office per Standard** checkbox to disable all Get post office functionality in Partner Manager and the XML Autoload, and in its place use 3 Get post offices, one for each standard. This will simplify usage by eliminating the need to continually specify where data is received.

If you uncheck this checkbox, the Launcher functionality method is restored and all original Get post offices are re-populated.

When using "One GET Post Office per Standard", the post office nicknames will be "X00" for X12, "E00" for EDIFACT, and "T00" for TRADACOMS, unless you already have a post office nickname with those values. If you already are using these nicknames, the final two numbers will be incremented until a unique value is reached. For example, if you previously have a "X00" and a "X01" post office nickname, the new post office nickname will be "X02".

Note: Close all Partner Manager windows before changing this functionality. In addition, all Message Manager functions must be stopped.
If you select the single Get post office option, the following functionality is affected in Partner Manager:

- The ability to change, "jump to" or "get info" on a Get post office on all inbound and outbound Trade Links is disabled.
- Post office maintenance on Get PO's is disabled
- Get post office entry in the Automatic Acknowledgements windows for X12 and EDIFACT is disabled
- You cannot delete any Get post offices
- The Get Post Offices in the Utilities...Field Defaults window is disabled
- The Get post offices in existing traffic report data are not converted as they represent historical data. You will still be able to select previously used Get post offices as selection criteria in the Reports window.
- You will not be able to save a Put post office having the same name or nickname as a Get post office that existed before you selected the "Use One GET Post Office per Standard". This is required in order to enable a restore of original Get PO's if the single Get PO option has been enabled, and then subsequently disabled.
- To maintain database consistency, the merge function is disabled if merging to a database where the value of this setting differs from the source value.
- In the initial Post Office view, the copy options on the Get PO are disabled.

Post Office search and replace

About this task

The Post Office Search and Replace function is used to replace Post Office Directory/Adapter command strings when deploying Message Manager on a different system.

To search and replace Post Offices

Procedure

1. Click the **Utilities** icon on the toolbar.
The **Utilities** navigator opens.
2. Click Configuration > **Post Office Search and Replace**.
The Post Office Search and Replace window opens.
3. Select a Post Office Type to be replace. You can choose to replace File Post Offices, All Post Offices, or you can choose a specific Post Office Type from the drop-down list.

4. Enter the existing Post Office Directory/Adapter Command string in the **Find What** text entry field.
 5. Enter the string that you want to replace the existing string with in the **Replace With** field.
 6. Click Replace.
-

Post Office types

The Post Office types window allows you to mark post offices that are not used by your organization as inactive. This window also allows you to add and delete post offices.

- [Marking a Post Office type inactive/active](#)
 - [Adding a Post Office type](#)
 - [Deleting a Post Office type](#)
-

Marking a Post Office type inactive/active

About this task

You can mark any post office type in the list as inactive as long as there are no post offices assigned to it. After the post office is marked as inactive, it will not appear in the list of post offices in the **Post Office** navigator.

To inactivate/activate Post Offices

Procedure

1. Click the **Utilities** icon on the toolbar.
The **Utilities** navigator opens.
 2. Click Configuration > **Post Office Types**.
The Post Office Types dialog opens.
 3. Select the Post Office that you want to make inactive and click **Edit**.
The Post Office Types Maintenance dialog opens.

Note: You cannot mark any post offices types as inactive if they currently have post offices assigned to them.
 4. Enable the **Inactive** check box.
You are returned to the **Post Office Types** form. Notice that a **Y** (Yes) now appears in the **Inactive** column of the form on the line associated with the post office that you deactivated.
 6. To make the Post Office active again, perform steps 1 - 3 of this procedure. When the Post Office Types Maintenance window opens, deactivate the Inactive check box and click **Save**.
An **N** (No) is displayed in the **Inactive** column of the Post Office Types dialog on the line associated with the post office that you activated.
-

Adding a Post Office type

About this task

You can add a Post Office Type.

To add a post office type

Procedure

1. Click Utilities icon on the toolbar.
The **Utilities** menu opens.
 2. Click Configuration > **Post Office Types**.
The Post Office Types dialog opens.
 3. Click **Add**.
The Post Office Types Maintenance dialog opens.
 4. Enter the post office type in the **Post Office Type** field.
 5. Enter a description of the post office type in the **Description** field.
 6. Click **Save**.
You are returned to the Post Office Types window. The new post office is displayed in the list.
-

Deleting a Post Office type

About this task

You can delete a Post Office Type.

Note: Supplied Post Offices cannot be deleted. These post offices include: OracleAQ; MessageQ Client; MessageQ Server; E-mail; File; FTP; HTTP; JMS; MQSeries Client; MQSeries Server; MSMQ; and VAN.

To delete a post office type

Procedure

1. Click the **Utilities** icon on the toolbar.
The **Utilities** menu opens.
2. Click Configuration > **Post Office Types**.
The Post Office Types dialog opens.
3. Select the post office to be deleted.
4. Click Delete.
A message box opens that asks you to confirm the delete.
5. Click Yes.
You are returned to the Post Office Types dialog. The post office is removed from the list.

Server directory configuration

About this task

The **Server Directory Configuration Maintenance** utility is used to:

- Specify the archive access method
- Specify FTP Connection Information
- Specify the **Archive** and **Resend** transmission data folder locations
- Specify the archive audit information
- Allow you to test the archive access and folder configuration

To access the Server Directory Configuration Maintenance utility

Procedure

1. From the Tools menu, select Server Directory Configuration.
The Server Directory Configuration Maintenance window opens.
2. Select the access method as either **FTP** or **Mapped Drive** by enabling the check box.
If **FTP** is selected, enter information in the fields in the **FTP Connection Information** area of the form.
3. Define the location of the archive and resend data folders.
4. Define the location of the share data folders. This initialization is needed for specifying the location of alias files and for use of the manual export function in the Message Manager Configuration utility.
See "[Managing Traffic Data](#)" for detailed information.

Standards

Note: **Incorrect use of this feature may result in invalidation of your trade links.** Ensure that you back up your Partner Manager database files before attempting the procedures described in this section.

The **Standards Maintenance** utility enables you to maintain X12, EDIFACT, and TRADACOMS standards such as versions, ID codes, and related standards components. You can add, edit, and delete versions.

The following procedures describe how to perform maintenance on X12, EDIFACT and TRADACOMS Standards.

- [Adding an X12 standard version](#)
- [Deleting an X12 standard version](#)
- [Adding X12 interchange standards or ID qualifiers](#)
- [Adding an X12 hex value](#)
- [X12 Structure Validation:Import](#)
- [X12 Structure Validation:Maintenance](#)
- [Deleting X12 interchange standards or ID qualifiers](#)
- [Selecting HIPAA institutions](#)
- [Importing HIPAA type qualifiers](#)
- [Adding an EDIFACT standard version](#)
- [Adding an EDIFACT partner ID code qualifier](#)
- [Adding an EDIFACT functional ID or message type](#)
- [Adding an EDIFACT hex value](#)
- [Deleting an EDIFACT standard](#)

Adding an X12 standard version

About this task

When you add a new X12 standard version, you must also add a functional ID and transaction set associated with that version. Partner Manager enables you to copy functional ID and transaction sets from an existing version. For example, you can create copies of versions with new version names.

To perform maintenance on X12 standards

Note: To exit from the Standards Maintenance window without adding a version or completing an add task, you must click Cancel. If you attempt to exit the dialog box by closing Partner Manager or the Partner Manager process, you may damage your Partner Manager database.

Procedure

1. From the Tools menu, select Standards.
The Standards Maintenance window opens.
2. Select X12 Versions from the **X12 Standards** drop-down menu.
3. Enter a version number in the **Version** field.
4. Click Save.
The Copy Transactions/Func ID's? dialog box appears.
5. Perform one of the following:
 - To copy functional IDs and transaction sets from another version, enter that version number and click OK.
 - To search for and select a functional ID, click Cancel.
6. Select X12 Functional ID from the **X12 Standards** drop-down menu.
The Standards Maintenance X12 Functional ID window appears.
7. Perform one of the following:
 - Enter a functional ID code in the **Functional ID Code** field.
 - Click Display Functional ID's to select a functional ID from the list box.
8. Click Save.
9. Select X12 Transaction Set from the **X12 Standards** drop-down menu.
The Standards Maintenance X12 Transaction Set window opens.
10. Perform one of the following:
 - Enter a transaction set ID in the **Transaction Set ID** field, or
 - Click Display Transaction Sets to select a transaction set from the scroll box.
11. Complete the **Transaction Set Description** field.
12. Click Save.

Deleting an X12 standard version

About this task

To delete an X12 standard version with associated transaction sets and functional IDs, delete its associated transactions sets and functional IDs first.

To delete an X12 standard version

Procedure

1. From the Tools menu, select Standards.
The Standards Maintenance form opens.
2. Select X12 Transaction Set from the **X12 Standards** drop-down menu.
The Standards Maintenance X12 Transaction Set window appears.
3. Click the **Display Transaction Sets** button.
The Find All Transaction Sets window opens.
4. Choose the transaction set associated with the version and functional ID and click Select.
You are returned to the Standards Maintenance X12 Transaction Set window.
5. Click Delete.
6. Select X12 Functional ID from the X12 Standards drop-down menu.
7. Click the **Display Functional IDs** button.
8. Select the functional ID associated with the version and click Select.
9. Click the **Delete** button.
10. Select X12 Versions from the X12 Standards drop-down menu.
11. Enter a version number in the **Version** field or click Display Versions to select a version number.
12. Click Delete.

Adding X12 interchange standards or ID qualifiers

About this task

You can add standards and ID qualifiers.

To add an interchange standard or ID qualifier

Procedure

1. From the Tools menu, select Standards
2. Select one of the following from the **X12 Standards** drop-down menu:
 - **X12 Interchange Standards**
 - **X12 Interchange ID Qualifiers**The **Standards Display X12 Interchange Standards**, or the Standards Display X12 Interchange ID Qualifiers window opens.
3. Enter a qualifier number in the **Qualifier** field.
4. Or click **Display Interchange Standards** or **Display Interchange ID Qualifiers** to select a number.
5. Click **Save**.
6. Click **Cancel**.

Adding an X12 hex value

About this task

Each X12 hexadecimal value supports up to two individual values, for example, 0D 0A (which is CR LF).

To add an X12 hex value

Procedure

1. From the Tools menu, select Standards.
2. Select X12 Hex Values from the **X12 Standards** drop-down menu.
The Standards Maintenance X12 Hex Values window appears.
3. Enter a hexadecimal value in the **Hex Value** field.
4. Enter a description in the **Description** field.
5. Click **Save**.

X12 Structure Validation:Import

About this task

Imports a file that is used by Message Manager to validate X12 Structure. This is a required step in the installation process for all databases other than Access.

To import an X12 Structure Validation file

From the Tools menu, select Standards.

Procedure

1. Select X12 Structure Validation:Import from the **X12 Standards** drop-down list.
The Standards Maintenance X12 Structure Validation: Import window appears.
2. Click the **Find File** button to browse for the file you wish to import.
The **StructureValidation.detl** file, located in the *install_dir\tmgr_vn.n\pmgr* directory, must be imported during installation.
3. Click **Begin Import**.

X12 Structure Validation:Maintenance

About this task

Allows additions, updates, and deletions of X12 Structure information.

Note: This is useful when new/custom standards are used.

To maintain X12 Structure Validation data

Procedure

1. From the Tools menu, select Standards.

2. Select X12 Structure Validation: Maintenance from the **X12 Standards** drop-down list.

The Standards Maintenance X12 Structure Validation: Maintenance window appears.

3. Enter information in the **Version**, **Transaction Set ID** and **Structure Text** fields.

4. Click Save.

Clicking Save will add or update the structure text.

Note: When you click the **Delete** button to delete a version, a dialog box appears instructing you to first delete the transaction set.

Deleting X12 interchange standards or ID qualifiers

About this task

You can delete standards and qualifiers.

To delete an interchange standard or ID qualifier

Procedure

1. From the Tools menu, select Standards.

2. Select one of the following from the **X12 Standards** drop-down list:

- **X12 Interchange Standards**
- **X12 Interchange ID Qualifiers**

The Standards Maintenance X12 Interchange Standards window, or the Standards Maintenance X12 Interchange Qualifiers window opens.

3. Enter a qualifier number in the **Qualifier** field.

- Or click Display Interchange Standards (if you opened the Standards Maintenance X12 Interchange Standards window) or
- **Display Interchange ID Qualifiers** (if you opened the Standards Maintenance X12 Interchange Qualifiers window) to select a number.

4. Click Delete.

Selecting HIPAA institutions

About this task

The **HIPAA Institutions** option allows you to populate the HIPAA Type 7 Institutions field in the X12 External Application Partners window.

To select HIPAA Institutions

Procedure

1. From the Tools menu, select Standards.

2. Select HIPAA Institutions from the **X12 Standards** drop-down menu.

3. Click the **Display Institutions** button.

The Find All HIPAA Institutions window opens.

4. Click on the **Medicare** option and click the **Select** button.

You are returned to the Standards Maintenance window.

5. Click Save.

Importing HIPAA type qualifiers

The HIPAA Type Qualifiers: Import menu item is available from the X12 Standards menu in the Standards Maintenance window. The use of this option is described in the Trading Manager Installation documentation.

Adding an EDIFACT standard version

About this task

An EDIFACT version label consists of three required fields and one optional field:

- Message Version Number
- Message Release Number
- Controlling Agency
- Association Assigned Code (optional)

To add an EDIFACT standard version

Procedure

1. From the Tools menu, select Standards.
2. Select EDIFACT Message Version Numbers from the EDIFACT Standards menu.
The Standards Maintenance EDIFACT Message Version Numbers window opens.
3. Enter a version number in the **Message Version No.** field.
4. Enter a description in the **Description** field.
5. Click Save.
6. Select EDIFACT Message Version Numbers from the EDIFACT Standards menu.
7. Enter a release number in the **Message Release No.** field.
8. Enter a description in the **Description** field.
9. Click Save.
10. Select EDIFACT Controlling Agency from the EDIFACT Standards menu.
11. Enter an abbreviation representing the version agency (such as the **UN**) in the **Controlling Agency** field.
12. Enter a description in the **Description** field.
13. Click Save.
14. (Optional) Select EDIFACT Association Assigned Code from the EDIFACT Standards menu.
15. Enter an abbreviation representing the association in the **Assoc Assign Cd** field.
16. Enter a description in the **Description** field.
17. Click Save.

Adding an EDIFACT partner ID code qualifier

About this task

You can add partner ID code qualifiers.

To add an EDIFACT partner ID code qualifier

Procedure

1. From the Tools menu, select Standards.
2. Select EDIFACT Partner ID Code Qualifiers from the EDIFACT Standards menu.
3. The Standards Maintenance EDIFACT Partner ID Code Qualifiers window opens.
4. Enter a code in the **ID Code Qualifier** field.
5. Enter a description of the partner in the **Description** field.
6. Click Save.

Adding an EDIFACT functional ID or message type

About this task

Adding an EDIFACT Functional ID/Message Type requires that you first add an EDIFACT standard version, as described in ["Adding an EDIFACT Standard Version"](#).

To add an EDIFACT functional ID or message type

Procedure

1. From the Tools menu, select Standards.
2. Select EDIFACT FuncIDMsgType from the EDIFACT Standards menu.
The Standards Maintenance EDIFACT Functional ID and Message Types window appears.
3. Select a message version number from the **Msg Version No.** list.
4. Select a message release number from the **Msg Release No.** list.
5. Select a controlling agency number from the **Controlling Agency** list.
6. (Optional) Select an associate assigned code from the **Assoc Assign Code** drop-down list.
7. Enter an abbreviation representing a functional ID or message type in the **FuncID/MsgType** field.
8. Enter a description in the **FuncID/MsgType Description** field.
9. Click Save.

Adding an EDIFACT hex value

Each EDIFACT hex value supports up to three individual values, for example, 27 0D 0A, as shown in the following table. The EDIFACT hex values delivered with Partner Manager are as follows:

| Hex | Value |
|-----|-----------------------|
| 1C | IS4 (File separator) |
| 1D | IS3 (Group separator) |

| Hex | Value |
|----------|--|
| 1E | IS2 (Record separator) |
| 1F | IS1 (Unit separator) |
| 20 | Space character |
| 27 | Single quote character (') |
| 27 0D 0A | Single quote-carriage return-line feed (` CR LF) |
| 2B | Plus sign (+) |
| 2C | Comma character (,) |
| 3A | Colon character (:) |
| 3F | Question mark character (?) |

To add an EDIFACT hex value

1. From the Tools menu, select Standards.
2. Select EDIFACT Hex Values from the **EDIFACT Standards** drop-down menu.
The Standards Maintenance EDIFACT Hex Values window opens.
3. Enter a hexadecimal value in the **Hex Value** field.
4. Enter a description in the **Description** field.
5. Click Save.

Deleting an EDIFACT standard

About this task

The following procedure describes how to delete the EDIFACT standards:

- Version
- Partner ID code qualifier
- Functional ID or message type

To delete EDIFACT standards

Procedure

1. From the **Tools** menu, select **Standards**.
2. Select a standard type from the **EDIFACT Standards** drop-down menu.
3. Enter the standard type information or click the display button to select a standard.
For example, to delete a message version number:
 - Click the **Display Message Version Numbers** button.
 - Choose a version number and click **Select**.
4. Click the **Delete** button.

Adding and deleting TRADACOMS standards

This section describes how to add and delete X12 Standards.

- [Adding a TRADACOMS document type](#)
- [Editing a TRADACOMS document type](#)
- [Deleting a TRADACOMS document type](#)

Adding a TRADACOMS document type

About this task

The following procedure describes how to add a TRADACOMS document type.

To add a TRADACOMS document type

Procedure

1. From the Tools menu, select Standards.
2. Select Document Types from the **TRADACOMS Standards** drop-down menu.
The Standards Maintenance window displays the TRADACOM information.
3. In the **Document Type** field, enter the document type you wish to add.
4. In the **Segment Versions** group box, enter the **Header**, **Trailer**, and **TAXCON Version** information assigned to this Document Type.
Note: The **TAXCON Version** is only enabled for **Invoice**, **Credit**, and **Utility Bill** types.
5. Enter the description in the **Description** field.

6. Click Save.

Editing a TRADACOMS document type

About this task

The following procedure describes how to edit an existing TRADACOMS document type.

To edit a TRADACOMS document type

Procedure

1. From the **Tools** menu, select **Standards**.
The Standards Maintenance window appears.
2. Select Document Types from the **TRADACOMS Standards** drop-down menu.
The Standards Maintenance window displays TRADACOM fields.
3. Click the **Display Document Types** button.
The **Find All TRADACOMS Document Types** window appears.
4. Choose a document type, and then click **Select**.
5. Edit the data fields as needed.
Note: The **TAXCON Version** is only enabled for **Invoice**, **Credit**, and **Utility Bill** types.
6. Click Save.

Deleting a TRADACOMS document type

About this task

The following procedure describes how to delete a TRADACOMS document type.

To delete a TRADACOMS document type

Procedure

1. From the Tools menu, select Standards.
2. Select Document Types from the TRADACOMS Standards drop-down menu.
3. Click Display Document Types.
4. The Find All TRADACOMS Document Types dialog box displays.
5. Choose a document type and click **Select**.
6. Your selection appears in the **Document Type** field.
Note: The remaining fields will automatically fill in after selecting the document type.
7. Click Delete.

Field defaults

To speed data entry, use this form to enter default values for many of the fields seen in Partner Manager.

Once entered here, these values will display when you are creating a new object such as a partner or trade link. Note that these defaults apply to users of the current database. The following default values can be entered.

- X12 ISA values such as ISA Address (qualifier), control version and separators
- X12 trading partner Security and Authorization settings
- EDIFACT partner qualifier, enveloping and duplicate control settings
- EDIFACT syntax defaults
- Post Office defaults
- **Deleting defaults**
When a field is optional in Partner Manager, you can delete an individual default by setting that field to blank.

Deleting defaults

When a field is optional in Partner Manager, you can delete an individual default by setting that field to blank.

You can also delete all defaults by clicking the **Delete All Defaults** button that appears at the bottom of the screen. This button will be displayed only if default values have been previously saved.

Database utilities

The **Database Utilities** contains the following:

- Merge
- Purge
- [Merge](#)
- [Purge](#)

Merge

About this task

Note: If user security is enabled, the user must have the following privileges to run the merge: **Folder Maintenance, Create Trading Partner, Create Application Partner, Create Folders, Create Inbound and Outbound Links and Create Post Offices.**

Partner Manager enables you to merge one database to another database. For example, this feature enables you to merge selected objects in a source test database into a destination production database.

The source database is the database currently open in Partner Manager and specified in the Data Source Name (DSN) profile. The information you can merge into the destination database includes Trading Partners, Trade Links, and Post Offices.

Note: To verify the current profile information, including DSN information, select About Partner Manager from the Help menu.

To merge a database into another database

Procedure

1. From the Tools menu, select **Merge to Another DB**.
The Merge: Select Destination Database window is displayed.
2. Select an existing profile or DSN.
Note: If you have not entered a profile to select, then enter the User ID, Password, Database (if not Oracle), and Database Vendor.
3. Click Next.
4. Select an option from the Merge Option dialog box:
5. Click Begin Merge.
6. Follow the merge wizard instructions and click Finish.

Results

The wizard varies slightly different depending on the item you select to merge. A message appears upon successful completion.

Note: The next time you perform a database merge, Partner Manager keeps the most-recently selected destination database as the default destination database.

- [Details on merging trade links](#)
- [Post Office and Trading Partner merge details](#)

Details on merging trade links

The merge function is useful for transferring information from a test environment to a production environment.

The **Inbound Trade Link** and **Outbound Trade Link** merge functions for X12 and EDIFACT transfer all Trade Link data to another database.

The functions also merge dependent information, such as Folders, Trading Partners and Application Partners (From, To, and Acknowledgement Partners), Post Offices, Contacts, and any Standards needed (EDIFACT, X12, Functional IDs, and Transaction Sets). Carefully review the initial and final analysis messages to ensure the Trade Link merged as you expected.

- The merge functions do not overwrite existing information; information is appended to destination databases. If the destination database has information in it that is identical to the source database, that information is not included in the merge from the source database. This feature allows you to transfer test Trade Links and related information before implementing them.
- Because the merge functions never overwrite information, you can add information to a copy of a production database, test it, and then **merge the new information only** to the production database.
- Review the initial and final analysis messages carefully on the Select to Merge dialog box to insure the accuracy of the merging databases; this dialog box provides Merge Analysis information about what specifically is to be merged.
- The EDIFACT Trade Link merge does not have the ability to merge a trade link that exists in the destination database.

Post Office and Trading Partner merge details

- Partner Manager does not complete a Post Office merge if the destination database contains a Post Office with the same **Name** or **Nickname**.
- Trading Partners merge their associated Application Partner information in the destination database.

- If the Trading Partner exists in the destination database but the associated Application Partner does not, the Application Partner is merged in the destination database.
- Partner Manager also creates any folders or subfolders you have created in the source database in the destination database. If the folder name exists in the destination database but is a different folder type than the source, Partner Manager merges the folder data in the appropriate folder. For example, data in a source X12 internal folder named **Track** is not merged into the destination X12 external folder named **Track**. Instead, Partner Manager merges the data into the default destination X12 *internal* folder **Internal X12**.

Purge

About this task

Use the following instructions to purge traffic and/or Partner Manager Log data. To purge data, open the Purge/Archive Traffic Reports window as follows

To open the Purge/Archive Traffic Reports window

Procedure

1. Click the **Utilities** icon in the Partner Manager toolbar.
2. Select Database > **Purge** in the **Utilities** navigator to open the window.
 - [Purging traffic or transmission data](#)
 - [Archiving batch traffic](#)

Purging traffic or transmission data

About this task

To purge traffic or transmission data

Procedure

1. With the Purge/Archive Traffic Reports window open, select the **Purge (Permanent Delete) Current Tables** button.
2. Select the type of data to be permanently deleted.
 - To permanently delete traffic data, continue with the next step.
 - To permanently delete transmission data, select the **Purge Transmission Data** check box.
3. All records will be purged before the date displayed in the **Purge/Move All Before this Date** field. If you want to choose a different date than the one displayed, open the calendar by clicking the arrow to the right of the field and select a new date.
Note: All records dated *before* this date will be purged. The purge will also remove any control numbers used for duplicate interchange control number checking, so the utility will display a warning prior to the purge.
4. Click **Begin Purge/Archive**. A message box opens that informs you that the purge is permanent and asks if you want to continue.
5. Click Yes.

Archiving batch traffic

About this task

To archive batch traffic

Procedure

1. With the Purge/Archive Traffic Reports window open, click the **Configure** button located in the **Batch Traffic Archive** area of the window. The Message Manager Configuration window opens with the Traffic Batch Archiving tab view displayed.
2. Check the **Enable Batch Traffic Archiving** check box.
3. Enter the number of days that the archive is to be kept. You can enter any integer between 1 and 365 (inclusive).
If you want to move *all* traffic to the online archive, enter 0 in the **Days to Keep** field. If you do not want to do this, continue with the next step. If you enter 0 the **Days to Keep Warning** will open which asks you to confirm your selection.
4. Click Save to close the Message Manager Configuration window and return to the Purge/Archive Traffic Reports window.
The number of days that the archive is to be kept is displayed in the window.

Results

Enabling this option will also remove any control numbers used for duplicate interchange control number checking (at the point the traffic is archived, not at the point the option is enabled), so that the utility will display a warning prior to saving this setting.

Folders

The **Folder Utilities** facility enables you to organize trading partners in subfolders under the main Address Book **Internal** and **External** folders.

Partner Manager enables you to add, rename, move, and delete internal and external X12 subfolders.

You may not delete or rename main folders. When you delete a subfolder, it deletes all objects (trading and application partners, contacts, transaction sets, and so on) in the subfolder.

- [Adding a subfolder](#)
- [Renaming a subfolder](#)
- [Moving a subfolder](#)
- [Deleting a Subfolder](#)

Adding a subfolder

About this task

To add a subfolder to a main folder

Procedure

1. From the Tools menu, select Folder **Utilities**.
The Folder Utilities window opens.
2. Select a folder.
3. Click Add Sub Folder.
The Folder Maintenance dialog box opens.
4. Enter a name in the **Folder Name** field.
Note: The name can be a maximum of 32 characters.
5. Click Save.
The new subfolder appears in the **Folder Utilities** list and the **Address Book** navigator.

Renaming a subfolder

About this task

To rename a subfolder

Procedure

1. From the Tools menu, select Folder **Utilities**.
The Folder Utilities dialog box appears.
2. Select a subfolder.
3. Click Rename.
The Rename Folder dialog box appears.
- Note: The name can be a maximum of 32 characters.
4. Change the folder name in the **Folder Name** field.
5. Click Save.
The folder is renamed.

Moving a subfolder

About this task

Moving a subfolder moves all objects (trading and application partners, contacts, transaction sets, and so on) in the subfolder.

Note: If the subfolder does not contain any trading partners, it cannot be moved.

To move the contents of one subfolder to another

Procedure

1. From the Tools menu, select Folder **Utilities**.
The Folder Utilities dialog box appears.

2. Select a subfolder.
3. Click Move. The Move Folder dialog box appears.
4. Enter an existing subfolder name in the text box and click OK.
A message informs you that the move was successful.
5. Click OK.

Deleting a Subfolder

About this task

When you delete a subfolder, it deletes all objects (trading and application partners, contacts, transaction sets, and so on) in the subfolder.

To delete a subfolder

Procedure

1. From the Tools menu, select Folder **Utilities**.
The Folder Utilities dialog box appears.
2. Select a subfolder.
3. Click Delete and confirm the delete action when prompted.

Security

The Security utility contains the following:

- ["Security Groups"](#)
- ["Security Parameters"](#)
- ["User Maintenance"](#)
- ["Prior Version Password Remover"](#)
- [Changing passwords](#)
- [Security groups](#)
- [Security parameters](#)
- [User maintenance](#)
- [Prior version password remover](#)

Changing passwords

You can change the password of the current user. This option is only available if security is in force; it is disabled until a valid user logs into Partner Manager.

- [Preventing easily guessed passwords](#)
- [Changing your password](#)
- [Password synchronization](#)

Password synchronization changes your Partner Manager password on all Partner Manager databases if it is changed in any.

Preventing easily guessed passwords

Passwords containing the user name and the words *secret* and *password*, *pass* and *word* will not be accepted as valid passwords. For example, if the user name were Fred, a password of *123Fred123* would be rejected as it contains the user name. This check will only be performed on newly entered passwords. Passwords converted from prior versions will not be subject to this restriction.

Changing your password

About this task

The following steps describe how to change passwords

To change your password

Procedure

1. From the Tools menu, select Security > **Change Password**.
The **Partner Manager Change Password** dialog box opens.

2. Complete the fields in the dialog box. See "[Preventing Easily Guessed Passwords](#)" before changing a password.
3. If you want this password synchronized across all your Trading Manager database profile, check the box labelled **Run Password Synchronization After Save**. See [Password synchronization](#).
4. Click OK.
A message box opens that tells you that the password has been changed.

Password synchronization

Password synchronization changes your Partner Manager password on all Partner Manager databases if it is changed in any.

The databases can be from different vendors, for example, a test Access database and a production DB2 database. This synchronizes the Partner Manager password only, not the password associated with the database. Database passwords are controlled by the database vendor's tools, so they cannot be synchronized by Partner Manager.

Three conditions control this feature:

- Condition 1 - Database profiles must be defined (found on the Database Settings dialog). The passwords are changed in the databases defined in these profiles.
- Condition 2 - The user being changed must exist in those databases defined.
- Condition 3 - The Security Group Parameter labeled **Allow Password Synchronization** must be checked "on" for the current user running Partner Manager. This feature is "off" for new installations or upgrades. This parameter is found in the Utilities, Security Groups section labeled **General Access**.

If condition 1 or 3 (above) are false, the **Run Password Synchronization After Save** checkbox enabling this feature will not be visible.

Passwords can be changed in two places in Partner Manager:

- in User Edit, when a user is created or modified
- through the **Change Password** popup

If a password is changed in either of the two forms, check the checkbox labeled **Run Password Synchronization After Save** to begin this procedure. When a password gets changed and this checkbox is checked, the system will attempt to find that user in all selected Database profiles and then change the password to the value just set.

- [Security parameters that impact passwords](#)

There are additional security parameters that impact passwords, specifically, Minimum Password Length and Password Re-use history in Security Parameters and User Cannot Change Password found on the User record itself.

- [Password synchronization run-time errors/messages](#)

Potential run-time errors may appear during password synchronization.

Security parameters that impact passwords

There are additional security parameters that impact passwords, specifically, Minimum Password Length and Password Re-use history in Security Parameters and User Cannot Change Password found on the User record itself.

These security parameters are set by database, so the possibility exists that the Minimum Password Length, Re-Use History, or ability to change a password differs in the profiled databases. The synchronization routine checks these conditions in all databases against the newly changed password, and will disallow the synchronization if required. The failure reason will be displayed during the synchronization phase, for example "New password has an invalid length in Profile XYZ", or "Password not allowed in Profile XYZ because Re-Use-Rule violated".

In addition, the Security Parameter "Log All Security Maintenance" is honored. If the synchronization changes a password with that setting enabled, a Partner Manager Log record will be created in the same database being changed. An additional Log Record in the current database summarizing the synchronization phase will be written if logging is enabled ("User name syncd password to n profile").

The **PW Expiration Date** field in the Users table will be updated to reflect the new expiration date, and the **User Must Change Password On Next Login** flag will be cleared on all accounts updated across all selected databases.

Failure reasons will display in the list of profiles selected. Because failure reason text can be lengthy, clicking on a Profile will display the complete status of that profile in a text box below the list.

An account that is currently locked out on a database will still have its password changed, but it will not unlock that account.

Note: Database profiles are stored individually by PC, in the Windows Registry, so Profiles can differ based on where partner manager is running. Ensure your Database Profiles reflect their database instances correctly.

Password synchronization run-time errors/messages

Potential run-time errors may appear during password synchronization.

You may encounter the following during synchronization:

- Database Profiles allow you to omit the database password, thus making you enter it during entry to Partner Manager. You will be asked for that database password during the synchronization phase if that is the case. This is due to the fact that Partner Manager passwords are not the same as Database Passwords.
- Database Profiles can be invalid for numerous reasons (for example: if the database user/password is wrong, server has moved, or the database is a different Partner Manager version). Some of these errors can only be determined during a database connection attempt, and are reported back by the database. Such error messages will not have a standard format; they will vary by database vendor and database version. It is not uncommon to see popup messages during the synchronization phase if Profiles are invalid.
- As a database transaction (begin/commit) cannot be performed across different databases, it will be possible that some of the passwords synchronized and others did not, if an error was reported.
- It is possible that no passwords were synchronized if you, as a Partner Manager user, do not exist in the profiles defined, or if all of the profiles are invalid.

Security groups

About this task

Partner Manager enables you to define groups with security permission attributes and assign users to those groups. Assigned users log into Partner Manager.

Note: From the Help menu, select About Partner Manager to view the current **User ID** and **Security Group**.

Defining security groups enables you to configure default sets of permissions that you can then assign to one or more Partner Manager users. You can use the security profiles provided, or adjust the access selections to fit your needs.

You can add, edit, and delete security groups. You then define and add users to security groups.

Partner Manager provides three suggested levels of group permissions. You can use the following as a template for your security needs:

- **Administrator** - Provides full permission to security, purge and archive, EDI wizard, access, create, edit, and resend functions
- **Power User** - Provides **Administrator** permissions, except for security and purge/archive functions
- **Read Only** - Provides access-only permissions for Trading Partner, Application Partner, Post Offices, Inbound Trade Links, and Outbound Trade Links information
- [Adding a new security group](#)
- [Editing security group settings](#)
- [Deleting a security group](#)

Adding a new security group

About this task

Adding a security group defines permissions for users that belong to that security group. At least one user must be added to a new security group before the security group can be used.

To add a new security group

Procedure

1. From the Tools menu, select Security>Security Groups.
The Security Group Maintenance window appears.
2. In the **Group ID** field, enter the new security group name (up to 10 characters).
3. Press **Enter**.
A confirmation dialog box appears.
4. Click Yes to create the new security group.
5. (Optional) In the **Group Desc.** field, enter a description for the group.
6. Define the security group permissions by clicking a **Security Profiles** button: **Administrator**, **Power User**, or **Read Only**.
7. The default settings for the category are enabled.
Note: Click Clear All to clear all permissions currently enabled.
8. To customize the permissions, enable or disable the check boxes for access settings.
9. Click Save to create the group.

Editing security group settings

About this task

Existing security groups can be modified.

To edit security settings for an existing group

Procedure

1. From the Tools menu, select Security>Security Groups.
The Security Group Maintenance dialog box appears.
2. Select the group ID for the existing group from the **Group ID** drop-down list.
Edit the permissions for this security group.
3. Click Save.

Deleting a security group

About this task

All users assigned to the security group must be deleted prior to deleting the security group.

To delete an existing security group

Procedure

1. From the Tools menu, select Security > Security Groups.
The Security Group Maintenance dialog box appears.
2. Select the security group from the **Group ID** drop-down list.
3. Click Delete.
A delete confirmation dialog box appears.
4. Click Yes.

Security parameters

About this task

This section describes how to set the various Partner Manager security parameters using the Security Parameters window.

To set security parameters

Procedure

1. From the Tools menu, select Security > Security Parameters.
The Security Parameters window opens.
2. If you want to enforce use of a password that consists of a minimum number of characters, enable the **Enforce Minimum Password Length** check box.
The **Minimum Length** field will become active and a default value will be displayed in the field. You can change the default value. The system will then detect existing passwords that do not meet the minimum length requirement.

Note: If you leave the field blank (check box disabled) any password length, including zero, will be valid. (See "[Preventing Easily Guessed Passwords](#)" before selecting a password.)
3. If you want to force a user to be locked out after a number of invalid logon attempts, enable the **Enforce Maximum Invalid Logins** check box.
The **Maximum Invalid Attempts** field will become active and a default value will be displayed in the field.
 - You can change the default value. The system will then lock out any user entering invalid logons for the specified number of times.
 - When the **Enforce Maximum Invalid Logins** check box is enabled, the **Log Accounts Locked Out** check box is active (not grayed out). When enabled, this check box will cause accounts logged out data to be written to the Partner Manager Log File. If you do not want the accounts logged out to be logged, disable this check box.
4. If you want to log all security procedures in the Partner Manager log, enable the **Log All Security Maintenance** check box.
Note: The security procedures logged include: creating and maintaining user ids, security groups, security parameters, and changing password.
5. If you want to log all user logon activity in the Partner Manager log, enable the **Log All Logon Activity** check box.
When this option is selected the Partner Manager log will record all user logon and logoffs, as well as record whenever invalid logon attempts occur.
6. If you want to activate the Password History option, enable the **Enforce Password History** check box.
The By user, prevent the following number of passwords from being used field will be enabled.
 - Enter a value in the field. The default value of the field is 4, and must be a value greater than 1. When a user changes his or her password, the system will prevent the new password from being the same as the last number of passwords specified in this field.
7. Click Save.
A message box opens that informs you that Security Parameters have been successfully updated
8. Click Ok.
The message box closes and the parameters are saved.

User maintenance

About this task

User permissions are defined in the security group permissions. Selecting the **Group ID** on the **User Information** dialog box assigns the user to a specific security group.

A user definition consists of:

- User ID (for logon)
- User Name (optional description)
- Password
- Confirm Password
- Group ID
- Password options

You can add, edit, and delete users. The Change Password feature allows users to change their password.

- [Adding a user to a security group](#)
 - [Editing a user](#)
 - [Deleting a user](#)
 - [User login with security](#)
-

Adding a user to a security group

About this task

To create a user, enter his/her name, password, password expiration rules, and select the Security Group to define the user's permissions.

Note: From the Help menu, select About Partner Manager to view the current **User ID** and **Security Group**.

To add a user to a security group

Procedure

1. From the Tools menu, select Security>User Maintenance.
The Security Users window opens.
2. Click Add.
The User Maintenance: Add window opens.
3. Enter the **User ID** for the new user.
4. Enter a **Group ID**.
Note: The **User ID** and **Group ID** fields are required fields. All others are optional. Complete the following steps if desired. If not continue with step 10.
 5. In the **User Name** field, enter a description for the user.
 6. In the **Password** field, enter a password for the user. (See "[Preventing Easily Guessed Passwords](#)" before selecting a password.)
 7. If you entered an optional password, enter the password again in the **Confirm Password** field.
 8. Select a **Group ID** to assign this user to a security group.
 9. Select any desired password options.
 - If you want to force the user to change their password at the next logon, enable the **User Must Change Password at Next Logon** check box.
 - If you want to disable the user's ability to change passwords, enable the **User Cannot Change Password** check box.
 - If you want to disable the account, enable the **Account is Disabled** check box.
 - If you want to select a number of days for password expiration, click Password expires every: and enter a number of days in the **days** field.
10. Click Save.
You are returned to the Security Users dialog box and the new user is added to the list.

Editing a user

About this task

You can edit information about a user.

To edit an existing user

Procedure

1. From the Tools menu, select Security>User Maintenance.
The User Information dialog box appears.
2. Select a User ID from the User ID drop-down list.
3. You can edit the password for this user or select a different security group from the **Group ID** drop-down list.
4. Click Save.

Deleting a user

About this task

You can delete users. You must delete users before deleting the security group they belong to.

To delete an existing user

Note: Deleting the last user in Partner Manager disables all user and group security.

Procedure

1. From the Tools menu, select Security>User Maintenance.
The User Information dialog box appears.
2. Select a **User ID** from the **User ID** drop-down list.

3. Click the **Delete** button.
A confirmation dialog box appears.
4. Click Yes to confirm the delete of the user.

User login with security

About this task

After you configure security groups and add users, exit Partner Manager. When the Partner Manager application is restarted, the Partner Manager User Login dialog box appears.

To start Partner Manager with security

Procedure

1. Start the Partner Manager application.
The Partner Manager User Login dialog box appears.
2. Enter a valid **User ID**.
Note: The next step is valid only if you configured a Password with the User ID.
3. Enter a valid Password.
4. Click OK.

To log in as another user from within Partner Manager

Procedure

1. From the File menu, select Login as another User.
The **Partner Manager** Login dialog box appears.
2. Enter a valid **User ID**.
3. (Option) Enter a valid **Password**.
4. Click OK.

Prior version password remover

About this task

You can remove prior Trading Manager passwords from the Windows registry by using the Prior Version Password Remover.

To remove old passwords

Procedure

1. Choose the **Utilities** icon from the Partner Manager toolbar, then select Utilities > **Prior Version Password Remover** from the **Utilities** navigator.
The Prior Version Password Remover window opens.
2. Click Begin to start the Windows registry search for prior passwords.
Note: This process may take several minutes.
When the process completes, passwords are cleared.
3. Click Cancel.

