Using a database as a source

About this task

After you have used the Database Interface Designer to define a query for a database, you can use that query as an input source.

Note: You can use either a standard SQL SELECT query or a query using a stored procedure. For specific information about using stored procedures, refer to [Using stored procedures](#).

To use a database query as a source:

Procedure

- Define the database using the Database Interface Designer.
 - Define a query to extract data from the database.
 - Generate a type tree for the query.
 - Use the Map Designer to create a map with an input card referencing the query.
- [Defining a database source in the Map Designer](#)
 - [Database GET > Source settings](#)

Defining a database source in the Map Designer

About this task

When you generate the type tree from a query, one of the types in the tree is a group representing the results from executing the query (for example, DBSelect). Select this type as the input card type when defining an input card for the executable map.

After you have defined the query and have generated the type tree, using a database as an input is very similar to using a file as input.

Using the Map Designer, specify Database as the GET > Source setting in the input card and supply the name of the MDQ file containing the definition of the database and query you want to use. see the following procedure and example.

To define a database as a data source:

Note: For more information about the map settings in this procedure, see the **Map Designer** documentation. This procedure specifically addresses database-specific parameters and settings.

Procedure

1. In the Map Designer, when defining the settings for SourceRule, select Database as the GET > Source setting.
The settings displayed in the Input Card dialog change to display the database adapter settings for a source.
 2. From the Card menu, select New.
The Add Input Card dialog appears.
 3. For the CardName setting, enter a name for the card that describes the data object represented by this card.
 4. For the TypeTree setting, select the type tree containing the group type that defines the desired query.
 5. For the TypeName setting, select the group type from the type tree that defines the desired query (for example, DBSelect).
 6. Specify the FetchAs, WorkArea, FetchUnit, and all Backup settings as desired. For detailed information about these settings, see the Map Designer documentation.
For database adapter-specific information about source settings, see the adapter-specific reference guide.
 7. For the GET > Source setting, select Database from the list.
The SourceRule settings change to display the database adapter settings.
 8. Specify the values as desired in the adapter settings and click OK.
-

Database GET> Source settings

After you select Database as the GET > Source setting and the database adapter settings become available for an input, configure the settings for a source that uses the database adapters.

Many of the adapter settings provide transactional control and connection management that allow you to control the connections made to your database. For information about specifying these particular GET > Source and **SourceRule** settings, see [Database Connections and Transactions](#).

- [GET> Source> Command setting](#)
-

GET> Source> Command setting

The **GET > Source > Command** setting is used to enter the applicable database adapter commands for this source. For general information about these settings, see the Map Designer documentation. For specific information about using database-specific adapter commands, see the Resource Adapters documentation.

Using a database as a target

About this task

After using the Database Interface Designer to define tables, views, message queues, or stored procedures for a database, use the database to specify the database adapter as the data target.

To use a database table, view, message queue, or stored procedure as a target:

Procedure

1. Define the database using the Database Interface Designer.
 2. Generate a type tree from a table, view, stored procedure, or message queue.
 3. Using the Map Designer, create a map with an output card that specifies the database table, view, message queue, or stored procedure as the data target.
- [Defining a database target in the map designer](#)
 - [Database PUT > Target settings](#)
-

Defining a database target in the map designer

About this task

When you generate the type tree for a table, view, message queue, or stored procedure, one of the types in the tree is a group representing the contents of the table, view, message queue, or stored procedure. For example, a type tree generated for a table or view is named **DBTable**. Use the Map Designer to select the appropriate type representing the contents as the output card type of the executable map.

After you have defined the database and have generated the type tree, using a database as an output is very similar to using a file as output.

Use the Map Designer to specify **Database** as the PUT > Target setting in the output card at the executable map level. Provide the name of the MDQ file containing the definition of the database, along with the table, view, message queue, or stored procedure to be used.

To define a database as a target:

Note: For more information about the map settings in this procedure, see the Map Designer documentation. This procedure specifically addresses database-specific parameters and settings.

Procedure

1. In the Map Designer, select the To window.
2. From the Card menu, select New.
The Add Output Card dialog is displayed, an example of which follows.
3. For the CardName setting, enter a name for the card.
4. For the TypeTree setting, select the type tree file containing the group type that defines the content of the desired output.
5. For the TypeName setting, select the group type from the type tree that defines the desired output (for example, DBSelect).
6. Specify all Backup settings as desired. For detailed information about these settings, see the Map Designer documentation.
7. For the PUT > Target setting, select Database from the list.
The settings displayed in the Output Card dialog change to display the database adapter settings for a target. For database adapter-specific information about target settings, see the adapter-specific reference guide.
8. Specify the values as desired in the adapter settings and click OK.

Database PUT > Target settings

After you select Database as the PUT > Target setting and the database adapter settings for a target become available in the output card, you can configure the settings for a target that uses the database adapters.

Many of the adapter settings provide transactional control and connection management that allow you to control the connections made to your database. For information about specifying these particular PUT > Target and **TargetRule** settings, see [Database connections and transactions](#).

- [PUT > Target > Command setting](#)
-

PUT > Target > Command setting

The PUT > Target > Command setting is used to enter the database adapter commands applicable for this target. For general information about these settings, see the Map Designer documentation. For specific information about using database-specific adapter commands, see the adapter-specific documentation.

Database connections and transactions

IBM Transformation Extender maps allow superior transactional control and connection management by providing settings that allow the scope of transactions to be controlled by the definitions provided in a map. It is important to understand how these connections to databases are controlled and how this relates to transactional scope.

- [Transactional control](#)
 - [Database connection management](#)
 - [Connection example](#)
-

Transactional control

Scope is one of the settings that may be specified for a source (GET > Source > Transaction > Scope) or target (PUT > Target > Transaction > Scope) in a map. For information about **Scope** settings, see the Map Designer documentation.

There is one restriction for **Scope**. If the value of the SourceRule > FetchAs setting in an input card is set to **Burst**, the **Scope** setting is always **Map**. The adapter scope is determined to be **Map** because the context of the SELECT statement cannot be maintained after the transaction has been terminated through a commit or rollback. Therefore, if **Burst** is the value for the SourceRule > FetchAs setting in an input card, any value in the **Scope** setting as well as any adapter command (-CCARD or -CSTMT) specified in the GET> Source > Command setting is ignored.

Additionally, the global transaction management functionality is available for certain adapters by using the Global Transaction Management (-GTX) adapter command in the **Command** setting. For more information about this functionality, see the Global Transaction Management documentation.

Database connection management

Connection management results in fewer connections being made to the database, which may improve performance. The IBM Transformation Extender engine reuses existing connections whenever possible. With global transaction management for those adapters able to take advantage of this functionality, connections have an even bigger role in maintaining data integrity. For more information about global transaction management, see the Global Transaction Management documentation.

There are two situations in which connection sharing occurs:

- between cards and maps within a map
- between multiple maps running serially within the Launcher

When connection sharing occurs between cards and maps within a map, the connection is described as active as long as there are one or more cards or rules that access a database and that have yet to be committed or rolled back. (For example, an active transaction exists.) When there are no such cards or rules, the connection is inactive, yet still alive.

When using a DBLOOKUP, DBQUERY, GET or PUT function, the Transaction > Scope setting defaults to **Map** when the map SourceRule > FetchAs setting is set to **Integral**. The Transaction > Scope setting will change to **Burst** when the map SourceRule > FetchAs setting is set to **Burst**; the Transaction > OnFailure setting is always **Rollback**.

- [Connection factors](#)
 - [Connection rules](#)
-

Connection factors

The factors determining whether a connection is reused are the following:

- the database type
- the connection string (if applicable), datasource, or database name
- the user ID
- the **OnFailure** setting (**Commit** or **Rollback**)
- the Transaction > Scope setting
- the SourceRule > FetchAs setting
- whether **-CCARD** or **-CSTMT** are specified within the adapter's command

Also, whether a connection will be part of a global transaction is determined by the usage of the Global Transaction (**-GTX**) adapter command in the **Command** setting.

Connection rules

Existing connections are reused whenever possible while adhering to certain connection rules. The rules are as follows:

- An inactive connection is reused if the database type, connection string, and user ID of the new card or rule match those of the previous card or rule that had established the connection.
- In addition to the database type, connection string and user ID, an active connection is reused only if the **OnFailure** and Transaction > Scope settings match in the previous card or rule and the new card or rule.
- If a card or rule has **-CSTMT** set within the adapter's command, this connection may be shared with any other card or rule that has **-CSTMT** set or that has an Transaction > Scope setting of **Card** (or **-CCARD** within the adapter's command).
- If **Burst** is the SourceRule > FetchAs setting for an active card, it (the card) is always executed in its own transaction. It establishes a connection that cannot be shared by any other card for the duration of the map.