EDI Wizard

The EDI Wizard creates type trees used by the Message Manager during the processing of your inbound and outbound data, therefore, it must be run before the Message Manager is built the first time. After you have defined your inbound and outbound trade links in your initial implementation, run the EDI Wizard to create the type trees.

Whenever a new transaction set or an existing transaction set for a new version of the standard is added, run the EDI Wizard again to update the definitions of the data to be recognized by the Message Manager.

- [EDI standard type trees](#)
- [Running the EDI Wizard](#)
- [Where the Type Trees are located](#)
- [When the EDI Wizard cannot locate a type tree](#)
- [When more than one type tree is found for a version](#)

EDI standard type trees

The EDI Wizard creates the following EDI standard type trees:

- **x12user.mtt** (X12 and EDIFACT): You can use the type tree in your application maps. If you have both X12 and EDIFACT data, two trees will be generated: **x12user.mtt** and **edifuser.mtt**. These type trees contain all the definitions for the EDI data processed by the Message Manager for all transaction sets for all versions of the standard required for the trade links that are defined.
- **x12mail.mtt** (X12) and **edifmail.mtt** (EDIFACT): Message Manager uses these type trees. They are referenced by a series of the Message Manager maps. When the EDI Wizard generates these type trees, they are placed in the same directory as the Message Manager maps and trees.
- **EDI Mail Trees:** The EDI Wizard will create both **x12mail.mtt** (X12) and **edifmail.mtt** (EDIFACT) trees if you have the trees for these standards. Message Manager uses these type trees. They are referenced by a series of Message Manager maps. When the EDI Wizard generates the type trees, it is placed in the same directory as the Message Manager maps and trees.
- **EDI User Trees:** You can use the type tree in your application maps. The EDI Wizard will create both X12(**x12user.mtt**) and EDIFACT (**edifuser.mtt**) trees if the 'Create User Trees' option is selected. This type tree contains all the definitions for the EDI data processed by the Message Manager for all transaction sets for all versions of the standard required for the trade links that are defined. These trees are created in the same directory as the Message Manager maps and trees.
Note: The EDI Wizard will not create TRADACOMS trees.

Running the EDI Wizard

About this task

The EDI Wizard creates type trees from Trade Link definitions.

To run the EDI Wizard

Procedure

1. Select EDI **Wizard** from the Wizard menu on the toolbar.
The Type Tree Wizard dialog box appears.
2. Click Next.
3. Click Next to begin to create the customized EDI type trees.
4. Follow the wizard instructions to create your type tree.

Where the Type Trees are located

About this task

The wizard prompts you to:

- Search the trading relationships defined in the Partner Manager.
- Enter the location of the type trees used to create the standard EDI type trees and searches for these trees.
- Enter the location and file name for the new type trees. When you first run the wizard, accept the default type tree names.

When prompted to specify a directory for new Message Manager Standard type trees, choose the directory where the Message Manager source maps and type trees are located. If you choose a different directory and attempt to create the type tree, a dialog box displays alerting you to this fact and asking you to confirm that you want to create this type tree in the specified directory.

If you have X12 trade links, the EDI Wizard will create the **x12mail.mtt** type tree in the specified directory.

If you have EDIFACT trade links, the EDI Wizard will create the **edifmail.mtt** type tree in the specified directory.

Note: if you are using a message version 90 (release 1), which contains the INVOICE and ORDERS messages, you must select the **edif90_1_ctrl.mtt** type tree when using the EDI Wizard to create the **edifmail** tree. Users who do not have message version 90 (release 1) messages need to use the **edifiso9735-4.mtt** when using the EDI Wizard to create the **edifmail** tree.

After the Wizard is finished, it displays a message that the customized type trees have been created.

After a new **x12mail.mtt** (X12) and/or **edifmail.mtt** (EDIFACT) type tree is created, you must redeploy both Trading Manager and Message Manager run maps. See Step 13 in Chapter 5 of the *Trading Manager Installation and User Guide* for instructions on this procedure.

When the EDI Wizard cannot locate a type tree

When the EDI Wizard cannot locate a type tree for a version that is needed, it displays a dialog box showing the type trees that it could not find. It is recommended that you cancel the wizard, install or re-locate the requested type trees, and then restart the wizard.

However, you can generate an incomplete type tree and add the other types manually. It is highly recommended that expert users perform the type tree modification only when a version of the requested type tree is not available. If you do select to continue to generate the type tree, a dialog box appears asking you to confirm creation of an incomplete type tree.

It should be noted that if you generate an incomplete type tree, you must manually add the types representing the transaction sets for the versions of the standard type trees that could not be found, before building the Message Manager maps.

When more than one type tree is found for a version

About this task

When the wizard locates more than one type tree for a particular version of the standard, it displays a dialog box listing those trees.

How to continue

Procedure

1. Select the appropriate type tree.
 2. Click Next.
When possible, use the original version of the standard trees that are installed for the type trees.
-

Database copy utility

The Database Copy Utility copies an existing Partner Manager Database to an empty (newly created) database. The newly created database can be a copy of **M4EC_Empty.mdb**, or a database created by ***inst.sql** scripts that ship with Partner Manager. This copy can be run with a transaction or without a transaction.

It should be noted that the default setting is within a transaction.

The **Run Copy Without Transaction Control** check box should only be enabled if the source database is very large and is causing **LogFile** full errors. If an error occurs when running without a transaction, no rollbacks occur. You must start over with an empty database.

The Database Copy Utility is accessed from the Start menu.

To start the Database Copy Utility

1. From the **Start** menu, click **Programs** IBM WebSphere Transformation Extender n.n.2_Trading Manager then **Database Copy Utility**.
The Partner Manager Copy Utility dialog box opens.
 - [Copying databases](#)
 - [Database scripts](#)
-

Copying databases

About this task

The Database Copy Utility enables you to copy an existing Partner Manager database to another empty database.

The empty database can be the **m4ec_empty.mdb** file or a newly created database created by the ***inst.sql** script files (both files are installed as part of Trading Manager).

This copy may be run without transaction control enabled if the source database is very large. If an error occurs when executing the database copy, and transaction control is not enabled, and no rollbacks occur; you must start over and create a new empty database (using the database drop, inst, and load scripts) or copy the **m4ec_empty.mdb** file (this file is valid for Microsoft Access database files only).

Database scripts

Run the ***drop**, ***inst**, and ***load** scripts on the database or for **Access** make another copy of **M4EC_Empty.mdb**.

- [*drop scripts](#)
 - [*inst scripts](#)
 - [*load scripts](#)
-

*drop scripts

These .sql files are installed in the *install_dir\tmgr_vn.n\pmgr\sql* directory:

- **db2dropnn.sql**
 - **oradropnn.sql**
 - **sqldropnn.sql**
 - **sybasedropnn.sql**
-

*inst scripts

These .sql files are installed in the *install_dir\tmgr_vn.n\pmgr\sql* directory:

- **db2instnn.sql**
- **orainstnn.sql**

- [sqlinstnn.sql](#)
- [sybaseinstnn.sql](#)

*load scripts

These .sql files are installed in the `install_dir \tmgr_vn.n\pmgr\sql\` directory:

- [db2loadnn.sql](#)
- [orainstnn.sql](#)
- [sqlinstnn.sql](#)
- [sybaseinstnn.sql](#)
- [sybaseinstnn_2.sql](#)

Managing traffic data

Partner Manager enables you to archive and purge the traffic record data in your Partner Manager database. (These records represent the Partner Manager e-commerce traffic.) Larger databases may slow down processing and result in unmanageable numbers of entries in each traffic report.

Partner Manager provides the following information management options that enable you to:

- Purge data from the Current traffic tables
- Purge data from the Online Archive traffic tables
- Archive data from the Current traffic tables to the Online Archive tables
- Archive data from the Current traffic tables to the zip file archives
- Archive data from the Online Archive tables to the zip file archives
- Restore data from a zip file archive

Partner Manager provides the following information management options:

| Option | Description |
|---|--|
| Purge (Permanent Delete) Current Tables | Permanently deletes traffic records before a specified date from the Partner manager database. These records cannot be restored. |
| Move to On-Line Archive | Places traffic records before a specified date in the Archive tables in the Partner Manager database. The records are then purged from the current Traffic tables. |
| Move to Current to Off-Line Zip File | Stores traffic records before a specified date in a zip file. These records are then purged from the current Traffic tables. |
| Move On-Line Archive to Off-Line Zip File | Stores traffic records before a specified date from the Archive tables in the Partner Manager database in a zip file. These records are then purged from the Archive tables. |
| Purge (Permanent Delete) of On-Line Archive | Permanently deletes traffic records before a specified date from the Archive tables in the Partner Manager database. These records cannot be restored. |
| Restore Zip File | Restore files archived in a compressed zip file using the Move to Current to Off-Line Zip File or Move On-Line Archive to Off-Line Zip File features. |

- [Purging current traffic or online archive data](#)
- [Archiving traffic data](#)

Purging current traffic or online archive data

About this task

This procedure permanently deletes traffic data from the **Current** traffic database tables.

Note: If the **Purge (Permanent Delete) Current Tables** or the **Purge (Permanent Delete) of Online Archives** purge option is enabled, a **Purge Transmission Data** check box is available. Enable the **Purge Transmission Data** check box to permanently delete the transmission archive of interchange data. This transmission archive folder is defined in the Directories > Archive field of the Server Directory Configuration Maintenance utility.

Before purging data, see the Check the Traffic Table Report Count section for information about traffic table counts.

To permanently delete current traffic information

Procedure

1. From the Tools menu, select Purge.
 2. The Purge/Archive Traffic Reports dialog box appears.
 3. Enable one of the following options:
 - Purge (Permanent Delete) Current Tables
 - Purge (Permanent Delete) of Online Archives
 4. Click the **Calendar** button to select a date.
 5. Click a date in the Calendar dialog box.
All traffic records before but not including this date are permanently deleted from the Partner Manager tables.
- Note: To quickly purge all records, add a future date.

6. Click Select.
 7. Click Begin Purge/Archive.
 8. Click Yes to confirm the purge action.
 9. As the traffic records are being deleted from the Partner Manager database, the current task displays in the **Purge Status** area. After the purge process is completed, a dialog box appears identifying the number of records purged.
 10. Click Cancel to close the Purge dialog box.
- [Check the traffic table report count](#)
-

Check the traffic table report count

About this task

This procedure enables you to check the number of traffic reports to determine whether you need to purge data. The Traffic Report Counts window shows the current number of reports by type using the actual database table name.

The following lists the database table name to the report name available from the **Reports** navigator. Any table name that includes the word **Archive** (such as **ECArtArchive**) shows the number of traffic reports in the traffic data archive.

| Database Table Name | View in Traffic Reports |
|---------------------|---|
| ECArt | Traffic Alert |
| ECICStatus | Data Type View |
| EDF_Status_IC | EDIFACT Interchanges |
| EDF_Status_FG | EDIFACT Functional Groups |
| EDF_Status_Msg | EDIFACT Messages |
| EDF_Status_SegErr | EDIFACT Segment Errors |
| EDF_Status_DEErr | EDIFACT Data Element Errors |
| X12DEError | X12 Data Element errors; if these errors exist, they are shown in the traffic reports segment error views. See Traffic Reports. |
| X12FGStatus | X12 Functional Groups |
| X12ICStatus | X12 Interchanges |
| X12SegError | X12 Segment errors; if these errors exist, they are shown in the Reports navigator under Transmissions. See Reports Navigator Overview. |
| X12TSSStatus | X12 Transactions |
| MapStatus | Transmissions |
| TRCICStatus | TRADACOMS interchanges |
| TRCDocHeader | TRADACOMS document header |
| TRCDocBody | TRADACOMS document body |
| TRCSegError | TRADACOMS document segment errors |
| TRCDError | TRADACOMS document data element errors |

To check the traffic table report count

Procedure

1. From the Tools menu, select Purge.
The Purge/Archive Traffic Reports dialog box appears.
 2. Click the **Traffic Counts** button.
The Traffic Report Counts window appears.
 3. Use the scroll bar to show the archived report information.
Click Copy to move the information to your Windows clipboard. You can paste this data into any Windows application that accepts clipboard text.
 4. Click OK to close the window.
-

Archiving traffic data

The following sections describe how to archive Partner Manager traffic data. Partner Manager enables you to:

- Archive data from the Current traffic tables to the Online Archive tables
 - Archive data from the Current traffic tables to the zip file archives
 - Archive data from the Online Archive tables to the zip file archives
 - [Archiving data from the current traffic tables to the online archive tables](#)
 - [Moving data from the current traffic tables to a zip file](#)
 - [Moving data from the online archive tables to a zip file](#)
 - [Restoring traffic data from a zip file](#)
-

Archiving data from the current traffic tables to the online archive tables

About this task

To move current traffic information to an online archive

Procedure

1. From the Tools menu, select Purge.
The Purge/Archive Traffic Reports dialog box appears.
 2. Enable **Move to On-Line Archive**.
 3. Enter a date in any valid date format in the **Purge/Move All Before This Date** field or click Calendar to select a date.
All traffic records before but not including this date are moved to the online archive tables.
 4. Click Begin Purge/Archive.
 5. Click Yes to confirm the move action.
As the traffic records are being archived into the archive tables and purged from the current tables, the current task is displayed in the **Purge Status**. After the process is completed, a dialog box appears identifying the number of records archived.
 6. Click Cancel to close the Purge dialog box.
-

Moving data from the current traffic tables to a zip file

About this task

To move current traffic information to a zip file

Procedure

1. From the Tools menu, select Purge.
The Purge/Archive Traffic Reports dialog box appears.
 2. Enable the **Move to Current to Off-Line Zip File** option button.
 3. Enter a date in any valid date format in the **Purge/Move All Before This Date** field or click Calendar to select a date.
All traffic records before but not including this date are moved to the online archive tables.
 4. Click Begin Purge/Archive.
 5. Click Yes to confirm.
The Select/Enter Zip File Destination dialog box appears.
 6. Enter a zip file archive file name and click Open.
7. The default name is **PartnerMgrCCYYMMDD.zip**, where CCYYMMDD represents the date you selected in Step 3.
 8. As the traffic records are being archived into the zip files and purged from the current tables, the current task is displayed in the **Purge Status**. After the process is completed, a dialog box appears identifying the number of records archived.
 9. Click Cancel to close the Purge dialog box.
-

Moving data from the online archive tables to a zip file

About this task

To move archived traffic information to a zip file

Procedure

1. From the Tools menu, select Purge.
 2. The Purge/Archive Traffic Reports dialog box appears.
 3. Enable **Move On-Line Archive to Off-Line Zip File**.
 4. Enter a date in any valid date format in the **Purge/Move All Before This Date** field or click Calendar to select a date.
All traffic records before but not including this date are moved to the online archive tables.
 5. Click Begin Purge/Archive.
 6. Click Yes to confirm.
The Select/Enter Zip File Destination dialog box appears.
 7. Enter a zip file archive file name and click Open.
The default name is **PartnerMgrCCYYMMDD.zip**, where CCYYMMDD represents the date you selected in Step 3.
 8. As the traffic records are being archived into the zip files and purged from the current tables, the current task is displayed in the **Purge Status**. After the process is completed, a dialog box appears identifying the number of records archived.
 9. Click Cancel to close the Purge dialog box.
-

Restoring traffic data from a zip file

About this task

To restore traffic data from a zip file

Procedure

1. From the Tools menu, select Purge.
The Purge/Archive Traffic Reports dialog box appears.
 2. Enable **Restore Zip File**.
 3. Enter the name of the zip file containing the traffic information to be restored. Click Find Zip to browse for the full file name and path of the zip file.
The default zip file name when files are archived is **PartnerMgrCCYYMMDD.zip**, where CCYYMMDD represents the date.
 4. Click Begin Restoration of Zip File to begin restoring the data.
The Purge/Archive Traffic Reports dialog box shows the records being restored. After the process is completed, a dialog box shows that the restore was completed successfully and the number of database tables that were processed.
 5. Click Yes to delete the zip file from which the traffic records were restored or click No to keep the file and return to the Purge/Archive Traffic Reports dialog box.
If you selected to delete the zip file, a dialog box appears confirming the deletion of that file.
 6. Click OK to return to the **Purge/Archive** Traffic Reports dialog box.
 7. Click Cancel to close the Purge dialog box.
-

Performance Tuning and Debugging

This documentation presented here is divided into two major parts. The first part provides a high level overview of the performance optimization techniques. The second part provides a checklist that you can use to guide you through the performance optimization process.

- [Overview](#)
 - [Tuning the IBM WebSphere Transformation Extender](#)
 - [Configuring Partner Manager](#)
 - [Debugging Trading Manager](#)
-

Overview

Throughout the discussions contained in this documentation, you should remember that Trading Manager is only one component in the B2B solution. The final performance depends on how well each of the various parts such as partner and application connectivity, individual data translation maps, routers and Trading Manager itself are configured.

- [Performance related considerations](#)
 - [Performance checklist](#)
-

Performance related considerations

Before continuing with the [Performance checklist](#) you should consider the following:

- CPU and memory requirements
 - transmission sizes
 - logical vs physical implementations
 - interface with non-IBM WebSphere Transformation Extender systems
 - resource pending configurations and how to avoid them
-
- [CPU and memory requirements](#)
 - [Analyze transmission sizes](#)
 - [Logical vs. physical implementations](#)
 - [Interfacing with non-IBM WebSphere Transformation Extender systems](#)
 - [Avoiding resource pending configurations](#)
-

CPU and memory requirements

Analyze the CPU and Memory requirements of other applications running on the same server as Message Manager.

Optimum performance is achieved when the competition for shared resources is minimized. Tuning Message Manager requires knowing how many resources are available to it. The IBM WebSphere Transformation Extender is, in an optimal configuration, a CPU intensive application that can degrade the performance of other applications (for example, databases) on the same server. The performance of the IBM WebSphere Transformation Extender can also be degraded by other applications on that server. For example, antivirus software that checks every file created for viruses will drastically hinder the performance of the IBM WebSphere Transformation Extender, and therefore Trading Manager and any application maps, due to the amount of files, such as work files, logs, and intermediate files, that are created during the normal course of events. Therefore, it is best to limit the number of other applications running on the IBM WebSphere Transformation Extender server.

Analyze transmission sizes

The size of the transmissions to be processed by Trading Manager determines the best configuration options for Message Manager. The default system, using workfiles in memory, is best for small to medium size transmissions. The cutoff transmission size depends on the amount of memory available to Message Manager on the server after accounting for other applications and services. See ["Analyzing Small Transmissions"](#) for additional information.

Logical vs. physical implementations

Consider the logical vs. physical implementations of Trading Manager. Trading Manager uses Post Offices to define the sources and destinations of data. They are logical sources and destinations that can match the same physical locations. If you have external processes to get the data from partners (either via a VAN or direct connect) you probably define a single Get Post Office in Trading Manager, the default location being:

`install_dir\tmgr_vn.n\mmgr\mail`.

The performance of the system can be increased if multiple GET Post Offices are defined (instead of one) even if they point to the same ...`\mail` folder, as long as the GET Post Office name can be easily derived from the input data. Message Manager handles trade link information by GET Post Office and defining multiple GET Post Offices spreads the trade link information, thus reducing overhead. For example, you can use a VAN for most of the inbound EDI traffic, but you can also have numerous other partners that connect via FTP. The best configuration is to create a single GET Post Office for the VAN transmissions and group all of the FTPs into another GET Post Office. There is no advantage in breaking up the transmissions retrieved from a VAN into multiple GET Post Offices since the overhead of breaking up the transmission, in most cases, overshadows the benefits.

Interfacing with non-IBM WebSphere Transformation Extender systems

Consider the following when interfacing non-IBM WebSphere Transformation Extender systems with the IBM WebSphere Transformation Extender. The Launcher triggers a map as soon as the trigger file is created. This can cause maps to execute before the trigger file is actually completed writing, especially with large files. To solve this problem, refer to "Solving IBM WebSphere Transformation Extender interface problems".

Avoiding resource pending configurations

Avoid configuring maps that can cause them to become "Resource Pending".

The Launcher prepares maps for execution through a two step process. The following is a simplified discussion of the process. For a detailed discussion, refer to the Launcher documentation.

Step 1: Allocates a thread for a map/trigger file combination. Map/trigger file combinations that fail to fulfill the requirements to successfully allocate a thread get placed on hold with a status of "Init Pending".

Step 2: Maps/trigger file combinations that have a thread allocated will then be executed unless they fail resource requirements. Such combinations will be placed on hold with a status of "Resource Pending".

The Launcher is configured with a finite number of threads to execute maps (either Message Manager maps and/or your own maps). If a map becomes **Resource Pending** (for example, if multiple instances of it append to a single file), it prevents other maps from using that thread. Multiple instances of the same map, except for the one that owns the resource in a Resource Pending state will, in effect, stall the Launcher's processing capabilities down to the one map that owns the resource. If this occurs, it is better to configure that map so that it becomes **Init Pending** before it can become **Resource Pending**, and therefore allow other maps to use the available thread.

Performance checklist

The following checklist is designed to help you configure Trading Manager for optimum performance. Although the steps in this checklist are presented in the order in which they should be executed, you should only implement those steps that are required for your particular system to achieve optimum performance.

- [Message Manager checklist](#)
- [External X12 partner checklist](#)
- [Inbound X12 trade link checklist](#)
- [Outbound X12 trade link checklist](#)
- [Small transmission size checklist](#)
- [Large transmission size checklist](#)

Message Manager checklist

About this task

The options described below are accessed from the **Message Manager Configuration Maintenance** window. Open this window as described in the section titled ["Opening the Message Manager Configuration Window"](#), then check the following options:

| | |
|-------|---|
| ----- | Option 1: Select the Use Stored Procedures option (under the Database tab). Turn ON if stored procedures are available. See "Use Stored Procedures" |
|-------|---|

| | |
|--|---|
| | option". |
| | Option 2: Optional X12/EDIFACT Validation (select Mapping Options tab). Turn OFF. See Optional X12/EDIFACT validation . |
| | Option 3: TSV Sort Option (select Database tab). Turn OFF. This option is needed only when using backend databases that sort rows without regard to upper or lower case. See " TSV Sort Option ". |
| | Option 4: TA1 Control option (select X12 Acknowledgements tab). Turn OFF if your partners are not capable of accepting and processing TA1 segments. See " TA1 Control Option ". |
| | Option 5: Store 997 Content option (select X12 Acknowledgements tab). Turn OFF if you do not need to view inbound and outbound 997 transactions. See " Store 997 Content Option " |
| | Option 6: Ignore Missing Trade Links option (select X12 Acknowledgements tab). Turn ON unless you want to post-process your partners 997s. See " Ignore Missing Trade Links Option ". |
| | Option 7: Inbound Transmissions into Trading Manager (Archive Options tab) Turn ON unless you already have a process in place to archive all of the transmissions received from your partners. See " Inbound Transmissions into Trading Manager ". |
| | Option 8: Outbound Transmissions into Trading Manager (Archive Options tab) . Turn OFF. See " Outbound Transmissions into Trading Manager ". |
| | Option 9: Inbound Interchange (Archive Options tab) . Turn OFF if testing is complete and the Edit/Resend feature is not needed. See " Inbound Interchange ". |
| | Option 10: Outbound Interchange before re-enveloping (Archive Options tab) . Turn OFF if testing is complete and the Edit/Resend feature is not needed. See " Outbound Interchange before re-enveloping ". |
| | Option 11: Outbound Interchange after re-enveloping (Archive Options tab) . Turn OFF if testing is complete and the Edit/Resend feature is not needed. See " Outbound Interchange after re-enveloping ". |
| | Option 12: Outbound Transmissions from Trading Manager (Archive Options tab) . Turn ON unless you have a process in place to archive all of the transmissions sent to your partners. See " Outbound Transmissions from Trading Manager ". |

External X12 partner checklist

About this task

The options described below are accessed from the Address Book for External X12 window. Open this window as described in "[Options for External X12 Partners](#)", then check the following options:

| | |
|--|--|
| | Option 1: Duplicate Control (Trading Partner tab) . Turn OFF if duplicate checking is not necessary. See " Duplicate Control Option ". |
| | Option 2: Authorization and Security Validation (Trading Partner tab). Turn OFF. This option is rarely used. See " Authorization and Security Validation ". |

Inbound X12 trade link checklist

About this task

The options described below are accessed from the X12 Inbound Trade Links window. Open this window as described in "[Options for Inbound X12 Trade Links](#)", then check the following options:

| | |
|--|---|
| | Option 1: Routing (Application Post Offices/Routing tab). Turn ON if the criteria described in " Routing Options (Inbound) " is met. |
| | Option 2: Acknowledgements (Acknowledgements/Validate By tab) . Turn OFF. See " Acknowledgments Option ". |
| | Option 3: HIPAA Validation Types option (HIPAA Validation Types tab). Turn OFF if you are using the Packs for HIPAA EDI elsewhere in your system. See " HIPAA Validation Option ". |

Outbound X12 trade link checklist

About this task

The following options are configured from the "[Opening the X12 Outbound Trade Links Window](#)" with the Application tab view displayed.

| | |
|--|---|
| | Option 1: Routing options. Turn ON for no X12 validation, or OFF for validation. See " Routing Options (Outbound) ". |
| | Option 2: Outbound 997s . Should always be defined as Route Only. See " Outbound 997's ". |

Small transmission size checklist

About this task

Options 1 and 2 in the following checklist are configured using the Integration Flow Designer. See the Integration Flow Designer documentation for more information. Options 3 and 4 are configured using the "[Opening the Message Manager Configuration Window](#)".

| | |
|--|--|
| | Option 1: In StampAndSort change output cards two and three from File to Sink . This affects both inbound and outbound X12 files. See " Analyzing Small Transmissions ". |
| | Option 2: In sendx12 change output cards two and three from File to Sink. This affects outbound X12 files. See " Analyzing Small Transmissions ". |

| | |
|-------|--|
| ===== | Option 3: Set the Work File options (Optimization tab). Set to -WM . See " Work File Option ". |
| ===== | Option 4: Set the X12 Outbound PO Packaging option (Optimization tab). Select the One File per Put PO button if you generate small batches of outbound data. See " X12 Outbound PO Packaging Option ". |

Large transmission size checklist

About this task

Option 1 in the following checklist is configured using the Integration Flow Designer. See the Integration Flow Designer documentation for more information. Options 2 and 5 are configured using the ["Opening the Message Manager Configuration Window"](#).

| | |
|-------|--|
| ===== | Option 1: Change workspace settings for stampandsortfile , sortx12 and sendx12 . This option is set using the msg_mgr.msd opened in the <i>Integration Flow Designer</i> . See " "StampandSort and sendx12" ". |
| ===== | Option 2: Set the Maximum X12 FG Validation Group option (Optimization tab). See " "Maximum FG Validation Size" ". |
| ===== | Option 3: Set Work File options (Optimization tab). Set to -WU . See " "Work File Option" ". |
| ===== | Option 4: Set the Maximum Reject File Size option (Mapping Options tab). See " "Select Maximum Reject File Size" ". |
| ===== | Option 5: Set the X12 Outbound PO Packaging option (Optimization tab). Select the One File per Put PO per Interchange button if you generate large batches of outbound data. See " "X12 Outbound PO Packaging Option" ". |

Tuning the IBM WebSphere Transformation Extender

This information presented here provides information about those IBM WebSphere Transformation Extender tuning procedures that may be required in order to achieve optimum performance from your Trading Manager application.

Specific information related to IBM WebSphere Transformation Extender tuning is contained in the IBM WebSphere Transformation Extender Performance documentation and in the Launcher documentation. You should familiarize yourself with the information before continuing with these procedures.

Note: When changing values in the **dtx.ini** file, some of the parameters mentioned here are shipped as a "remark". Any parameter beginning with a semi-colon is a remark and is ignored. When changing these parameters, make sure you *remove* the semi-colon to activate it.

- [Turning on the Launcher trace file](#)
- [Updating the max threads parameter](#)
- [Solving IBM Transformation Extender interface problems](#)
- [Running multiple Launchers](#)

Turning on the Launcher trace file

Turn on the Launcher trace file in the **dtx.ini** file. This option facilitates debugging in both Trading Manager and the application maps. The option for performing this task is:

LauncherLog=ewsc

See the IBM Transformation Extender Launcher documentation for additional information.

Note: Turning on trace will significantly slow down the Launcher process. Once a problem has been solved, remember to turn off trace by adding a "remark" (semi-colon) in front of the parameter in the **dtx.ini** file, and recycling the Launcher service.

Updating the max threads parameter

The Max Threads parameter is updated in the **dtx.ini** file. By default the IBM WebSphere Transformation Extender is configured to have a maximum number of threads of 20 . This might be too high for platforms with one or two CPUs. Low end Windows platforms with only one CPU will do best with an approximate setting of 5 but it depends on what else is loaded on that server. Perform benchmarks with a range of settings to determine the best setting. The option is:

MaxThreads=20

For specific information on the Max Threads parameter, as well as all other Launcher performance parameters, refer to the IBM WebSphere Transformation Extender Performance documentation. Also see the IBM WebSphere Transformation Extender Launcher documentation.

Solving IBM Transformation Extender interface problems

There are two ways to solve the problems that occur when interfacing non-IBM Transformation Extender systems a with IBM Transformation Extender systems:

- Create files with a **.tmp** extension and rename the file when done writing. The IBM Transformation Extender with Launcher ignores any file with a **.tmp** extension and will process the file after it is renamed. This is the technique used by the IBM Transformation Extender internally, and it is called a "shadow file".
- Create two files: first the actual data file and then a one-byte trigger file. This is a popular option when FTPing into a system running under the Launcher, there has to be a relationship in the file names between the trigger file and the data file, so that the Launcher can derive the name of the data file from the trigger file name. The triggered map has to have the trigger file card before the data file card and the data file card should not be a trigger, only the trigger card should be a trigger.

Running multiple Launchers

If you are running UNIX, you have probably created multiple instances of the Launcher and segregated your application maps across them. Trading Manager is distributed to run in a single instance and even with the new multi-instance capabilities of the Launcher, the benefits of breaking Message Manager into multiple instances will only be obtained in the most extreme cases. Segregating application maps, however, into a separate system from Message Manager is still a good way to control and improve maintainability, performance, and throughput.

Configuring Partner Manager

This section describes how to change the configuration settings Partner Manager in order to achieve optimum performance in the Trading Manager application.

These procedures are, for the most part, detailed descriptions of the checklist items provided in the ["Overview and Performance Checklist"](#).

- [Overview](#)
- [Configuring Message Manager](#)
- [Options for external X12 partners](#)
- [Options for inbound X12 trade links](#)
- [Options for outbound X12 trade links](#)
- [Analyzing small transmissions](#)
- [Analyzing large transmissions](#)

Overview

Trading Manager provides a rich set of functionality that you may, or may not require. It contains functions may be turned on or off as needed. Functions such as:

- extended X12 validation
- TA1 generation and routing
- several layers of archiving, etc.

All of these require processing that translates into wasted overhead if the functionality is not used.

In the sections that follow, turn OFF any functionality that you do not need, and turn on functionality that you can use.

Configuring Message Manager

The Message Manager options described here are all accessed using the Message Manager Configuration Maintenance window. Access the window as described in the following section, then refer to the following sections for option details.

- [Opening the Message Manager Configuration Window](#)

Opening the Message Manager Configuration Window

About this task

To access Message Manager configuration options, first open the Message Manager Configuration Maintenance window:

Procedure

1. Start Partner Manager.
2. Select Utilities from the Partner Manager toolbar.
3. Expand **Configuration** in the **Utilities** navigator and select Message Manager Config.

Results

The Message Manager Configuration window opens:

- [Use stored procedures option](#)
- [TSV sort option](#)
- [Optional X12/EDIFACT validation](#)
- [TA1 control option](#)
- [Store 997 content option](#)
- [Ignore missing trade links option](#)
- [Archive options](#)

Use stored procedures option

About this task

By default, Message Manager uses in-line SQL statements to generate thread ids and control numbers. Trading Manager provides stored procedures for those databases that support it. If these stored procedures are available they should be used.

To set this option:

Procedure

1. Perform the steps provided in "[Opening the Message Manager Configuration Window](#)".
 2. Select the Database tab view.
 3. Turn the option ON by checking the **Use Stored Procedures** checkbox.
-

TSV sort option

About this task

This option impacts export processing performance. It forces a resorting of the TSV (Trading Manager files containing partner and transaction information) during the export so that the Trading Manager maps can take advantage of the SEARCHUP function. If the sort order of your database matches the sort order expected by the SEARCHUP function, you do not need to use the TSV Sort Option. The sort order expected by the SEARCHUP function depends on the operating system running Message Manager. Refer to the SEARCHUP documentation.

To set this option:

Procedure

1. Perform the steps provided in "[Opening the Message Manager Configuration Window](#)".
 2. Select the Database tab view.
 3. Disable the option by unchecking the **Sort TSV Files During Extract** checkbox, if you do not need this functionality.
-

Optional X12/EDIFACT validation

About this task

Although it is important that this option be enabled when testing with a new partner, after testing is concluded it is not necessary for it to remain in that state. For this reason, it is recommended that this option be turned OFF.

To set this option:

Procedure

1. Perform the steps provided in "[Opening the Message Manager Configuration Window](#)".
 2. Select the **Mapping Options** tab view.
 3. Uncheck the checkbox in the **Optional X12/EDIFACT Validation** area of the window.
-

TA1 control option

About this task

This option should be turned OFF if your partners are not capable of accepting and processing TA1 segments.

To set this option:

Procedure

1. Perform the steps provided in "[Opening the Message Manager Configuration Window](#)".
 2. Select the **Acknowledgements** tab view.
 3. Check the **No TA1's** button.
-

Store 997 content option

About this task

This option should be turned OFF unless you have the explicit need to view inbound and outbound 997 transactions online.

To set this option:

Procedure

1. Perform the steps provided in "[Opening the Message Manager Configuration Window](#)".
 2. Select the **Acknowledgements** tab view.
 3. Uncheck the **Store 997 Content in Database**.
-

Ignore missing trade links option

About this task

This option should be turned ON unless you are planning on post-processing your partner's X12 997 and EDIFACT CONTRL messages. To save memory, you should also avoid creating tradelinks for these message types if you can safely ignore them. Note, however, that not creating tradelinks for these messages may result in an inaccurate **Overdue Acknowledgment Reporting**.

To set this option:

Procedure

1. Perform the steps provided in "[Opening the Message Manager Configuration Window](#)".
 2. Select the **Acknowledgements** tab view.
 3. Check the **Ignore Missing Trade Links for Inbound 997/CONTRL**.
-

Archive options

About this task

Archive Options: Message Manager archives data at different times and some of the options might be redundant:

To set these options:

Procedure

1. Perform the steps provided in "[Opening the Message Manager Configuration Window](#)".
2. Select the **Archive** tab view.
3. Make selections to the checkboxes.

Inbound Transmissions into Trading Manager

About this task

This option should always be ON (checkbox checked) unless you already have a process in place to archive all the transmissions received from your partners elsewhere.

Outbound Transmissions into Trading Manager

About this task

Turn this option ON (checkbox checked) if you want to archive all outbound transmissions, i.e. files created by your "Application to EDI" conversion maps using data from your internal systems. These files can usually be recreated from your internal applications and, therefore, it is recommended that this option be turned OFF.

Inbound Interchange

About this task

When enabled (checkbox checked) a text file is created for each inbound interchange and the **Edit/Resend** feature in Partner Manager is enabled. Although this feature may be useful during testing it can be turned OFF if the **Edit/Resend** feature is not used or not allowed.

Outbound Interchange before re-enveloping

About this task

When enabled (checkbox checked) a text file is created for each outbound interchange and the **Edit/Resend** feature in Partner Manager is enabled. Although this feature may be useful during testing it can be turned OFF if the **Edit/Resend** feature is not used or not allowed.

Outbound Interchange after re-enveloping

About this task

When enabled (checkbox checked) a text file is created for each outbound interchange and the **Edit/Resend** feature in Partner Manager is enabled. Although this feature may be useful during testing it can be turned OFF if the **Edit/Resend** feature is not used or not allowed.

Outbound Transmissions from Trading Manager

About this task

This option should always be ON unless you already have a process in place to archive all the transmissions sent to your partners elsewhere.

Options for external X12 partners

Options for each External X12 Partner in the Address Book are accessed as follows. These options are set using the Edit X12 Trading Partner in External Folder X12 window.

- [Opening the Edit X12 Trading Partner Window](#)
-

Opening the Edit X12 Trading Partner Window

About this task

Refer to the following steps to open the window:

Procedure

1. Start Partner Manager.
2. Select Address Book from the Partner Manager toolbar.
The Address Book for External X12 window opens.
3. Select a Trading Partner from the listbox.
The Edit X12 Trading Partner In External X12 window opens with the Trading Partner tab view displayed.

Results

The following sections describe how to set options to maximize Trading Manager performance.

- [Duplicate control option](#)
 - [Authorization and security validation](#)
-

Duplicate control option

About this task

When the Edit X12 Trading Partner in External X12 window opens, the Trading Partner tab is displayed. If this is not the case, click the Trading Partner tab.

To set this option:

Procedure

1. Perform the steps provided in the ["Opening the Edit X12 Trading Partner Window"](#).
 2. Select the **Trading Partner** tab view.
 3. Note the condition of the **Duplicate Control** checkboxes and set accordingly:
Turn the option ON (checkboxes checked) only if it is required for the partner. Most partners have internal controls that make duplicate checking unnecessary.
-

Authorization and security validation

About this task

The **Validate Authorization** and the **Validate Security** options should ordinarily be turned OFF as these options are rarely used.

To set these options:

Procedure

1. Perform the steps provided in the ["Opening the Edit X12 Trading Partner Window"](#).
2. Select the **Authorization/Security** tab view.

3. Ensure that the **Validation** check boxes are turned OFF.

Options for inbound X12 trade links

Options for each Inbound X12 Trade Link are accessed as follows.

- [Opening the X12 Inbound Trade Links Window](#)

Opening the X12 Inbound Trade Links Window

About this task

Open the window as follows:

Procedure

1. Start Partner Manager.
2. Select Trade Links from the Partner Manager toolbar.
3. Make certain that **Inbound** is expanded in the navigator and select Inbound > **X12**.
The **X12 Inbound Trade Links** window opens. Select a trade link to modify using the **Search** buttons at the top of the screen.
4. Click the Applications tab.
 - [Routing options \(inbound\)](#)
 - [Acknowledgments option](#)
 - [HIPAA validation option](#)

Routing options (inbound)

About this task

This option allows you to use Trading Manager to route EDI data without performing data validation.

Acknowledgments, if configured, report transactions with the **Routing** option as valid.

In deciding whether or not to turn this option ON or OFF, remember the following points:

- If you have an external system in place before Trading Manager that performs validation (for example, the IBM Healthcare Packs) there is no need to perform any additional validation in Trading Manager. Therefore, turn this option ON to improve performance.
- This option can also be turned ON for those transactions that are known to be good (inbound 997s), or when you trust the partner and have some error detection/reporting process in place in your **EDI to Application** conversion maps.

To set this option:

Procedure

1. Perform the steps provided in "[Opening the X12 Inbound Trade Links Window](#)" to open the window.
2. Select the **Post Offices Routing** tab view.
3. Enable or disable the **Route Only; No Validation** checkbox and set according to your individual requirements.

Acknowledgments option

About this task

Most partners require acknowledgments to be returned. There may, however, be select cases in which they are not needed. If this is the case, proceed as follows:

Make certain that you check with each partner before turning off acknowledgements.

To change this option:

Procedure

1. Perform the steps provided in "[Opening the X12 Inbound Trade Links Window](#)" to open the window.
2. Select the **Acknowledgements/Validate By** tab view.
3. In the **Ack Level** field, select No Acknowledgement from the drop down menu.

HIPAA validation option

To change the HIPAA validation options:

1. Perform the steps provided in [Opening the X12 Inbound Trade Links Window](#).
2. HIPAA validation settings are only available when a HIPAA version is selected. Therefore, you should check only those settings that are required by your installation.

Note: If you are using the IBM WebSphere Transformation Extender Pack for HIPAA EDI as the pre-processor for Trading Manager, the validation settings here will duplicate the functionality of that pack, so enabling these settings are not required.

Options for outbound X12 trade links

The options discussed in this section are configured for each outbound X12 trade link. The options are accessed from the **X12** Outbound Trade Links window.

- [Opening the X12 Outbound Trade Links Window](#)

Opening the X12 Outbound Trade Links Window

Procedure

1. Start Partner Manager.
2. Select Trade Links from the Partner Manager toolbar.
3. Make certain that **Outbound** is expanded in the navigator and select Outbound > **X12**.
The **X12 Outbound Trade Links** dialog opens.
4. Click the Applications tab.
 - [Routing options \(outbound\)](#)
 - [Outbound 997's](#)

Routing options (outbound)

About this task

This option allows you to use Trading Manager to route EDI data without performing data validation.