Connection example

A map has four database input cards. Assume the connections specified (datasource, userID, and so on) are the same for each.

In this example,

- A connection will be made and a transaction started for **Card 1**.
- Because **Card 2** has Transaction > Scope set to **Card**, this initial connection cannot be shared. Therefore, another connection will be made for this card.
- For **Card 3**, because its **OnFailure** setting differs from the setting for **Card 1**, the connection established in **Card 1** cannot be reused. However, the connection established for **Card 2** is inactive (because Transaction > Scope was set to **Card** and the card has completed) and, therefore, will be reused for **Card 3**. A new transaction is started on this existing connection.
- **Card 4** is able to share the connection established by **Card 1** and can be part of the same transaction because all of its settings match.

If the map fails, the transaction containing both **Card 1** and **Card 4** will be rolled back and the transaction for **Card 3** will be committed.

Updating database tables

This topic discusses how you can designate specific columns in your database to be updated with data produced by a mapping operation.

- [Using key and update columns](#)
 - [Defining key and update columns](#)
 - [Specifying update mode](#)
 - [Update key columns](#)
 - [Example using update columns](#)
-

Using key and update columns

The data produced by a mapping operation can be inserted as new rows in a database table or can update only specific columns in a table as designated.

Designate particular columns in a table to be used as key columns determining whether output data updates an existing row or whether it is inserted as a new row in the table or view. In addition to specifying key columns, you can designate the columns in a table that will be affected by any update operation. You define the columns to update.

The term key in this usage does not necessarily mean that the column is part of a database primary or foreign key.

For any update to be performed, update mode must be specified for the target. This is accomplished by specifying the Update adapter command (-UPDATE) in the PUT > Target > Command settings using the Map Designer or Integration Flow Designer, or by passing it with the override execution command on the command line at execution time. For more information about how to enable update mode, refer to [Specifying update mode](#).

Defining key and update columns

About this task

To update a table from a map, use the Database Interface Designer to specify the columns in a table to be used as key columns and to specifically specify the columns that will be updated.

To designate columns as key columns or columns to update:

Procedure

1. In the Navigator, select the database containing the table for which you want to set update keys.
2. From the Database menu, choose Set Update Keys.
The Set Table Update Key Columns dialog appears.
3. From the Table name list, select the table containing the columns to be updated.
The columns in the table appear in the Columns list.
4. To set a column as a key column, select it from the Columns list and click the right arrow button associated with the Key columns list.
The selected column moves to the Key columns list.
5. To designate a column as a column to update, select it from the Columns list and click the right arrow button associated with the Columns to update list.
The selected column moves to the Columns to update list.
6. To specify all non-key columns as Columns to update, click the all button associated with the Columns to update list.
All of the columns in the Columns list move to the Columns to update list.
7. To remove columns from either the Key columns list or the Columns to update list, select the column and click the associated "delete" button.
The selected columns are moved back to the Columns list.

Results

A generated type tree with specified update keys is represented in the Navigator under Tables.

Specifying update mode

To update a table, you must specify update mode using the Map Designer, Integration Flow Designer, or the command line. By specifying update mode in one of these ways, an update operation can be performed in which each row produced by your map is analyzed and the update is performed based upon the update keys and columns defined in the Database Interface Designer.

- [Using the Map Designer or Integration Flow Designer](#)
- [Using an adapter command at execution time](#)

Using the Map Designer or Integration Flow Designer

After key columns and update columns are defined for a table, specify the table as a target in the **TargetRule** settings in the Map Designer or in the **Output(s)** settings in the Integration Flow Designer.

You must specify -UPDATE in the PUT > Target > Command setting so that your specified columns are automatically updated.

Using an adapter command at execution time

The update mode for a table can be specified at execution time by using the command line to pass the -UPDATE database adapter command. Specify OFF or ONLY to control the updating operation. For more information about using database-specific adapter commands, see the Resource Adapters documentation.

Update key columns

When you specify a column as a key column, the value in that column is used to determine whether a row produced by a mapping operation should be inserted as a new row into the table or should be used to update existing row(s) in a table.