By default, Trading Manager validates each outbound transaction and guarantees that the partner always receives valid X12 data. Once a system is in production, however, the likelihood of it creating invalid data is minimal, and a partner's negative acknowledgement would highlight when it occurs.

You can increase the performance of Trading Manager by turning ON the **Route Only; No Validation** option for outbound transactions with minimal risk. To further minimize the risk, since this option applies by outbound Functional Group, it can be used only for those transactions with which you feel comfortable.

To set this option:

Procedure

1. Perform the steps provided in "[Opening the X12 Outbound Trade Links Window](#)" to open the window.
2. Select the **Post Offices Routing** tab view.
3. Turn ON or OFF the **Route Only; No Validation** checkbox and according to your individual requirements. In most cases, this checkbox will be ON (checked).

Outbound 997's

Outbound 997's should always be defined as Route Only (**Route Only; No Validation** checkbox checked).

Analyzing small transmissions

In order to maximize Trading Manager performance, it is important that you analyze the size of your:

- Transmission
- Interchange
- Functional Group
- Transaction.

Servers that have large amounts of memory available but are used to process small transmissions, and are used primarily for Message Manager can further increase Trading Manager performance by:

- In **stampandsortfile** change output cards #2 and #4 from:
 - **File**
to
 - **Sink** This affects inbound and outbound files.
- In **sendx12** change output cards #2 and #3 from:
 - **File**
to
 - **Sink** This affects outbound X12 files.

The procedures required to change these options are described in the following sections.

- [Changing stampandsort options](#)
 - [Changing sendx12 options](#)
 - [Work file option for small transmissions](#)
-

Changing stampandsort options

About this task

To perform this procedure follow these steps:

Procedure

1. Open the **msg_mgr.msd** file located in: *install_dir\tmgr_vn.n\mmgr*
This file opens in the Integration Flow Designer. For more information, see the Integration Flow Designer documentation.
 2. In **stampandsortfile** change output cards #2 and #4 from **File** to **Sink**.
-

Changing sendx12 options

Procedure

1. Open the **msg_mgr.msd** file located in: *install_dir\tmgr_vn.n\mmgr*
This file opens in the Integration Flow Designer. For more information, see the Integration Flow Designer documentation.
 2. In **sendx12** change output cards #2 and #3 from **File** to **Sink**.
-

Work file option for small transmissions

About this task

To set this option for small transmissions:

Procedure

1. Perform the steps provided in the "[Opening the Message Manager Configuration Window](#)".
 2. Select the Optimization tab view.
 3. Select -WM from the **Work File Options** drop-down menu.
-

Analyzing large transmissions

About this task

Servers processing large transmissions and/or not having much memory available will have to configure Message Manager so that the amount of memory used for processing is reduced.

With one exception, the options described here are accessed through the Message Manager Configuration Maintenance window. Access the window as described in "[Opening the Message Manager Configuration Window](#)".

Open the window and then refer to the following sections for option details.

- [stampandsort and sendx12](#)
- [Maximum FG validation size](#)

- [Work file option](#)
 - [Select maximum reject file size](#)
 - [X12 outbound PO packaging option](#)
-

stampandsort and sendx12

About this task

For very large transmissions, Trading Manager performance can be improved by changing the work space settings for **stampandsortfile** (affects both inbound and outbound), **sortx12** (affects inbound X12), and **sendx12** (affects outbound X12).

To perform this procedure follow these steps:

Procedure

1. Open the **msg_mgr.msd** file located in: *install_dir\tmgr_vn.n\mmgr*
This file opens in the Integration Flow Designer. For more information, see the *Integration Flow Designer Reference Guide*.
 2. Change the entry in the **WorkSpace** field for **stampandsortfile**, **sortx12** and **sendx12** from **Memory** to **File**.
-

Maximum FG validation size

About this task

To select this option:

Procedure

1. Perform the steps provided in the "[Opening the Message Manager Configuration Window](#)".
 2. Select the Optimization tab view.
 3. Specify the maximum size of a functional group to validate in a single pass. Enter this value in the **Maximum Validation Size** field.
The value is in Megabytes. Start with a value that reflects the average size of your functional groups or ¼ of the RAM memory available (whichever is less) and decrease as needed.
-

Work file option

About this task

To select this option:

Procedure

1. Perform the steps provided in the "[Opening the Message Manager Configuration Window](#)".
2. Select the Optimization tab view.
3. In the **Work Options** field, select -WU from the **Work File Options** drop down menu.

Results

This will reduce the amount of memory used by the Message Manager system in general.

Select maximum reject file size

About this task

Under mapping options, select the maximum size of the reject file to be created by the system.:

To select this option:

Procedure

1. Perform the steps provided in the "[Opening the Message Manager Configuration Window](#)".
2. Select the **Mapping Options** tab view.
3. Enter the desired value in the **Maximum Reject File Size** field.

4. If you are processing large X12 transactions you should define a **Max Reject Size** limit to prevent the server from becoming overloaded when generating reject files. A size of 1-5 Kb is adequate to provide accurate information about the transaction in error.

X12 outbound PO packaging option

About this task

To select this option:

Procedure

1. Perform the steps provided in the "[Opening the Message Manager Configuration Window](#)".
2. Select the Optimization tab view
3. Select the **One File per Put PO per Interchange** button for each Interchange in the mapping options screen.

Debugging Trading Manager

These topics describe how to perform debugging operations on the Trading Manager system. It describes:

- ["Deployment Errors and Failures"](#)
- ["Startup Errors"](#)
- ["Running Message Manager"](#)
- [Deployment errors and failures](#)
- [Startup errors](#)
- [Running Message Manager](#)

Deployment errors and failures

It is important to remember that both **MessageManager** and **RunMaps** have to be deployed, one after the other. Deploying **MessageManager** will not include the **RunMaps**. Failing to deploy RunMaps will cause export run maps to fail with condition code 3 (map not available).

The **msg_mgr.msd** provides three different deployment definitions for MessageManager and one for RunMaps, all preconfigured for a default Windows platform. The following should be checked:

| Check | Notes |
|---|---|
| Build and transfer maps | This should display the mmgr folder on the server that is going to run Message Manager. If it is not correct, the global search/replace failed and has to be redone. Showing a Windows path when the server is a UNIX variant is an indication the global search/replace failed or was not done at all |
| Generate and transfer Launcher Control File | Must be configured to point to the systems folder on the server and must be done manually for all deployment scripts that have it check marked |
| Transfer Additional Files | Must be configured to point to the mmgr folder on the server and must be done manually for all deployment scripts that have it check marked. You have to press ENTER for the path to take, simply clicking OK after editing a path will result in the edited path being lost. This option is only necessary if transferring files to a server or different Windows drive. For example, if the mmgr.mrn file is being transferred to a UNIX server. If the design and runtime installs are the same, (deploying and running on the same Windows machine, this option can be left unchecked). |

Startup errors

Startup is completed successfully if the export process manages to build all the **tsv** files the system needs in the **mmgr\share** directory. Typical errors are:

| Error condition | Reason |
|---|--|
| Export runs fine but there are no files in the mmgr\share folder. The tsv files are then found in the mmgr folder, some of them preceded with the string %export_dir%. | This means that the user failed to properly configure the Launcher Resource Registry (mrc and/or mrn files) and/or the Launcher Administration tool. The Launcher Administration tool has to point to a user-created mrc file that in turn has to point to the mmgr.mrn file provided with CM |
| Export runs but fails with "Source Not Available". | The back end database is not properly configured, usually an error in the startup.mdq file. Adding "-t" to the database card will generate a database trace that can be used to determine the problem. Both MessageManager and RunMaps have to be re-deployed once the mdq file has been corrected. |
| Export runs, but creates a reject file indicating all run maps failed with return code 3. | Run Maps have not been deployed. |
| Export runs, but creates a reject file indicating some or all run maps failed with return code 12 or similar. | Run Maps have not been deployed after fixing the update.mdq file, or the database creation failed. |

| Error condition | Reason |
|--|--|
| Export runs, but creates a reject file indicating that a dll/so is either not found or the wrong version. | Message Manager requires two dll/so's: cmsvc and cmsvu . They have to be deployed in binary mode and their properties have to be defined as executables. On Windows the dlls have to be in the mmgr folder, on UNIX the so's have to be in the DSTX libs folder. |
| Export runs, but creates a reject file indicating HIPAA components are missing. | If you select HIPAA validation, the export process verifies that the components required by Trading Manager from the HIPAA Pack have been deployed. Two maps from the HIPAA Pack (x4010hipaasegmentdataaudit.mmc and x12type6qualifier.mmc) have to be deployed into the mmgr folder on the server. Additionally, one file (hipaa_x12_type_6_value.dat) has to be deployed into the mmgr\share folder on the server. See Validating HIPAA X12 Data the IBM WebSphere Transformation Extender Pack for HIPAA EDI documentation. for more information. |
| Launcher starts up fine but nothing is running, the Management Console is blank. | The Launcher did not find any msl Launcher Control file. Either Trading Manager was not deployed or the location in the deployment definition is incorrect. Redeploy and review the MSEDploy.TXT file to verify where the maps and *.msl file are being deployed. |
| Launcher startup, customer maps are running, but files are piling up in the mmgr\mail folder. | See previous error condition. |

Running Message Manager

Trading Manager has been enhanced to create logs with more detailed information about failures while running Message Manager. Therefore it is critical that all reject files be examined to get additional information about errors.

| Error condition | Reason |
|---|--|
| System runs slow, high CPU utilization. | Could be caused by Max Threads parameter being set too high in the dtx.ini file. A lower setting allows the server to perform more useful work and less swapping between threads. |
| Random map failures due to not enough memory available | Could be caused by Max Threads parameter being set too high in the dtx.ini file. See the section titled " Analyzing Large Transmissions " for more memory reduction options. |
| Files do not show up in the PUT Post Office | Usually occurs when the path is not correctly defined in Partner Manager. A reject file and the Partner Manager Traffic Log provide specific error information. At times a reject file is not created; in that case the files might be found in the root of the server. The Partner Manager Traffic report will show the location where the files are written |
| Reject files getting created by StampAndSort containing partial files. | Occurs when files are written to the mail folder by an application other than the IBM Transformation Extender. See the section titled " Interfacing with non-IBM Transformation Extender systems " for additional information. |
| System runs slow, low CPU utilization; most maps are in Resource pending state. | This is a configuration error. Avoid configuring maps that can cause them to become Resource Pending. See the section titled " Avoiding Resource Pending Configurations " for additional information. |
| File errors when writing to other servers. | If the paths are correct and/or the drive mappings have not been reset then it is most likely a permission problem. The Launcher user id must have write permissions on all the folders that are configured as PUT Post Offices. |
| Valid files fail X12 Validation. | Each new transaction/version combination is added, the EDI Wizard has to be executed to generate a new x12mail.mtt type tree that has to go into the folder where all the Message Manager sources are located. Next, the customer has to deploy the RunMaps system for the new transactions to go into effect on the server. Deploying MessageManager is not needed. |
| Tradelink errors even though the Trade Links have just been added to Partner Manager. | Message manager exports the Trade Links information at Launcher startup and each night at midnight. For new Trade Links to go in effect immediately, the export has to be triggered from the Message Manager Config. section in Partner Manager. The export has to be triggered using the Run Export Process on Demand feature from the Message Manager Config. section in Partner Manager. |
| Valid files are getting rejected by StampAndSort as invalid file names when they do conform to the Trading Manager standards | Message Manager is failing to access the database. Either RunMaps where not redeployed after correcting the update.mdq file or the database is not available. |

XML Autoload Utility

The XML Autoload Utility contains the following key components:

- Utilities
- Run Options
- Remember Database User and Password
- Data Exceeding Maximum Length
- Report Options
- [Overview](#)
- [Using the XML Autoload Utility](#)
- [Defining tables and fields](#)

Overview

The XML Autoload Utility enables you to add, change, or delete selected data objects in the IBM WebSphere Transformation Extender Partner Manager database without the need for manual data entry in the Partner Manager GUI. A custom program may be used to create the XML input file, or it can be created using maps that use a Transformation Extender Type Tree based on the XML DTD file included with the product. The XML AutoLoad Utility can be run interactively, or it can be run silently through command line parameters. An embedded security function is also included to prevent inadvertent additions, changes, or deletions of data.

This utility is provided with XML input and open database connectivity (ODBC) system data source name (DSN) pointing to the destination database. This ensures that duplicate data are rejected, foreign keys exist, range values are achieved, and surrogate keys are generated.

Note: If you have used the XML AutoLoad Utility previously, be aware that in this version of the product, a test post office has been introduced to X12 outbound links. The existing post office field, PutMailPO, is now the production post office. If you make no changes to your XML script generation, the post office that you have used previously for X12 Outbound Links will be this production post office. See the fields TestIndicator, ProdIndicator and TestPutPO fields in the tag X12OBAppLink for more information. If you do not want to take advantage of these new test vs. production post offices, set the two post offices to the same value.

- [Add, change, or delete](#)
 - [Embedded security](#)
-

Add, change, or delete

The XML Autoload Utility enables you to add (from any source), change, or delete the following data objects in the Partner Manager database:

- Post Offices (both Get and Put)
 - Trading Partners/Application Partners (X12, EDIFACT, and TRADACOMS, Internal and External).
 - Contact information associated with Trading/Application Partners.
 - Trade Links(X12, EDIFACT, and TRADACOMS, Internal and External).
-

Embedded security

The embedded security feature, originally a function of Partner Manager, prevents the potential security risk of users changing or deleting data in your database.

If you have Partner Manager Users defined, the XML Autoload will open a window that requests a User Name and Password. The user must have the XML Autoload check box enabled in their Partner Manager's Security Group Maintenance window to proceed.

The **XML Autoload** check box is disabled as a result of a conversion from a prior revision.

To prevent inadvertent additions, changes, or deletions, the check boxes **Allow Add**, **Allow Change**, and **Allow Delete** in the Partner Manager XML Data Load Utility dialog box must be enabled to allow the operations to proceed.

Using the XML Autoload Utility

The IBM WebSphere Transformation Extender XML Autoload Utility contains the following key components:

- Utilities
- Run Options
- Update Options
- Remember Database User and Password
- Data Exceeding Maximum Length
- Report Options

Foreign Keys Requirement - Because data is inserted by an SQL transaction, before you use the XML AutoLoad Utility, foreign keys (dependencies) must already be in the database. For example, you cannot add **Trading Partners** and then a **Trade Link** for those new **Trading Partners** within the same XML input file; separate these two into two XML files.

Another example is **Post Offices**. You cannot add a new **Post Office** and then reference that new **Post Office** in a **Trade Link** within the same XML file. You must separate these into separate utility runs.

There are two exceptions to this rule. **Application Partners** and **Contacts** do not require their parent records added in a previous run of this utility because these records are direct siblings in the XML input format (their definition exists only within their parent record).

When entering data in Partner Manager be aware that case sensitivity can vary by Database Vendor and even by database instance. For example, Microsoft Access considers "Acme" to equal "ACME"; most other databases consider these fields unequal. Consult your Database Administrator to determine if your database is case sensitive and plan your database entries accordingly, especially if using Partner Manager to copy and merge functionality between database vendors.

-

Starting the XML Autoload Utility

About this task

The XML AutoLoad Utility may be started from the Start menu or a desktop icon.

To start the XML AutoLoad Utility from the Start menu:

Procedure

Click **Programs -> Trading Manager -> XML AutoLoad Utility**. The WebSphere DataStage TX Partner Manager XML AutoLoad Utility window opens.

Utilities

The **Utilities** command box in the **XML Autoload** window contains the **Edit XML File** and **Generate Config** buttons. The Edit XML File function is explained below. The Generate Config button is described in the section titled "[Generating a Configuration File](#)".

- [Edit XML file](#)
-

Edit XML file

You click the **Edit XML File** command button to activate the **Autoload XML Editor** window. The Autoload XML Editor is a word-processor designed for XML syntax. It can validate the XML against a document type definition (DTD) and automatically indent your XML for easy debugging.

DTD for XML Data Validation - XML data is validated through the **tmnn.dtd** that is installed in the *install_dir\tmgr_vn.n\pmgr* directory (where *nn* and *n.n* represent the current Trading Manager version number).

Run Options

The **Run Options** box on the **XML Autoload** window contains two buttons: **Run Load** and **Validate Only; Do not change Database**.

- [Run Load](#)
 - [Validate only](#)
-

Run Load

When you enable the **Run Load** button the utility will change your database.

Validate only

When you enable the **Validation Only; Do not change Database** button, the database is not updated. Data is checked and reports all errors/warnings. Errors that could only be found if the data was written to the database are not reported. For example, if you add a **Trading Partner** and then add the same **Trading Partner** later in the validation run, that error is not caught in a **Validation Only** run, as the database was not updated.

Note: It is recommended to run your XML using the **Validation Only** option first to find syntax and other foreign key validation errors.

Update options

The **Update Options** group box on the **XML Autoload** window contains three check boxes. To prevent inadvertent additions, changes, or deletions, these check boxes, **Allow Add**, **Allow Change**, and **Allow Delete** must be enabled to allow the operations to proceed. The check boxes permit the control of the processing and prevent accidental changes and options to control the processing of errors during additions, changes, and deletions.

- [Allow add](#)
 - [Allow change](#)
 - [Allow delete](#)
 - [Change or delete error processing options](#)
-

Allow add

Enable this check box to allow the XML Autoload Utility to add data, the default processing option.

Allow change

Enable this check box to allow the XML Autoload Utility to change existing data.

Allow delete

Enable this check box to allow the XML Autoload Utility to delete existing data.

Change or delete error processing options

The following options are available during a change or delete operation. This setting is useful, for example, if you want to ignore deletions or changes that can not be processed because the record does not exist, and you want to continue processing the other records in the XML input file. Most errors will be reported as "warnings" when the **Continue Processing** option is enabled. Due to the complexity of **Trade Link** records, these settings only apply to **Post Offices** and **Trading Partners**. An error reported during a change to a **Trade Link** will always abort the entire run. These settings only apply to change or delete processing. Errors reported while adding new data will always abort. These settings do not apply when running a **Validate Only** run, or if the **Allow Update/Delete** options are not enabled.

- **Abort Run** - Choose this option to stop processing at the first error detected
- **Continue Processing** - Choose this option to skip the record in error and continue processing. Certain fatal errors (for example, database errors and XML structure errors) will abort regardless of this setting.

It is recommended that you choose the **Abort Run** as a default option.

Remember database user and password

As an additional security function, the **WebSphere DataSage TX Partner Manager XML Autoload** XML Data Load Utility window includes a **Remember Database User and Password** check box. If this check box is disabled, the **User** and **Password** fields must be populated manually each time the utility is run.

This is the user and password assigned by your DBA for access to your database. It is *not* the user and password created in Partner Manager.

For more information on the security features see the **Security** section of the Partner Manager documentation.

Data exceeding maximum length

The **Data Exceeding Maximum Length** option box on the **XML Autoload XML Data Load Utility** window contains two buttons: **Reject** and **Truncate**:

- The **Reject** - choose this option to truncate data that is too long for the database definitions.
- The **Truncate** - choose this option to truncate data that is too long for the database definitions. Truncated data is reported as a warning.

Report options

The **Report Options** group box in the **XML Autoload** window contains two buttons: **Detailed** and **Summary**.

- [Detailed](#)
- [Summary](#)
- [Print report](#)

Detailed

When you enable the **Detailed** option button it displays every field and record as it is processed.

Summary

When you enable the **Summary** option button it displays only the errors, warnings, and final results of the processing. A report listing warnings/errors is displayed.

Warnings are preceded by and followed by three dashes (---). Errors are preceded by and followed by three asterisks (***) . The contents of this report can also be copied to your clipboard.

To copy the report to your clipboard:

1. Click on the report area.
2. Press **Ctrl+A** to select all.
3. Press **Ctrl+C** to copy it to your clipboard.

Print report

Once an XML file has been processed, the **Print Report** button on the **XML Autoload** window is enabled. Pressing this button prints the contents of the report listing warnings and errors.

Unattended operation

The XML Autoload Utility can run unattended by setting options that are available from a configuration file and using command line flags. The configuration file can be built manually, or one can be generated from the parameters on the GUI. Instead of the report generated on the screen of the XML Autoload, all output is written to a file that you specify.

The default configuration file, **PMAutoloadConfig.xml**, is found in the same location as the XML Autoload Utility executable. It is supplied with all options empty. Parameters are specified in XML format. For example, if the XML input file is **c:\xml\input.xml**, the configuration file would contain:

```
<xmlsource>c:\xml\input.xml</xmlsource>
```

You can have as many configuration files as needed. A command line flag (**-cf**) specifies the configuration file to use. For example, you could have one configuration file that is "Validate Only", and another that actually updates the database.

All configuration files are validated by the DTD: **XMLConfignn.dtd**. This DTD is supplied in the same directory as the programs; typically this is:

IBM\WebSphere Transformation Extender\tnmgr_vn.n\pmgr

where *n.n* is the product version number.

You cannot create a configuration file without referencing this DTD.

When the program completes, the **End Of Report** message will contain:

Process Return Code: X

where x is 0 = OK, -1 = Error; no database changes made, 2 = Warnings issued.

This allows you to parse the output file to determine success or failure.

Warning: The XML Autoload may need a password to connect to your database, and also may need a Partner Manager user ID and password if those are in use. These passwords will be protected in the configuration file if you build the configuration file from the XML Autoload Utility. If you build the configuration file yourself, you will have to enter passwords in "clear text", which will be readable from anyone with access to your system. It is recommended you always start with a generated configuration file and do not attempt to modify the passwords manually.

- [Generating a configuration file](#)
 - [Command line flags](#)
 - [Running unattended](#)
 - [Configuration and command line parameters](#)
 - [Examples](#)
-

Generating a configuration file

About this task

To automatically generate a configuration file, refer to the following procedures:

Procedure

1. Run the XML Autoload as you normally would, for example, from the **Start** > Programs menu item.
2. Set all options to be saved to the configuration file.
3. In the **Utilities** group box, click the **Generate Config...** button. The system will check to make certain that the database connection information is correct.
4. The system will determine if a Partner Manager user id and password is required in that database. If they are required, you will be asked to provide them.
5. The system will prompt you for the name of the configuration file to save, defaulting to **PMAutoloadConfig.xml**. If the file exists, a message will be displayed that asks if it is OK to over-write the file. The saved configuration file is then ready for use, or for manual modification. You will be given the option of viewing and editing the generated file when the process completes.

Results

Note: Only one configuration can be placed in a file. For example, you cannot duplicate the input file with the expectation that the XML Autoload will run twice. A XML DTD is also supplied to enforce this rule.

Command line flags

Command line flags are used to run the XML Autoload, and will override the values in a configuration file. All command line flags must begin with "-" (a dash), and are two characters in length, with the parameter value immediately following (no space separating flag and value). For example, to specify the XML source (input) file **c:\xml\my.xml**, the command line flag is **-xs**, and the entire command line would be:

```
PMAutoload.exe -xsc:c:\xml\my.xml
```

If a command line parameter value contains a space or a "-", it must be enclosed in double quotes (""). Use of a single quote in parameter values is not supported. Also, do not use a forward slash ("\\") in file names. You must always use a back-slash ("\\").

Command line parameters that are not specified will be looked up in the file: **PMAutoLoadConfig.xml**, or the file specified in "-cf".

Running unattended

To run unattended, run the XML Autoload and supply the command line flag "-cf". For example, the following DOS Command, if issued from the directory the XML Autoload program is located in, will run the XML Autoload using the default configuration file, **PMAutoLoadConfig.xml**:

PMAutoLoad.exe -cf

By default, the XML Autoload Utility is installed in the following directory:*install_dir \WebSphere Transformation Extender\tnmgr_vn.n\pmgr* directory. If the XML Autoload Utility is not located in this directory, you must fully specify the location of **PMAutoLoad.exe** in the command line.

Unattended operation is a background process that is not readily apparent to you. Assuming no error messages appear on the screen, you can check the status of the program's execution by looking at the **Output File**. See the <outputfile> tag, below, for more information

Debugging a Background Task

- [**Debugging a background task**](#)

A special command-line flag, **-dm** (debug mode), exists to help you with the potentially difficult task of debugging a background task.

Debugging a background task

A special command-line flag, **-dm** (debug mode), exists to help you with the potentially difficult task of debugging a background task.

If you are having trouble with your command line flags or configuration file, add **-dm** and the following will occur:

- The screen will be visible, and you can see your settings on the GUI.
- In debug mode, the program will not exit by itself. The following message will be displayed to inform you that the program is terminating: **Program ending in debug mode; Press OK**
- All messages normally written to the output file will also appear as popup messages. Because many messages may appear, two options will be presented when displaying these popup messages: **End Program** or **Stop Displaying Messages**.

Debug mode can only be activated if the **Run** option is **Validate Only**. This is to insure that you cannot modify the parameters through the GUI, or cancel the program when it is updating the database.

Configuration and command line parameters

All parameters not specified "optional" in the following table must be specified, either in the configuration file or in concert with the command line flags.

Even if a parameter is optional, it may be required by your database configuration.

If the command line is malformed to the extent that further processing cannot proceed, the output file cannot be determined, or a fatal file operation occurs, a message will display on the screen that describes the error. In this case, nothing will be written to an output file. A record of the fatal error will display in your Windows **Event Viewer**, under the **Application Log** group, with a source name of **XML Autoload**. Examples include failing to close a quote in a parameter, or being unable to create an output file due to permission errors. All other errors will be reported in the output file.

Warning: Use care when specifying output file options. If you specify "overwrite" the contents of the last output file will be lost; you will not be prompted of this condition. If a file is overwritten a warning will appear in the output file.

In addition, remember the following as you work with these command line options:

- All parameter values are case sensitive except file names.
- All XML tags and command line flags must be lowercase.
- XML tags must be entered in the order displayed (the DTD validation will fail otherwise)
- The command line flags can be listed in any order, but cannot be repeated.

| Configuration Parameter | Command Line | Notes |
|-------------------------|--------------|--|
| Not applicable | -cf | Configuration file name: specify the configuration file to run unattended.
Required to run in unattended mode. Parameter value, if not specified, will default to PMAutoLoadConfig.xml. |
| <xmlsource> | -xs | XML Input file. When used in the command line enclose in quotes if contains a space or a dash. |
| <pwprotection> | | Password protection: 0=clear text (no protection) 1=protected. Tells system format of passwords listed below. |
| <dsn> | | ODBC Data Source Name. |
| <dbuser> | | Database user name. Optional; may be required for your database. |
| <dbpass> | | Database password. Optional; may be required for your database. |
| <database> | | Database name. Optional; may be required for your db. |
| <dbvendor> | | Database vendor: Access, DB2, SQL Server, Oracle, Sybase |
| <pmluser> | | Partner Manager User ID. Optional; required if users are defined in Partner manager |
| <pmpass> | | Password for Partner Manager User ID. Optional; required if <pmluser> above has a password. |
| <rptformat> | | Report Format Option: d=Detailed, s=Summary. |
| <exceedmax> | | Data exceeding Max Len: r=Reject, t=Truncate. |

| Configuration Parameter | Command Line | Notes |
|-------------------------|--------------|---|
| <runoption> | | Run Option: r=Run, v=Validation Only. |
| <updateoption> | | Update Options: a=Allow Add, c=Allow Change, d=Allow Delete. Can combine; for example, to allow all: <update option>acd</update option> |
| <errors> | | Change/Delete Error Processing Control: a=Abort, c=Continue |
| <outputfile> | -of | File to write of all messages/errors. Optional; default: PMAutoloadOut.txt, in same directory as exe. |
| <outputcontrol> | -oc | If output file exists, a=Append, o=Overwrite. No warning issued when overwriting, but a message will appear in output file. Default is "a" (Append) |

Examples

The following examples show how to use the XML Autoload Utility.

Example 1

The XML Autoload is to run unattended, using all parameters set in the default configuration file: **PMAutoload.exe -cf**

Example 2

The XML Autoload is run in its normal mode, with the GUI displayed: **PMAutoload.exe**

Example 3

The XML Autoload is to run unattended, using the configuration file **c:\My Files\MyXML.xml**, and with the output control to "append". The file name contains spaces, so it is enclosed in double quotes:

PMAutoload.exe -cf"c:\My Files\MyXML.xml" -oca

Defining tables and fields

The XML Autoload Utility field and table definitions, provided here, are used for adding new objects or changing or deleting objects in the Partner Manager database.

The following are field descriptions for the XML tables

- **Field Label** is the label on the screen as it appears in Partner Manager.
- **FieldName/Tag** is the database field name (if one exists), and is used as the XML tag. There are two distinct sets of XML tags included in the XML Autoload Utility: one set is used to add data and another set is used to change existing data. These separated tags ensure backward compatibility for users of prior versions of this utility. (Your script generation routines for adding data remain unchanged.) The separation of tags also prevents you from accidentally changing data when you intended to add data. The new change and delete tags always end with **Change** or **Delete**, for example, **AddChangeDelete**. The tags related to Documents on a Trade Link always end with **AddChangeDelete**, for example, **X12InboundGroupsAddChangeDelete**.
- **Req'd** means this field must be in the input to AutoLoad, it is not the database definition of required. The abbreviation **fk** = Foreign Key (that value must exist in the specified table).
- **Max. Len.** is the maximum length of the field (minimums, if any, are in the notes).
- **Validation** defines the valid values for the fields.
- **Notes** contain detailed information about the tag. System generated fields such as Surrogate keys, Optimistic Locking Fields, and Audit Information (for example, **CreatedBy/DateCreated**) and are not listed here. These fields are populated automatically by the Autoload Utility. Leading and trailing spaces, if any, are trimmed before saving to the database. **CreatedBy** is set to **AutoLoad** so that any problems associated with this utility can be tracked.
- [Table and Field Types](#)
- [Post offices](#)
- [Contacts](#)
- [X12 Trading Partners](#)
- [Automatic creation of X12 acknowledgement trade links](#)
The documentation provided here describes the tags needed to create trade links in the XML AutoLoad Utility. An additional feature for X12 trade links is the ability to automatically create the acknowledgement trade link at the same time.
- [X12 inbound trade links](#)
- [X12 outbound trade links](#)
- [EDIFACT partners](#)
- [EDIFACT inbound trade links](#)
- [EDIFACT outbound trade links](#)
- [TRADACOMS Trading/Application Partners](#)
- [TRADACOMS inbound trade links](#)
- [TRADACOMS Outbound Trade Links](#)

Table and Field Types

The following sections describe the specific requirements for defining the XML input files' table and field requirements for the XML AutoLoad Utility. The table and field types described in these sections are:

- "[Post Offices](#)"
- "[Contacts](#)"
- "[X12 Trading Partners](#)"
- "[X12 Inbound Trade Links](#)"
- "[X12 Outbound Trade Links](#)"
- "[EDIFACT Partners](#)"
- "[EDIFACT Inbound Trade Links](#)"
- "[EDIFACT Outbound Trade Links](#)"
- "[TRADACOMS Trading/Application Partners](#)"
- "[TRADACOMS Inbound Trade Links](#)"
- "[TRADACOMS Outbound Trade Links](#)"

Post offices

The following table, field, and tag descriptions are for Post Offices fields associated with the XML Autoload Utility:

- "[Post Offices \(Tag: PostOffices\)](#)"
- "[Post Offices Delete \(Tag: PostOfficesDelete\)](#)"
- "[Post Offices Change \(Tag: PostOfficesChange\)](#)"

WARNING: If the "Use One GET Post Office per Standard" is set, you will be prevented from adding a Get Post Office, changing a Put Post Office, or deleting a Get Post Office. Any Get Post Office specified in an XML input file will be ignored.

- [Post Offices \(Tag: PostOffices\)](#)
- [Post Offices Delete \(Tag: PostOfficesDelete\)](#)
- [Post Offices Change \(Tag: PostOfficesChange\)](#)

Post Offices (Tag: PostOffices)

Use this tag to add new Post Office records. A warning is reported (or an error if **Abort Run** is selected) if the Post Office already exists in the Partner Manager database.

The tag and field descriptions are:

| Field Label | FieldName/Tag | Req'd | Max. Len. | Validation | Notes |
|-----------------------------|-------------------|-------|-----------|-------------------|-------|
| Post Office Name | POName | Yes | 50 | Unique | |
| Get/Put | Get_Put_Indicator | Yes | 1 | G or P | |
| PO Type | POType | Yes | 50 | See note 1 | 1 |
| Nickname | PONickname | No | 3 | Unique if present | 2 |
| Directory or Adapter String | AdapterString1 | No | 255 | | 3 |

Notes:

1. The PO Type must be an active Post Office Type, as maintained in Partner Manager. Examples include: VAN, FILE, and EMAIL.
2. If the PO Nickname is not supplied, it is generated by the system when saved. Must be 3 characters long if supplied, and not already in use.
3. If the type is File then a trailing right or left slash (\, /) is appended if not present and this field was supplied (UNIX or DOS directory separator).

Post Offices Delete (Tag: PostOfficesDelete)

Use this tag to delete existing Post Office records. A warning is reported (or error if **Abort Run** is selected) and will not delete if a Post Office is assigned to a trade link. A warning is reported (or an error if **Abort Run** is selected) if a Post Office does not exist.

The tag and field descriptions are:

| Field Label | FieldName/Tag | Req'd | Max. Len. | Validation | Notes |
|------------------|---------------|-------------|-----------|------------|-------|
| Post Office Name | POName | See Note 1. | 50 | | 1 |
| Nickname | PONickname | See Note 1. | 3 | | 1 |

Notes:

1. Supply **POName**, **PONickname**, or both to delete. At least one of these fields must be specified.

Post Offices Change (Tag: PostOfficesChange)

Use this tag to change existing Post Office records. A warning is reported (or an error if **Abort Run** is selected) if the Post Office does not exist.

The tag and field descriptions are:

| Field Label | FieldName/Tag | Req'd | Max. Len. | Validation | Note |
|-------------|---------------|-------|-----------|------------|------|
| | | | | | |

| Field Label | FieldName/Tag | Req'd | Max. Len. | Validation | Note |
|-----------------------------|-------------------|-------------|-----------|-------------|------|
| Post Office Name | POName | See Note 1. | 50 | | 1 |
| Get/Put | Get_Put_Indicator | Yes | 1 | G or P | |
| PO Type | POType | No | 50 | See Note 2. | 2 |
| Nickname | PONickname | See Note 1. | 3 | | 1 |
| Directory or Adapter String | AdapterString1 | No | 255 | | 3 |
| N/A | PONameChange | N | 50 | | 4 |
| N/A | PONicknameChange | N | 3 | | 4 |

Notes:

- Specify the **POName**, **PONickname**, or both, of the existing Post Office you wish to change. Do not use these fields to change a Post Office name or nickname; see the fields **PONameChange** and **PONicknameChange**.
- The PO Type, if specified, must be an active Post Office Type, as maintained in Partner Manager. Examples include: VAN, FILE, and EMAIL.
- If the type is File then a trailing right or left slash (\, /) is appended if not present and this field was supplied. (UNIX or DOS directory separator).
- If you want to change the name, or nickname, of an existing PostOffice, specify the change in these two fields. These fields, if specified, must be unique: they cannot already be in use on another Post Office. Changing the name does not automatically change the nickname.

Contacts

The following table, field, and tag descriptions are for **Contacts** fields associated with the XML Autoload Utility.

- [Contacts \(Tag: Contacts\)](#)
-

Contacts (Tag: Contacts)

Contacts may be associated with the Trading or Application Partner being added. For example, the **<Contacts>...</Contacts>** group(s) may be between the **<X12TradingPartners>...</X12TradingPartners** and **<X12AppPartners>...</X12AppPartners>** (or similar EDIFACT and TRADACOMS tag, and/or associated Change) tags. Adding contacts to an existing Trading or Application Partner in the Partner Manager database is supported if nested within a Change tag. When adding contacts to an existing object you cannot add a contact if one previously exists with the same last and first names through this utility. There can be zero or many contacts associated with each Trading or Application Partner. If the associated Trading or Application Partner is rejected, all contacts for the rejected Partner are rejected. The tag and field descriptions are described in the following table:

| Field Label | FieldName/Tag | Req'd | Max. Len. | Validation | Notes |
|-----------------------------------|------------------|-------|-----------|---------------|-------|
| Last Name | LastName | Yes | 30 | | |
| First Name | FirstName | Yes | 30 | | |
| Title | Title | No | 25 | | |
| Primary Address | Address_1 | No | 25 | | |
| Secondary Address | Address_2 | No | 25 | | |
| City | City | No | 30 | | |
| State | State | No | 30 | | |
| Zip Code | ZipCode | No | 30 | | |
| Country | Country | No | 30 | | |
| Phone | Phone | No | 20 | | |
| E-Mail | Email | No | 255 | | |
| Beeper | Beeper | No | 20 | | |
| Notes | Notes | No | 255 | | |
| Alert Type | AlertType | No | 50 | Internal Only | 1, 2 |
| (Alert Options)
E-Mail | AlertEmail | No | 255 | Internal Only | 3 |
| (Alert Options) Monitor Directory | MonitorDirectory | No | 255 | Internal Only | 3 |
| Attach Data | AlertEmailAttach | No | 1 | T/F | 4 |

Notes:

- All Alert fields apply to Internal Trading/Application Partners only. The valid values for AlertType are: UFO, Syntax, and ANY. The values are case sensitive. This is for future use.
- Default: UFO
- If any of these exist, the corresponding Ind (check box on the form) field is set to True (-1) in the Contacts table, otherwise set the Ind fields to False (0). Unlike the data entry form, the AlertEmail field does not default to the Email field; you must specify both if requiring both.
- Set to T (true) to attach the data to the email alert. Requires an email address in the field AlertMail.

X12 Trading Partners

The following table, field, and tag descriptions are for X12 Trading Partners fields associated with the XML AutoLoad Utility:

- "[X12 Trading Partners \(Tag: X12TradingPartners\)](#)"
- "[X12 Application Partners \(Tag: X12AppPartners\)](#)"
- "[X12 Application Partners Delete \(Tag: X12AppPartnersDelete\)](#)"
- "[X12 Application Partners Change: \(Tag X12AppPartnersAddChange\)](#)"
- "[X12 Trading Partners Change \(Tag: X12TradingPartnersChange\)"](#)
- "[X12 Trading Partners Delete \(Tag: X12TradingPartnersDelete\)"](#)

- [**X12 Trading Partners \(Tag: X12TradingPartners\)**](#)
- [**X12 Application Partners \(Tag: X12AppPartners\)**](#)
- [**X12 Application Partners Delete \(Tag: X12AppPartnersDelete\)**](#)
- [**X12 Application Partners Change: \(Tag X12AppPartnersAddChange\)**](#)
- [**X12 Trading Partners Change \(Tag: X12TradingPartnersChange\)**](#)
- [**X12 Trading Partners Delete \(Tag: X12TradingPartnersDelete\)**](#)

X12 Trading Partners (Tag: X12TradingPartners)

Use this tag to add new X12 Trading Partners.

Trading Partners can have **Contacts** added at the same time; nest the Contact record within the Trading Partner tags. See [Contacts](#) for more information.

The tag and field descriptions are described in the following table:

| Field Label | FieldName/Tag | Req'd | Max. Len. | Validation | Notes |
|--|---------------------|-------|-----------|------------------------------------|-------|
| Internal/
External | IntExt | Yes | 1 | "I" or "E" | 1, 2 |
| Partner Name | PartnerName | Yes | 35 | Unique | 3 |
| ISA Address | IchgQual | Yes | 2 | fk to IchgIDQualifiers | 4 |
| Interchange ID | IchgID | Yes | 15 | Unique with IchgQual | |
| Authorization Qualifier | INBAAAuthQual | No | 2 | fk to AuthQualifiers | 14 |
| Authorization ID | INBAAuth | No | 10 | | 14 |
| Security Qualifier | INBSecurityQual | No | 2 | fk to SecurityQualifiers | 14 |
| Security Password | INBSecurityPWD | No | 30 | | 14 |
| Interchange Standards ID or Repetition Character | IchgCtrlStdsID | No | 8 | fk to IchgStandardsIC or HexValues | 6 |
| Interchange Ctl Version ID | IchgCtrlVerNo | No | 5 | fk to IchgStandardsVer | 7 |
| Element Separator | ElementSeparator | No | 5 | fk to HexValues | 8, 9 |
| Sub Element Separator | SubElementSeparator | No | 5 | fk to HexValues | 9, 10 |
| Segment Terminator | SegmentTerminator | No | 5 | fk to HexValues | 9, 11 |
| Duplicate Control | Duplicate_Control | No | 3 | | 13 |
| Last Interchange Control # | ISAControlNoValue | No | 9 | | 12 |
| TA1GetPO | TA1 Get Post Office | No | 3 | Nickname of a Get PO | |
| TA1PutPO | TA1 Put Post Office | No | 3 | Nickname of a Put PO | |
| Authorization Qualifier | OUTBAAuthQual | No | 2 | fk to AuthQualifiers | 14 |

| Security Qualifier | OUTBSecurityQual | No | 2 | fk to SecurityQualifiers | 14 |
| Security Password | OUTBSecurityPWD | No | 30 | | 14 |
| Validate Authorization | ValidateAuth | No | 1 | Y/N | 15 |
| Validate Security | ValidateSec | No | 1 | Y/N | 15 |

Notes:

1. Determines folder.
2. Standard Internal and External X12 Folders are used (no custom folders). These custom folders are: -2 = Internal FolderNo; and -21 = External FolderNo.
3. Do not use the name "UNKNOWN, or "ALL", or any variation of the case of these two words. For example, do not use "Unknown", or "All". Unique across all X12 Trading Partners.
4. Cannot contain single or double quotation marks. Combination of **IchgQual + IchgID** must be unique across all X12 Trading Partners.
5. Default: 00
6. The field **IchgCtrlStdsID** takes on two meanings, depending on the value of the next field, **IchgCtrlVerNo**. If the **IchgCtrlVerNo** is greater than, or equal to, 00402, this field is the Repetition Character, otherwise it is the Interchange Standards ID. Both field types are optional: the default value is "A" (caret, Hex 5E) if the field denotes the Repetition Character; the default value is "U" for the Interchange Standards ID. When specifying the Repetition Character, use the hexadecimal values as stored in the table HexValues. When specifying an Interchange Standards ID, the value must be in the table **IchgStandardsIC**. The reason for this dual meaning is that the X12 committee stopped using the Interchange Standards ID and replaced it with the Repetition Character, starting with Interchange Control version 00402.
7. Default: 00305
8. Default: 2A
9. If more than one hex value, separate by a space (for example, 0D 0A). Defaults are: 2A (*); 3A (colon); and 0A: Linefeed.
10. Default: 3A
11. Default: 0A
12. Field can only be set for External Trading Partners that have a Duplicate Control Interchange setting of Y. If set, it must be a positive integer no longer than nine characters.
13. This field can only be specified for external partners. This is a three character string containing the letters **N** or **Y**: set each position to a **Y** if the **Duplicate Control** checkbox is checked as follows: position 1=Interchange, position 2=FG within Interchange, position 3=Transaction within FG.
14. Use for External Trading Partners only.
15. Use for External Trading Partners only. Default is **N**.

X12 Application Partners (Tag: X12AppPartners)

Use this tag to add X12 Application Partners while adding X12 Trading Partners. There can be zero or more Application Partners associated with a Trading Partner, however, an Application Partner is required when a Trade Link is created for a Trading Partner. If any Trading Partners are rejected, all associated Application Partners are rejected as well. X12 Application Partners can have contacts added. See "[Contacts](#)" for more information.

The tag and field descriptions are:

| Field Label | FieldName/Tag | Req'd | Max. Len. | Validation | Notes |
|--------------------------|------------------|-------|-----------|--------------------------------------|-------|
| N/A (ISA + IID) | ISA_IID | Yes | 17 | IchgQual + IchgID of Trading Partner | 1 |
| Application Partner Name | ApplicationName | Yes | 35 | Unique within the Trading Partner | 2 |
| GS Address | GS_ApplicationID | Yes | 15 | Unique within the Trading Partner | 3 |
| Alias | AliasName | No | 20 | Unique if present | 4 |
| User Defined 1 | UserDefined1 | No | 20 | | |
| User Defined 2 | UserDefined2 | No | 20 | | |
| Institution | Institution | No | 255 | | 5 |

Notes:

- Combination of previous Trading Partner's ISA Address and Interchange ID. Used to confirm that the XML is properly formed (Application Partners nested within the parent Trading Partner).
- Do not use the name "UNKNOWN", or "ALL", or any variation of the case of these two words. For example, do not use "Unknown", or "All".
- Cannot contain single or double quotes.
- Alias Names are unique across all X12 Application Partners, if present.
- Specify optional HIPAA Institution, used for HIPAA Type 7 validations. If specified, must exist in the table HIPAA_Institutions. Valid only for External Application Partners.

X12 Application Partners Delete (Tag: X12AppPartnersDelete)

Use this tag to delete an X12 Application Partner. It will also delete any contacts associated with the Application Partner, but will not delete if Application Partner is assigned to a trade link (see [X12TradingPartnersDelete](#) if this functionality is needed). It reports a warning (or error if **Abort Run** is selected) if Application Partner does not exist.

To identify the Application Partner to delete, you must specify the **ISA_IID**, ad then identify the Application Partner via **ApplicationName** and/or **GS_ApplicationID**. You can specify just **ApplicationName**, or **GS_ApplicationID**, or both. If specifying both, the system will ensure that name belongs to the ID. The tag and field descriptions are:

| Field Label | FieldName/Tag | Req'd | Max. Len. | Validation | Notes |
|--------------------------|------------------|-------|-----------|--------------------------------------|-------|
| Application Partner Name | ApplicationName | No | 35 | | |
| GS Address | GS_ApplicationID | No | 15 | | |
| N/A (ISA + IID) | ISA_IID | Yes | 17 | IchgQual + IchgID of Trading Partner | |

X12 Application Partners Change: (Tag X12AppPartnersAddChange)

Use this tag to add an X12 Application Partner to an existing Trading Partner, or change an existing Application Partner. To add, set the tag "AddFlag" to **Y**; leaving "AddFlag" blank, not specified, or set to **N** will change the existing X12 Application Partner if it exists.

Contacts can be added via this tag as well; include a [Contacts](#) tag set within the **X12AppPartnersAddChange** tags to add new Contacts to an existing Application Partner. You cannot add a Contact if one exists with that First and Last Name.

Note: Deleting or changing existing Contacts is not supported by the XML Autoload Utility, and must be done using Partner Manager.

ApplicationName and **GS_ApplicationID** together are not required when changing, but at least 1 must be specified to identify the Application Partner. If AddFlag is **Y**, then these two fields are required.

If changing the Application Name or GS Address, use **ApplicationNameChange** and **GS_ApplicationIDChange**. These "Change" fields cannot be specified when the **AddFlag** is **Y**. The tag and field descriptions are:

| Field Label | FieldName/Tag | Req'd | Max. Len. | Validation | Notes |
|--------------------------|------------------------|-------|-----------|--------------------------------------|-------|
| N/A (ISA + IID) | ISA_IID | Yes | 17 | IchgQual + IchgID of Trading Partner | 1 |
| Application Partner Name | ApplicationName | No | 35 | Unique within the Trading Partner | 2 |
| GS Address | GS_ApplicationID | No | 15 | Unique within the Trading Partner | 3 |
| Alias | AliasName | No | 20 | Unique if present | 4 |
| User Defined 1 | UserDefined1 | No | 20 | | |
| User Defined 2 | UserDefined2 | No | 20 | | |
| Institution | Institution | No | 255 | | 5 |
| N/A | AddFlag | No | Y/N | | |
| N/A | ApplicationNameChange | No | 35 | | |
| N/A | GS_ApplicationIDChange | No | 15 | | |

Notes:

1. Combination Trading Partner's ISA Address and Interchange ID associated with this Application Partner.
2. Do not use the name "UNKNOWN", or "ALL", or any variation of the case of these two words. For example, do not use "Unknown", or "All".
3. Cannot contain single/double quotes.
4. Alias Names are unique across all X12 Application Partners, if present.
5. Specify optional HIPAA Institution, used for HIPAA Type 7 validations. If specified, must exist in the table HIPAA_Institutions. Valid only for External Application Partners.

X12 Trading Partners Change(Tag: X12TradingPartnersChange)

Use this tag to change existing X12 Trading Partners. The fields in this tag are similar to X12 Trading Partners, but the **IntExt** (Internal/External) field is not specified because you cannot change an Internal Trading Partner to an External using this tag. If this is required, delete and re-add the partner. Also, unlike the tag **X12TradingPartners**, **X12AppPartners** are not nested within this tag. (Use the [X12AppPartnersAddChange](#) tag to add Application Partners to an existing Trading Partner, or to change existing Application Partners).

To specify Trading Partner to change, specify **PartnerName**, **IchgQual** and **IchgID**, or all 3 (you must specify both the Qualifier and ID if specifying either). To change the fields that identify a Partner (the Partner Name, Interchange Qualifier, or Interchange ID), use the fields **PartnerNameChange**, **IchgQualChange**, or **IchgIDChange** tags.

Trading Partners can have [Contacts](#) added at the same time; nest the Contact record within the Trading Partner tags. Use this tag, along with the Contacts tag, to add Contacts to an existing Trading Partner.

The tag and field descriptions are described in the following table:

| Field Label | FieldName/Tag | Req'd | Max. Len. | Validation | Notes |
|----------------------------|----------------------|------------|-----------|--------------------------|-------|
| Partner Name | PartnerName | See Note 1 | 35 | Unique | 1 |
| ISA Address | IchgQual | See Note 1 | 2 | fk to IchgIDQualifiers | 1 |
| Interchange ID | IchgID | See Note 1 | 15 | Unique with IchgQual | 1 |
| Authorization Qualifier | INBAAuthQual | No | 2 | fk to AuthQualifiers | |
| Authorization ID | INBAAuth | No | 10 | | |
| Security Qualifier | INBSecurityQual | No | 2 | fk to SecurityQualifiers | |
| Security Password | INBSecurityPassword | No | 30 | | |
| Interchange Standards ID | IchgCtrlStdsID | No | 1 | fk to IchgStandardsIC | |
| Interchange Ctl Version ID | IchgCtrlVerNo | No | 5 | fk to IchgStandardsVer | |
| Element Separator | ElementSeparator | No | 5 | fk to HexValues | 2 |
| Sub Element Separator | SubElementSeparator | No | 5 | fk to HexValues | 2 |
| Segment Terminator | SegmentTerminator | No | 5 | fk to HexValues | 2 |
| Duplicate Control | Duplicate_Control | No | 3 | | 3 |
| Last Interchange Control # | ISAControlNoValue | No | 9 | | 6 |
| N/A | PartnerNameChange | No | 35 | | 4 |
| N/A | IchgQualChange | No | 2 | | 4 |
| N/A | IchgIDChange | No | 15 | | 4 |
| Reset ISA Control | ResetISA_Ind | No | 1 | T/F | 5 |
| TA1GetPO | TA1 Get Post Office | No | 3 | Nickname of a Get PO | |
| TA1PutPO | TA1 Put Post Office | No | 3 | Nickname of a Put PO | |
| Authorization Qualifier | OUTBAAuthQual | No | 2 | fk to AuthQualifiers | |
| Authorization ID | OUTBAAuth | No | 10 | | |
| Security Qualifier | OUTBSecurityQual | No | 2 | fk to SecurityQualifiers | |
| Security Password | OUTBSecurityPassword | No | 30 | | |

Notes:

1. Identify the Partner using these three fields. You can specify just the name, or both ID and Qualifier, or all three.
2. If more than one Hex Value, separate by a space (for example, 0D 0A).
3. This field can only be specified for external partners. This is a three character string containing the letters N or Y: set each position to a Y if the **Duplicate Control** checkbox is checked as follows: position 1=Interchange, position 2=FG within Interchange, position 3=Transaction within FG.
4. Use these fields to change a Partner Name, or the unique identifier for a Trading Partner (Interchange ID and ISA Address/Qualifier).
5. Valid value is **T** or **F** (**T**=True/enabled; **F**=False/disabled). If setting to **T**, you must specify **ISAControlNoValue** (on screen as "Last Interchange Control Number"); if you specified an **ISAControlNoValue** this field will be set to enabled for you. If setting to **F**, this will clear the existing **ISAControlNoValue**. You can only specify **ResetISA_Ind** on External Trading Partners.
6. Field can only be set for External Trading Partners that have a duplicate Control Interchange setting of Y. If set, it must be a positive integer no longer than nine characters.

X12 Trading Partners Delete (Tag: X12TradingPartnersDelete)

Use this tag to delete existing X12 Trading Partners. To delete, specify either the Partner Name, or the combination of ISA Address (Qualifier) and Interchange ID. You can also specify all three values; the system will insure that name exists with that Qualifier/Interchange ID. A warning is reported (or error if **Abort Run** is selected), if a Trading Partner does not exist.

Use with caution, as this tag deletes all records associated with the Trading Partner - all Application Partners, Contacts, and Inbound/Outbound Trade Links.

The tag and field descriptions are described in the following table:

| Field Label | FieldName/Tag | Req'd | Max Len. | Validation | Notes |
|----------------|---------------|----------|----------|------------------------|-------|
| Partner Name | PartnerName | See Note | 35 | Unique | |
| ISA Address | IchgQual | See Note | 2 | fk to IchgIDQualifiers | |
| Interchange ID | IchgID | See Note | 15 | Unique with IchgQual | |

Automatic creation of X12 acknowledgement trade links

The documentation provided here describes the tags needed to create trade links in the XML AutoLoad Utility. An additional feature for X12 trade links is the ability to automatically create the acknowledgement trade link at the same time.

Here you will find documentation that explains how to use this automatic acknowledgement feature.

Creating or modifying a trade link so that an acknowledgement is required, or expected, will check to see if the corresponding trade link needs to be created. If that link does not exist, it will be created for you if you specify the **Acknowledgement Post Offices** option. The corresponding trade link has the same internal and external partners, but in the opposite (inbound and outbound) direction. An acknowledgement is *required* on an Inbound trade link when the XML tag Ack Level is set to a non-zero value in the XML file. An acknowledgement is *expected* on an Outbound trade link when the XML tag **ACK_Within** (number of hours an acknowledgement is expected) is set to a non-zero value. This feature duplicates the automatic acknowledgement creation feature found in Partner Manager.

Note: If you would prefer to create the acknowledgement trade link yourself, do not specify the **Acknowledgement Post Offices** and skip the remainder of this procedure. The automatic creation feature supports three different acknowledgement functional groups:

- 824
- 997
- 999

How the system determines which functional group to use is described in the following procedures.

Note: The tags mentioned are explained in detail in the trade link tables found in this documentation.

- **Inbound/outbound trade link acknowledgments**

For an inbound trade link, the acknowledgement can be a 824, 997, and/or a 999. For outbound trade links, the acknowledgement will only be 997, set to the version specified on the outbound trade link

- **Activating the feature**

In order to activate this feature, you must specify the **Acknowledgement Post Offices** option. These are the post offices that are used on the corresponding trade link. In all four X12 trade link application tags, three optional tags are used to specify these post offices:

Inbound/outbound trade link acknowledgments

For an inbound trade link, the acknowledgement can be a 824, 997, and/or a 999. For outbound trade links, the acknowledgement will only be 997, set to the version specified on the outbound trade link

For inbound trade links, it should be noted that the transaction(s) created will be based on the **HIPAA Validation Type** XML tag **ValType**, or will just be a 997 if it is a non-HIPAA transaction. The version of the 824 created depends on the setting of the 824 **Ack Version** tag specified (and will default to 4050 if not specified). The version of the 997 created depends on the setting of the **HIPAAAckFlag** tag specified (and will default to the version of the Inbound application if not specified). The version of the 999 is always version 5010.

Activating the feature

In order to activate this feature, you must specify the **Acknowledgement Post Offices** option. These are the post offices that are used on the corresponding trade link. In all four X12 trade link application tags, three optional tags are used to specify these post offices:

- **AckGetPO**
- **AckProdPutPO**
- **AckTestPutPO**

All three tags are optional, but if any are specified, at least one Put post office (test or production) must be specified.

The Get post office will become required if a Put is specified, and the corresponding trade link does not exist already. If this Get post office is specified, and the trade link exists already, the Get post office set here will be ignored (and the one used on the existing trade link remains). Failure to specify an **AckGetPO** when one is required will result in warnings in the XMLautoload in process.

These Acknowledgment Post Offices are used in the following tags and are explained in detail below:

- [X12 Outbound Applications Trade Links \(Tag: X12OBAppLink\)](#)
- [X12 Inbound Trade Links Applications Add, Change, Delete \(Tag: X12InboundGroupsAddChangeDelete\)](#)
- [X12 Inbound Trade Link Applications \(Tag: X12InboundGroups\)](#)
- [X12 Inbound Trade Links Applications Add, Change, Delete \(Tag: X12InboundGroupsAddChangeDelete\)](#)

When this feature is activated and the XML AutoLoad Utility **Reporting Options** is set to **Detailed**, information messages such as *X12 Outbound 824 Acknowledgement added to an existing trade link*, and *X12 Outbound 824 Acknowledgement added to an existing trade link*, and *X12 Inbound 997 Acknowledgement added to a newly created trade link* will be included in the report. When the XML AutoLoad Utility is in **Validation** mode, this message may repeat more than once, as the data is not actually created. In **Validation** mode, these messages will read: *would have been added* instead of *added*. No messages regarding this feature will be displayed if the reporting option is set to **Summary**.

X12 inbound trade links

Trade links can be added, changed, or deleted. In addition, existing Trade Links can have their individual Applications added, changed, or deleted ("Applications" are identified by the combination of Version and Functional ID, and are also known as "Documents").

To add a trade link, use one of the following tags and nest **X12InboundGroups** tags within the tag:

- **X12IBTradeLink**
- **X12Unknown_Link**

Note: There are two types of X12 Inbound Trade Links: Known and Unknown. When creating a Known Trade Link, start with the **X12IBTradeLink** tag. When creating an Unknown Trade Link, start with the **X12UnknownLink** tag.

To change an existing X12 Inbound Trade Link, use the tags **X12IBTradeLinkChange** and **X12InboundGroupsAddChange**. You define the link to change using the **X12IBTradeLinkChange** tag, and add, change, or delete applications using the **X12InboundGroupsAddChangeDelete** tag.

When adding a Trade Link, one or more Applications (for example, 3010 PO) must be included in the XML data. The Application data structure does not differ by Known/Unknown status. For example, the XML structure for one Known Link having two Applications, and one Unknown Link having just one Application would be:

```
<x12IBTradeLink>
  ...header data
  <x12InboundGroups>
    ...application data #1
  </x12InboundGroups>
  <x12InboundGroups>
    ...application data #2
  </x12InboundGroups>
</x12IBTradeLink>
<x12Unknown_Link>
  ...header data
  <x12InboundGroups>
    ...application data
  </x12InboundGroups>
</x12Unknown_Link>
```

Note: ALL Transaction Sets for a given Application is automatically written to the Trade Link (into table **X12IBTrans**).

Trade Links are associated with the From and To Application Partners, and Application Partners are identified by GS Application ID. However, GS Application ID's are not unique across the system. There could be the same GS Application ID but for different Trading Partners. For this reason, both the ISA and GS Identifiers are required when specifying Trade Links (same applies for Outbound X12 Trade Links as well), and the Trading Partners must previously exist in the database for the Trade Link to be added.

The following table, field, and tag descriptions are for X12 inbound trade links:

- ["X12 Known Inbound Trade Link: \(Tag: X12IBTradeLink\)"](#)
- ["X12 Unknown Inbound Trade Link \(Tag: X12Unknown_Link\)"](#)
- ["X12 Unknown Inbound Trade Link Change \(Tag: X12Unknown_LinkChange\)"](#)
- ["X12 Inbound Trade Link Applications \(Tag: X12InboundGroups\)"](#)
- ["X12 Known Inbound Trade Link Change \(Tag: X12IBTradeLinkChange\)"](#)
- ["X12 Inbound Trade Links Applications Add, Change, Delete \(Tag: X12InboundGroupsAddChangeDelete\)"](#)
- ["X12 Known Inbound Trade Link Delete \(Tag: X12IBTradeLinkDelete\)"](#)
- ["X12 Unknown Inbound Trade Link Delete \(Tag: X12Unknown_LinkDelete\)"](#)
- ["X12 Known Inbound Trade Link: \(Tag: X12IBTradeLink\)"](#)
- ["X12 Unknown Inbound Trade Link \(Tag: X12Unknown_Link\)"](#)
- ["X12 Unknown Inbound Trade Link Change \(Tag: X12Unknown_LinkChange\)"](#)
- ["X12 Inbound Trade Link Applications \(Tag: X12InboundGroups\)"](#)
- ["X12 Known Inbound Trade Link Change \(Tag: X12IBTradeLinkChange\)"](#)
- ["X12 Inbound Trade Links Applications Add, Change, Delete \(Tag: X12InboundGroupsAddChangeDelete\)"](#)
- ["X12 Known Inbound Trade Link Delete \(Tag: X12IBTradeLinkDelete\)"](#)
- ["X12 Unknown Inbound Trade Link Delete \(Tag: X12Unknown_LinkDelete\)"](#)

X12 Known Inbound Trade Link: (Tag: X12IBTradeLink)

Use this tag to add a new X12 Known Inbound Trade Link. There is one **X12IBTradeLink** record per **Known Trade Link**. All fields are required.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A (From ISA + IID)	From_ISA_IID	Yes	17	IchgQual + IchgID of From Trading Partner	1, 2
N/A (To ISA + IID)	To_ISA_IID	Yes	17	IchgQual + IchgID of To Trading Partner	3, 4
N/A (From GS Address)	From_GS_ID	Yes	15	GS_ApplicationID of From Ap Partner	5, 2
N/A (To GS Address)	To_GS_ID	Yes	15	GS_ApplicationID of To Ap Partner	6, 4
Get Post Office	GetMailPO	Yes	3	Nickname of Get PO	7

Notes:

1. Must match an existing External Trading Partner.
2. Combination of these two fields must match an External Trading Partner/Application Partner association (for example, the Application Partner must belong to the specified Trading Partner, not just be a valid Application Partner). This relationship can be in any External X12 Folder.
3. Must match an existing Internal Trading Partner.

4. Combination of these two fields must match an Internal Trading Partner/Application Partner association (for example, the Application Partner must belong to the specified Trading Partner, not just be a valid Application Partner). This relationship can be in any Internal X12 Folder.
5. Must match an existing External Application Partner.
6. Must match an existing Internal Application Partner.
7. Must be exactly 3 characters long. Nickname must exist as a Get Post Office.

X12 Unknown Inbound Trade Link (Tag: X12Unknown_Link)

Use this tag to add a new X12 Unknown Inbound Trade Link.

There is one **X12Unknown_Link** record per Unknown Trade Link. There is no From Partner in an Unknown Link.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A (To ISA + IID)	To_ISA_IID	Yes	17	IchgQual + IchgID of To Trading Partner	1
N/A (To GS Address)	To_GS_ID	Yes	15	GS_ApplicationID of To Ap Partner	2
Get Post Office	GetMailPO	Yes	3	Nickname	3

Notes:

1. Must match an existing Internal Trading Partner.
2. Must match an existing Internal Application Partner.
3. Must be exactly 3 characters long. Nickname must exist as a Get Post Office.

X12 Unknown Inbound Trade Link Change (Tag: X12Unknown_LinkChange)

Use this tag to change an existing X12 Unknown Inbound Trade Link. To add, change, or delete applications on an existing X12 Unknown Trade Link, nest **X12InboundGroupsAddChangeDelete** records within this tag.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A (To ISA + IID)	To_ISA_IID	Yes	17	IchgQual + IchgID of To Trading Partner	1
N/A (To GS Address)	To_GS_ID	Yes	15	GS_ApplicationID of To Ap Partner	2
Get Post Office	GetMailPO	No	3	Nickname	3

Notes:

1. Must match an existing Internal Trading Partner.
2. Must match an existing Internal Application Partner.
3. must be exactly 3 characters long, if specified. Nickname must exist as a Get Post Office.

X12 Inbound Trade Link Applications (Tag: X12InboundGroups)

Use this tag to add applications to a new X12 Inbound (Known or Unknown) Trade Link.

Note: Zero or more Applications per Link. This is optional, but without it the Trade Link is not complete (such links are valid in Partner Manager in the event you wish to complete it at a later time).

The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Application Version	GS_VersionRelease	Yes	12	fk to X12_Version	1
Functional ID	GS_FunctionalID	Yes	2	fk to X12_FuncID with Version	1
Ack Level	AckLevel	No	1	0,1,2,3,4	2
Ack To Application Partner	AckTo_ISA_IID and AckTo_GS_ID	No	17,15	See note	3
Validate By	ValidateByInd	No	1	F=Functional Group, T=Transaction Set I =Interchange Default: T	
Test Indicator	TestIndicator	No	1	T=True, F=False Default: F	4
Production Indicator	ProdIndicator	No	1	T=True, F=False Default: T	4
Test PO Nickname	TestPutPO	Yes if Test Indicator is T	3	Nickname of Valid Put PO	5

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Prod PO Nickname	ProdPutPO	Yes if ProdIndicator is T	3	Nickname of Valid Put PO	6
HIPAA Validation Type	ValType	If HIPAA	7	See " HIPAA Validation Type Description "	
Map Name	Type3MapName	No	255	See " HIPAA Validation Type Description "	
997 Version	HIPAAAckFlag	No	12		7
Routing: Route Only	RouteOnly	No	1	Y/N Default: N	
4050X151 PI BIN Validation (824/999)	BinSegmentValidation	No	1		8
824 Ack Version	Version824Ack	No	12		9
AckGetPO		No	3		10
AckProdPutPO		No	3		11
AckTestPutPO		No	3		12

Notes:

1. Version + Functional ID must be unique within the same Trade Link.
2. **N/A** for Unknown Links; **0**=No Ack; **1**=Functional Group Level; **2**=Transaction Set Level; **3**=Segment Level; **4**=Data Element Level; Default is **0** (zero).
3. N/A for **Unknown Links**. Note the two **FieldNames/Tags**, both are required if **AckTo** is specified. Must point to a valid (existing) External Trading/Application Partner association. Defaults to the external (from) Ap Partner if not specified and the **AckLevel** (above) is not zero.
4. At least one of (**TestIndicator** or **ProdIndicator**) must be **T** (True).
5. Must be exactly 3 characters if present. Ignored if **TestIndicator** is **F** (False), required otherwise. Nickname must point to a valid Put Post Office.
6. Must be exactly 3 characters if present. Ignored if **ProdIndicator** is False, required otherwise. Nickname must point to a valid Put Post Office.
7. Set the **HIPAAAckFlag** to the 997 version of the Acknowledgement desired (if any). Defaults to the version specified in **GS_VersionRelease**. This field is useful for HIPAA data in particular, when the 997 must be a different version from the incoming data and may be used for non-HIPAA data as well.
8. Available for 4050X151 PI (275) documents when Type 4 Validation is selected for 824 or 999 reporting. Set to **N** for "no validation", **X** for "validate XML format only", or **S** for "validate XML format and against schema". The schema must be in the same directory as the Message Manager maps. The default value for this field is **N**.
9. Specifies the version of the Outbound 824 Acknowledgement that can be used for this inbound document. Applicable only if HIPAA type 3, type 4, and/or type 6 is enabled and reported as an 824. If not specified, the value will default to 4050. Valid values are 4010 or 4050, but others will be accepted if entries are manually added to the table **HIPAA824Versions**.
10. To automatically create an acknowledgement link, specify the Get post office nickname. The nickname will be used to create that acknowledgement. See [Automatic creation of X12 acknowledgement trade links](#).
11. To automatically create an acknowledgement link, specify at least one Put post office. You can specify the Production post office nickname here, and/or use **AckTestPutPO**. See [Automatic creation of X12 acknowledgement trade links](#).
12. To automatically create an acknowledgement link, specify at least one Put post office. You can specify the Test post office here, and/or use **AckProdPutPO**. See [Automatic creation of X12 acknowledgement trade links](#).
- [HIPAA validation type description](#)

HIPAA validation type description

This field is required if this Inbound Group is for a HIPAA Version; do not specify if this is not a HIPAA Inbound Group. This field is a 7 character position string, each position denoting the HIPAA Validation Type (for example, position 1 is for Type 1; position 3 is for Type 3). The values for these positions are as follows:

- position 1: **0** = Disabled, **2** = Enabled, Reported in 997
- position 2: 0 = Disabled, 1 = Enabled, 2=Enabled, reported in 999, 3=Enabled, Reported in 997.
- position 3: 0 = Disabled, 1 = Enabled, 2=Enabled, reported in 999, 3=Enabled, Reported in 824, 4=Enabled, Execute Map. If 4 is specified, the field **Type3MapName** must contain a value.
- position 4: **0** = Disabled, **1** = Enabled, 2=Enabled, reported in 999, 3=Enabled, Reported in 824.
- position 5: **0** = Disabled, **1** = Enabled, 2=Enabled, reported in 999, 3=Enabled, Reported in 997.
- position 6: **0** = Disabled, **1** = Enabled, 2=Enabled, reported in 999, 3=Enabled, Reported in 824.
- position 7: **0** = Disabled, **1** = Enabled, 2=Enabled, reported in 999, 3=Enabled, Reported in 824. You can only specify Type 7 (options **1** or **3**) if the External Application Partner for this link has a "HIPAA Institution" set.

The XML Autoload will perform the following validations:

- HIPAA Qualifier records exist when Types 3, 4, 6 and 7 are specified. These are loaded in Standards Maintenance.
- If a 997/999 is specified, an Acknowledgement Level (field **AckLevel**) has been selected.
- If an Acknowledgement Level is set, at least one of above selections denote a 997/999.
- If Types 3, 4, 5, 6, and 7 are set to anything other than **Disabled**, Type 2 must also not be disabled.

X12 Known Inbound Trade Link Change (Tag: X12IBTradeLinkChange)

Use this tag to change an existing X12 Inbound Trade Link. This tag is required to identify the Trade Link, and must exist even if you are not changing any data at this level. The fields in this tag are the same as X12IBTradeLink, but here the Get Post Office is optional. The Trade Link specified must exist.

The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
-------------	---------------	-------	-----------	------------	-------

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A (From ISA + IID)	From_ISA_IID	Yes	17	IchgQual + IchgID of From Trading Partner	1, 2
N/A (To ISA + IID)	To_ISA_IID	Yes	17	IchgQual + IchgID of To Trading Partner	3, 4
N/A (From GS Address)	From_GS_ID	Yes	15	GS_ApplicationID of From Ap Partner	5, 2
N/A (To GS Address)	To_GS_ID	Yes	15	GS_ApplicationID of To Ap Partner	6, 4
Get Post Office	GetMailPO	No	3	Nickname of Get PO	7

Notes:

1. Must match an existing External Trading Partner.
2. Must match an existing Internal Trading Partner.
3. Combination of these two fields must match an External Trading Partner/Application Partner association (for example, the Application Partner must belong to the specified Trading Partner, not just be a valid Application Partner). This relationship can be in any External X12 Folder.
4. Must match an existing External Application Partner.
5. Must match an existing Internal Application Partner.
6. Combination of these two fields must match an Internal Trading Partner/Application Partner association (for example, the Application Partner must belong to the specified Trading Partner, not just be a valid Application Partner). This relationship can be in any Internal X12 Folder.
7. If specified, must be exactly 3 characters long a

X12 Inbound Trade Links Applications Add, Change, Delete (Tag: X12InboundGroupsAddChangeDelete)

Use this tag to add, change or delete Applications on an existing X12 Inbound Trade Link. To add an application, set the **AddFlag** to Y. If you want to delete an existing Application, set the **DeleteFlag** to Y. Set both flags to N, or do not specify them at all, to change an existing Application.

This tag must be nested within the **X12IBTradeLinkChange** tag.

The fields in this tag are similar when adding using **X12InboundGroups**, with one major exception: The Test and Production Indicators can be set to R to remove one of those Post Offices. See Note 4 below for more information on this "Remove" feature. The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Application Version	GS_VersionRelease	Yes	12	fk to X12_Version	1
Functional ID	GS_FunctionalID	Yes	2	fk to X12_FuncID with Version	1
Ack Level	AckLevel	No	1	0, 1, 2, 3, 4	2
Ack To Application Partner	AckTo_ISA_IID and AckTo_GS_ID	No	17,15	See note 3	3
Validate By	ValidateByInd	No	1	F=Functional Group, T=Transaction Set, I = Interchange	
Test Indicator	TestIndicator	No	1	T=True, F=False, R=Remove	4
Production Indicator	ProdIndicator	No	1	T=True, F=False, R=Remove	4
Test PO Nickname	TestPutPO	Yes if Test Indicator is T	3	Nickname of Valid Put PO	5
Prod PO Nickname	ProdPutPO	Yes if Prod Indicator is T	3	Nickname of Valid Put PO	6
HIPAA Validation Type	ValType	If HIPAA	7	See " HIPAA Validation Type Description "	
Map Name	Type3MapName		255		7
N/A	AddFlag	No	1	Y=Add as new Application	
N/A	DeleteFlag	No	1	Y=Delete the existing Application	8
997 Version	HIPAAAckFlag	No	12		9
Routing: Route Only	RouteOnly	No	1	Y/N Default: N	
4050X151 PI BIN Validation 9824/999	BinSegmentValidation	No	1		10
824 Ack Version	Version824Ack	No	12		11
AckGetPO		No	3		12
AckProdPutPO		No	3		13
AckTestPutPO		No	3		14

Notes:

1. **Note 1:** Version + Functional ID must be unique within the same Trade Link.
2. **Note 2: N/A** for Unknown Links; **0**=No Ack; **1**=Functional Group Level; **2**=Transaction Set Level; **3**=Segment Level; **4**=Data Element Level; Default is **0** (zero)
3. N/A for Unknown Links. Note the two FieldNames/Tags, both are required if **AckTo** is specified. Must point to a valid (existing) External Trading/Application Partner association. Defaults to the external (from) Ap Partner if not specified and the **AckLevel** (above) is not zero.
4. At least one of (**TestIndicator** or **ProdIndicator**) on this Application must end up being True when the change completes. If you want to remove an existing Test or Production Post Office, set this field to "R". For example, this is available in the event you want to change an existing group from Test only to Production Only: set the **TestIndicator** to R, which will remove the Test Post Office, and set the **Production Indicator** to T and specify the new Production Post Office in **ProdPutPO**. When setting this field to "R", you must specify the other (test/production) Post Office if one does not already exist on the group.
5. Must be exactly 3 characters if present. Ignored if **TestIndicator** is False. Nickname must point to a valid Put Post Office.
6. Must be exactly 3 characters if present. Ignored if **ProdIndicator** is False. Nickname must point to a valid Put Post Office.

7. The **Type3MapName** is required if position 3 of **ValType** is 4. This means that you must perform HIPAA Type 3 validation using this map name. This map must be in the Trading Manager **mmgr** directory, and is a custom map supplied by you. The map name is not validated by the XML Autoload Utility, as it may be on another system (for example UNIX).
8. Set the **DeleteFlag** to **Y** if you wish to remove an Inbound Group from an existing Trade Link. Specify only the **GS_VersionRelease**, **GS_FunctionalID**, and this flag when deleting a group; all other fields will be ignored.
9. Set the **HIPAAAckFlag** to the 997 version of the Acknowledgement desired (if any). When adding a new group, this field defaults to the version of the **GS_VersionRelease** field specified. This field is useful for HIPAA data in particular, when the 997 must be a different version from the incoming data and may be used for non-HIPAA data as well.
10. Available for 4050X151 PI (275) documents when Type 4 Validation is selected for 824 or 999 reporting. Set to **N** for "no validation", **X** for "validate XML format only", or **S** for "validate XML format and against schema". The schema must be in the same directory as the Message Manager maps. The default value for this field is **N**.
11. Specifies the version of the Outbound 824 Acknowledgement that can be used for this inbound document. Applicable only if HIPAA type 3, type 4, and/or type 6 is enabled and reported as an 824. If not specified, the value will default to 4050. Valid values are 4010 or 4050, but others will be accepted if entries are manually added to the table HIPAA824Versions.
12. To automatically create an acknowledgement link, specifically the Get Post Office nickname. The nickname will be used to create that acknowledgement. See [Automatic creation of X12 acknowledgement trade links](#)
13. To automatically create an acknowledgment link, specify at least one Put post office. You can specify the Production post office nickname here, and/or use **AckTestPutPO**. See [Automatic creation of X12 acknowledgement trade links](#).
14. To automatically create an acknowledgement link, specify at least one Put post office. You can specify the test post office nickname here, and/or use **AckProdPutPO**. See [Automatic creation of X12 acknowledgement trade links](#).

X12 Known Inbound Trade Link Delete (Tag: X12IBTradeLinkDelete)

Use this tag to delete an existing X12 Inbound Trade Link. Supply the Identifiers of the "From" and "To" Trading and Application Partners (see: **From_ISA_IID**, **To_ISA_IID**, **From_GS_ID**, and **To_GS_ID**). This tag deletes the entire trade link which includes all applications and transaction sets associated with the link. A warning report (or error if **Abort Run** is selected) is issued if Trade Link does not exist. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max Len.	Validation	Notes
N/A (From ISA + IID)	From_ISA_IID	Yes	17	IchgQual + IchgID of From Trading Partner	1, 3
N/A (To ISA + IID)	To_ISA_IID	Yes	17	IchgQual + IchgID of To Trading Partner	2, 6
N/A (From GS Address)	From_GS_ID	Yes	15	GS_ApplicationID of From Ap Partner	4, 3
N/A (To GS Address)	To_GS_ID	Yes	15	GS_ApplicationID of To Ap Partner	5, 6

Notes:

1. Must match an existing External Trading Partner.
2. Must match an existing Internal Trading Partner.
3. Combination of these two fields must match an External Trading Partner/Application Partner association (for example, the Application Partner must belong to the specified Trading Partner, not just be a valid Application Partner).
4. Must match an existing External Application Partner.
5. Must match an existing Internal Application Partner.
6. Combination of these two fields must match an Internal Trading Partner/Application Partner association (for example, the Application Partner must belong to the specified Trading Partner, not just be a valid Application Partner).

X12 Unknown Inbound Trade Link Delete (Tag: X12Unknown_LinkDelete)

Use this tag to delete an existing X12 Unknown Inbound Trade Link. Supply the Identifiers of the "To" Trading and Application Partners (see **X12Unknown_Link**, **To_ISA_IID** and **To_GS_ID**). This tag deletes the entire trade link which includes all applications and transaction sets associated with the link. A warning report (or error if **Abort Run** is selected) is issued if Trade Link does not exist. The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A (To ISA + IID)	To_ISA_IID	Yes	17	IchgQual + IchgID of To Trading Partner	1
N/A (To GS Address)	To_GS_ID	Yes	15	GS_ApplicationID of To Ap Partner	2

Notes:

1. Must match an existing Internal Trading Partner.
2. Must match an existing Internal Application Partner.

X12 outbound trade links

Trade links can be added, changed, or deleted. In addition, existing Trade Links can have their individual Applications (also known as "Documents") added, changed, or deleted.

To add a new X12 Outbound trade link, use the following tags:

- [X12OBTPLink](#)
- [X12OBApPartnerLnk](#)
- [X12OBAppLink](#)

To change an existing X12 Outbound Trade Link, use the tags:

- [X12OBTPLinkChange](#)
- [X12OBApPartnerLnkChange](#)
- [X12OBAppLinkAddChangeDelete](#)

To delete an entire X12 Outbound Trade Link, see [X12OBTradeLinkDelete](#).

There are 4 levels of data in an Outbound Trade Link:

- The Trading Partner (ISA)
- Application Partner (GS)
- Applications (Versions/Functional ID's)
- Transaction Levels (ST)

Unlike Inbound Trade Links, there is no such thing as an Unknown Outbound Trade Link, and like Inbound Trade Links, the lowest level (transactions) is not supported in the AutoLoad input; all transactions for a given Version/Functional ID is written to the Transaction tables (with a blank ST Reset value). In the unusual case the ST Reset values are required on an Outbound Trade Link use Partner Manager after the AutoLoad is completed.

Complicating this structure is the fact that the Trading Partner level (ISA) may already exist, but for different Application Partners (GS) than the one being added by the AutoLoad Utility. If this is detected, then any entry in the Trading Partner level is ignored, a warning is issued, and the Link is added. Note the Trading Partner level is required in the input file even if the user knows this level exists.

Nesting is similar to Inbound Trade Links. If multiple Application Partners are specified, they have to be nested under the Trading Partner, and if multiple Applications (Versions/Functional ID's) are specified then they have to be nested under the Application Partner. For example, one trade link, two application partners, each having one application during an "add" operation:

```
<X12OBTPLink>
  <X12OBApPartnerLnk>
    <X12OBAppLink>
      </X12OBAppLink>
    </X12OBApPartnerLnk>
    <X12OBApPartnerLnk>
      <X12OBAppLink>
        </X12OBAppLink>
    </X12OBApPartnerLnk>
  </X12OBTPLink>
```

Adding an Application (also known as a Document) to an existing Trade Link is supported in the following tags:

- [X12OBTPLinkChange](#)
- [X12OBApPartnerLnkChange](#)
- [X12OBAppLinkAddChangeDelete](#)

During a change operation, you can change the Trading Partner Level, change the Application Partner Level, or add, change, or delete the Application level.