- If the values in the rows generated by the mapping operation match the values in the key columns as defined in the Database Interface Designer, the specified update columns are updated.
- If the values in the rows generated by the mapping operation do *not* match the values in the key columns, the rows are inserted as new rows into the table or view as defined in the Database Interface Designer.

Note: You can override the behavior defined in the Database Interface Designer by using the command line to specify the appropriate database adapter commands for the database adapter. For information about the database-specific adapter commands, see the Resource Adapters documentation.

- If more than one column is designated as a key column, the values generated by a map must match the values in each designated key column for the row to be updated.
- If your map generates a row with key column values that match more than one existing record, all of the matching records in the columns you have specified as update columns are updated with the new row values.
- If your map produces multiple rows with the same values for the key columns, you lose any updates that are made as a result of all but the last row. The updates produced by each row are overwritten by the updates from subsequent rows with the same key values.

Example using update columns

When only some columns in a table are specified as columns to be updated, the values corresponding to all other columns are ignored when the update statement is built and executed. For any row produced by the map, if the values for the update key columns do not match any of the existing rows in the table or view, the values of all columns will be inserted in the new row.

In the following example, a table (**PersonalInfo**) has the following key columns and update columns defined in the Database Interface Designer.

When this map runs, because **-UPDATE** is enabled for the output, the database adapter will first go through the results of the map and update all rows in the table matching the key columns in the output produced. Essentially, the following SQL statements are executed:

```
UPDATE PersonalInfo
SET FirstName='Karl', LastName='March', PhoneNumber='(847)
555-1234'
WHERE ID = 10
UPDATE PersonalInfo
SET FirstName='Janice', LastName='Armstrong',
PhoneNumber='(203) 555-9898'
WHERE ID=14
```

In the first UPDATE statement, because this statement does not find any rows to update, the following SQL statement is executed.

```
INSERT INTO PersonalInfo VALUES (10,'Karl', 'March',
'(847) 555-1234', '999-88-7766')
```

This execution creates a new row in the table for **Karl March**-including values for the **ID**, **FirstName**, **LastName**, **PhoneNumber**, and **SSN** columns.

In the second UPDATE statement, because an existing row has an **ID** value of **14**, only the values of the **FirstName**, **LastName**, and **PhoneNumber** columns are updated because of the settings specified in the **Columns to update** list in the Set Table Update Key Columns dialog of the Database Interface Designer. In this example, **Janice Taylor**'s last name changed to **Armstrong** and her telephone number is changed to **(203) 555-9898**. Her social security number remains unchanged because it is not a column that has been designated for update.

Database functions

This topic discusses two functions (**DBLOOKUP** and **DBQUERY**) that are designed exclusively for use with databases. These functions can be used in component rules in the Type Designer and map rules in the Map Designer when creating a map to be used with a database.

- [Accessing database information in a map rule](#)
- [Using DBLOOKUP and DBQUERY](#)
- [Using bind values in database functions](#)

Accessing database information in a map rule

In many cases, database information for a map will be one of the following:

- the results of a database query or a stored procedure defined as the data source for an input card
- the rows to update or insert into a table defined as the target for an output card.

However, there are certain situations in which you might not want to define the entire query as a data source or the table as a target. For example, you may have a very large table that is used as a source for cross-reference in your map. However, because of its size, reading in and validating all of the information as an input card is impractical. In other situations, you may want to call one map from another using the **RUN** function when one of the data sources is a dynamically built query.

Two functions provide the ability to access database information from within a rule:**DBLOOKUP** and **DBQUERY**. The difference between the two functions is subtle and is based upon how the data resulting from either function is returned.

Using DBLOOKUP and DBQUERY

A single-text-item is returned by either the **DBLOOKUP** and **DBQUERY** function. If your SQL statement is a **SELECT** statement, the **DBLOOKUP** or **DBQUERY** function returns the results of the query in the same format as a query specified in a map input card. If your SQL statement is anything other than a **SELECT** statement, these functions return **NONE**.

Both functions return the results of a query (SQL **SELECT** statement) in the same format as a query specified for a map input card, using the delimited row format. However, the **DBLOOKUP** function strips off the last carriage return/line feed. Because this information is stripped, it is easier to make use of a single value extracted from a database.

`DBLOOKUP` and `DBQUERY` execute an SQL statement within a rule against the database. The SQL statement can be any statement permitted by your database management system or database-specific driver.