Example nesting of these "Change" tags is:

```
<X12OBTPLinkChange> (required)
<X12OBApPartnerLnkChange>
  (optional, but required if changing a document)
<X12OBAppLinkAddChangeDelete>
  (optional Document level)
</X12OBAppLinkAddChangeDelete>
</X12OBApPartnerLnkChange>
</X12OBTPLinkChange>
```

The following table, field, and tag descriptions are for X12 outbound trade links:

- ["X12 Outbound Trading Partner Trade Links \(Tag: X12OBTPLink\)"](#)
- ["X12 Outbound Application Partner Trade Links \(Tag: X12OBApPartnerLnk\)"](#)
- ["X12 Outbound Applications Trade Links \(Tag: X12OBAppLink\)"](#)
- ["X12 Outbound Trading Partner Trade Link Delete \(Tag: X12OBTradeLinkDelete\)"](#)
- ["X12 Outbound Trading Partner Trade Links \(Tag: X12OBTPLink\)"](#)
- ["X12 Outbound Application Partner Trade Links \(Tag: X12OBApPartnerLnk\)"](#)
- ["X12 Outbound Applications Trade Links \(Tag: X12OBAppLink\)"](#)
- ["X12 Outbound Trading Partner Trade Links Change \(Tag: X12OBTPLinkChange\)"](#)
- ["X12 Outbound Application Partner Trade Links Change \(Tag: X12OBApPartnerLnkChange\)"](#)
- ["X12 Outbound Applications Trade Links Add/Change/Delete \(Tag: X12OBAppLinkAddChangeDelete\)"](#)
- ["X12 Outbound Trading Partner Trade Link Delete \(Tag: X12OBTradeLinkDelete\)"](#)

X12 Outbound Trading Partner Trade Links (Tag: X12OBTPLink)

Use this tag to add a new X12 Outbound Trade Link.

Note: One **X12OBTPLink** record per Outbound Trade Link is required.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Note
N/A (From ISA + IID)	From_ISA_IID	Yes	17	IchgQual + IchgID of From Trading Partner	1
N/A (To ISA + IID)	To_ISA_IID	Yes	17	IchgQual + IchgID of To Trading Partner	2
Interchange Control # Scheme	ISAControlNoScheme	No	1	U = User Defined, I = Increment Default: I	
Interchange Control # Map	ISAControlNoMap	Yes, if scheme is "U"	255	Not validated	3
Group Control # Scheme	GSControlNoScheme	No	1	U,T,A,F, R See note 4 Default: R	4
Group Control # Map	GSControlNoMap	Yes, if scheme is "U"	255	Not validated	5
Reset: Interchange Control # (ISA)	ISAControlNoValue	No	9	Numeric, positive integer	
Reset: Group Control # (GS)	GSControlNoValue	No	10	Numeric, positive integer specified here ONLY is GS Scheme is T or U.	6

Notes:

1. Must match an existing Internal Trading Partner.
2. Must match an existing External Trading Partner.
3. Required only if **ISAControlNoScheme** is **U**. Typically, the **.mmc** file is used here. For the purposes of **AutoLoad**, this filename is not validated (Partner Manager does insist it can find this file), except to check for single/double quotes (not allowed).
4. **U**=User Defined; **T**=Increment by Trading Partner; **A**=Increment by Application Partner; **F**=Increment by Functional ID; **R**=Relative (the default if not specified)
5. Required only if **GSControlNoScheme** is **U**. Typically, the **.mmc** file is used here. For the purposes of AutoLoad, this filename is not validated (Partner Manager does insist it can find this file), except to check for single/double quotes (not allowed).
6. Only include if GS Scheme is **T** (Increment by Trading Partner), or **U** (User Defined via map). **ResetGS_Ind** is set in the table to True if a value is present here. These two fields are only stored in X12OBTPLink if the GS Scheme is **T** or **U**, otherwise, they are stored in the GS Level (**X12OBAppPartnerLnk**), if Scheme is **A**; otherwise, it is at the Application Level (Scheme is **F**). If included here and the GS Scheme is not in (**T**, **U**) then the entire link is rejected. A GS Scheme of **R** (Relative) means that no GS Reset Value is ever entered; any present is ignored.

X12 Outbound Application Partner Trade Links (Tag: X12OBAppPartnerLnk)

Use this tag to specify the Application Partners on a new X12 Outbound Trade Link. See the related tag [X12OBAppPartnerLnkChange](#), if changing an existing Trade Link. One or more X12OBAppPartnerLnk record(s) per Outbound Trade Link is required. If more than one Application Partner combination is defined, then the next level (Application) must be nested within this tag.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A (From GS App ID)	From_GS_ID	Yes	15	See note 1	1
N/A (To GS App ID)	To_GS_ID	Yes	15	See note 2	2
Reset: Group Control # (GS)	GSControlNoValue	No	9	Numeric, positive integer. Only if scheme is A .	3
Get Post Office	GetMailPO	Yes	3	Get PO	4

Notes:

1. Must point to a valid Internal Application Partner that belongs to the Internal Trading Partner specified at the level above.
2. Must point to a valid External Application Partner that belongs to the External Trading Partner specified at the level above.
3. Optionally, specify only if the GS Scheme, specified in the level above (X12OBTPLink), is **A**.
4. Must be exactly 3 characters in length and exist as a Get Post Office Nickname.

X12 Outbound Applications Trade Links (Tag: X12OBAppLink)

Note: If you have used the XML AutoLoad Utility previously, be aware that in this version of the product, a test post office has been introduced to X12 outbound links. The existing post office field, PutMailPO, is now the production post office. If you make no changes to your XML script generation, the post office that you have used previously for X12 Outbound Links will be this production post office. See the fields TestIndicator, ProdIndicator and TestPutPO fields in the tag X12OBAppLink for more information. If you do not want to take advantage of these new test vs. production post offices, set the two post offices to the same value.

Use this tag to add Applications (documents) to a new X12 Outbound Trade Link. To add, change, or delete Applications on an existing Trade Link, see the related tag: [X12OBAppLinkAddChangeDelete](#). One or more Applications per Trade Link are required. At least one record is required per link. The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Application Version	GS_VersionRelease	Yes	12	fk to X12_Version	1
Functional ID	GS_FunctionalID	Yes	2	fk to X12_FuncID with Version	1
Reset GS Control # Value	GSControlNoValue	No	10	Only if GS Scheme is "F". Numeric, positive integer	2

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
ST Control Scheme	STControlNoScheme	No	1	U, R, or T	3 Default: R
ST Control Map	STControlNoMap	No	255	Only if ST Scheme is U	
Put Post Office	PutMailPO	Yes	3	Put PO	4, 11
Validate By	ValidateByInd	No	1	F, T, or I	5 Default: I
Acknowledgement Hours	ACK_Within	No	5	> 0 and < 99999	6 Default: 0
Application Format	Leave_Intact	No	1	Y=Fully N=Partial M=Control Numbers Only (aka "Mostly")	Default: N
Routing: RouteOnly	RouteOnly	No	1	Y/N	Default: N
GS Time Stamp Option	TimeStampOption	No	1	0, 1, 2, 3	7
Test Indicator	TestIndicator	No	1	T=True, F=False Default: F	4
Production Indicator	ProdIndicator	No	1	T=True, F=False Default: F	4
Test PO Nickname	TestPutPO	Yes if Test Ind. is T	3	Nickname of Valid Put PO	5
AckGetPO		No	3		8
AckProdPutPO		No	3		9
AckTestPutPo		No	3		10

Notes:

1. Version/Functional ID is verified to be unique within this Application Partner Link.
2. GS Scheme, specified at the Trading Partner level, must be F (functional group) to specify GS Reset values here.
3. **U**=User Defined; **R**=relative; **T**=Increment by Transaction. If **U** then **STMap** is required.
4. Must be exactly 3 characters in length and exist as a Put Post Office Nickname.
5. Valid values, if specified are **F**=Functional Group, **T**= Transaction Set, **I**=interchange. Defaults to **I**.
6. Number of hours an acknowledgement is expected.
7. **0**=hhmm, **1**=hhmmss, **2**=hhmmssd, **3**=hhmmssdd. If not specified, the default will be zero (hhmm) if the version is less than 4010, otherwise the default is one (hhmmss)
8. To automatically create an acknowledgement link, specify the Get Post Office nickname. That nickname will be used to create the acknowledgement. See [Automatic creation of X12 acknowledgement trade links](#).
9. To automatically create an acknowledgement link, specify at least one Put post office. You can specify the Production post office nicnname here, and/or use AckTestPutPO. See [Automatic creation of X12 acknowledgement trade links](#).
10. To automatically create an acknowledgement link, specify at least one Put post office. You can specify the Test Post Office nickname here and/or use AckProdPutPO. See [Automatic creation of X12 acknowledgement trade links](#).
11. This is the production post office.

X12 Outbound Trading Partner Trade Links Change (Tag: X12OBTPLinkChange)

Use this tag to change an existing X12 Outbound Trade Link. At a minimum, specify the unique Identifier of the two Trading Partners (**From_ISA_IID** and **To_ISA_IID**). The remaining fields need not be specified if your changes are at a lower level (Application Partner or Document). Note changes here will impact all the Trade Links defined for these two Trading Partners, even if multiple Application Partner-level Trade Links are defined. Changes here relate to the "ISA Control" popup, and if the GS Control Scheme is "Trading Partner", the "GS Control" popup found in Partner Manager. If the desired changes are only at this level, the remaining tags need not be specified. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A (From ISA + IID)	From_ISA_IID	Yes	17	IchgQual + IchgID of From Trading Partner	1
N/A (To ISA + IID)	To_ISA_IID	Yes	17	IchgQual + IchgID of To Trading Partner	2
Interchange Control # Scheme	ISAControlNoScheme	No	1	U = User Defined, I = Increment	
Interchange Control # Map	ISAControlNoMap	Yes, if scheme is "U"	255	Not validated	3
Group Control # Scheme	GSControlNoScheme	No	1	U,T,A,F,R See note	4
Group Control # Map	GSControlNoMap	Yes, if scheme is "U"	255	Not validated	5
Reset: Interchange Control # (ISA)	ISAControlNoValue	No	9	Numeric, positive integer	
Reset: Group Control # (GS)	GSControlNoValue	No	10	Numeric, positive integer specified here ONLY is GS Scheme is T or U.	6

Notes:

1. Must match an existing Internal Trading Partner.
2. Must match an existing External Trading Partner.
3. Required only if **ISAControlNoScheme** is **U**. Typically, the **.mmc** file is used here. For the purposes of **AutoLoad**, this filename is not validated (Partner Manager does insist it can find this file), except to check for single/double quotes (not allowed).

4. **U**=User Defined; **T**=Increment by Trading Partner; **A**=Increment by Application Partner; **F**=Increment by Functional ID; **R**=Relative (the default if not specified)
5. Required only if **GSControlNoScheme** is **U**. Typically, the **.mme** file is used here. For the purposes of **AutoLoad**, this filename is not validated (Partner Manager does insist it can find this file), except to check for single/double quotes (not allowed).
6. Only include if GS Scheme is **T** (Increment by Trading Partner), or **U** (User Defined via map). These two fields are only stored in **X12OBTPLink** if the GS Scheme is **T** or **U**, otherwise, they are stored in the GS Level (**X12OBAppPartnerLnk**), if Scheme is **A**; otherwise, it is at the Application Level (Scheme is **F**). If included here and the GS Scheme is not in (**T**, **U**) then the entire link is rejected. A GS Scheme of **R** (Relative) means that no GS Reset Value is ever entered; any present is ignored.

X12 Outbound Application Partner Trade Links Change (Tag: **X12OBAppPartnerLnkChange**)

Use this tag to change the Application Partner level information on an X12 Outbound Trade Link, or if changing the Document Level information on an existing X12 Outbound Trade Link. The Application Partner Level must already exist; to add one, the tags [X12OBTPLink](#), [X12OBAppPartnerLnk](#), and [X12OBAppLink](#) must be used instead.

The fields are identical to the [X12OBAppPartnerLnk](#) tag, except **GetMailPO** is optional. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A (From GS App ID)	From_GS_ID	Yes	15	See note 1	1
N/A (To GS App ID)	To_GS_ID	Yes	15	See note 2	2
Reset: Group Control # (GS)	GSControlNoValue	No	9	Numeric, positive integer. Only if scheme is A.	3
Get Post Office	GetMailPO	No	3	Get PO	4

Notes:

1. Must point to a valid Internal Application Partner that belongs to the Internal Trading Partner specified at the level above.
2. Must point to a valid External Application Partner that belongs to the External Trading Partner specified at the level above.
3. Optionally, specify only if the GS Scheme, specified in the level above (X12OBTPLink) is **A**.
4. If specified, must be exactly 3 characters in length and exist as a Get Post Office Nickname.

X12 Outbound Applications Trade Links Add/Change/Delete (Tag: **X12OBAppLinkAddChangeDelete**)

Use this tag to add, change, or delete Applications on an existing X12 Outbound Trade Link. This tag is always nested within an [X12OBAppPartnerLnkChange](#) tag.

Specify the unique identifier for the Application: **GS_VersionRelease** and **GS_FunctionalID**. If you are adding, set the **AddFlag** to **Y**. If you want to delete just this Document from the Trade Link, set the **DeleteFlag** to **Y**. Deleting a record requires tags **GS_VersionRelease** and **GS_FunctionalID**; any values specified in the other tags will be ignored. The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Application Version	GS_VersionRelease	Yes	12	fk to X12_Version	1
Functional ID	GS_FunctionalID	Yes	2	fk to X12_FuncID with Version	1
Reset GS Control # Value	GSControlNoValue	No	10	Only if GS Scheme is "F". Numeric	2
ST Control Scheme	STControlNoScheme	No	1	U, R, or T	3
ST Control Map	STControlNoMap	No	255	Only if ST Scheme is U	
Put Post Office	PutMailPO	No	3	Put PO	4, 11
Validate By	ValidateByInd	No	1	F, T, or I	5
Acknowledgement Hours	ACK_Within	No	5	> 0 and < 99999	6
N/A	AddFlag	No	1	Y or N	
N/A	DeleteFlag	No	1	Y or N	
Application Format	Leave_Intact	No	1	Y=Fully N=Partial M=Control Numbers Only (aka "Mostly")	Default: N
Routing: RouteOnly	RouteOnly	No	1	Y/N Default: "N"	
GS Time Stamp Option	TimeStampOption	No	1	0, 1, 2, 3	7
Test Indicator	TestIndicator	No	1	T=True, F=False Default: F	4
ProdIndicator	ProdIndicator	No	1	T=True, F=False Default: T	4
Test PO Nickname	TestPutPO	Yes if Test Ind.is T	3	Nickname of Valid Put PO	6
AckGetPO		No	3		8
AckProdPutPO		No	3		9
AckTestPutPO		No	3		10

Notes:

1. Version/Functional ID is verified to be unique within this Application Partner Link.
2. GS Scheme, specified at the Trading Partner level, must be **F** (functional group) to specify GS Reset values here.
3. User Defined; **R**=relative; **T**=Increment by Transaction. If **U** then **STMap** is required.
4. If specified must be exactly 3 characters in length and exist as a Put Post Office Nickname. Required if adding.
5. Valid values (if specified) are: **F**=Functional Group; **T**=Transaction Set; **I**=interchange. Defaults to **I**.
6. Number of hours an acknowledgement is expected.
7. **0**=hhmm, **1**=hhmmss, **2**=hhmmssd, **3**=hhmmssdd. If not specified, the default will be zero (hhmm) if the version is less than 4010, otherwise the default is one (hhmmss)
8. To automatically create an acknowledgement link, specify the Get post office nickname. This nickname will be used to create that acknowledgement. See [Automatic creation of X12 acknowledgement trade links](#)
9. To automatically create an acknowledgement link, specify at least one Put post office. You can specify the production post office nickname here, and/or use **AckTestPutPO**. See [Automatic creation of X12 acknowledgement trade links](#)
10. To automatically create an acknowledgement link, specify at least one Put post office. You can specify the test post office nickname here, and/or use **AckProdPutPO**. See [Automatic creation of X12 acknowledgement trade links](#)
11. This is the production Put post office.

X12 Outbound Trading Partner Trade Link Delete (Tag: X12OBTradeLinkDelete)

Use this tag to delete an existing X12 Outbound Trade Link. Supply the Identifiers of the "From" and "To" Trading and Application Partners (see [X12OBTPLink](#)): **From_ISA_IID**, **To_ISA_IID**, **From_GS_ID**, and **To_GS_ID**. This tag deletes the entire trade link which includes all applications and transaction sets associated with the link. A warning report (or error if Abort Run is selected) is issued if Trade Link does not exist. The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A (From ISA + IID)	From_ISA_IID	Yes	17	IchgQual + IchgID of From Trading Partner	1, 2
N/A (To ISA + IID)	To_ISA_IID	Yes	17	IchgQual + IchgID of To Trading Partner	3, 4
N/A (From GS Address)	From_GS_ID	Yes	15	GS_ApplicationID of From Ap Partner	5, 2
N/A (To GS Address)	To_GS_ID	Yes	15	GS_ApplicationID of To Ap Partner	6, 4

Notes:

1. Must match an existing Internal Trading Partner.
2. Combination of these two fields must match an Internal Trading Partner/Application Partner association (for example, the Application Partner must belong to the specified Trading Partner, not just be a valid Application Partner).
3. Must match an existing External Trading Partner.
4. Combination of these two fields must match an External Trading Partner/Application Partner association (for example, the Application Partner must belong to the specified Trading Partner, not just be a valid Application Partner).
5. Must match an existing Internal Application Partner.
6. Must match an existing External Application Partner.

EDIFACT partners

The following table, field, and tag descriptions are for EDIFACT Trading Partners:

- ["EDIFACT Trading Partners \(Tag: EDFTradingPartners\)"](#)
- ["EDIFACT Trading Partners Change \(Tag: EDFTradingPartnersChange\)"](#)
- ["EDIFACT Trading Partners Delete \(Tag: EDFTradingPartnersDelete\)"](#)
- ["EDIFACT Application Partners \(Tag: EDFAppPartners\)"](#)
- ["EDIFACT Application Partners Change \(Tag: EDFAppPartnersAddChange\)"](#)
- ["EDIFACT Application Partners Delete \(Tag: EDFAppPartnersDelete\)"](#)
- ["EDIFACT Trading Partners \(Tag: EDFTradingPartners\)"](#)
- ["EDIFACT Trading Partners Change \(Tag: EDFTradingPartnersChange\)"](#)
- ["EDIFACT Trading Partners Delete \(Tag: EDFTradingPartnersDelete\)"](#)
- ["EDIFACT Application Partners \(Tag: EDFAppPartners\)"](#)
- ["EDIFACT Application Partners Change \(Tag: EDFAppPartnersAddChange\)"](#)
- ["EDIFACT Application Partners Delete \(Tag: EDFAppPartnersDelete\)"](#)

EDIFACT Trading Partners (Tag: EDFTradingPartners)

Use this tag to add new EDIFACT Trading Partners. EDIFACT Trading Partners can have Contacts added as well.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Internal/External	IntExt	Yes	1	"I" or "E"	1 Determines Folder
Partner Name	PartnerName	Yes	35	Unique	2
Syntax ID	SyntaxID	No	4	fk to EDFSyntaxID (UNOA-H)	3
Syntax Version	SyntaxVer	No	10	>0 (Numeric; decimals allowed) if specified	4 Default: 1

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Partner ID Code Qualifier	IchgIdCdQual	No	4	fk to EDFIdCdQual	5 Defaults to 4 spaces (None)
Interchange ID	IchgID	Yes	35	unique; see note; Cannot be "UNKNOWN" (lower or upper case)	5
Routing Address	RoutingAddress	No	14	See note	5
Password	Password	No	14	External only	6
Password Qualifier	PasswordQual	No	2	External only; "AA" or "BB"	6
Enveloping Option	Leave_Intact	No	1	F= Fully, P= Partial. Internal partners only. Default: "P"	
Use UNA Segment	AddUNASeg	No	1	"T" = True; "F" = False Default: "F"	
Component Data Element Separator	ComponentDESep	No	2	fk to EDFHexValues	7
Data Element Separator	DESeparator	No	2	fk to EDFHexValues	7
Decimal Notation Separator	DecimalNotation	No	2	fk to EDFHexValues	7
Release Indicator Separator	ReleaseIndicator	No	2	fk to EDFHexValues	7
Segment Terminator Separator	SegmentTerminator	No	8	fk to EDFHexValues	7
Reserved Character Separator	ReservedCharacter	No	2	fk to EDFHexValues	7
Comm Agreement ID	CommAgreementID	No	35		
Duplicate Control	Duplicate_Control	No	1	N = none I = Interchange External Only Default: "N"	
Last UNB Control #	UNBControlNoValue	No	14		8

Notes:

- The standard Internal and External EDIFACT folders is used (no custom folders). These custom folders are: -3=Internal FolderNo and -23=External FolderNo.
- Do not use the name "UNKNOWN, or "ALL", or any variation of the case of these two words. For example, do not use "Unknown", or "All". Unique across all EDIFACT Trading Partners.
- Defaults to UNOA. If specified, must be in table EDFSyntaxID, which currently contains UNOA, UNOB, UNOC, UNOD, UNOE, UNOF, UNOG, and UNOH.
- Default is 1. If specifying, must be an integer from 1 to 9.
- Cannot contain single or double quotation marks. Combination of IchgIdCdQual+ IchgID + RoutingAddress must be unique across all EDIFACT Trading Partners.
- Password and Password Qualifier must only be specified for External Trading Partners.
- The default values are: ComponentDESep = 3A, DESeparator = 2B, SegmentTerminator = 27, ReleaseIndicator = 3F, DecimalNotation = 2C, and ReservedCharacter = 20.
- This field can only be set for External Trading Partners that have the Duplicate Control flag set to I (Interchange). If set, it must be a positive integer no longer than nine characters in length.

EDIFACT Trading Partners Change (Tag: EDFTradingPartnersChange)

Use this tag to change an existing EDIFACT Trading Partner. The fields in this tag are similar to EDFTradingPartners, but the **IntExt** (Internal/External) field is not specified because you cannot change an Internal Trading Partner to an External using this tag. If this is required, delete and re-add the partner. Also, unlike the tag EDFTradingPartners, EDFAppPartners are not nested within this tag.

To specify the Trading Partner to change, supply **PartnerName**, or the codes that create the unique identifier of an EDIFACT Trading Partner: **IchgIdCdQual** plus **IchgID**, and if required, the **RoutingAddress**. You can also supply both the Partner Name and the unique identifier. The **RoutingAddress** is required if more than one Partner has the same **IchgIdCdQual** and **IchgID**. To change the fields that identify a Partner (**PartnerName**, **IchgIdCdQual**, **IchgID**, or **RoutingAddress**) use the fields **PartnerNameChange**, **IchgIdCdQualChange**, **IchgIDChange**, or **RoutingAddressChange**.

Trading Partners can have [Contacts](#) added at the same time; nest the Contact record within the Trading Partner tags (see "[Contacts](#)"). Use this tag, along with the Contacts tag, to add Contacts to an existing Trading Partner.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Partner Name	PartnerName	No	35	Unique	1
Syntax ID	SyntaxID	No	4	fk to EDFSyntaxID (UNOA-H)	2
Syntax Version	SyntaxVer	No	10	>0 (Numeric; decimals allowed) if specified	3
Partner ID Code Qualifier	IchgIdCdQual	No	4	fk to EDFIdCdQual	4
Interchange ID	IchgID	Yes	35	unique; see note; Cannot be "UNKNOWN" (lower or upper case)	4
Routing Address	RoutingAddress	No	14	See note	4
Password	Password	No	14	External only	5
Password Qualifier	PasswordQual	No	2	External only; "AA" or "BB"	5

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Enveloping Option	Leave_Intact	No	1	F= Fully, P= Partial Internal partners only.	
Use UNA Segment	AddUNASeg	No	1	T=True, F=False	
Component Data Element Separator	ComponentDESep	No	2	fk to EDFHexValues	
Data Element Separator	DESeparator	No	2	fk to EDFHexValues	
Decimal Notation Separator	DecimalNotation	No	2	fk to EDFHexValues	
Release Indicator Separator	ReleaseIndicator	No	2	fk to EDFHexValues	
Segment Terminator Separator	SegmentTerminator	No	8	fk to EDFHexValues	
Reserved Character Separator	ReservedCharacter	No	2	fk to EDFHexValues	
Comm Agreement ID	CommAgreementID	No	35		
Duplicate Control	Duplicate_Control	No	1	N = none, I = Interchange External Only	
Last UNB Control #	UNBControlNoValue	No	14		6
N/A	PartnerNameChange	No	35		7
N/A	IchgIdCdQualChange	No	4		7
N/A	IchgIDChange	No	35		7
N/A	RoutingAddressChange	No	14		7
Reset UNB Control	ResetUNB_Ind	No	T/F		8

Notes:

1. Do not use the name "UNKNOWN, or "ALL", or any variation of the case of these two words. For example, do not use "Unknown", or "All". Unique across all EDIFACT Trading Partners.
2. If specified, must be in table EDFSyntaxID, which currently contains UNOA, UNOB, UNOC, UNOD, UNOE, UNOF, UNOG, and UNOH.
3. If specifying, must be an integer from 1 to 9.
4. Cannot contain single or double quotation marks. Combination of IchgIdCdQual+ IchgID + RoutingAddress must be unique across all EDIFACT Trading Partners.
5. Password and Password Qualifier must only be specified for External Trading Partners.
6. This field can only be set for External Trading Partners that have the Duplicate Control flag set to I (Interchange). If set, it must be a positive integer no longer than nine characters in length.
7. Use these fields to change the unique identifiers of an EDIFACT Trading Partner. Any, all, or none of these "change" fields can be specified. The resulting name/identifier must not already exist in the database.
8. Valid values are T or F (T =True/enabled, F=False/disabled). If setting to T, you must specify UNBControlNoValue (on screen as "Last UNB Control Number"); if you specified an UNBControlNoValue this field will be set to T by default. If setting to F, this will clear the existing UNBControlNoValue. You can only specify this field on external Trading Partners.

EDIFACT Trading Partners Delete (Tag: EDFTradingPartnersDelete)

Use this tag to delete an EDIFACT Trading Partner.

Use with caution, deleting a Trading Partner will delete all Application Partners, Contacts, and Trade Links associated with that Trading Partner.

Supply **PartnerName**, or the codes that create the unique identifier of an EDIFACT Trading Partner: **IchgIdCdQual** plus **IchgID**, and if required, the **RoutingAddress**. You can also supply both the Partner Name and the unique identifier. The **RoutingAddress** field is required if more than one Partner has the same **IchgIdCdQual** and **IchgID**.

This tag reports a warning (or error if **Abort Run** is selected) if a Trading Partner does not exist.

Though all required fields are set to **No** (see **Req'd** field in the following table) you must specify the Partner Name and/or the unique identifier of the Trading Partner to delete.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation
Partner Name	PartnerName	No	35	Unique
Partner ID Code Qualifier	IchgIdCdQual	No	4	fk to EDFIdCdQual
Interchange ID	IchgID	No	35	
Routing Address	RoutingAddress	No	14	

EDIFACT Application Partners (Tag: EDFAppPartners)

As with X12 Trading Partners, there can be zero or more Application Partners associated with an EDIFACT Trading Partner. Unlike X12, Application Partners are not required to create a Trade Link. Use this tag, when nested within a Trading Partner, to add Application Partners at the same time. If any Trading Partners are rejected, all associated Application Partners are rejected as well. EDIFACT Application Partners can have [Contacts](#) added . The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	IchgIdCdQual	Yes	4	IchgIdCdQual of Trading Partner. May be 4 spaces	1
N/A	IchgID	Yes	35	IchgID of Trading Partner	1

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	RoutingAddress	No	14	Routing Address of Trading Partner	1
Application Partner Name	ApplicationName	Yes	35	Unique within the Trading Partner	2
UNG Application ID	UNG_AppID	Yes	35	Unique within the Trading Partner	
Application Partner ID Code Qualifier	IDCdQual	No	4 Default: 4 spaces (None)	fk to EDFIdCdQual	
Password	Password	No	14	External only	
Alias	AliasName	No	20	Unique if present	3
User Defined 1	UserDefined1	No	20		
User Defined 2	UserDefined2	No	20		

Notes:

1. The IDs of the owner of this Application Partner; equal to the previously specified Trading Partner. Used to confirm that the XML is properly formed (Application Partners nested within the parent Trading Partner).
2. Do not use the name "UNKNOWN", or "ALL", or any variation of the case of these two words. For example, do not use "Unknown", or "All".
3. Alias Names are unique across all EDIFACT Application Partners, if present.

EDIFACT Application Partners Change (Tag: EDFAppPartnersAddChange)

Use this tag to add an EDIFACT Application Partner to an existing Trading Partner, or change an existing EDIFACT Application Partner. To add, set the tag **AddFlag** to **Y**; leaving **AddFlag** blank, not specified, or set to **N** will change the existing EDIFACT Application Partner if it exists. If **AddFlag** is **Y**, the **ApplicationName** and **UNG_AppID** fields are required.

To change the unique identifiers of an EDIFACT Application Partner, use the fields **ApplicationNameChange** and **UNG_AppIDChange**. Do not specify these fields when the AddFlag is **Y**. The resulting change from these fields cannot already exist in the database.

Application Partners can have Contacts added at the same time; nest the Contact record within this tag. Use this tag, along with the [Contacts](#) tag, to add Contacts to an existing Application Partner.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	IchgIdCdQual	No	4	IchgIdCdQual of Trading Partner. May be 4 spaces	1
N/A	IchgID	Yes	35	IchgID of Trading Partner	1
N/A	RoutingAddress	No	14	Routing Address of Trading Partner	1
Application Partner Name	ApplicationName	No	35	Unique within the Trading Partner	2
UNG Application ID	UNG_AppID	No	35	Unique within the Trading Partner	
Application Partner ID Code Qualifier	IDCdQual	No	4	fk to EDFIdCdQual	
Password	Password	No	14	External only	
Alias	AliasName	No	20	Unique if present	3
User Defined 1	UserDefined1	No	20		
User Defined 2	UserDefined2	No	20		
N/A	AddFlag	No	1	Y/N	
N/A	ApplicationNameChange	No	35		
N/A	UNG_AppIDChange	No	15		

Notes:

1. ID's of the owner of this Application Partner (Trading Partner's unique identifier).
2. Do not use the name "UNKNOWN", or "ALL", or any variation of the case of these two words. For example, do not use "Unknown", or "All".
3. Alias Names are unique across all EDIFACT Application Partners, if present.

EDIFACT Application Partners Delete (Tag: EDFAppPartnersDelete)

Use this tag to delete an existing EDIFACT Application Partner. Supply the Application Partner's Name in **ApplicationName**, and/or the Application Partners **UNG_AppID**. You must also supply the associated Trading Partner's name in **PartnerName** and/or the Trading Partner's unique identifier, which is the combination of **IchgIdCdQual** plus **IchgID**, and if required, the **RoutingAddress**. You can also supply both the **PartnerName** and the unique identifier. The **RoutingAddress** is required if more than one Trading Partner has the same **IchgIdCdQual** and **IchgID**. This tag will also delete any Contacts associated with the Application Partner. This tag will not delete if Application Partner is assigned to a trade link (see [EDFTradingPartnersDelete](#) if this is functionality needed). A warning report (or error if "Abort Run" is selected) is issued if Trade Link does not exist. The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation
Application Partner Name	ApplicationName	No	35	
UNG Application ID	UNG_AppID	No	35	

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation
N/A	IchgIdCdQual	Yes	4	IchgIdCdQual of Trading Partner. May be 4 spaces
N/A	IchgID	Yes	35	IchgID of Trading Partner
N/A	RoutingAddress	No	14	Routing Address of Trading Partner

EDIFACT inbound trade links

Trade links can be added, changed, or deleted. In addition, existing Trade Links can have their individual Documents added, changed, or deleted.

To add a new EDIFACT Inbound trade link, use the tags **EDFIBTradeLink**, **EDFIBAPLink**, and **EDFIInboundGroups**. To change an existing EDIFACT Inbound Trade Link, use the tags **EDFIBTradeLinkChange**, **EDFIBAPLinkChange**, and **EDFIInboundGroupsAddChangeDelete**. To delete an entire EDIFACT Inbound Trade Link, use **EDFIBTLDelete**.

There are two types of EDIFACT Inbound Trade Links: **Known** and **Unknown**. Unlike X12, there is no special Unknown Record type for EDIFACT Inbound Trade Links. Define unknown Trading Partners by setting the **FromIchgID** to **UNKNOWN** and leaving **FromIchgIdCdQual** and **FromRoutingAddress** blank (or not specified) in the XML data.

- Applications are specified in the **EDFIInboundGroups** record when adding a new Trade Link; otherwise use the **EDFIInboundGroupsAddChangeDelete** tag. An Application is the unique combination of **Message Version**, **Message Release**, **Controlling Agency**, the optional **Association Assign Code**, and a **Functional ID/Message Type**. Adding Applications to an existing Trade Link is supported in the "change" tags. See:
 - [EDFIBTradeLinkChange](#)
 - [EDFIBAPLinkChange](#)
 - [EDIFACT Inbound Applications Trade Links Add, Change, Delete \(Tag: EDFIInboundGroupsAddChangeDelete\)](#)

Trading/Application Partners must previously exist in the database for the Trade Link to be added. Unlike X12, Application Partners may or may not be specified on a Trade Link, depending on the setting of **MandatoryUNG**. Application Partners, if required, are specified within the **EDFIBAPLink** and **EDFIBAPLinkChange** tags, and must belong to the Trading Partner specified in the **EDFIBTradeLink/EDFIBTradeLinkChange** tags. Application Partners can only be specified if the **MandatoryUNG** field in **EDFIBTradeLink** is set to **O** (optional) or **M** (mandatory).

Applications (Documents) are nested within the Trade Link record when there is no **UNG** level; otherwise Applications are nested within the Application Partner record (**EDFIBAPLink/EDFIBAPLinkChange**). The same Application cannot appear more than once within a Trade Link.

- [Examples](#)
- [EDIFACT Inbound Trade Links \(Tag: EDFIBTradeLink\)](#)
- [EDIFACT Inbound Application Partner Trade Links \(Tag: EDFIBAPLink\)](#)
- [EDIFACT Inbound Applications Trade Links \(Tag: EDFIInboundGroups\)](#)
- [EDIFACT Inbound Trade Link Change \(Tag: EDFIBTradeLinkChange\)](#)
- [EDIFACT Inbound Application Partner Trade Links Change \(Tag: EDFIBAPLinkChange\)](#)
- [EDIFACT Inbound Applications Trade Links Add, Change, Delete \(Tag: EDFIInboundGroupsAddChangeDelete\)](#)
- [EDIFACT Inbound Trade Links Delete \(Tag: EDFIBTLDelete\)](#)

Examples

The following examples show how the XML data would look during an add operation:

Example 1 - Mandatory

Example 1: If **MandatoryUNG** is **M** (Mandatory), the XML would look like:

```
<EDFIBTradeLink>
  ...header data
  <EDFIBAPLink>
    ...specify application partners here
    <EDFIInboundGroups>
      ...application data
    </EDFIInboundGroups>
  </EDFIBAPLink>
</EDFIBTradeLink>
```

Example 2 - None

Example 2: If **MandatoryUNG** is **N** (None), the XML would look like:

```
<EDFIBTradeLink>
  ...header data
  <EDFIInboundGroups>
    ...application data
  </EDFIInboundGroups>
</EDFIBTradeLink>
```

Example 3 - Optional

Example 3: **MandatoryUNG** is **O** (Optional), and only one of the Applications is associated with an Application Partner (UNG). The XML would look like:

```

<EDFIBTradeLink>
...header data
<EDFIBAPLink>
...specify application partners here
<EDFIboundGroups>
...application data associated with the Application Partner
</EDFIboundGroups>
</EDFIBAPLink>
<EDFIboundGroups>
...application data not associated with any Application Partner
</EDFIboundGroups>
</EDFIBTradeLink>

```

The following table, field, and tag descriptions are for EDIFACT inbound trade links:

- "[EDIFACT Inbound Trade Links \(Tag: EDFIBTradeLink\)](#)"
- "[EDIFACT Inbound Application Partner Trade Links \(Tag: EDFIBAPLink\)](#)"
- "[EDIFACT Inbound Applications Trade Links \(Tag: EDFIboundGroups\)](#)"
- "[EDIFACT Inbound Trade Link Change \(Tag: EDFIBTradeLinkChange\)](#)"
- "[EDIFACT Inbound Application Partner Trade Links Change \(Tag: EDFIBAPLinkChange\)](#)"
- "[EDIFACT Inbound Applications Trade Links Add, Change, Delete \(Tag: EDFIboundGroupsAddChangeDelete\)](#)"
- "[EDIFACT Inbound Trade Links Delete \(Tag: EDFIBTLDelete\)](#)"

EDIFACT Inbound Trade Links (Tag: EDFIBTradeLink)

Use this tag to add a new EDIFACT Inbound Trade Link. It should be noted that there is one **EDFIBTradeLink** record per Trade Link.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	FromIchgIdCdQual	No	4	fk to EDFIdCdQual	1, 5
N/A	FromIchgID	Yes	35		1
N/A	FromRoutingAddress	No	14		1
N/A	ToIchgIdCdQual	No	4	fk to EDFIdCdQual	2, 5
N/A	ToIchgID	Yes	35		2
N/A	ToRoutingAddress	No	14		2
Get PostOffice	GetMailPO	Yes	3	Nickname of Get PO	3
UNG Option	MandatoryUNG	Yes	1	N = No UNG; O = Optional UNG; M = Mandatory UNG	4

Notes:

1. These three fields are confirmed to match an existing External Trading Partner. This partner can be in any EDIFACT folder or sub-folder. Set **FromIchgID** to **UNKNOWN** for the unknown partner, leaving **FromIchgIdCdQual** and **FromRoutingAddress** blank or un-specified.
2. These three fields must match an existing Internal Trading Partner. This partner can be in any EDIFACT folder or sub-folder
3. Must be exactly 3 characters long. Nickname must exist as a Get Post Office.
4. If **MandatoryUNG** is **M** (Mandatory) then Application Partners must be specified in **EDFIBAPLink** for every Application added (for example, **EDFIboundGroups** are nested within the **EDFIBAPLink** record). If **O** (Optional) then some or all Applications can be nested within an **EDFIBAPLink** record. If **N** (None) then no **EDFIBAPLink** records can be specified.
5. Defaults to 4 blanks.

EDIFACT Inbound Application Partner Trade Links (Tag: EDFIBAPLink)

Use this tag to associate Application Partners with a new EDIFACT Inbound Trade Link. This tag is required only if **MandatoryUNG** is **M** (Mandatory) in **EDFIBTradeLink**. May be included if **MandatoryUNG** is **O** (Optional). It cannot be used if **MandatoryUNG** is **N** (None). When used, one or more **EDFIboundGroups** records must be nested within this record. The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	FromUNG_AppID	Yes	35		1
N/A	ToUNG_AppID	Yes	35		2

Notes:

1. Equal to an existing EDIFACT Application Partner's **UNG_AppID** that is owned by the External Trading Partner as defined in the three **From** fields in **EDFIBTradeLink**.
2. Equal to an existing EDIFACT Application Partner's **UNG_AppID** that is owned by the Internal Trading Partner as defined in the three **To** fields in **EDFIBTradeLink**.

EDIFACT Inbound Applications Trade Links (Tag: EDFInboundGroups)

Use this tag to add Documents to a new EDIFACT Inbound Trade Link. This record can appear within a Trade Link or within an Application Partner record. This record type is optional when not within an Application Partner record, however, if not included you will have an incomplete Trade Link (such links are valid in Partner Manager in the event you wish to complete it at a later time). The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Message Version Number	MessageVersionNo	Yes	3	fk to EDFMsgVerNo	1
Message Release Number	MessageRelNo	Yes	3	fk to EDFMsgRelNo	1
Controlling Agency	ControllingAgency	Yes	2	fk to EDFControlAgency	1
Association Assign Code	AssocAssignCd	No	6	fk to EDFAssocAssignCd	1
Functional ID/Message Type	Func_MsgType	Yes	6	fk to EDF_FuncID along with the above fields	1
Test Indicator	TestIndicator	No	1	T=True, F=False Default: F	2
Production Indicator	ProdIndicator	No	1	T=True, F=False Default: T	2
Validate By	ValidateByInd	No	1	"M"= Message; "F"=Functional Group/Interchange Default M.	3
Test PO Nickname	TestPutPO	Yes if TestIndicator is T	3	Nickname of Valid Put PO	4
Prod PO Nickname	ProdPutPO	Yes if ProdIndicator is T	3	Nickname of Valid Put PO	5
AckLevel	AckLevel	No	1	See Note	6
Routing: Route Only	RouteOnly	No	1	Y/N Default: N	

Notes:

1. The combinations of these five fields define the Application and must be unique within one Trade Link. For example, do not duplicate the Application in a **EDFIBAPLink** as well as within an **EDFIBTradeLink**, even if the **MandatoryUNG** is **O** (Optional).
2. At least one of (**TestIndicator** or **ProdIndicator**) must be **True**.
3. Note the field labels within Partner Manager change for this field depending on **MandatoryUNG** in **EDFIBTradeLink**. When **MandatoryUNG** is set to **N** (None), **Validate By** can be **Message** or **Interchange**. When **MandatoryUNG** is set to **M** (Mandatory) or **O** (Optional), **Validate By** can be **Message** or **Functional Group**. For the purposes of this XML input, set to **M** or **F** where **F** can mean either **Functional Group** or **Interchange** and **M** denotes **Message**.
4. Must be exactly 3 characters if present. Ignored if **TestIndicator** is **False**, required otherwise. Nickname must point to a valid Put Post Office.
5. Must be exactly 3 characters if present. Ignored if **ProdIndicator** is **False**, required otherwise. Nickname must point to a valid Put Post Office.
6. Specify the optional Acknowledgement Level. If not specified, this value will be zero, No Acknowledgement. Valid values are **0**, **1**, **2**, **3**, **4** or **5**. These values are: **0** = No Acknowledgement, **1** = Interchange Level, **2** = Functional Group Level, **3** = Message Level, **4** = Segment Level, **5** = Data Element Level. Value **2** (Functional Group Level) can only be specified if Mandatory **UNG** is in use (Application Partners in tag **EDFIBAPLink** are defined for this link).

EDIFACT Inbound Trade Link Change (Tag: EDFIBTradeLinkChange)

Use this tag to change an existing EDIFACT Inbound Trade Link. This tag is used to determine the existing Trade Link at the Trading Partner level, so you must specify the From and To Trading Partner ID in the first 6 fields. Notice that the Routing Address fields are only required if more than one Trading Partner exists for the Interchange ID/Qualifiers. The remaining field, **GetMailPO**, is optional when changing a Trade Link. The child tags (**EDFIBAPLinkChange** and **EDFInboundGroupsAddChangeDelete**) need not be included if only changing data at this level (you only want to change the Get Post Office).

Changing the **UNG** option (Mandatory/None/Optional) is not supported. If you need to change the **UNG** option, use Partner Manager, or remove the existing trade link with **EDFIBTLDelete**, then add it again using **EDFIBTradeLink**.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	FromIchgIdCdQual	No	4	fk to EDFIdCdQual	1, 4
N/A	FromIchgID	Yes	35		1
N/A	FromRoutingAddress	No	14		1
N/A	ToIchgIdCdQual	No	4	fk to EDFIdCdQual	1, 4
N/A	ToIchgID	Yes	35		2
N/A	ToRoutingAddress	No	14		2
Get PostOffice	GetMailPO	No	3	Nickname of Get PO	3

Notes:

1. These three fields are confirmed to match an existing External Trading Partner. This partner can be in any EDIFACT folder or sub-folder. Set **FromIchgID** to **UNKNOWN** for the unknown partner, leaving **FromIchgIdCdQual** and **FromRoutingAddress** blank or un-specified.
2. These three fields must match an existing Internal Trading Partner. This partner can be in any EDIFACT folder or sub-folder.
3. Must be 3 characters long (if specified). Nickname must exist as a Get Post Office.
4. Defaults to 4 blanks.

EDIFACT Inbound Application Partner Trade Links Change (Tag: EDFIBAPLinkChange)

Use this tag to identify the Application Partners associated with an EDIFACT Inbound Trade Link you wish to change. This tag is required only if **MandatoryUNG** is **M** (Mandatory) in **EDFIBTradeLink**. May be included if **MandatoryUNG** is **O** (Optional). It cannot be used if **MandatoryUNG** is **N** (None). This tag's sole purpose is to identify the Application Partners associated with groups at the next level (**EDFIInboundGroupsAddChangeDelete**). No changes to the database can be made within this tag itself. The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	FromUNG_AppID	Yes	35		1
N/A	ToUNG_AppID	Yes	35		2

Notes:

1. Equal to an existing EDIFACT Application Partner's **UNG_AppID** that is owned by the External Trading Partner as defined in the three **From** fields in **EDFIBTradeLinkChange**.
2. Equal to an existing EDIFACT Application Partner's **UNG_AppID** that is owned by the Internal Trading Partner as defined in the three **To** fields in **EDFIBTradeLinkChange**.

EDIFACT Inbound Applications Trade Links Add, Change, Delete (Tag: EDFIInboundGroupsAddChangeDelete)

Use this tag to add Documents to an existing Inbound EDIFACT Trade Link, or to change existing Documents. This tag must be nested within **EDFIBTradeLinkChange** tag, or if required, the **EDFIBAPLinkChange** tag. To add a Document, set the **AddFlag** to **Y**. To delete, set the **DeleteFlag** to **Y**. Note when adding or changing a Document so that it requires an acknowledgement, the outbound acknowledgement trade link (CONTRL) record must already exist. The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Message Version Number	MessageVersionNo	Yes	3	fk to EDFMsgVerNo	1
Message Release Number	MessageRelNo	Yes	3	fk to EDFMsgRelNo	1
Controlling Agency	ControllingAgency	Yes	2	fk to EDFControlAgency	1
Association Assign Code	AssocAssignCd	No	6	fk to EDFAssocAssignCd	1
Functional ID/Message Type	Func_MsgType	Yes	6	fk to EDF_FuncID along with the above fields	1
Test Indicator	TestIndicator	No	1	T=True, F=False, R=Remove	2
Production Indicator	ProdIndicator	No	1	T=True, F=False, R=Remove	2
Validate By	ValidateByInd	No	1	"M"= Message; "F"=Functional Group/Interchange	3
Test PO Nickname	TestPutPO	Yes if TestIndicator is T	3	Nickname of Valid Put PO	4
nProd PO Nickname	ProdPutPO	Yes if ProdIndicator is T	3	Nickname of Valid Put PO	5
AckLevel	AckLevel	No	1	See Note	6
N/A	AddFlag	No	1		
N/A	DeleteFlag	No	1		7
Routing: Route Only	RouteOnly	No	1	Y/N Default: N	

Notes:

1. The combinations of these five fields define the Application and must be unique within one Trade Link. For example, do not duplicate the Application in a EDFIBAPLink as well as within an EDFIBTradeLink, even if the MandatoryUNG is O (Optional).
2. At least one of (**TestIndicator** or **ProdIndicator**) must be **True** after completion of any database change. If you want to remove an existing Test or Production Post Office, set this field to **R**. For example, this is available in the event you want to change an existing group from Test only to Production Only: set the **TestIndicator** to **R**, which will remove the Test Post Office, and set the ProductionIndicator to **T** and specify the new Production Post Office in **ProdPutPO**. When setting this field to **R**, you must specify the other (test/production) Post Office if one does not already exist on the group.
3. Note the field labels within Partner Manager change for this field depending on **MandatoryUNG** in **EDFIBTradeLink**. When **MandatoryUNG** is set to **N** (None), **Validate By** can be **Message** or **Interchange**. When **MandatoryUNG** is set to **M** (Mandatory) or **O** (Optional), **Validate By** can be **Message** or **Functional Group**. For the purposes of this XML input, set to **M** or **F** where **F** can mean either **Functional Group** or **Interchange** and **M** denotes **Message**.
4. Must be exactly 3 characters if present. Ignored if **TestIndicator** is **False**, required otherwise. Nickname must points to a valid Put Post Office.
5. Must be exactly 3 characters if present. Ignored if **ProdIndicator** is **False**, required otherwise. Nickname must points to a valid Put Post Office.
6. Specify the optional Acknowledgement Level. If not specified, this value will be zero, No Acknowledgement. Valid values are **0**, **1**, **2**, **3**, **4**, or **5**. These values are: **0** = No Acknowledgement, **1** = Interchange Level, **2** = Functional Group Level, **3** = Message Level, **4** = Segment Level, **5** = Data Element Level. Value **2** (Functional Group Level) can only be specified if Mandatory **UNG** is in use (Application Partners in tag **EDFIBAPLink** are defined for this link).
7. Set to **Y** if you wish to remove an Inbound Group from a Trade Link. Specify only the first four fields and this flag when deleting a group; all other fields will be ignored. If you want to completely delete a Group with Optional **UNG**, you must delete both records that exist in this case: one with the Application Partners (use the tag **EDFIBAPLinkChange**), and the one without Application Partners (do not use the tag **EDFIBAPLinkChange**).

EDIFACT Inbound Trade Links Delete (Tag: EDFIBTLDelete)

Use this tag to delete an existing EDIFACT Inbound Trade Link. It requires the unique identifier of the EDIFACT 'From' (External) Trading Partner: **FromIchgIdCdQual** plus **FromIchgID**, and if required, the **FromRoutingAddress**. This tag also requires the unique identifier of the EDIFACT 'To' (Internal) Trading Partner: **ToIchgIdCdQual** plus **ToIchgID**, and if required, the **ToRoutingAddress**. The Routing Addresses are required if more than one Partner has the same **IchgIdCdQual** and **IchgID**. A warning report (or error if "Abort Run" is selected) is issued if Trade Link does not exist.

Warning: Use with caution: this will delete *all* Trade Links defined for this Inbound Trading Partner relationship, including all Application Partner-level links that may exist.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	FromIchgIdCdQual	No	4	fk to EDFIdCdQual	1, 3
N/A	FromIchgID	Yes	35		1
N/A	FromRoutingAddress	No	14		1
N/A	ToIchgID	Yes	35		2
N/A	ToRoutingAddress	No	14		2

Notes:

- These three fields are confirmed to match an existing External Trading Partner. This partner can be in any EDIFACT folder or sub-folder. Set **FromIchgID** to **UNKNOWN** for the unknown partner, leaving **FromIchgIdCdQual** and **FromRoutingAddress** blank or un-specified.
- These three fields must match an existing Internal Trading Partner.
- Defaults to 4 blanks.

EDIFACT outbound trade links

Trade links can be added, changed, or deleted. In addition, existing Trade Links can have their individual Messages (also known as Documents or Groups) added, changed, or deleted.

To add a new EDIFACT Outbound trade link, use the tags **EDFOBTPLink**, **EDFOBAPLink**, and **EDFOBMsgLink**. To change an existing EDIFACT Outbound Trade Link, use the tags **EDFOBTPLinkChange**, **EDFOBAPLinkChange**, and **EDFOBMsgLinkAddChangeDelete**. To delete an entire EDIFACT Outbound Trade Link, use **EDFOBTLDelete**.

EDIFACT Outbound Trade Links are very similar to Inbound Trade Links. The main difference is no Unknown Outbound Trade Links. All Post Offices are defined at the Message level. Applications are specified in the tag **EDFOBMsgLink** when adding, or **EDFOBMsgLinkAddChangeDelete** tag when changing.

Trading/Application Partners must previously exist in the database for the Trade Link to be added. As with Inbound Trade Links, Application Partners may or may not be specified, depending on the setting of **MandatoryUNG**. Application Partners, if required, are specified within the **EDFOBAPLink** or **EDFOBAPLinkChange** tags, and must "belong" to the Trading Partner specified in the **EDFOBTPLink/EDFOBTPLinkChange** tag. Application Partners can only be specified if the **MandatoryUNG** field is set to **O** (optional) or **M** (mandatory).

Applications are nested within the Trade Link record when there is no UNG level; otherwise Applications are nested within the Application Partner record. The same Application cannot appear more than once within a Trade Link. The following table, field, and tag descriptions are for EDIFACT outbound trade links:

- ["EDIFACT Outbound Trade Links \(Tag: EDFOBTPLink\)"](#)
- ["EDIFACT Outbound Application Partner Trade Links \(Tag: EDFOBAPLink\)"](#)
- ["EDIFACT Outbound Applications Trade Links \(Tag: EDFOBMsgLink\)"](#)
- ["EDIFACT Outbound Trade Links Change \(Tag: EDFOBTPLinkChange\)"](#)
- ["EDIFACT Outbound Applications Trade Links Add, Change, Delete \(Tag: EDFOBMsgLinkAddChangeDelete\)"](#)
- ["EDIFACT Outbound Trade Link Delete \(Tag: EDFOBTLDelete\)"](#)
- ["EDIFACT Outbound Trade Links \(Tag: EDFOBTLDelete\)"](#)
- ["EDIFACT Outbound Application Partner Trade Links \(Tag: EDFOBAPLink\)"](#)
- ["EDIFACT Outbound Applications Trade Links \(Tag: EDFOBMsgLink\)"](#)
- ["EDIFACT Outbound Trade Links Change \(Tag: EDFOBTPLinkChange\)"](#)
- ["EDIFACT Outbound Application Partner Trade Links Change \(Tag: EDFOBAPLinkChange\)"](#)
- ["EDIFACT Outbound Applications Trade Links Add, Change, Delete \(Tag: EDFOBMsgLinkAddChangeDelete\)"](#)
- ["EDIFACT Outbound Trade Link Delete \(Tag: EDFOBTLDelete\)"](#)

EDIFACT Outbound Trade Links (Tag: EDFOBTPLink)

Use this tag to add a new EDIFACT Outbound Trade Link.

There is One **EDFOBTPLink** record per Trade Link.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	FromIchgIdCdQual	No	4	fk to EDFIdCdQual	1, 7
N/A	FromIchgID	Yes	35		1
N/A	FromRoutingAddress	No	14		1
N/A	ToIchgIdCdQual	No	4	fk to EDFIdCdQual	2, 7
N/A	ToIchgID	Yes	35		2
N/A	ToRoutingAddress	No	14		2
UNG Option	MandatoryUNG	Yes	1	N = No UNG; O = Optional UNG; M = Mandatory UNG	3
Control Scheme	UNBControlNoScheme	No	1		4

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Control Map	UNBControlNoMap	Yes, if scheme is 2	255		5
UNB Control Number	UNBControlNoValue	No	14		6

Notes:

1. These three fields must match an existing Internal Trading Partner. This partner can be in any EDIFACT folder or sub-folder.
2. These three fields must match an existing External Trading Partner. This partner can be in any EDIFACT folder or sub-folder.
3. If **MandatoryUNG** is **M** (Mandatory) then Application Partners must be specified in **EDFOBAPLink** for every Application added (for example, **EDFOBMsgLink** records are nested within the **EDFOBAPLink** record). If **O** (Optional), than some or all Applications can be nested within an **EDFOBAPLink** record. If **N** (None), then no **EDFOBAPLink** records can be specified.
4. Valid values for **UNBControlNoScheme** are: **0**=Trade Link; **1**=Message; **2**=User Defined; **3**=None. The default value is **0** (Trade Link). If set to **2** (User Defined), a **UNBControlNoMap** is required. If set to 1 (Message), control numbers may be set at the Message level (see [EDFOBMsgLink](#)).
5. A Control Number Map is required and can only be specified if **UNBControlNoScheme** is set to 2.
6. A Control Number can only be specified if **UNBControlNoScheme** is either set to or defaults to **0** (Trade Link), or is set to **2** (User Defined). If specified, this value must be a positive integer no longer than 14 characters.
7. Defaults to 4 blanks.

EDIFACT Outbound Application Partner Trade Links (Tag: **EDFOBAPLink**)

Use this tag to add the associated Application Partners to a new EDIFACT Outbound Trade Link. If changing an existing EDIFACT Outbound Link with Application Partners, see [EDFOBAPLinkChange](#).

This tag is required only if **MandatoryUNG** is **M** (Mandatory) in **EDFOBTPLink**, above. It may be included if **MandatoryUNG** is **O** (Optional). This tag cannot be used if **MandatoryUNG** is **N** (None). When used, one or more **EDFOBMsgLink** records must be nested within this record.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Notes
N/A	FromUNG_AppID	Yes	35	1
N/A	ToUNG_AppID	Yes	35	1

Notes:

1. Equal to an existing EDIFACT Application Partner's UNG_AppID that is owned by the Internal Trading Partner as defined in the three From fields in **EDFOBTPLink**.
2. Equal to an existing EDIFACT Application Partner's **UNG_AppID** that is owned by the External Trading Partner as defined in the three **To** fields in **EDFOBTPLink**.

EDIFACT Outbound Applications Trade Links (Tag: **EDFOBMsgLink**)

Use this tag to add Messages (also known as Documents) to a new EDIFACT Outbound Trade Link. This record can appear within a Trade Link, or within an Application Partner record. This record type is optional when not within an Application Partner record, but in this case, you do not have a complete Trade Link (such links are valid in Partner Manager in the event you wish to complete it at a later time). The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Message Version Number	MessageVersionNo	Yes	3	fk to EDFMsgVerNo	1
Message Release Number	MessageRelNo	Yes	3	fk to EDFMsgRelNo	1
Controlling Agency	ControllingAgency	Yes	2	fk to EDFControlAgency	1
Association Assign Code	AssocAssignCd	No	6	fk to EDFAssocAssignCd	1
Functional ID/Message Type	MessageType	Yes	6	fk to EDF_FuncID along with the above fields	1
Get Post Office	GetMailPO	Yes	3	Nickname of valid Get PO	
Test Indicator	TestIndicator	No	1	T=True, F=False Default: F	2
Production Indicator	ProdIndicator	No	1	T=True, F=False Default: T	2
Test PO Nickname	TestPutPO	Yes if TestIndicator is T	3	Nickname of valid Put PO	3
Prod PO Nickname	ProdPutPO	Yes if ProdIndicator is T	3	Nickname of Valid Put PO	4
Control No	LastMsgRefNo	No	14		5
Routing: Route Only	RouteOnly	No	1	Y/N Default: N	

Notes:

1. The combination of these five fields define the Application and must be unique within one Trade Link. For example, do not duplicate the Application in a **EDFOBAPLink** as well as within a **EDFOBTPLink**, even if the **MandatoryUNG** is **O** (Optional).
2. At least one of (**TestIndicator** or **ProdIndicator**) must be **True**.
3. Must be exactly 3 characters if present. Ignored if **TestIndicator** is **False**, required otherwise. Nickname must point to a valid Put Post Office.
4. Must be exactly 3 characters if present. Ignored if **ProdIndicator** is **False**, required otherwise. Nickname must point to a valid Put Post Office.
5. If the Control Numbering Scheme of this Trade Link is Message (see the [EDFOBTPLink](#) field **UNBControlNoScheme**) then you may over-ride the control number by placing a value here. If specified, this value must be a positive integer no longer than 14 characters in length.

EDIFACT Outbound Trade Links Change (Tag: EDFOBTPLinkChange)

Use this tag to change an existing EDIFACT Outbound Trade Link. This tag is used to determine the existing Trade Link at the Trading Partner level, so you must specify the From and To Trading Partner ID in the first 6 fields. Note the Routing Address fields are only required if more than one Trading Partner exists for the Interchange ID/Qualifiers. The remaining fields are optional when changing a Trade Link.

The child tags (**EDFOBAPLinkChange** and **EDFOBMsgLinkAddChangeDelete**) need not be included if only changing data at this level.

Changing the **UNG** option (Mandatory/None/Optional) is not supported. If you need to change the **UNG** option, use Partner Manager, or remove the existing trade link with **EDFOBTLDelete**, then add it again using **EDFOBTradeLink** tag.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	FromIchgIdCdQual	No	4	fk to EDFIdCdQual	1, 6
N/A	FromIchgID	Yes	35		1
N/A	FromRoutingAddress	No	14		1
N/A	ToIchgIdCdQual	No	4	fk to EDFIdCdQual	2, 6
N/A	ToIchgID	Yes	35		2
N/A	ToRoutingAddress	No	14		2
Control Scheme	UNBControlNoScheme	No	1		3
Control Map	UNBControlNoMap	Yes, if scheme is 2	255		4
UNB Control Number	UNBControlNoValue	No	14		5

Notes:

1. These three fields must match an existing Internal Trading Partner. This partner can be in any EDIFACT folder or sub-folder.
2. These three fields must match an existing External Trading Partner. This partner can be in any EDIFACT folder or sub-folder.
3. Valid values for **UNBControlNoScheme** are: **0**=Trade Link; **1**=Message; **2**=User Defined; **3**=None. The default value is **0** (Trade Link). If set to **2** (User Defined), a **UNBControlNoMap** is required. If set to **1** (Message), control numbers may be set at the Message level (see [EDFOBMsgLink](#)).
4. A Control Number Map is required and can only be specified if **UNBControlNoScheme** is set to **2**.
5. Control Number can only be specified if **UNBControlNoScheme** is either set to or exists as **0** (Trade Link), or **2** (User Defined).
6. Defaults to 4 blanks.

EDIFACT Outbound Application Partner Trade Links Change (Tag: EDFOBAPLinkChange)

This tag is required if the trade link uses Application Partners; i.e., the Trade Link contains a **MandatoryUNG** setting of "Optional" or "Mandatory". If the **MandatoryUNG** flag is None, do not use this tag. This tag's sole purpose is to identify the Application Partners associated with messages at the next level; no changes to the database can be made within this tag itself. The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	FromUNG_AppID	Yes	35		1
N/A	ToUNG_AppID	Yes	35		2

Notes:

1. Equal to an existing EDIFACT Application Partner's **UNG_AppID** that is owned by the Internal Trading Partner as defined in the three From fields in **EDFOBTPLinkChange**.
2. Equal to an existing EDIFACT Application Partner's **UNG_AppID** that is owned by the External Trading Partner as defined in the three **To** fields in **EDFOBTPLinkChange**.

EDIFACT Outbound Applications Trade Links Add, Change, Delete (Tag: EDFOBMsgLinkAddChangeDelete)

This tag is used to add, change, or delete an Application (Message or Group) in an existing EDIFACT Outbound Trade Link. Must be nested within **EDFOBTradeLinkChange** tag, or if required, the **EDFOBAPLinkChange** tag. To add an Application, set the **AddFlag** to **Y**. To delete, set the **DeleteFlag** to **Y**.

This tag is similar to the **EDFOBMsgLink** tag used when adding a new Trade Link, with the following significant differences:

- You can remove a Test or Production Post Office by setting the Test/Production Indicators to **R**. See Note 2 for more information on this feature.
- To add a new Message to an existing link, set **AddFlag** to **Y**.
- To remove an existing Message, set the **DeleteFlag** to **Y**.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Message Version Number	MessageVersionNo	Yes	3	fk to EDFMsgVerNo	1

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Message Release Number	MessageRelNo	Yes	3	fk to EDFMsgRelNo	1
Controlling Agency	ControllingAgency	Yes	2	fk to EDFControlAgency	1
Association Assign Code	AssocAssignCd	No	6	fk to EDFAssocAssignCd	1
Functional ID/Message Type	MessageType	Yes	6	fk to EDF_FuncID along with the above fields	1
Get Post Office	GetMailPO	No	3	Nickname of valid Get PO	
Test Indicator	TestIndicator	No	1	T=True, F=False, R=Remove	2
Production Indicator	ProdIndicator	No	1	T=True, F=False, R=Remove	2
Test PO Nickname	TestPutPO	Yes if TestIndicator is T	3	Nickname of valid Put PO	3
Prod PO Nickname	ProdPutPO	Yes if ProdIndicator is T	3	Nickname of Valid Put PO	4
Control No	LastMsgRefNo	No	14		5
N/A	AddFlag	No	1	Y/N	
N/A	DeleteFlag	No	1	Y/N	6
Routing: Route Only	RouteOnly	No	1	Y/N Default: N	

Notes:

- The combination of these five fields define the Application and must be unique within one Trade Link. For example, do not duplicate the Application within a EDOBAPLinkChange as well as within a EDOBTPLinkChange, even if the MandatoryUNG is O (Optional).
- After all changes are applied, at least one of (**TestIndicator** or **ProdIndicator**) must be **True**. If you want to remove an existing Test or Production Post Office, set this field to "R". For example, this is available in the event you want to change an existing message from Test only to Production Only: set the TestIndicator to "R", which will remove the Test Post Office, and set the ProductionIndicator to **T** and specify the new Production Post Office in ProdPutPO. When setting this field to **R**, you must specify the other (test/production) Post Office if one does not already exist on the message
- Must be exactly 3 characters if present. Ignored if **TestIndicator** is **False**, required otherwise. Nickname must point to a valid Put Post Office.
- Must be exactly 3 characters if present. Ignored if **ProdIndicator** is **False**, required otherwise. Nickname must point to a valid Put Post Office.
- If the Control Numbering Scheme of this Trade Link is Message (see [EDOBTPLinkChange](#) field **UNBControlNoScheme**) then you may over-ride the control number by placing a value here. If specified, this value must be a positive integer no longer than 14 characters in length.
- Set the DeleteFlag to **Y** if you wish to remove an existing message from a Trade Link. Specify only the first five fields and this flag when deleting a group; all other fields will be ignored. If you want to complete delete a Group with Optional UNG, you must delete both records that exist in this case: one with the Application Partners (use the tag [EDOBAPLinkChange](#)), and the one without Application Partners (do not use the tag [EDOBAPLinkChange](#)).

EDIFACT Outbound Trade Link Delete (Tag: EDOBTDelete)

Use this tag to delete an existing EDIFACT Outbound Trade Link. Requires the unique identifier of the EDIFACT 'From' (Internal) Trading Partner: **FromIchgIdCdQual** plus **FromIchgID**, and if required, the **FromRoutingAddress**. Also requires the unique identifier of the EDIFACT 'To' (External) Trading Partner: **ToIchgIdCdQual** plus **ToIchgID**, and if required, the **ToRoutingAddress**. The Routing Addresses are required if more than one Partner has the same **IchgIdCdQual** and **IchgID**. A warning report (or error if "Abort Run" is selected) is issued if Trade Link does not exist.

Warning Use with caution: this will delete all Trade Links defined for this Outbound Trading Partner relationship, including all Application Partner-level links that may exist.

The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	FromIchgIdCdQual	No	4	fk to EDFIdCdQual	1, 3
N/A	FromIchgID	Yes	35		1
N/A	FromRoutingAddress	No	14		1
N/A	ToIchgIdCdQual	No	4	fk to EDFIdCdQual	2, 3
N/A	ToIchgID	Yes	35		2
N/A	ToRoutingAddress	No	14		2

Notes:

- These three fields must match an existing Internal Trading Partner. This partner can be in any EDIFACT folder or sub-folder.
- These three fields must match an existing External Trading Partner. This partner can be in any EDIFACT folder or sub-folder.
- Defaults to 4 blanks.

TRADACOMS Trading/Application Partners

The following table, field, and tag descriptions are for TRADACOMS Partners:

- ["TRADACOMS Trading Partners: \(Tag TRCTradingPartners\)"](#)
- ["TRADACOMS Trading Partners Change \(Tag: TRCTradingPartnersChange\)"](#)
- ["TRADACOMS Trading Partners Delete \(Tag: TRCTradingPartnersDelete\)"](#)
- ["TRADACOMS Application Partners \(Tag: TRCAppPartners\)"](#)
- ["TRADACOMS Application Partners Change \(Tag: TRCAppPartnersChange\)"](#)
- ["TRADACOMS Application Partners Delete \(Tag: TRCAppPartnersDelete\)"](#)

For information about inbound TRADACOMS trade links, see ["TRADACOMS Inbound Trade Links"](#).

- ["TRADACOMS Trading Partners: \(Tag TRCTradingPartners\)"](#)

- [TRADACOMS Trading Partners Change \(Tag: TRCTradingPartnersChange\)](#)
- [TRADACOMS Trading Partners Delete \(Tag: TRCTradingPartnersDelete\)](#)
- [TRADACOMS Application Partners \(Tag: TRCAppPartners\)](#)
- [TRADACOMS Application Partners Change \(Tag: TRCAppPartnersChange\)](#)
- [TRADACOMS Application Partners Delete \(Tag: TRCAppPartnersDelete\)](#)

TRADACOMS Trading Partners: (Tag TRCTradingPartners)

Use this tag to add new TRADACOMS Trading Partners. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	IntExt	Yes	1	I or E I=Internal, E=External	2
Trading Partner Name	PartnerName	Yes	35		
Partner ID	PartnerID	Yes	35		2
Duplicate Control	Duplicate_Control	No	1		3

Notes

1. Cannot be "all" or "unknown".
2. Typically, an EAN number is used in TRADACOMS to identify partners. However, if an EAN is not available and the partners agree, this field can be a name.
3. **N**=none; **I**=Interchange. Can only be set on External Partners.

TRADACOMS Trading Partners Change (Tag: TRCTradingPartnersChange)

Use this tag to change existing TRADACOMS Trading Partners. Fields are similar to TRCTradingPartners, except you there is no "IntExt" field: you cannot change the Internal/External designation of a Trading Partner. Identify the Trading Partner to change using **PartnerName**, **PartnerID**, or both. If you wish to change the name or ID, use the fields **PartnerNameChange** and **PartnerIDChange**. Contacts can be added via this tag; include the <Contact> tag nested within this tag to add. This tag reports a warning (or error if "Abort Run" is selected) if Trading Partner does not exist. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Trading Partner Name	PartnerName	No	35		
Partner ID	PartnerID	No	35		1
Duplicate Control	Duplicate_Control	No	1		2
N/A	PartnerNameChange	No	35		
N/A	PartnerIDChange	No	35		

Notes:

1. Typically, an EAN number is used in TRADACOMS to identify partners. However, if an EAN is not available and the partners agree, this field can be a name.
2. **N**=none; **I**=Interchange. Can only be set on External Partners.

TRADACOMS Trading Partners Delete (Tag: TRCTradingPartnersDelete)

Use this tag to delete a TRADACOMS Trading Partner and all associated data with that Partner. Supply **PartnerName**, **PartnerID**, or both. Use with caution: Deleting a Trading Partner will delete all Application Partners, Contacts, and Trade Links associated with that trading partner.

This tag reports a warning (or error if "Abort Run" is selected) if Trading Partner does not exist. The tag and field descriptions are described in the following table:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Trading Partner Name	PartnerName	No	35		
Partner ID	PartnerID	No	35		

TRADACOMS Application Partners (Tag: TRCAppPartners)

TRADACOMS Application Partners (Tag: TRCAppPartners)

Use this tag, when nested within a Trading Partner, to add Application Partners at the same time. Application Partners are optional in TRADACOMS. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	PartnerID	Yes	35		1
Application Partner Name	ApplicationName	Yes	35		2
Application Partner ID	AppPartnerID	Yes	35		3
Alias	AliasName	No	20		4
User Defined 1	UserDefined1	No	20		

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
User Defined 2	UserDefined2	No	20		

Notes:

1. ID's of the owner of this Application Partner; equal to the previously specified Trading Partner. Used to confirm that the XML is properly formed (Application Partners nested within the parent Trading Partner).
2. Do not use the name "UNKNOWN, or "ALL", or any variation of the case of these two words. For example, do not use "Unknown", or "All".
3. Typically, an EAN number is used in TRADACOMS to identify partners. However, if an EAN is not available and the partners agree, this field can be a name.
4. Alias Names are unique across all TRADACOMS Application Partners, if present.

TRADACOMS Application Partners Change (Tag: TRCApPartnersChange)

Use this tag to add an TRADACOMS Application Partner to an existing Trading Partner, or change an existing Application Partner. To add, set the tag **AddFlag** to **Y**; leaving **AddFlag** blank, not specified, or set to **N** will change the existing TRADACOMS Application Partner if it exists.

To change the unique identifiers of an TRADACOMS Application Partner, use the fields **ApplicationNameChange** and **AppPartnerIDChange**. Do not specify these fields when the AddFlag is **Y**. The resulting change from these fields cannot already exist in the database. Application Partners can have Contacts [Contacts \(Tag: Contacts\)](#) added at the same time; nest the Contact record within this tag. Use this tag, along with the [Contacts](#) tag, to add Contacts to an existing Application Partner.

The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	PartnerID	Yes	35		1
Application Partner Name	ApplicationName	No	35		2
Application Partner ID	AppPartnerID	No	35		3
Alias	AliasName	No	20		4
User Defined 1	UserDefined1	No	20		
User Defined 2	UserDefined2	No	20		
N/A	AddFlag	No	1	Y/N	
N/A	ApplicationNameChange	No	35		
N/A	AppPartnerIDChange	No	35		

Notes:

1. ID's of the owner of this Application Partner (Trading Partner's unique identifier)
2. Do not use the name "UNKNOWN, or "ALL", or any variation of the case of these two words. For example, do not use "Unknown", or "All".
3. Typically, an EAN number is used in TRADACOMS to identify partners. However, if an EAN is not available and the partners agree, this field can be a name.
4. Alias Names are unique across all TRADACOMS Application Partners, if present.

TRADACOMS Application Partners Delete (Tag: TRCApPartnersDelete)

Use this tag to delete a TRADACOMS Application Partner. Supply the Application Partner's Name in **ApplicationName**, and/or the Application Partner's **AppPartnerID**. You must also supply the associated Trading Partner's name in **PartnerName** and/or the Trading Partner's **PartnerID**. This tag will also delete any Contacts associated with the Application Partner. It will not delete if Application Partner is assigned to a trade link (see [TRCTradingPartnersDelete](#) if this functionality is needed). A warning report (or error if "Abort Run" is selected) is issued if Trade Link does not exist. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	PartnerName	No	35		
N/A	PartnerID	No	35		
Application Partner Name	ApplicationName	No	35		
Application Partner ID	AppPartnerID	No	35		

TRADACOMS inbound trade links

Trade links can be added, changed, or deleted. In addition, existing Trade Links can have their individual Documents added, changed, or deleted.

TRADACOMS trade links are defined by two record types: Link and Doc. The Link record defines the trading/application partners and the Doc record defines the documents exchanged. A trade link requires one Link record, followed by 1 or more Doc record(s). There is no support for Unknown TRADACOMS links. Unique to TRADACOMS is how Application Partners are optional. The [TRCIBLink](#) fields **From_TP_or_AP** and **To_TP_Or_AP** are employed so the XML Autoload Utility knows what type of Partner is in use. To add a new TRADACOMS Inbound trade link, use the tags:

- [TRCIBLink](#)
- [TRCIBTLDocs](#)

To change an existing TRADACOMS Inbound Trade Link, use the tags:

- [TRCIBLink](#)
- [TRCIBLinkChange](#)

To delete an entire TRADACOMS Inbound Trade Link, use [TRCIBLinkDelete](#).

The following table, field, and tag descriptions are for TRADACOMS inbound trade links:

- ["TRADACOMS Inbound Trade Link \(Tag: TRCIBLink\)"](#)
- ["TRADACOMS Inbound Trade Link Document \(Tag: TRCIBTLDocs\)"](#)
- ["TRADACOMS Inbound Trade Link Change \(Tag: TRCIBLinkChange\)"](#)
- ["TRADACOMS Inbound Trade Link Document Add, Change, Delete \(Tag: TRCIBTLDocsAddChangeDelete\)"](#)
- ["TRADACOMS Inbound Trade Link Delete \(Tag: TRCIBLinkDelete\)"](#)

- [**TRADACOMS Inbound Trade Link \(Tag: TRCIBLink\)**](#)
- [**TRADACOMS Inbound Trade Link Document \(Tag: TRCIBTLDocs\)**](#)
- [**TRADACOMS Inbound Trade Link Change \(Tag: TRCIBLinkChange\)**](#)
- [**TRADACOMS Inbound Trade Link Document Add, Change, Delete \(Tag: TRCIBTLDocsAddChangeDelete\)**](#)
- [**TRADACOMS Inbound Trade Link Delete \(Tag: TRCIBLinkDelete\)**](#)

TRADACOMS Inbound Trade Link (Tag: TRCIBLink)

Use this tag to add a new TRADACOMS Inbound Trade Link. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	From_TP_Or_AP	Yes	1	T or A	1
N/A	From_Partner_ID	Yes	35		1
N/A	To_TP_Or_AP	Yes	1	T or A	2
N/A	To_Partner_ID	Yes	35		2
Reset	ResetTL_Ind	No	1	T or F	3
STX Control Number	TLControlNoValue	Yes, only if ResetTL_Ind is T	14	must be a number	4

Notes:

1. Set **From_TP_or_AP** to **T** to specify the From Partner as a Trading Partner or set to **A** to specify the From Partner as an Application Partner. When set to **T**, set **From_Partner_ID** to the **PartnerID** found in TRADACOMS Trading Partner screens; otherwise set it to the **AppPartnerID** found in TRADACOMS Application Partner screens.
2. Set **To_TP_or_AP** to **T** to specify the To Partner as a Trading Partner or set to **A** if the To Partner is an Application Partner. When set to **T**, set **To_Partner_ID** to the **PartnerID** found in **TRCTradingPartners**; otherwise set it to the **AppPartnerID** found in **TRCAppPartners**.
3. True/False; reset STX Control Number. Default: F.
4. Only set this value if the **Reset** is set to **T** (True). Setting this field to any value when the **Reset** is **F** (false) will reject this link.

TRADACOMS Inbound Trade Link Document (Tag: TRCIBTLDocs)

The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Document Type	DocType	Yes	10		1
From Application Partner SDT/CDT	From_SDT_CDT	No	1	S or C	2
To Application Partner SDT/CDT	To_SDT_CDT	No	1	S or C	3
Get Mail Post Office Nickname	GetMailPO	Yes	3	valid Get PO	
Test (check box)	TestIndicator	No	1	T (True) or F (false)	4
Test Post Office Nickname	TestPutPO	Yes, if Test Indicator =T	3	valid Put Post Office	5
Production (check box)	ProdIndicator	No	1	T (True) or F (false)	6
Production Post Office Nickname	ProdPutPO	Yes, if Prod Indicator = T	3	valid Put Post Office	5
Generate VAT Report	GenerateVATReport	No	1	T (True) or F (false)	7

Notes:

1. Document includes the version appended, for example: INVOIC9. This value must exist as a valid Document Type in the table **TRCDocTypes**, maintainable in Standards Maintenance in Partner Manager.
2. **From_SDT_CDT** is used only if the From Partner is an Application Partner; it is not used when that Partner is a Trading Partner. It indicates that the From Partner appears in either the SDT Segment (set to **S**) or the CDT segment (set to **C**). This field defaults to **S** and must be the opposite value of the next field, **To_SDT_CDT**.
3. **To_SDT_CDT** is used only if the To Partner is an Application Partner; it is not used when that Partner is a Trading Partner. It indicates that the To Partner appears in either the SDT Segment (set to **S**) or the CDT segment (set to **C**). This field defaults to **C** and must be the opposite value of the previous field, **From_SDT_CDT**.
4. Default: **F**. Set to **T** if including a Test Post Office
5. At least one of the Test/Prod Post Offices must be set (both cannot be blank).
6. Default: **T**. Set to **T** if including a Production Post Office
7. **GenerateVATReport** can only be set if the Document Type is CREDIT, INVOIC, or UTLBIL, and will default to **True** if not specified for these 3 document types.

TRADACOMS Inbound Trade Link Change (Tag: TRCIBLinkChange)

Use this tag to change an existing TRADACOMS Inbound Trade Link. This tag is required to identify the Trade Link via the first four fields in the tag. The remaining fields, **ResetTL_Ind** and **TLControlNoValue**, need not be specified if your only changes are to the documents. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	From_TP_Or_AP	Yes	1	T or A	1
N/A	From_Partner_ID	Yes	35		1
N/A	To_TP_Or_AP	Yes	1	T or A	2
N/A	To_Partner_ID	Yes	35		2
Reset	ResetTL_Ind	No	1	T or F	3
STX Control Number	TLControlNoValue	Yes, only if ResetTL_Ind is T	14	must be a number	4

Notes:

1. Set **From_TP_or_AP** to **T** to specify the **From** Partner as a Trading Partner or set to **A** to specify the **From** Partner as an Application Partner. When set to **T**, set **From_Partner_ID** to the **PartnerID** found in TRADACOMS Trading Partner screens; otherwise set it to the **AppPartnerID** found in TRADACOMS Application Partner screens.
2. Set **To_TP_or_AP** to **T** to specify the **To** Partner as a Trading Partner or set to **A** if the **To** Partner is an Application Partner. When set to **T**, set **To_Partner_ID** to the **PartnerID** found in **TRCTradingPartners**; otherwise set it to the **AppPartnerID** found in **TRCAppPartners**.
3. True/False; reset STX Control Number.
4. Only set this value if the **Reset** is set to **T** (True). Setting this field to any value when the **Reset** is **F** (false) will reject this link.