There are two syntax methods that can be used to specify the arguments for these two functions: Syntax1 and Syntax2.

- [Syntax1 - using a static MDQ file](#)
- [Syntax2 - using dynamic adapter commands](#)
- [Examples](#)
- [Uses](#)

Syntax1 - using a static MDQ file

Use Syntax1 to execute a SELECT statement that retrieves a specific column value from a large table in a database using the value of another input, as opposed to having to define the entire table as an input card and using other functions such as `LOOKUP`, `SEARCHDOWN`, or `SEARCHUP`. For more information about these functions, see the *Functions and Expressions documentation*.

If column data from a table or database varies because it may be based upon a parameter file, use Syntax2. For more information, refer to [Syntax2 - using dynamic adapter commands](#).

Syntax1 is a three-argument syntax, examples of which follow:

```
DBLOOKUP
(
    SQL_statement,mdq_file,database_name[:adapter_commands])
DBQUERY
(
    SQL_statement,mdq_file,database_name[:adapter_commands])
```

Using this syntax, `DBLOOKUP` and `DBQUERY` use the following arguments.

Argument	Explanation	Must Be
<code>SQL_statement</code>	single-text-expression	a valid SQL statement
<code>mdq_file</code>	single-filename	a string literal
<code>database_name</code>	single-database-name	a string literal
<code>adapter_commands</code>	adapter-commands	a valid adapter command(s)

The following table describes these arguments in more detail.

Argument	Description
<code>SQL_statement</code>	SQL statement as a text string. It can be any valid SQL statement permitted by your database management system and supported by your database-specific driver. In addition to a fixed SQL statement, this argument can be a concatenation of text literals and data objects, enabling the concatenation of data values into your SQL statement.
<code>mdq_file</code>	Name of a database/query file (MDQ) produced by the Database Interface Designer. It contains the definition of the database against which the SQL SELECT statement is to be executed. If the MDQ file is in a directory other than the directory of the map, the complete path must be specified. Note: The MDQ file is accessed at map build time and is not needed at runtime.
<code>database_name</code>	Name of a database in the MDQ file as defined in the Database Interface Designer. Note: This name is case-sensitive and must exactly match the name as defined in the Database Interface Designer.
<code>adapter_commands</code>	Name of an adapter command or commands. This name is an optional argument that appears after <code>database_name</code> , which allows you to specify database adapter commands in component rules in the Type Designer and map rules in the Map Designer. Note: The rules are defined and compiled into your map at design time. Note: All adapter commands (for example, <code>-CS</code>) can be either uppercase or lowercase, but not mixed case.

Syntax2 - using dynamic adapter commands

Use Syntax2 to execute a SELECT statement that retrieves a specific column value from a table or database when the database, table, or other database parameters may vary. This can be used when parameters are being supplied by a parameter file.

```
DBLOOKUP (
    SQL_statement,adapter_commands
)
DBQUERY (
    SQL_statement,adapter_commands
)
```

Using this syntax and the Syntax 2 formatting issues ([Syntax2 formatting issues](#)), `DBLOOKUP` and `DBQUERY` use the following arguments.

Argument	Explanation
<code>SQL_statement</code>	single_text_expression
<code>adapter_commands</code>	Either <code>-MDQ mdq_file -DBNAME db_name</code> or <code>-DBTYPE database_type [database_adapter_commands]</code>

The following table describes these arguments in more detail.

Argument	Description
SQL_statement	SQL statement as a text string. It can be any valid SQL statement permitted by your database management system and supported by your database-specific driver. In addition to a fixed SQL statement, this argument can be a concatenation of text literals and data objects, enabling the concatenation of data values into your SQL statement.
adapter_commands	Either the <code>-MDQ</code> or the <code>-DBTYPE</code> adapter command can be used for this argument.
<code>-MDQ</code>	This adapter command is followed by the name of the MDQ file produced by the Database Interface Designer. This MDQ file contains the definition of the database against which the SQL statement is to be executed. If the MDQ file is in a directory other than the directory of the map, the path must be specified. The MDQ file name is followed by the <code>-DBNAME</code> adapter command and the name of the database in the MDQ file, as defined in the Database Interface Designer.
	Using this syntax, the specified MDQ file must be available at run time.
<code>-DBTYPE</code>	This adapter command is followed by the type of database (for example, <code>ORACLE</code> or <code>ODBC</code>) followed, optionally, by database-specific adapter commands. This syntax does not use an MDQ file because the database-specific adapter commands provide the information required to connect to the database. For more information about your particular database adapter and database-specific adapter commands, see the adapter-specific documentation in the adapter reference guides.
• Syntax2 formatting issues	

Syntax2 formatting issues

When using Syntax2 for `DBLOOKUP` or `DBQUERY`, your function must conform to these rules:

- All adapter commands (for example, `-DBTYPE`) can be either upper or lower case, but not mixed case.
- A space is required between the adapter command and its value (for example, `-DT database_adapter`).
- The order of the adapter commands is not important.

Examples

The section presents different `DBLOOKUP` and `DBQUERY` examples.

- [Example 1 - obtaining a single column value](#)
- [Example 2 - using DBQUERY to obtain multiple columns or rows](#)
- [Example 3 - using DBQUERY to provide map input to RUN function](#)
- [Example 4 - using WORD to parse multi-column output from DBQUERY](#)
- [Example 5 - using DBQUERY with adapter commands to obtain a single column value](#)

Example 1 - obtaining a single column value

Assume that you have a table named **PARTS** that consists of the following data:

PART_NUMBER	PART_NAME
1	1/4" x 3" Bolt
2	1/4" x 4" Bolt

Also assume that this database has been defined in a file named **mytest.mdq** using the Database Interface Designer. The name of the database, as specified in the MDQ file, is **PartsDB**. Notice the difference between the returned values from the execution of the following two Syntax1-formatted functions.

Function	Returns PART_NAME
<code>DBLOOKUP ("SELECT PART_NAME from PARTS where PART_NUMBER =1", "mytest.mdq", "PartsDB")</code>	1/4" x 3" Bolt
<code>DBQUERY ("SELECT PART_NAME from PARTS where PART_NUMBER =1", "mytest.mdq", "PartsDB")</code>	1/4" x 3" Bolt<cr/lf> where <cr/lf> is a carriage return followed by a line feed

Using Syntax2, you can also specify the `DBLOOKUP` or `DBQUERY` functions as in the following examples.

```
DBLOOKUP ("SELECT PART_NAME from PARTS where PART_NUMBER =1",
          "-MDQ mytest.mdq -DBNAME PartsDB")
DBQUERY ("SELECT PART_NAME from PARTS where PART_NUMBER =1",
          "-MDQ mytest.mdq -DBNAME PartsDB")
```

Note that both the MDQ file name and database name are specified.

The examples below use the Syntax2 format to specify the database type and the appropriate database-specific adapter commands (in this example, using the `-DBTYPE`, `-CONNECT`, `-USER`, and `-PASSWORD` commands for an Oracle database):

```
DBLOOKUP ("SELECT PART_NAME from PARTS where PART_NUMBER =1",
          "-DBTYPE ORACLE -CONNECT MyDatabase
          -USER janes -PASSWORD secretpw")
DBQUERY (" SELECT PART_NAME from PARTS where PART_NUMBER =1",
          "-DBTYPE ORACLE -CONNECT MyDatabase
          -USER janes -PASSWORD secretpw")
```

Example 2 - using DBQUERY to obtain multiple columns or rows

Assume that you have a table named **PARTS** that consists of the following data:

PART_NUMBER	PART_NAME
1	1/4" x 3" Bolt
2	1/4" x 4" Bolt

Also assume that this database has been defined in a file named **mytest.mdq** using the Database Interface Designer. The name of the database, as specified in the MDQ file, is **PartsDB**.

Using the Syntax1 format, the following DBQUERY function:

```
DBQUERY ("SELECT * from PARTS", "mytest.mdq", "PartsDB")
```

returns:

```
1|1/4" x 3" Bolt<cr/lf>2|1/4" x 4" Bolt<cr/lf>
```

where <cr/lf> is a carriage return followed by a line feed.

Notice that if the same function was executed using DBLOOKUP, the results would be:

```
1|1/4" x 3" Bolt<cr/lf>2|1/4" x 4" Bolt
```

The difference between the two results is that the final carriage return/line feed is stripped off the end of the results of the DBLOOKUP function.