TRADACOMS Inbound Trade Link Document Add, Change, Delete (Tag: TRCIBTLDocsAddChangeDelete)

This tag is used to add, change, or delete a Document in an existing TRADACOM Inbound Trade Link. It must be nested within **TRCIBLinkChange** tag. To add a Document, set the **AddFlag** to **Y**. To delete, set the **DeleteFlag** to **Y**. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Document Type	DocType	Yes	10		1
From Application Partner SDT/CDT	From_SDT_CDT	No	1	S or C	2
To Application Partner SDT/CDT	To_SDT_CDT	No	1	S or C	3
Get Mail Post Office Nickname	GetMailPO	No	3	valid Get PO	
Test (check box)	TestIndicator	No	1	T (True) or F (false) or R (remove)	4
Test Post Office Nickname	TestPutPO	Yes, if TestIndicator=T	3	valid Put Post Office	4
Production (check box)	ProdIndicator	No	1	T (True) or F (false) or R (remove)	4
Production Post Office Nickname	ProdPutPO	Yes, if ProdIndicator = T	3	valid Put Post Office	4
Generate VAT Report	GenerateVATReport	No	1	T (True) or F (false)	5
N/A	AddFlag	No	1	Y or N	
N/A	DeleteFlag	No	1	Y or N	6

Notes:

1. Document includes the version appended, for example: INVOIC9. This value must exist as a valid Document Type in the table **TRCDocTypes**, maintainable in Standards Maintenance in Partner Manager.
2. **From_SDT_CDT** is used only if the From Partner is an Application Partner; it is not used when that Partner is a Trading Partner. It indicates that the From Partner appears in either the SDT Segment (set to **S**) or the CDT segment (set to **C**). This field must be the opposite value of the next field, **To_SDT_CDT**.
3. **To_SDT_CDT** is used only if the To Partner is an Application Partner; it is not used when that Partner is a Trading Partner. It indicates that the To Partner appears in either the SDT Segment (set to **S**) or the CDT segment (set to **C**). This field must be the opposite value of the previous field, **From_SDT_CDT**.
4. After all changes are applied, at least one of the Test/Prod Post Offices must be set (both cannot be blank). If you want to remove an existing Test or Production Post Office, set test Test/Production Indicator field to "R". For example, this is available in the event you want to change an existing group from Test only to Production Only: set the **TestIndicator** to "R", which will remove the Test Post Office, and set the **ProductionIndicator** to **T** and specify the new Production Post Office in **ProdPutPO**. When setting this field to **R**, you must specify the other (test/production) Post Office if one does not already exist on the group.
5. **GenerateVATReport** can only be set if the Document Type is CREDIT, INVOIC, or UTLBL.
6. Set to **Y** if you wish to remove a Document from a Trade Link. Specify only the first field and this flag when deleting a group; all other fields will be ignored.

TRADACOMS Inbound Trade Link Delete (Tag: TRCIBLinkDelete)

Use this tag to delete an existing TRADACOMS Inbound Trade Link. This requires the **From_TP_Or_AP**, **From_Partner_ID**, **To_TP_Or_AP**, and **To_Partner_ID** to identify the Trade Link to delete. A warning report (or error if "Abort Run" is selected) is issued if Trade Link does not exist. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	From_TP_Or_AP	Yes	1	T or A	1
N/A	From_Partner_ID	Yes	35		1
N/A	To_TP_Or_AP	Yes	1	T or A	2
N/A	To_Partner_ID	Yes	35		2

Notes:

1. Set **From_TP_Or_AP** to **T** to specify the **From** Partner as a Trading Partner or set to **A** to specify the **From** Partner as an Application Partner. When set to **T**, set **From_Partner_ID** to the **PartnerID** found in TRADACOMS Trading Partner screens; otherwise set it to the **AppPartnerID** found in TRADACOMS Application Partner screens.
2. Set **To_TP_Or_AP** to **T** to specify the **To** Partner as a Trading Partner or set to "A" if the **To** Partner is an Application Partner. When set to **T**, set **To_Partner_ID** to the **PartnerID** found in **TRCTradingPartners**; otherwise set it to the **AppPartnerID** found in **TRCAppPartners**.

TRADACOMS Outbound Trade Links

The following table, field, and tag descriptions are for TRADACOMS outbound trade links:

- ["TRADACOMS Outbound Trade Link \(Tag: TRCOBLink\)"](#)
- ["TRADACOMS Outbound Trade Link Document: \(Tag: TRCOBTLDocs\)"](#)
- ["TRADACOMS Outbound Trade Link Change \(Tag: TRCOBLinkChange\)"](#)
- ["TRADACOMS Outbound Trade Link Document Add, Change, Delete \(Tag: TRCOBTLDocsAddChangeDelete\)"](#)
- ["TRADACOMS Outbound Trade Link Delete \(Tag: TRCOBLinkDelete\)"](#)
- [TRADACOMS Outbound Trade Link \(Tag: TRCOBLink\)](#)
- [TRADACOMS Outbound Trade Link \(Tag: TRCOBLink\)](#)
- [TRADACOMS Outbound Trade Link Document: \(Tag: TRCOBTLDocs\)](#)
- [TRADACOMS Outbound Trade Link Change \(Tag: TRCOBLinkChange\)](#)
- [TRADACOMS Outbound Trade Link Document Add, Change, Delete \(Tag: TRCOBTLDocsAddChangeDelete\)](#)
- [TRADACOMS Outbound Trade Link Delete \(Tag: TRCOBLinkDelete\)](#)

TRADACOMS Outbound Trade Link (Tag: TRCOBLink)

Use this tag to add a new TRADACOMS Outbound Trade Link. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	From_TP_Or_AP	Yes		1	T or A
N/A	From_Partner_ID	Yes		35	
N/A	To_TP_Or_AP	Yes		1	T or A
N/A	To_Partner_ID	Yes		35	
Scheme	ControlNoScheme	No		1	0,1,2,3,4 Default: 0
Map	ControlNoMap	Yes, if ControlNoScheme is 2 (user defined)		255	
Reset (Control #)	ResetTL_Ind	No		1	T or F
STX Control Number	TLControlNoValue	Yes, only if ResetTL_Ind is T		14	must be a number

Notes:

1. Set **From_TP_Or_AP** to **T** to specify the **From** Partner as a Trading Partner or set to **A** to specify the **From** Partner as an Application Partner. When set to **T**, set **From_Partner_ID** to the **PartnerID** found in the TRADACOMS Trading Partner screens; otherwise set it to the **AppPartnerID** found in the TRADACOMS Application Partner screens.
2. Set **To_TP_Or_AP** to **T** to specify the **To** Partner as a Trading Partner or set to "A" to specify the **To** Partner as an Application Partner. When set to **T**, set **To_Partner_ID** to the **PartnerID** found in **TRCTradingPartners**; otherwise set it to the **AppPartnerID** found in **TRCAppPartners**.
3. Scheme defaults to "0" (Trade Link). Valid values are: 0=TradeLink; 1=Document; 2=User Defined; 3=none. A User Defined Scheme requires a Map Name in the next field, **ControlNoMap**.
4. True/False; reset STX Control #. Default: **F**
5. Only set this value if the **Reset** is set to **T** (True). Setting this field to any value when the **Reset** is **F** (false) will reject this link.

TRADACOMS Outbound Trade Link Document: (Tag: TRCOBTLDocs)

Use this tag to add a Document to a new TRADACOMS Outbound Trade Link. Tag must be nested within TRCOBLink. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Document Type	DocType	Yes	10		1

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
From Application Partner SDT/CDT	From_SDT_CDT	No	1	S or C	2
To Application Partner SDT/CDT	To_SDT_CDT	No	1	S or C	3
RSG Expected	RSGExpected	No	1	N, P, or C	4
RSG Version	RSGVersion	No	1	1-9	4
Get Mail Post Office Nickname	GetMailPO	Yes	3	valid Get PO	
Test (check box)	TestIndicator	No	1	T (True) or F (false) Default: F Set to T if including a Test Post Office	
Test Post Office Nickname	TestPutPO	Yes, if Test Indicator=T	3	valid Put Post Office	5
Production (check box)	ProdIndicator	No	1	T (True) or F (false). Default: T Set to T if including a Production Post Office	
Production Post Office Nickname	ProdPutPO	Yes, if Prod Indicator=T	3	valid Put Post Office	5
Generate VAT Report	GenerateVATReport	No	1	T (True) or F (false)	6
Reset (Control #)	ResetDoc_Ind	No	1	T or F	7
Document Control Number	DocControlNoValue	Yes, if Reset Doc_Ind is T	14	must be a positive whole number	8

Notes:

1. Document includes the version appended, for example: INVOIC9. This value must exist as a valid Document Type in the table **TRCDocTypes**, that are maintained in Standards Maintenance in Partner Manager.
2. **From_SDT_CDT** is used only if the From Partner is an Application Partner; it is not used when that Partner is a Trading Partner. It indicates that the **From** Partner appears in either the SDT Segment (set to **S**) or the CDT segment (set to **C**). This field defaults to **S** and must be the opposite value of the next field, **To_SDT_CDT**.
3. **To_SDT_CDT** is used only if the To Partner is an Application Partner; it is not used when that Partner is a Trading Partner. It indicates that the To Partner appears in either the SDT Segment (set to **S**) or the CDT segment (set to **C**). This field defaults to **C** and must be the opposite value of the previous field, **From_SDT_CDT**.
4. **RSG Expected** defaults to **N**(none) and is one of the following values: **N**=None; **P**=Present; **C**=Create. If set to **C** (Create) the next field, **RSGVersion**, can be set to an integer from 1 to 9. The **RSGVersion** will default to "2" if not specified and **RSG Expected** is **C**.
5. At least one of the Test/Prod Post Offices must be set (both cannot be blank).
6. **GenerateVATReport** can only be set if the Document Type is **CREDIT**, **INVOIC**, or **UTLBIL**, and will default to **True** if not specified for these 3 document types.
7. True/False; reset Document-Level Control Number. Default: F.
8. Only set this value if the **Reset** is set to **T** (True). Setting this field to any value when the **Reset** is **F** (false) will reject this link.

TRADACOMS Outbound Trade Link Change (Tag: TRCOBLinkChange)

Use this tag to change an existing TRADACOMS Outbound Trade Link. This tag is required to identify the Trade Link via the first four fields in the tag. The remaining fields need not be specified if your only changes are to the documents. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	From_TP_Or_AP	Yes	1	T or A	1
N/A	From_Partner_ID	Yes	35		1
N/A	To_TP_Or_AP	Yes	1	T or A	2
N/A	To_Partner_ID	Yes	35		2
Scheme	ControlNoScheme	No	1	0,1,2,3,4	3
Map	ControlNoMap	Yes, if ControlNo Scheme is 2 (user defined)	255		
Reset (Control #)	ResetTL_Ind	No	1	T or F	4
STX Control Number	TLControlNoValue	Yes, only if Reset TL_ Ind is T	14	must be a number	5

Notes:

1. Set **From_TP_Or_AP** to **T** to specify the **From** Partner as a Trading Partner or set to **A** to specify the **From** Partner as an Application Partner. When set to **T**, set **From_Partner_ID** to the **PartnerID** found in the TRADACOMS Trading Partner screens; otherwise set it to the **AppPartnerID** found in the TRADACOMS Application Partner screens.
2. Set **To_TP_Or_AP** to **T** to specify the To Partner as a Trading Partner or set to **A** to specify the To Partner as an Application Partner. When set to **T**, set **To_Partner_ID** to the **PartnerID** found in **TRCTradingPartners**; otherwise set it to the **AppPartnerID** found in **TRCApPartners**.
3. Valid values are: **0**=TradeLink; **1**=Document; **2**=User Defined; **3**=none. A User Defined Scheme requires a Map Name in the next field, **ControlNoMap**.
4. True/False; reset STX Control Number.
5. Only set this value if the **Reset** is set to **T** (True). Setting this field to any value when the **Reset** is **F** (false) will reject this link.

TRADACOMS Outbound Trade Link Document Add, Change, Delete (Tag: TRCOBTLDocsAddChangeDelete)

Use this tag to add, change, or delete a Document on an existing TRADACOMS Outbound Trade Link. Tag must be nested within **TRCOBLinkChange**. To add a Document, set the **AddFlag** to **Y**. To delete, set the **DeleteFlag** to **Y**. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
Document Type	DocType	Yes	10		1
From Application Partner SDT/CDT	From_SDT_CDT	No	1	S or C	2
To Application Partner SDT/CDT	To_SDT_CDT	No	1	S or C	3
RSG Expected	RSGExpected	No	1	N, P, or C	4
RSG Version	RSGVersion	No	1	1-9	4
Get Mail Post Office Nickname	GetMailPO	No	3	valid Get PO	
Test (check box)	TestIndicator	No	1	T (True) or F (false) or R (remove)	5
Test Post Office Nickname	TestPutPO	Yes, if TestIndicator=T	3	valid Put Post Office	5
Production (check box)	ProdIndicator	No	1	T (True) or F (false).	5
Production Post Office Nickname	ProdPutPO	Yes, if ProdIndicator=T	3	valid Put Post Office	5
Generate VAT Report	GenerateVATReport	No	1	T (True) or F (false)	6
Reset (Control #)	ResetDoc_Ind	No	1	T or F	7
Document Control Number	DocControlNoValue	Yes, only if ResetDoc_Ind is T	14	must be a positive whole number	8
N/A	AddFlag	No	1	Y/N	
N/A	DeleteFlag	No	1	Y/N	

Notes:

1. Document includes the version appended, for example: INVOIC9. This value must exist as a valid Document Type in the table **TRCDocTypes**, maintainable in Standards Maintenance in Partner Manager.
2. **From_SDT_CDT** is used only if the From Partner is an Application Partner; it is not used when that Partner is a Trading Partner. It indicates that the **From** Partner appears in either the SDT Segment (set to **S**) or the CDT segment (set to **C**). This field defaults to **S** and must be the opposite value of the next field, **To_SDT_CDT**.
3. **To_SDT_CDT** is used only if the To Partner is an Application Partner; it is not used when that Partner is a Trading Partner. It indicates that the To Partner appears in either the SDT Segment (set to **S**) or the CDT segment (set to **C**). This field defaults to **C** and must be the opposite value of the previous field, **From_SDT_CDT**.
4. **RSG Expected** valid values are: N=None; P=Present; C=Create. If set to **C** (Create) the next field, **RSGVersion**, can be set to an integer from 1 to 9. The **RSVersion** will default to **2** if not specified and **RSG Expected** is **C**.
5. After all changes are applied, at least one of the Test/Prod Post Offices must be set (both cannot be blank). If you want to remove an existing Test or Production Post Office, set test Test/Production Indicator field to **R**. For example, this is available in the event you want to change an existing group from Test only to Production Only: set the **TestIndicator** to **R**, which will remove the Test Post Office, and set the **ProductionIndicator** to **T** and specify the new Production Post Office in **ProdPutPO**. When setting this field to **R**, you must specify the other (test/production) Post Office if one does not already exist on the group.
6. **GenerateVATReport** can only be set if the Document Type is **CREDIT**, **INVOIC**, or **UTLBIL**.
7. True/False; reset Document-Level Control #. Default: **F**
8. Only set this value if the **Reset** is set to **T** (True). Setting this field to any value when the **Reset** is **F** (False) will reject this link.

TRADACOMS Outbound Trade Link Delete (Tag: TRCOBLinkDelete)

Use this tag to delete an existing TRADACOMS Outbound Trade Link. This tag requires the fields **From_TP_Or_AP**, **From_Partner_ID**, **To_TP_Or_AP**, and **To_Partner_ID** to identify the link to delete. A warning report (or error if **Abort Run** is selected) is issued if Trade Link does not exist. The tag and field descriptions are:

Field Label	FieldName/Tag	Req'd	Max. Len.	Validation	Notes
N/A	From_TP_Or_AP	Yes	1	T or A	1
N/A	From_Partner_ID	Yes	35		1
N/A	To_TP_Or_AP	Yes	1	T or A	2
N/A	To_Partner_ID	Yes	35		2

Notes:

1. Set **From_TP_Or_AP** to **T** to specify the **From** Partner as a Trading Partner or set to **A** to specify the **From** Partner as an Application Partner. When set to "T", set **From_Partner_ID** to the **PartnerID** found in the TRADACOMS Trading Partner screens; otherwise set it to the **AppPartnerID** found in the TRADACOMS Application Partner screens.
2. Set **To_TP_Or_AP** to **T** to specify the To Partner as a Trading Partner or set to "A" to specify the To Partner as an Application Partner. When set to **T**, set **To_Partner_ID** to the **PartnerID** found in **TRCTradingPartners**; otherwise set it to the **AppPartnerID** found in **TRCAppPartners**.

Setting up the tutorial

This chapter describes the tutorial setup. These requirements must be met before you continue with the tutorial.

- [Software requirements](#)
- [Using Partner Manager](#)

Software requirements

Ensure that the following are installed on your PC:

----- IBM WebSphere Transformation Extender with Launcher

_____ IBM WebSphere Transformation Extender with Launcher Windows

_____ IBM WebSphere Transformation Extender Trading Manager

_____ Microsoft Access

_____ Tutorial exercise files located in :

C:\install_dir\<tmgr_vn.n\tutorial

(where *install_dir* is the Trading Manager installation directory and *n.n* is the Trading Manager version number)

The tutorial contains the following folders under:

C:\install_dir\<tmgr_vn.n\tutorial\exercises:

- **data** contains text (.txt), XML or database files
 - **maps** contains IBM WebSphere Transformation Extender map source (.mms) and map executable (.mmc) files
 - **trees** contains IBM WebSphere Transformation Extender type tree (.mtt) files
 - **myfiles** is the student working folder
- You need to create the directory structure (folders) for **myfiles**. This directory structure is used for the Post Offices in Trading Manager. To do this, in the exercises folder, create the folder **myfiles**, then under **myfiles**, create the following structure:
- /in/app850in
 - /out/app810out
 - /out/externalapp

Using Partner Manager

- [Tutorial exercise 1: defining the Partner Manager database](#)

 - [Tutorial exercise 5: creating trade link type trees](#)
-

Tutorial exercise 1: defining the Partner Manager database

About this task

Trading Manager uses a relational database to store information about trading partners, routing instructions, access privileges, document tracking and trading relationships. A sample Microsoft Access database is included with the Partner Manager installation.

In this exercise you will create an ODBC DataSource for the Trading Manager sample database and define the database in Partner Manager.

The following file is required for this exercise:

tmgrnn.mdb

This is the sample Trading Manager database. You will find this file in: **C:\install_dir\<tmgr_vn.n\pmgr**

Note: Throughout this tutorial *install_dir*, is used to refer to the current install directory of your IBM WebSphere Transformation Extender software and *n.n* refers to the current version of Trading Manager.

- [Task: define the ODBC data source](#)
 - [Task: define the database in Partner Manager](#)
 - [Task: define server directories in Partner Manager](#)
-

Task: define the ODBC data source

About this task

Before you can define the sample database in Partner Manager, you must first define a System Data Source Name (DSN) as described in the following procedures:

Procedure

1. From the Windows Start menu, select Settings > Control Panel > Administrative Tools > Data Sources ODBC.
The ODBC Data Source Administrator dialog opens.
2. Select the System DSN tab, and then click the **Add** button.
The Create New Data Source dialog opens.
3. Select Microsoft Access Driver (*.mdb) from the list box, and then click **Finish**.
The ODBC Microsoft Access Setup dialog opens.
4. In the **Data Source Name** field, enter the following information: **TradingManagerTutorial**

5. Click Select.
The Select Database dialog opens.
6. Navigate to C:\install_dir\<tmgr_vn.n\pmgr and select the tmgrnn.mdb file.
7. Click OK.
The Select Database dialog closes. The new entry, **TradingManagerTutorial**, is now displayed in the ODBC Data Source Administration dialog in the **System Data Sources** list box.
8. Click OK.
The **ODBC Data Source Administrator** dialog closes and the System Data Source Name is defined.

Task: define the database in Partner Manager

About this task

Partner Manager **Utilities** include an option for defining multiple Trading Manager databases such as Test, Development and Production.

To define a Trading Manager database:

Procedure

1. Start Partner Manager. From the Start menu, select Programs > IBM WebSphere Transformation Extender n.n > Trading Manager > Partner Manager.
2. Click on the **Utilities** icon in the Partner Manager tool bar.
3. On the **Utilities** navigator, click Database Settings. The Partner Manager Database Selection dialog appears.
4. Select Microsoft Access from **Database Vendor** drop-down list as shown below.
5. Select TradingManagerTutorial from the DSN drop-down menu.
6. Click OK.
7. Partner Manager will restart to activate the new database.

Task: define server directories in Partner Manager

Server directories direct the maps to the physical files. In Partner Manager, select **Utilities** and then **Server Directory Configuration**. For this tutorial, we will use the local file system for our directories. Make certain that the following settings are entered:

Access Method: Mapped Drive
Archive: C:\install_dir\<tmgr_vn.n\mmgr\archive
Resend: C:\install_dir\<tmgr_vn.n\mmgr\resend
Share: C:\install_dir\<tmgr_vn.n\mmgr\share

Use the **Test Configuration** button to check the configuration. If it is correct, save this data

Tutorial exercise 2: defining trading partners

About this task

In this exercise you will demonstrate your understanding of the Address Book by defining an internal and external Trading Partner Address Book entry and corresponding Application Partners. You will:

- View the file **edi850inmi.edi** and verify that the information for the Internal and External Trading Partners matches the data tables shown in the tasks.
- Define an Internal Trading Partner and Application Partner.
- Define an External Trading Partner and Application Partner.

The **edi850inmi.edi** file is required for this exercise. This test data file is located in:

C:\install_dir\tmgr_vn.n\tutorial\exercises\data

More information about this file is provided in the following section.

- [Task: analyze the EDI file](#)
- [Task: define an internal trading partner](#)
- [Task: define an external trading partner](#)
- [Task: define an administrative contact for an external trading partner](#)

Task: analyze the EDI file

About this task

Using a text editor such as Windows Notepad, view the file **edi850inmi.edi** and confirm internal partner IDs, qualifiers, ISA and GS addresses, interchange control version ID, element separators (*) and terminators (NL) required for setup.

Task: define an internal trading partner

Procedure

1. Open Partner Manager.
2. From the Address Book navigator, select Internal > X12.
The Address Book for Internal X12 window opens.
3. Click Add.
The **Add X12 Trading/Application Partner** window opens.
4. Refer to the following table to enter information for My Internal Company into the **Add X12 Trading/Application Partner In Internal Folder X12** window.

In Field...	Enter...
Trading Partner tab:	
Trading Partner Name	My Internal Company
ISA Address	12-phone (telephone companies)
Interchange ID	9395100193
ISA Options tab:	
Interchange Control Version ID	00306 – Draft Standards for Trial Use Approved for Publication by ASC X12 Procedures Review board through oc
Interchange Standards ID	U – U.S. EDI Community of ASC X12, TDCC, and UCS
Separators Box	
Element	2A
Sub Element	3E >
Segment Terminator	OD OA CR/LF
Application Partner tab:	
Application Partner Name	Sales
GS Address	3959910033
Alias Name	
User Defined 1	
User Defined 2	
- For values not shown, accept the default values.
5. Click Save. The Address Book will display the entry.
6. Close the **Address Book** window.

Task: define an external trading partner

Procedure

1. From the Address Book navigator, select External > X12.
The Address Book for External X12 window opens.
2. Click the **Add** button.
The **Add X12 Trading/Application Partner** window opens.
3. Refer to the following table to enter information for Johnson Office Supplies into the **Add X12 Trading/Application Partner in External Folder X12** window.
Note: For values not shown, accept the default values.

In Field...	Enter...
Trading Partner tab:	
Trading Partner Name	Johnson Office Supplies
ISA Address	12 – phone (telephone companies)
Interchange ID	8473179000
ISA Options tab:	
Interchange Control Version ID	00306 – Draft Standards for Trial Use Approved for Publication by ASC X12 Procedures Review Board through oc
Interchange Standards ID	U – U.S. EDI Community of ASC X12, TDCC, and UCS
Separators Box	
Element	2A*
Sub Element	3E >
Segment Terminator	OD OA CR/LF
Application Partner tab:	
Application Partner Name	Purchasing
GS Address	006250740
Alias Name	
User Defined 1	
User Defined 2	
4. Click Save.
The information that you have entered is displayed in the Address Book for External X12 window.

Task: define an administrative contact for an external trading partner

About this task

The definition for the external trading partner, Johnson Office Supplies, needs to include some contact information.

Procedure

1. In the Address Book for External X12 window, select Johnson Office Supplies.
2. Click **Contacts**. The Contacts for Johnson Office Supplies window is displayed.
3. Click Add.
The Add a Contact for Johnson Office Supplies window opens.
4. Refer to the following table to add contact information into the Add A Contact for Johnson Office Supplies window.

In Field...	Enter...
Last Name	Jordan
First Name	William
Phone	555-555-1000
5. Click Save.
The contact information is now displayed in the Contacts for Johnson Office Supplies window.
6. Close the Contacts window and the **Address Book for X12 External** window.

Tutorial exercise 3: defining post offices

About this task

In this exercise you will demonstrate your understanding of Post Offices by defining several **Get** and **Put** File Post Offices. You will:

- Define the File Get Post Office where EDI data will be retrieved for processing.
- Define the File Put Post Office where EDI data will be routed for processing by an external application.
- Define the File Put Post Office where Functional Acknowledgments (997) will be routed for transmission.
- [Task: add a file get post office](#)
- [Task: add a file put post office](#)
- [Task: add another put post office](#)

Task: add a file get post office

Procedure

1. Click Post Offices from Partner Manager toolbar.
2. Select **All Post Offices**.
3. Click Add.
The Add Post Office window opens.
4. Enter the information in the following table into the fields in the **Add Post Office** (Get Post Office) window:

In field...	Enter...
Name	EDI data ready for processing
Nickname	EDI
Adapter Type	File
Get/Put indicator	Get Post Office
Directory	install_dir\tmgr_vn.n\mmgr\mail
5. Click Save to save the information.
The **Add Post Office** window closes and the information that you entered is displayed in the All Post Offices window as shown:
6. Close the All Post Offices window.

Task: add a file put post office

Procedure

1. Click Post Offices in the Partner Manager toolbar.
2. Select All Post Offices.
3. Click Add.
The Add Post Office window opens.

4. Enter the information in the following table into the fields in the **Add Post Office** (Put Post Office) window:

In Field...	Enter...
Name	EDI data ready for App Map
Nickname	APP
Adapter Type	File
Get/Put Indicator	Put Post Office
Directory	install_dir\mgr_vn.n\tutorial\exercises\myfiles\in\app850in

5. **Save** your changes.

The Put Post Office will be listed in the **All Post Offices** list box.

Task: add another put post office

Procedure

1. Click Post Offices in the Partner Manager toolbar.

2. Select All Post Offices.

3. Click Add.

The Add Post Office window opens.

4. Enter the information in the following table into the fields in the **Add Post Office** (Put Post Office) window:

In Field...	Enter...
Name	externalapp data ready to send
Nickname	XAP
Adapter Type	File
Get/Put Indicator	Put Post Office
Directory	install_dir\mgr_vn.n\tutorial\exercises\myfiles\out\externalapp

5. **Save** your changes.

The Put Post Office will be listed in the **All Post Offices** list box.

Tutorial exercise 4: defining inbound trade links

About this task

In this exercise you will learn how to define an Inbound Trade Link.

In the following tasks, the External Trading Partner, Johnson Office Supplies, will be sending ANSI 850 Purchase Orders to an Internal Trading Partner called "My Internal Company". Johnson Office Supplies requires that the Internal Trading Partner, My Internal Company, send them a 997 Functional Acknowledgement.

- [Task: define the trade link](#)

Task: define the trade link

Procedure

1. Click Trade Links in the Partner Manager tool bar.

2. Select Inbound.

The X12 Inbound Trade Links window opens.

3. In the X12 Inbound Trade Links window click Add Link. This will open the **X12 Inbound Trade Links Add Wizard**.

4. Select the External Trading Partner (the 'from' partner) by clicking **Find All**. This will open up the X12 Folder Look up In Dialog.

5. Choose the X12 Johnson Office Supplies Purchasing line and click Select.

6. Click Next. Select the Internal Trading Partner (the 'to' partner) by clicking **Find All**. This will open up the **X12 Partner Lookup in Folder: Internal** dialog.

7. Choose the X12 My Internal Company Sales line and click Select.

8. Click Next. Select the Get Post Office for the trade link from the drop down list.

9. The EDI data ready for Processing should be the only available selection. Click Next.

10. Click Finish. The **X12 Trade Link: Add Application** dialog will open. Enter 3060 for the **Version**, and select PO Purchase Order (850) for the **Functional ID**.

11. Click OK. The X12 Inbound Trade Links dialog will open. Use the table below to update:

In Field...	Enter or confirm...
Trade Link:	
From Trading Partner	Johnson Trading Supplies
To Trading Partner	My Internal Company
Get Post Office	EDI data ready for Processing
Post Offices/Routing:	
Test and/or Production	Enable Test Disable Production
Test Put Post Office	EDI data ready for App Map

In Field...	Enter or confirm...
Acknowledgments / Validate By tab:	
Ack Level	Transaction Set Level
997 Version	3060
Validate By	Transaction Set

12. Click Save.

The Automatic Outbound Acknowledgement Creation for Version 3060 dialog will open.

13. Select **Edi data ready for processing** from the **Get Post Office** drop down list, and select **externalapp data ready to send** from the **Test Put Post Office** drop down list. Leave the Production post office blank. Click **Create**.

14. Close the X12 Inbound Trade Links window.

Tutorial exercise 5: creating trade link type trees

About this task

In this exercise you will run the EDI Wizard to generate type trees based on Trade Link information.

These type trees will be used by the Message Manager system to validate data against the ANSI X12 standards.

- [Task: run the EDI wizard](#)
- [Using message manager](#)

Task: run the EDI wizard

Procedure

1. Click EDI Wizard on the from the Partner Manager menu bar. The only menu option available is **EDI Wizard**.
The **EDI Wizard** opens.

2. Refer to the following table to specify the paths for the IBM WebSphere Transformation Extender Design Studio installation and type tree locations:
Remember that *install_dir* refers to the current install directory of your IBM WebSphere Transformation Extender software and *n.n* refers to the current version of Trading Manager.

In Field...	Select...
Directory location of Transformation Extender software	<i>install_dir</i>
Directory location of EDI type trees	<i>install_dir\tmgr_vn.n\tutorial\exercises\trees</i>
Directory for your new message manager trees	<i>install_dir\tmgr_vn.n\mmgr</i>

3. Click Next.
The wizard will warn you that you already have an **x12mail.mtt** tree. This is the default tree the installation provides. You will also receive a warning about the **edfmail.mtt** tree, the default tree for EDIFACT, which is not used in this tutorial.
4. Click OK to update the tree.
The wizard creates the **x12mail.mtt** from your existing X12 trees. Upon successful creation, you will see the message **Your customized type tree(s) have been created successfully**.
5. Click Done, and close **Partner Manager**.

Using message manager

This chapter contains the following tutorials that are related to the use of Message Manager:

- ["Tutorial Exercise 6: Deploying Message Manager"](#)
- ["Tutorial Exercise 7: Configuring System Resources and the Launcher"](#)
- ["Tutorial exercise 6: deploying message manager"](#)
- ["Tutorial exercise 7: configuring system resources and the Launcher"](#)

Tutorial exercise 6: deploying message manager

About this task

In this exercise you will demonstrate your understanding of the deployment process by deploying the Message Manager system of maps.

- Identify the Trading Manager database
- Deploy the **Message Manager** system maps.
- Deploy the **Runmaps** system of maps.

- [Task: identify the trading manager database](#)
 - [Task: deploy the message manager system](#)
 - [Task: deploy the RunMaps system](#)
-

Task: identify the trading manager database

Procedure

1. Open the **update.mdq** file, located in the *install_dir\<tmgr_vn.n\mmgr* directory, in the IBM WebSphere Transformation Extender Database Interface Designer.
 2. In the navigator, right-click on **TmgrDB** and select Edit.
The Database Definition dialog opens.
 3. Expand the Adapter setting.
 4. Select ODBC as the Adapter **Type** and **Microsoft Windows** as the **Platform**.
Note: It is recommended that you select a native adapter type where possible.
 5. Under the **Data Source** options, select TradingManagerTutorial for both **Database Interface Designer** and **Runtime** databases.
 6. Click OK.
 7. Verify the connection by right-clicking on the database in the Database Interface Designer Navigator and selecting Generate Type Tree from Tables.
Note: If a list of tables is displayed, the database connection was successfully established.
 8. Click Close, and then **Save** in the Database Interface Designer.
-

Task: deploy the message manager system

Before you begin

Note: If you have multiple versions of WebSphere Transformation Extender installed, check the "About" box (using Help...About) in the Integration Flow Designer before continuing with this procedure. The major and minor version displayed (for example, 8.2) must match *exactly* the version you are using for this tutorial. If the version does not match, run the Integration Flow Designer manually and select **msg_mgr.msd** in the *<tmgr_vn.n>* directory.

Procedure

1. Start Message Manager by going to the Start Menu and selecting IBM Transformation Extender n.n...>Trading Manager...>Message Manager.
 2. In the Navigator click the Composition tab to expand **msg_mgr**.
 3. Select Message Manager system in the Navigator, then from the menu bar, select System...>Deploy...>Definitions. The **Define Deploy Scripts for Message Manager** dialog opens.
 4. Ensure that **DeployMessageManager** is selected and then select Generate and Transfer Launcher Control File. Make certain that **Build and Transfer Maps** is also selected.
 5. Click Details.
 6. In the Launcher control file path on server dialog box, verify that the **msg_mrg.msl** will be saved in IBM Transformation Extender Design Studio \systems subdirectory.
 7. Run the **DeployMessageManager** deploy script by selecting Message Manager system in the Navigator, then from the menu bar, select System...>Deploy...>Deploy_MRN_Update.
 8. Verify that the system was deployed successfully.
Note: When you deploy the system, the maps will have warnings. This is expected behavior.
-

Task: deploy the RunMaps system

Procedure

1. Select RunMaps system and run the **BuildRunMaps** deploy script.
 2. Verify that the system was deployed successfully.
 3. Close **msg_mgr.msd** file and save the changes.
-

Tutorial exercise 7: configuring system resources and the Launcher

About this task

In this exercise you will demonstrate your understanding of the Resource Registry and Launcher tools by configuring the Resource Registry to work with the Message Manager system and monitoring process activity with the Launcher Monitoring tools.

In this exercise you will:

Procedure

1. Configure the Resource Registry to create the **Resource.mrc** file used by Message Manager to define the Message Manager system to the Resource Registry.
 2. Configure Launcher Administration and Management Console and start Launcher Service.
-

3. Open Launcher Service Monitor.
 4. Drop test file to trigger the system to run.
 5. Verify data validated and routed in Snapshot Viewer.
 6. Record any errors, your solutions and check corrections
- [Task: create resource configuration files](#)
 - [Task: configure the IBM WebSphere Transformation Extender with Launcher](#)
 - [Task: define the IBM WebSphere Transformation Extender with Launcher in the management Console](#)
 - [Task: run the IBM WebSphere Transformation Extender with Launcher](#)
 - [Task: drop the test file](#)
 - [Task: verify that data was validated and routed in Snapshot Viewer](#)
 - [Task: record any errors and your solutions and check corrections](#)
 - [Integrating external systems](#)
-

Task: create resource configuration files

Procedure

1. Start the Resource Registry from the IBM WebSphere Transformation Extender Start menu link. This may be on the **Launcher** submenu, depending upon how the product was installed.
 2. Right-click on **Configuration Files** and select New
 3. Save new Resource Configuration file as **Resource.mrc** under the **C:\install_dir\<tmgr_vn.n\mmgr** directory.
 4. Expand **Resource**.
 5. Right-click on **Launcher** then select Add.
 6. In the **Add New System** dialog, click the browse button and select the **Msg_Mgr.msl** file located in the deploy directory **C:\install_dir\systems**
 7. Click Select then click **OK**. Under Launcher you should have a new entry named **msg_mgr**.
 8. Right-click on **Msg_Mgr** and select Edit. Click Add in the **Edit Resources** dialog.
 9. Browse and select the **mmgr.mrn** file located in the **C:\install_dir\<tmgr_v>n.n\mmgr** directory and click Select, then click OK.
 10. Right-click on Command Server and select Edit.
 11. Add the **mmgr.mrn** file to the Command Server.
 12. Using the same technique you used for changing the Command Server resource, change the **Global** resource to **mmgr.mrn**.
 13. Select File->Exit and click **Yes** to save changes.
-

Task: configure the IBM WebSphere Transformation Extender with Launcher

Procedure

1. The Launcher Administration application defines the Launcher startup parameters, valid deployment directories and access privileges. Access the Launcher Administration by selecting Launcher Administration from the IBM WebSphere Transformation Extender Start menu link. This may be on the Launcher submenu, depending upon how the product was installed.
 2. On the General tab, disable **Automatic Startup** to allow the system to be started manually in the Management Console. Make sure that **Separate Launcher Process** is unchecked. Checking this box will cause the tutorial to fail.
 3. Identify the Resource Configuration file for the Launcher by selecting Resource.mrc under **C:\install_dir\tmgr_vn.n\mmgr** as the **Resource Configuration File**.
 4. On the Deployment Directories tab, ensure that **C:\install_dir\systems** (where you deployed the Message Manager system) is specified as a deployment directory.
 5. Create an account that will allow you to monitor and control the Launcher in the **Access** tab by clicking **Add** then entering a **User Name** (your name), **Login Name** (your initials), and **Password** (*letmein*)
 6. Change the **Access Rights** from **Revoke** to **Grant** for all actions.
 7. Click OK to exit out of the **Launcher Administration** tool.
-

Task: define the IBM WebSphere Transformation Extender with Launcher in the management Console

About this task

The IBM WebSphere Transformation Extender Management Console controls and monitors Launcher systems.

Procedure

1. Start the Management Console by selecting Management Console from the IBM WebSphere Transformation Extender Start menu link or the IBM WebSphere Transformation Extender Design Studio Start menu link. This may be on the **Launcher** submenu, depending upon how the product was installed.
2. Select Launcher >New.
3. Enter a server **Name of MessageManager**.
4. Enter the Launcher **Host Name of localhost**.
5. Enter **User Name** (your initials) and **Password** (*letmein*).
6. Click OK. The **MessageManager** system will now appear in the console window. Leave the Management Console open and continue.

Task: run the IBM WebSphere Transformation Extender with Launcher

Procedure

1. Start the Launcher service in the Windows **Services**, which can be accessed through the Windows Control Panel > Administrative Tools Control Panel.
2. The Launcher Monitor will allow you to monitor the Message Manager system graphically. Access the Launcher Monitor by selecting by selecting Launcher Monitor from the IBM WebSphere Transformation Extender Start menu link or the IBM WebSphere Transformation Extender Design Studio Start menu link.
3. Select Options > Select Launcher and click Add to add a new server.
4. Enter the Launcher Name as **MessageManager**.
5. Enter User Login (**your initials**) and Password (**letmein**).
6. Enter **LocalHost** for **Server**.
7. Click Connect.
8. Select the Message Manager system then click OK and click OK again.
9. In the **Management Console**, right-click the MessageManager Launcher and select Connect.
10. Right-click CompoundSystem and select Start.
11. The Export map will run as soon as the Launcher is started. Check the Management Console to verify it completed successfully before proceeding to the next step. There will be 2 completed maps under History Successes, and the History Total will also be 2.
12. The first time that you run the event server, you may receive a History Function Failure. This is because the export map is looking for a non-existent backup file in the mmgr\share directory. The second and subsequent times the event server is launched, this error will not repeat. To test this, stop the event server and restart it by right clicking on the **CompoundSystem** icon, selecting Stop, then right click again and select Start.
Note: You may see a history failure: **failed at run function** for the argument **checkhipaafiles** in the export component. This failure can be safely ignored if you are not planning to run Health Insurance Portability and Accountability Act (HIPAA) data through the system. If you plan to use HIPAA data, search the Pack for HIPAA EDI documentation for the file **hipaa_x12_type_6_value.dat** for instructions on how to add this support.

Task: drop the test file

Procedure

1. Copy the file **edi850inmi.edi**, located in:
C:\install_dir\tmgr_vn.n\tutorial\exercises\data,
to:
C:\install_dir\tmgr_vn.n\mmgr\mail
The appearance of this file should trigger the system to start.
Note: This file is automatically deleted a few seconds after you copy the file. This is done by Message Manager, indicating that the file was processed.
2. Click the **Snapshot** button in the **Launcher Monitor** as the activity begins to create a snapshot (.mss file).

Task: verify that data was validated and routed in Snapshot Viewer

About this task

The IBM WebSphere Transformation Extender Snapshot Viewer allows you to view the snapshots of Launcher activity taken in the Launcher Monitor. Snapshots are saved in the IBM WebSphere Transformation Extender install directory as **.mss** file.

Procedure

1. Start the Snapshot Viewer, by selecting by selecting Snapshot Viewer from the IBM WebSphere Transformation Extender with Launcher Start menu link or the IBM WebSphere Transformation Extender Design Studio Start menu link
2. The snapshot file name is the date and time the snapshot was taken. Open the snapshot you just created.
3. Right-click on the map time lines to view the detailed processing information.

Task: record any errors and your solutions and check corrections

About this task

A validated 850 PO and 997 Ack should appear in the Put Post Office locations you specified in the Partner Manager exercise.

Procedure

1. If necessary, make any corrections and re-run the system until it completes successfully.
2. When successful, delete *.app file from **Put Directory** location of **C:\install_dir\tmgr_vn.n\tutorial\exercises\myfiles\In\app850in**.

Integrating external systems

This chapter contains the following tutorials that are related to integrating external systems:

- ["Tutorial Exercise 8: Deploying an Inbound Application System"](#)
 - ["Tutorial Exercise 9: Deploying an Outbound Application System"](#)
 - [Tutorial exercise 8: deploying an inbound application system](#)
 - [Tutorial exercise 9: deploying an outbound application system](#)
-

Tutorial exercise 8: deploying an inbound application system

About this task

Your company (My Internal Company) is using Trading Manager and all its components to begin e-commerce activity with an additional trading partner Acme Corp. Follow the exercises to setup and begin this e-commerce activity with this new Partner.

You have already set up My Internal Company as the internal X12 trading partner. All you need to do is set up Acme Corp as an X12 external trading partner.

To your test database, Acme Corp will begin sending purchase orders (850). You will also need to define an AppMap system to handle processing of the Purchase Orders. The AppMap **EDI850IN** is provided.

In this exercise you will:

- Setup Acme Corp as a new trading partner in Partner Manager
 - Deploy Message Manager and an inbound application system (Purchase Order)
 - Deploy outbound application system (Invoice)
 - Modify the system trigger
 - Deploy and test the system
 - [Assumptions](#)
 - [Task: Define a new external trading partner](#)
 - [Task: define a get post office](#)
 - [Task: define a trade link and select acknowledgement level](#)
 - [Task: define an application subsystem](#)
 - [Task: restart the Launcher and run the system](#)
-

Assumptions

About this task

It should be noted that **PO850mi.DAT** is an input data file located in the following directory :

C:\install_dir\tmgr_vn.n\tutorial\exercises\data

The following files are required to complete this exercise.

- **EDI850IN.mms**
An application map source file located in the following directory :
C:\install_dir\tmgr_vn.n\tutorial\exercises\maps
 - **App810ot.mms**
A source map used to convert data for an outbound invoice is located in the following directory :
C:\install_dir\tmgr_vn.n\tutorial\exercises\maps
-

Task: Define a new external trading partner

Procedure

1. Using a text editor such as Microsoft Notepad open the data file **PO850mi.DAT** to confirm partner IDs, element separators(*) and terminators (NL) required for the setup.
2. Review the information in the following Trading Partner Information table about the External Trading Partner, Acme Corp.
3. Referring to the following table, define an External Trading Partner Address Book entry.

In Field...	Enter...
Trading Partner Tab:	
Trading Partner Name:	ACME Corp.
ISA Address:	ZZ - Mutually Defined
Interchange ID:	ACMECORP
ISA Options Tab:	
Interchange Control Version ID:	00306 - Draft Standards for Trial Use Approved for Publication by ASC X12 Procedures Review Board through oc
Interchange Standards ID:	U - U.S. EDI Community of ASC X12, TDCC, and UCS
Separators Box	
Element	2A*

In Field...	Enter...
Sub Element	3E >
Segment Terminator	OD OA CR/LF
Application Partner tab:	
Application Partner Name	PURCHASING
GS Address	ACMECORP

Task: define a get post office

About this task

Referring to the following information, define a new GET Post Office.

Add Post Office	(Get Post Office)
Name:	PO data ready for Processing
Nickname	DAT
Adapter Type	File
Get /Put Indicator	<tmgr directory>\mmgr\mail

Task: define a trade link and select acknowledgement level

About this task

Referring to the information below, define an **Inbound** Trade Link to "**My Internal Company**" from "**ACME Corp**".

Add Trade Link	(Inbound)
From Trading/Application Partner:	ACME Corp.
To Trading/Application Partner:	My Internal Company
Get Post Office:	PO data ready for Processing
Version:	3060
Functional ID:	PO Purchase Order (850)
Post Offices/Routing tab:	
Test/Production Indicators:	Enable Test; Disable Production
Test Post Office	EDI data ready for App Map
Acknowledgements/Validate By Tab:	
Ack Level:	Transaction Set
Validate By:	Transaction Set
997 Version:	3060
	Save the link, then in Automatic Outbound Assistant
Put Post Office (FA)	externalapp data ready to send
Get Post Office (FA)	PO data ready for processing

Task: define an application subsystem

About this task

In this task you will define an application subsystem to take the inbound purchase order and transform it so it can be processed by your internal purchasing application.

Use the **EDI850IN.mms** map to convert the data in the subsystem. You want this map to execute based on the arrival of data in the Put Post Office directory that you defined for Acme Corp. with an extension of ***.app**

Procedure

1. Start the Integration Flow Designer and open a new system definition file.
2. Save the new system definition file in **C:\install_dir\tmgr_vn.n\tutorial\exercises\myfiles** as **AppMap**.
3. Rename **System1** to **Inbound**.
4. Add the map in the **EDI850IN.mms** source map to the Inbound system.
5. Right click on the **EDI850IN** map in the Inbound system and select **Edit Launcher Settings** to set the input trigger and override the source and destination file paths as follows:
 - Input card
Source Event is On
Source file: **C:\install_dir\tmgr_vn.n\tutorial\exercises\myfiles\in\app850in*.app**
 - Output card #1
Target file: **C:\install_dir\tutorial\exercises\myfiles\in\app850in*.ord**

- Output card #2
Target file: **C:\install_dir\tmgr_vn.n\tutorial\exercises\myfiles\in\app850in*.lin**
6. Change the from the Server drop-down list to Local Server.
 7. Create a deploy script named as Inbound with **C:\install_dir\systems** directory as the deploy directory.
Note: Select option Build and Transfer Maps as well.
 8. Deploy the Inbound system.
 9. Save the changes to the system definition file.
 10. Verify that all ***.app** files were deleted from the directory:

Results

C:\install_dir\tmgr_vn.n\tutorial\exercises\MyFiles\In\app850in

Task: restart the Launcher and run the system

Procedure

1. In the Management Console, stop the CompoundSystem.
2. Right-click on MessageManager and select Disconnect.
3. Stop then start the Launcher service.
4. Start the Launcher Monitor and select the Launcher.
5. Open the Management Console and connect to the Launcher (configured in a previous exercise).
6. Start the CompoundSystem.
7. Using Windows Explorer, copy the data file **PO850mi.DAT** in **C:\install_dir\tmgr_vn.n\tutorial\exercises\Data** to the **C:\install_dir\tmgr\mmgr\mail** directory.
This file is the trigger for the **Message Manager** system
8. Take a snapshot of the system in the Launcher Monitor and verify the maps completed successfully.
A validated 850 PO and 997 Ack should appear in the Put Post Office locations:
C:\install_dir\tmgr_vn.n\tutorial\exercises\MyFiles\In\app850in*.app and **C:\install_dir\tmgr_vn.n\tutorial\exercises\MyFiles\Out\externalapp*.xap**
Note: You will also see **lin** and **ord** files created in the **app850in** directory. These were created by the application map.
9. Upon successful completion delete all files under:
C:\install_dir\tmgr_vn.n\tutorial\exercises\MyFiles\In\App850in\.
10. In the Management Console, stop the **CompoundSystem** and disconnect from **MessageManager**.
11. Stop the Launcher service.

Tutorial exercise 9: deploying an outbound application system

About this task

Now that the inbound application system is completed and tested, you must deploy an outbound application system that takes the inbound Purchase Order (850) created in the Message Manager exercise and formats an outbound Invoice (810). The system will be executed based on triggers.

Use the **App810ot.mms** map for your outbound system.

In this exercise you will:

- Use Partner Manager to:
 - Define a new application for My Internal Company and Acme Corp
 - Define a **PUT Post Office**
 - Define an outbound **TradeLink**
- Use the Integration Flow Designer to:
 - Define an outbound application system
 - Define wild card input triggers and wild card output file names
 - Deploy the outbound system
- Use the IBM WebSphere Transformation Extender to:
 - Run the system with the Launcher
 - Monitor the system using the Management Console and Launcher Monitor
- **Files for this exercise:**
- [**Task: define the application partner**](#)
- [**Task: define a post office for outgoing invoice**](#)
- [**Task: define a new trade link for the outgoing 810**](#)
- [**Task: run EDI type tree wizard**](#)
- [**Task: deploy message manager system and RunMaps system**](#)
- [**Task: define new application map in the AppMap system**](#)
- [**Task: start the Launcher and monitor the system**](#)
- [**Partner Manager monitoring**](#)
- [**Trading Manager maintenance**](#)

Files for this exercise:

About this task

- **PO850mi.dat**
Data file located in **C:\install_dir\tmgr_vn.n\tutorial\exercises\data**
 - **App810ot.mms**
Map source file located in **C:\install_dir\tmgr_vn.n\tutorial\exercises\maps**
 - **EDI type trees** (trimmed for class)
Type trees required by EDI Wizard located in the **C:\install_dir\tmgr_vn.n\tutorial\exercises\trees**
 - **itemxref.txt**
Input file for **App810ot.mms** located in **C:\install_dir\tmgr_vn.n\tutorial\exercises\data**
 - **profile2.txt**
Input file for **App810ot.mms** located in **C:\install_dir\tmgr_vn.n\tutorial\exercises\data**
-

Task: define the application partner

Procedure

1. For internal Trading Partner My Internal Company enter a new Application Partner as follows:
 2. **Application Partner Name:** Invoice
 3. **GS Address:** 3959910032
 4. For external Trading Partner Acme Corp enter a new application Partner as follows:
 5. **Application Partner Name:** Invoice
 6. **GS Address:** ACMECO
-

Task: define a post office for outgoing invoice

About this task

Referring to the following information, define a new **PUT Post Office**.

- **PO Name:** Invoices ready to send
 - **PO Nickname:** INV
 - **Adapter Type:** File
 - **PO Path** **C:\install_dir\tmgr_vn.n\tutorial\exercises\myfiles\out\app810out**
-

Task: define a new trade link for the outgoing 810

About this task

Referring to the information below, define an X12 Outbound Trade Link from "My Internal Company" to "Acme".

Add Trade Link	(Outbound)
From Trading/Application Partner:	
Trading Partner	My Internal Company
Application Partner	Invoice
To Trading/Application Partner:	
Trading Partner	ACME Corp.
Application Partner	Invoice
Get Post Office	EDI data ready for Processing
Interchange Control# Scheme	Increment
Group Control# Scheme	Relative
Version	3060
Functional ID	IN Invoice Information (810, 819)
PO/Validation/Ack:	
Put Post Office	Invoices ready to send

Task: run EDI type tree wizard

About this task

Refer to Exercise 5: Creating Trade Link Type Trees exercise if you require step by step instructions.

Task: deploy message manager system and RunMaps system

About this task

Refer to Message Manager Exercise 6 - Task: Deploy the Message Manager System if you require step by step instructions.

Task: define new application map in the AppMap system

Procedure

1. Open the AppMap system definition file that was created in the task titled: "[Task: Define an application subsystem](#)".
2. Create a new system named **Outbound**.
3. Add the source map **App810ot.mms** located in **C:\install_dir\tmgr_vn.n\tutorial\exercises\maps** to this system.
4. Click the Launcher Settings button on **App810ot** and set the input trigger and override the destination file paths as follows:
 - Input card #1: Source Event **ON**
Source file: **C:\install_dir\tmgr_vn.n\tutorial\exercises\myfiles\In\App850in*.ord**
 - Input card #2: Source Event **ON**
Source file: **C:\install_dir\tmgr_vn.n\tutorial\exercises\myfiles\In\App850in*.lin**
 - Input card #3:
Source file: **C:\install_dir\tmgr_vn.n\tutorial\exercises\data\ITEMXREF.TXT**
 - Input card #4:
Source file: **C:\install_dir\tmgr_vn.n\tutorial\exercises\data\profile2.txt**
 - Output card#1:
Target file: **C:\install_dir\tmgr_vn.n\mmgr\mail*mo.edi**
 - Output card #2:
Target file: **C:\install_dir\tmgr_vn.n\tutorial\exercises\data\profile2.txt**
5. Change **Server** to **Local Server**.
6. Create a deploy script for the Outbound system that deploys the Launcher file (**.msl**) to the IBM WebSphere Transformation Extender\systems directory.
7. Deploy the Outbound system.
8. Save your changes.

Task: start the Launcher and monitor the system

Procedure

1. Start **Launcher** service.
2. Start the Launcher Monitor and connect to the Launcher.
3. Open the Management Console and **Connect** to the Launcher and start the CompoundSystem.
4. Using Windows Explorer, locate data file **PO850mi.DAT** in **C:\install_dir\tmgr_vn.n\tutorial\exercises\data**. Copy **PO850mi.DAT** to the **install_dir\tmgr_vn.n\mmgr\mail** directory.
The appearance of this file in the directory will trigger the Message Manager system. The files produced by Message Manager will trigger the AppMap **Inbound** system.
5. Record any errors and your solutions and check corrections
6. Take a snapshot of the system in the Launcher Monitor and verify the maps completed successfully.
A validated 850 PO, 810 INV and 997 Ack should appear in the Put Post Office locations you specified in the Partner Manager exercise.
7. After making any corrections to the dropped test file and running **Launcher** to verify success, delete all files under **C:\install_dir\tmgr_vn.n\tutorial\exercises\myfiles\In\App850in**.
8. In the Management Console, stop the **CompoundSystem** and disconnect from the Launcher.
9. Stop the Launcher service.

Partner Manager monitoring

This chapter contains the following tutorials that are related to the monitoring of Partner Manager :

- "[Tutorial Exercise 10: Running Traffic Reports](#)"
- "[Tutorial Exercise 11: Running Additional Reports](#)"
- [**Tutorial exercise 10: running traffic reports**](#)
- [**Tutorial exercise 11: running additional reports**](#)

Tutorial exercise 10: running traffic reports

About this task

In this exercise you will demonstrate your understanding of monitoring traffic activity by running and exporting a transmission level report for previously processed e-commerce data.

In this exercise you will:

- Run a report for previous exercise activity.
 - Select Display Detail option to view transmission detail.
 - Select Report Info option to view report detail
 - Select drilldown option to query the details of the transmission.
 - Make note of any errors
 - Export a traffic report
- [Task: run inbound transmission traffic report](#)**
- [Task: display transmission detail](#)**
- [Task: export transaction set detail report](#)**
-

Task: run inbound transmission traffic report

Procedure

1. Click on **Reports** in the **Partner Manager** toolbar.
 2. Create a Traffic report that will report Inbound Transmissions for All Dates
The **Inbound Transmission Report View** panel should be displayed.
 3. Right-click on a transmission entry and select Display Detail to review transmission detail information.
 4. Click Close.
 5. Right-click on a transmission entry and select Report Info. Review **Report Information**.
-

Task: display transmission detail

Procedure

1. Right-click on a transmission entry and select Drilldown. Review displayed transmission information. Note that drilldown can also be seen by double-clicking on a traffic report entry.
 2. Right-click on a transmission entry and select Drilldown. Review displayed interchange information.
 3. Right-click on an interchange entry and select Drilldown. Review displayed Functional Group information.
 4. Right-click on functional group entry and select Drilldown. Review displayed Transaction Set information.
 5. Right-click on a transaction set entry and select Display Detail. Review transaction set detail information.
 6. Click Back.
-

Task: export transaction set detail report

Procedure

1. Right-click on a transaction set entry and select Export in the Traffic Report Export dialog.
 2. In the Traffic Report Export dialog, click **Browse** for export file name.
 3. Save the file to: **C:\install_dir\tnmgr_vn.n\tutorial\exercises\myfiles** (where *n.n* indicates current version number), and accept the default file name. Click Open.
The file name and location appear in the **Export File Name** field.
 4. Click Begin **Export**. Your Internet browser is automatically launched.
 5. Review the exported report.
-

Tutorial exercise 11: running additional reports

About this task

In this exercise you will demonstrate your understanding of reviewing Trading Partner setup information by running, reviewing, printing and Trading Partner information.

In this exercise you will:

- Run an Additional Report
 - Review Additional Report information
 - Print Additional Report
 - Export Additional Report
- [Task: run inbound trade link report](#)**
- [Task: export additional report](#)**

- [Task: Print additional report](#)

Task: run inbound trade link report

Procedure

1. Click on **Reports** in the **Partner Manager** toolbar. The Reports navigator appears.
2. Select Report Type: Additional Reports
3. Select Report: X12 Trade Link Inbound Application
4. Click Run Report. The X12 Trade Link Inbound Application Report panel appears.
5. Accept the report default run parameters, click Run Report.
6. Review report information.

Task: export additional report

Procedure

1. Click the **Export** icon within Report Viewer.
 - Select location: **C:\install_dir\tmgr_vn.n\tutorial\exercises\myfiles**
 - Enter File name: **X12_Inbound_Links**
 - File Type: **HTML**
2. In the Traffic Report Export dialog, click **Browse** for export file name.
3. Save the file to: **C:\install_dir\tmgr_vn.n\tutorial\exercises\myfiles** (where *n.n* indicates current version number), and accept the default file name. Click Open. The file name and location appear in the **Export File Name** field.
4. Click Begin Export. Your Internet browser is automatically launched.
5. Review the exported report.

Task: Print additional report

Procedure

1. In the browser window, select **File > Print**.
2. Review the report.

Trading Manager maintenance

This chapter contains the following tutorials that are related to the maintenance of Trading Manager:

- ["Tutorial Exercise 12: Copying the Partner Manager Database"](#)
- ["Tutorial Exercise 13: Security Setup"](#)
- ["Tutorial exercise 12: copying the Partner Manager database"](#)
- ["Tutorial exercise 13: security setup"](#)

Tutorial exercise 12: copying the Partner Manager database

About this task

In exercise you will demonstrate your understanding of Partner Manager database utilities by using the Database Copy utility to create a copy of the current Partner Manager database.

- [Task: create DSN for empty database](#)
- [Task: copy Partner Manager database](#)

Task: create DSN for empty database

Procedure

1. Using Windows Explorer, browse to the **C:\install_dir\<tmgr_vn.n\pmgr** directory.
2. Copy **m4EC_empty.mdb** to your working directory (**C:\install_dir\<tmgr_vn.n\tutorial\exercises\myfiles**) as **CM_Test.mdb**.
3. Start the **Data Sources (ODBC)** application from the Windows **Administrative** Tools menu.

4. On the System DSN tab, click Add.
 5. Select Microsoft Access Driver (*.mdb) and click Finish.
 6. Enter a Data Source Name of **CM_DB_TEST** and a description of **CM_DB_TEST Database**
 7. Click Select. The **Select Database Dialog** appears.
 8. Browse to **C:\install_dir\<tmgr_vn.\tutorial\exercises\myfiles** and select CM_test.mdb
 9. Click OK to save the changes and click OK again to exit the ODBC Data Sources application
-

Task: copy Partner Manager database

Procedure

1. Start the Partner Manager Database Copy utility from the start menu.
 2. Select the DSN of the database you are currently using (**TradingManagerTutorial**)
 3. Select Source Database Vendor: **Microsoft Access**.
 4. Select the new DSN you created in the previous task as the Destination DSN.
 5. Select Destination Database Vendor: **Microsoft Access**.
 6. Click Begin Copy.
-

Tutorial exercise 13: security setup

About this task

In exercise you will demonstrate your understanding of Partner Security by setting secure access to Partner Manager.

In this exercise you will:

- Define a security group.
 - Create a User ID.
 - Restart Partner Manager and sign-on with a User ID.
 - [Task: create security group](#)
 - [Task: create user ID and assign to security group](#)
 - [Task: restart Partner Manager and log on](#)
-

Task: create security group

Procedure

1. Select Security Groups from the **Utilities** navigator. The **Group Information** panel appears.
 2. Enter Security Groups Name of **EDI Admin** and press **ENTER**.
 3. Click **Yes** to create.
 4. Select Security Profile of **Administrator**.
 5. Disable the **EDI Wizard** option.
 6. Save the Security Group.
-

Task: create user ID and assign to security group

Procedure

1. Select User Maintenance from the **Utilities** navigator.
 2. Click Add.
The User Maintenance: Add dialog opens.
 3. Enter your user information in the **User ID** and **User Name** fields.
 4. In the **Group ID** drop down menu, select EDI Admin.
 5. Enter a **Password**.
 6. Enable **Password Expires Every** and enter **30** days.
 7. Save the new user account.
-

Task: restart Partner Manager and log on

Procedure

1. Restart Partner Manager.

2. Enter the User ID and Password you created in the previous task to logon.
3. Verify that the EDI Wizard option is now grayed out.
4. Delete the User ID created above to complete this tutorial. Note the warning shown when deleting the last user from Partner Manager.

Glossary

Look up terms and definitions that you find in IBM® WebSphere® Transformation Extender products and documentation.

This glossary includes terms and definitions for IBM WebSphere Transformation Extender.

The following cross-references are used in this glossary:

- See refers you from a term to a preferred synonym, or from an acronym or abbreviation to the defined full form.
- See also refers you to a related or contrasting term.

[A](#) [B](#) [C](#) [D](#) [E](#) [F](#) [G](#) [H](#) [I](#) [J](#) [L](#) [M](#) [O](#) [P](#) [R](#) [S](#) [T](#) [U](#) [V](#) [W](#)

A

A2A

See [application to application](#).

activity

An action designed to achieve a particular business process. An activity is performed on a set of targets on a specific schedule.

adapter

An intermediary software component that allows two other software components to communicate with one another.

adapter object

An object used in the TX Programming Interface that represents a resource adapter.

API

See [application programming interface](#).

Applicability Statement 2 (AS2)

An EDI protocol for securely exchanging data over the Internet, by using HTTP as a transport.

application programming interface (API)

An interface that allows an application program that is written in a high-level language to use specific data or functions of the operating system or another program.

application to application (A2A)

A data transformation from the output of one application to the input of another application.

AS2

See [Applicability Statement 2](#).

audit log

A log file containing a record of system events and responses.

B

BAPI

See [Business Application Programming Interface](#).

big endian

A format for storage or transmission of binary data in which the most significant value is placed first. See also [little endian](#).

Boolean

Characteristic of an expression or variable that can only have a value of true or false.

bound component

In the Type Designer, a component for which each occurrence of the data can be identified without considering the context in which that occurrence is placed.

bound type

In the Type Designer, a type whose data object can be identified without considering the context in which that data object is placed.

BPML

See [Business Process Modeling Language](#).

BPML activity

A step in a business process that provides directions for how data should be handled.

Business Application Programming Interface (BAPI)

A programming interface that is used to access SAP databases from with SAP or other development platforms. BAPI is used to achieve integration between the R/3 System and external applications and legacy systems.

Business Process Modeling Language (BPML)

An XML-based language that describes business processes designed by the Business Process Management Initiative (www.bpmi.org).

C

card

In the Map Designer, a data object. There are two types of map cards: input and output.

card object

An object used in the TX Programming Interface that represents an input or output card of a map in program memory.

category

A type class that is used to organize types in a type tree in the Type Designer. Categories organize types that have common properties.

certificate

In computer security, a digital document that binds a public key to the identity of the certificate owner, thereby enabling the certificate owner to be authenticated. A certificate is issued by a certificate authority and is digitally signed by that authority.

choice type

A group type with a subclass equal to choice that is used to define a selection from a set of components. A choice type defines a choice group, which is valid when the data matches one of the components in the choice group.

class
A basic unit of the classification hierarchy used in the Type Designer. There are three classes: item, group, and category.

classification hierarchy
The hierarchy of a type tree in the Type Designer. The deeper the subtype, the more specific the data characteristics are. See also [compositional hierarchy](#).

cloud
See [cloud computing](#).

cloud computing (cloud)
A computing platform where users can have access to applications or computing resources, as services, from anywhere through their connected devices. A simplified user interface and application programming interface (API) makes the infrastructure supporting such services transparent to users.

code list
One or many dynamic pairs of code values that contains sender code and receiver code. Each code pair has one description and up to four additional codes relating to the pair.

code list table
A repository for lists of codes that can further define fields.

compiled map component
An Integration Flow Designer object that references an executable map in compiled file format.

complete type name
The name of a type that represents its hierarchical structure within a type tree, which includes the names of all the types in the path from the root type down.

component rule
An expression about one or more components, which is defined in the Type Designer. A component rule is used for validating data and specifies what must be true for the data that is defined by that component to be valid.

composite
A group of related data elements used in EDI transactions.

compositional hierarchy
A hierarchy in which the composition of the data is reflected in the structure of the group type in the group window. See also [classification hierarchy](#).

contracted component
In the Integration Flow Designer, a component that does not display the sources and targets associated with it. See also [expanded component](#).

correlation
Data that enables a user to record document-specific correlation parameters generated during translation, by the correlation service, or by document tracking functions.

D

data element
A unit of data that cannot be divided. An example is the data element "age of a person" with values consisting of all 3-decimal digit combinations.

data object
A portion of data in a data stream that can be recognized as belonging to a specific type.

data structure
The composition of the data, including repeating sub-structures, nested groupings, sequences, and choices.

decode
To convert data by reversing the effect of some previous encoding.

de-enveloping
The process of removing one or more envelopes from a document or a set of documents.

delimited format
Data that has data objects that are separated by delimiters.

delimiter
1. A character, such as comma or tab, used to group or separate units of text by marking the boundary between them.
2. A flag that is formed by a character or a sequence of characters to group or separate items of data by marking the beginning and end of a unit of data. The delimiter is not a part of the flagged unit of data.

dequeue
To remove items from a queue. See also [enqueue](#).

distinguishable types
Types that do not have common data objects.

document envelope
A structure that is applied to a document to prepare it for exchange between trading partners.

document type definition (DTD)
The rules that specify the structure for a particular class of SGML or XML documents. The DTD defines the structure with elements, attributes, and notations, and it establishes constraints for how each element, attribute, and notation can be used within the particular class of documents.

DTD
See [document type definition](#).

E

EDI
See [electronic data interchange](#).

EDI loop
A group of consecutive EDI segments that repeat together in an EDI document definition. There is no object type in Data Interchange Services that defines an EDI loop on its own. EDI loops are logically defined within an EDI document definition.

EDI message
See [EDI transaction](#).

EDI transaction
In X12 EDI Standards, a group of logically related data that makes up an electronic business document, such as an invoice. The layout of an EDI transaction is described by an EDI Document Definition in Data Interchange Services.

electronic data interchange (EDI)
The exchange of structured electronic data between computer systems according to predefined message standards.

element
A component of a document, such as an EDI, XML, or ROD record. An element can be a simple element or a compound element.

encode
To convert data by the use of a code in such a manner that reconversion to the original form is possible.

enqueue
To put a message or item in a queue. See also [dequeue](#).

envelope
A combination of header, trailer, and control segments that define the start and end of an individual EDI message. Each envelope contains a header segment and a trailer segment, which separate the envelope from other envelopes and provide information about the contents of the envelope.

executable map
A compiled map.

execution settings
Settings that influence how a component behaves at execution time. These settings are compiled into the map file or system file. Many of these settings compiled into the map can be overridden (or partially overridden) using execution commands and options.

expanded component
A component that displays the sources and targets that are associated with it in the Integration Flow Designer. See also [contracted component](#).

explicit format
A format that relies upon syntax to separate data objects. Each data object can be identified by its position or by a delimiter in the data. Delimiters will also appear for missing data objects. See also [implicit format](#).

expression
A statement about data objects. Expressions are a combination of literals, object names, operators, functions, and map names. Component rules are expressions that evaluate to either TRUE or FALSE. Map rules are expressions that evaluate to data to produce the desired output.

external link
In the Integration Flow Designer, solid lines displayed in a system definition diagram that visually represent the data flow between two map components.

F

fixed syntax
A group whose components have a fixed size. Each component is padded to a fixed size or its minimum and maximum content size values are equal.

functional acknowledgment
An electronic acknowledgment returned to the sender to indicate acceptance or rejection of EDI documents.

G

global transaction management (GTX)
The monitoring of transactions that can include operations on two or more different data sources. This feature enables databases or servers to be returned to a pre-transaction state if an error occurs. Either all databases and servers are updated or none are. The advantage of this strategy is that databases and servers remain synchronized and data remains consistent.

GPM
See [Graphical Process Modeler](#).

Graphical Process Modeler (GPM)
A stand-alone graphical interface tool that is used in Sterling B2B Integrator to create and modify business processes. The GPM converts the graphical representation of business processes to well-formed BPMN (source code) and saves the effort of writing code.

group
A complex data object that consists of components.

GTX
See [global transaction management](#).

H

hypervisor
Software or a physical device that enables multiple instances of operating systems to run simultaneously on the same hardware.

I

identifier attribute
An attribute that can be assigned to one component to identify a collection of components, when creating type trees and defining components of a group. An identifier attribute is used during data validation to determine whether a data object exists.

image
See [virtual image](#).

implicit format
A format that defines a group type whose data objects are distinguishable by content, not syntax. Implicit format relies on the properties of the component types. Unlike explicit format, if delimiters separate data objects, they do not appear for missing data objects. See also [explicit format](#).

initiator
1. A syntax object in a data stream that signals the beginning of a data object. For example, if a record begins with an asterisk (*), the asterisk would be the record's initiator.
2. In distributed queueing, a program that requests network connections on another system.

input card
In the Map Designer, a component that contains the complete definition of input for the map, including information such as source identification, retrieval specifics, and the behavior that should occur during processing.

interchange
The exchange of information between trading partners. Also a set of documents grouped together, such as EDI documents enclosed within an EDI envelope.

internal link
In the Integration Flow Designer, a solid line displayed by an expanded map component that visually represents the source and target of the map.

item
A simple data object that does not consist of other objects. An item type is represented by a blue dot next to the type name in the type tree.

J

- Java**
An object-oriented programming language for portable interpretive code that supports interaction among remote objects. Java was developed and specified by Sun Microsystems, Incorporated.
- Java Database Connectivity (JDBC)**
An industry standard for database-independent connectivity between the Java platform and a wide range of databases. The JDBC interface provides a call level interface for SQL-based and XQuery-based database access.
- Java EE**
See [Java Platform, Enterprise Edition](#).
- Java Message Service (JMS)**
An application programming interface that provides Java language functions for handling messages.
- Java Platform, Enterprise Edition (Java EE)**
An environment for developing and deploying enterprise applications, defined by Oracle. The Java EE platform consists of a set of services, application programming interfaces (APIs), and protocols that provide the functionality for developing multitiered, web-based applications. (Oracle)
- Java runtime environment (JRE)**
A subset of a Java developer kit that contains the core executable programs and files that constitute the standard Java platform. The JRE includes the Java virtual machine (JVM), core classes, and supporting files.
- Java Secure Socket Extension (JSSE)**
A Java package that enables secure Internet communications. It implements a Java version of the Secure Sockets Layer (SSL) and Transport Layer Security (TSL) protocols and supports data encryption, server authentication, message integrity, and optionally client authentication.
- Java SE Development Kit**
The name of the software development kit that Sun Microsystems provides for the Java platform.
- Java virtual machine (JVM)**
A software implementation of a processor that runs compiled Java code (applets and applications).
- JDBC**
See [Java Database Connectivity](#).
- JMS**
See [Java Message Service](#).
- JRE**
See [Java runtime environment](#).
- JSSE**
See [Java Secure Socket Extension](#).
- JVM**
See [Java virtual machine](#).

L

- literal**
A symbol or a quantity in a source program that is itself data, rather than a reference to data.
- little endian**
A format for storage or transmission of binary data in which the least significant value is placed first. See also [big endian](#).
- local server**
A predefined server that designates the current computer to run the Integration Flow Designer.

M

- map component**
An Integration Flow Designer object that encapsulates a reference to an executable map, along with its execution settings. There are three types of map components: source, compiled, and pseudo.
- map object**
An object used in the TX Programming Interface that represents an instance of a map in the program memory.
- map rule**
An expression that evaluates to data and produces the required output. A map rule is entered on an output card in the Map Designer and cannot be longer than 32KB.
- member**
In the Type Designer, a single occurrence of a component in a group in a type tree. If a component has a range, each occurrence of that component might be referred to as a member of a series.
- message header**
The part of a message that contains control information such as a unique message ID, the sender and receiver of the message, the message priority, and the type of message.
- message queue**
A named destination to which messages can be sent until they are retrieved by programs that service the queue.
- messaging API**
A programming interface that enables an application to send and receive messages and attached files over a messaging system.
- messaging middleware**
Software that provides an interface between applications, allowing them to send data back and forth to each other asynchronously. Data sent by one program can be stored and then forwarded to the receiving program when it becomes available to process it.
- messaging system**
Software used to deliver electronic messages.
- metadata**
Data that describes the characteristics of data; descriptive data.

O

- optional component**

Within a group type, a component that can be defined to represent a data object that is not required to be present in the data. The component range maximum specifies how many occurrences of the data object might optionally exist.

output card

In the Map Designer, a card that contains the complete definition of an output for the map including information such as target identification, destination specifics and the behavior that should occur during processing.

override

An execution setting that overrides default source and target settings of a map.

P

pad character

A character used to fill empty space. For example, in a database application, a field that is ten characters in length that has the word "file" in it contains four text characters and six pad characters.

partition

To divide a type into subtypes that are mutually exclusive.

partitioned type

A type whose subtypes are distinguishable or mutually exclusive.

pattern

A reusable solution that encapsulates a tested approach to solving a common architecture, design, or deployment task in a particular context.

persistence level

A level that determines the degree of detail written to the database as a business process runs. Decreasing the persistence level increases the business process performance at the cost of full tracking for each step of the business process.

predefined business process

A business process that is ready to use upon installation of Sterling B2B Integrator.

primary document

A document that the services in a business process act on or in relation to. A primary document is usually the document passed to a business process by the initiating adapter.

process control information

Map component settings that can be changed at run time by specifying overrides at the command line, in a command file, or by configuring the Launcher.

process data

Data that is accumulated in an XML document about a business process during the life of the process. Activities in the process add elements to the process data and use components of the process data to complete configured processing tasks.

propagation

The point at which the properties of a type are inherited by its subtypes.

property

A characteristic of an object that describes the object. A property can be changed or modified. Properties can describe an object name, type, value, or behavior, among other things.

pseudolink

In the Integration Flow Designer, dotted lines manually drawn in a system definition diagram that visually represent a data flow relationship between two map components that has not yet been determined precisely.

pseudomap component

An Integration Flow Designer object that is a placeholder for an executable map that has not yet been implemented.

R

range

1. The number of consecutive occurrences of the component in the data stream. The range is composed of two numbers separated by a colon.
2. The categorization of an attribute into different segments.

relative type name

The name of a type relative to another type. Relative type names are used when defining components, syntax items, and comment types.

release character

The character that indicates that a separator or delimiter is to be used as text data instead of as a separator or delimiter. The release character must immediately precede the delimiter.

required component

A component that can be defined within a group type to represent a data object that must be present in the data. The component range minimum specifies how many occurrences of the data object are required.

resource adapter

Map input and output data sources that are used to retrieve and route data. Resource adapters provide access to databases, files, messaging systems, and other data sources and targets. Each adapter includes a set of adapter commands that can be used to customize its operation.

restart attribute

An attribute that specifies that processing of the input data should continue even though a data object of the component is invalid. The restart attribute provides instructions for handling errors encountered in a data stream and can be assigned to a component within a group type.

role-based security

Security that provides access rights to certain files, business processes, web templates, and features, according to the permissions associated with the user account.

rollback

The process of restoring data that was changed by an application program or user.

root type

The type from which all other types stem. The root type represents the data objects of all the types in the tree.

row

The horizontal component of a table, consisting of a sequence of values, one for each column of the table.

run map

An executable map that is called using the RUN function.

S

SDK

See [software development kit](#).

Secure FTP

An FTP protocol that uses Secure Sockets Layer (SSL) protocol.

segment

1. A portion of a profile. The format of each segment is defined by a template.
2. An EDI logical unit of information. EDI segments are made up of data elements and composites. Segments are delimited; their components are separated by a delimiter.

series

The consecutive occurrences of a component. In map rules, the [] characters denote an indexed member of a series.

server definition

A definition for a computer that hosts a command server, to which systems under development in the Integration Flow Designer can be assigned as the intended execution server.

service-oriented architecture (SOA)

A conceptual description of the structure of a software system in terms of its components and the services they provide, without regard for the underlying implementation of these components, services and connections between components.

simple type name

The type name that appears next to the type icon in the type tree.

sized attribute

An attribute that can be assigned to one or more components within a group type, whose value specifies the size, in bytes, of the component immediately following it.

SOA

See [service-oriented architecture](#).

SOAP

A lightweight, XML-based protocol for exchanging information in a decentralized, distributed environment. SOAP can be used to query and return information and invoke services across the Internet. See also [web service](#).

software development kit (SDK)

A set of tools, APIs, and documentation to assist with the development of software in a specific computer language or for a particular operating environment.

source map component

An object that references an executable map within a source map file.

stream object

An object used in the TX Programming Interface that permits overrides to the loaded map input and output specifications.

subflow

A sequence of processing steps, implemented using message flow nodes, that is designed to be embedded in a message flow or in another subflow. A subflow must include at least one Input or Output node. A subflow can be executed by a broker only as part of the message flow in which it is embedded, and therefore it cannot be deployed.

subsystem component

An Integration Flow Designer object that references another system which a user has defined.

subtree

A branch of a type tree that includes a type and all of the subtypes that stem underneath it.

subtype

A type that extends or implements another type; the supertype.

supertype

In a type hierarchy, a type that subtypes inherit attributes from.

syntax object

One or more characters used as separators between portions of data. A syntax object can be a number separator, a delimiter, a terminator, an initiator, or a release character.

system

A collection of referenced executable maps that are organized into a unit.

system definition diagram

The graphical representation of a system viewed within a system window in the Integration Flow Designer. A user can interact with system definition diagrams to design systems.

system window

A window in the Integration Flow Designer in which system definition diagrams are created, maintained, and displayed.

T**terminator**

A syntax object that signifies the end of a data object. For example, a carriage return or line feed at the end of a record might be the record's terminator.

transaction set

The basic business document in EDI data. Transaction sets are enclosed in an envelope that separates one transaction set from another. Groups of transaction sets that are functionally related are enclosed in a functional group envelope.

translation object

A source map that has been compiled to provide instructions for translating from one format to another in a way that can be interpreted by the translator.

transmission type

The largest object in an EDI type tree. A transmission might include many interchanges from or to many trading partners.

transport adapter

An adapter (such as an HTTP Adapter) that is used with an encoding/decoding adapter to support various protocols (for example, SOAP) in a transport-independent way. The transport adapter is used to transport the data either from the source or to the destination.

transporting

A method of conveying data using a specified adapter following either an encode or decode command.

trigger

A mechanism that detects an occurrence and can cause additional processing in response.

tuple

See [row](#).

type

The definition of a data object or set of data objects that is graphically represented in a type tree in the Type Designer.

type tree

In the Type Designer, the graphical representation of the definition and organization of data objects.

U

unbound set

The set of all possible types of data that might be listed last in a group.

Unicode

A character encoding standard that supports the interchange, processing, and display of text that is written in the common languages around the world, plus many classical and historical texts.

Uniform Resource Indicator (URI)

A unique address that is used to identify content on the web, such as a page of text, a video or sound clip, a still or animated image, or a program. The most common form of URI is the web page address, which is a particular form or subset of URI called a Uniform Resource Locator (URL). A URI typically describes how to access the resource, the computer that contains the resource, and the name of the resource (a file name) on the computer.

URI

See [Uniform Resource Indicator](#).

user account

The login directory and other information that gives a user access to the system.

UTF-8

Unicode Transformation Format, 8-bit encoding form, which is designed for ease of use with existing ASCII-based systems. The CCSID value for data in UTF-8 format is 1208.

V

variable component name

A component of a group type that includes the literal at the end of the name because it represents more than one type. The literal ANY acts like a wild card, which represents any type whose name could appear in that place.

virtual image (image)

The operating system and product binary files that are required to create a virtual system pattern.

virtual machine

An abstract specification for a computing device that can be implemented in different ways in software and hardware.

W

watch

A map, including the set of events that initiate it, as defined from the Integration Flow Designer.

web service

A self-contained, self-describing modular application that can be published, discovered, and invoked over a network using standard network protocols. Typically, XML is used to tag the data, SOAP is used to transfer the data, WSDL is used for describing the services available, and UDDI is used for listing what services are available. See also [SOAP](#), [Web Services Description Language](#).

Web Services Description Language (WSDL)

An XML-based specification for describing networked services as a set of endpoints operating on messages containing either document-oriented or procedure-oriented information. See also [web service](#).

workbench

The user interface and integrated development environment (IDE) in Eclipse and Eclipse-based tools such as IBM Rational Application Developer.

WSDL

See [Web Services Description Language](#).