Using Syntax2, you can obtain the same results as in the previous DBQUERY function as shown in the following examples:

```
DBQUERY ("SELECT * from PARTS where PART_NUMBER =1",
        "-MDQ mytest.mdq -DBNAME PartsDB")
```

or:

```
DBQUERY      ("SELECT * from PARTS where PART_NUMBER =1",
              "-DBTYPE ORACLE -CONNECT MyDatabase -USER janes
              -PASSWORD secretpw")
```

Example 3 - using DBQUERY to provide map input to RUN function

In another example, assume that you have an input file containing one order record. To map that order to another proprietary format, you also have a **PARTS** table with pricing information for every part for every customer-a very large table. Rather than using the entire **PARTS** table as the input to your map, you might include the **RUN** function with your Syntax1-formatted DBQUERY to dynamically select only those rows from the **PARTS** table corresponding to the customer in the order file, as follows:

```
RUN ("MapOrder.MMC",
     "-IE2'" + DBQUERY ("SELECT * FROM PARTS WHERE CustID =" +
CustomerNo:OrderRecord:OrderFile +
" ORDER BY PARTNO",
"PartsDB.MDQ",
"PartsDatabase") +"'")
```

Example 4 - using WORD to parse multi-column output from DBQUERY

In certain situations, you may want to use one of the database functions, rather than a database source, due to the size of a cross-reference table. However, you need the function to return the data from several different columns.

For example, assume you need to create a map that processes inventory requests, one order at a time, using a messaging system. Within the transformation of your data, you need to reference the item master table that contains hundreds of thousands of rows. However, for each item within the inventory request, you need to get the internal item number, vendor ID, and description column value. You can select from several available options, such as:

- Use a database source.
Define a query for only those columns needed. Use this for a database source that you can then use within a **LOOKUP**, **EXTRACT**, or **SEARCHUP/SEARCHDOWN** function. However, due to the size of the item master table, this might mean validating hundreds of thousands of rows to find the item information for only a few items.
- Use multiple DBLOOKUP functions.
Assuming that the internal item number, vendor ID, and description column values are going to be used within different outputs, you could use three separate DBLOOKUP functions to get the appropriate column value for each item. However, this means executing three SQL statements to access the same row within the item master table.
- Use the DBLOOKUP and WORD functions.
Assuming that a functional map will be used to build an object containing the three desired columns, a DBLOOKUP could be used as an argument to the functional map that retrieves the desired column values. see the following example:

```
=F_MakeOne ( Item Set:SomeInput ,
DBLOOKUP ( "SELECT INT_ITEM_NO, VENDOR, ITEM_DESC " +
```

```
"FROM ITEM_MASTER WHERE ITEM_NO = '" +  
CatalogID:.:SomeInput + "'", "PRODXL.MDQ"  
"WDDM" ) )
```

The functional map **F_MakeOne** has two inputs: an **Item Set** and a text item (that is the result of the **DBLOOKUP** function). The text item will contain the three column values separated by the pipe character (|). An example follows:

```
ARQJ06X6|DFQCO|6' Jump Rope
```

Then, each rule requiring one of these pieces of data will use the **WORD** function to access the appropriate column's data. For example, if the input card for the results of the **DBLOOKUP** function was called **ItemData**, the rule using the vendor ID column would be:

```
=WORD ( ItemData , "|" , 2 )
```

The values of the other columns can be retrieved in a similar manner.

Example 5 - using DBQUERY with adapter commands to obtain a single column value

This example demonstrates how you can use the **DBQUERY** function to enter adapter commands as an argument following **database_name** using the **Syntax1** format:

```
DBQUERY("SELECT PART_NAME from PARTS  
where PART_NUMBER =1",  
"mytest.mdq","PartsDB : -T -CS")
```

In the **DBQUERY** example above, the **PART_NAME** column value in the row that contains the **PART_NUMBER** column value of 1 will be retrieved from the **PARTS** table. The **PARTS** table is in the **PartsDB** Oracle database specified in the **mytest.mdq** file, which was produced by the Database Interface Designer.

This example uses optional database-specific adapter commands. The Trace (-T) adapter command will produce a database trace file. The Commit by Statement (-CS) adapter command will commit or rollback the transaction after the rule executes.

Uses

When you might want to use **DBLOOKUP** to execute an SQL statement:

- To retrieve a single column value from a database based upon another value in your data without the carriage return/line feed row terminator

When you might want to use **DBQUERY** to execute an SQL statement:

- To look up multiple column values for multiple rows in a database using a parameterized query based upon another value in your data
- When your SQL statement is a **SELECT** statement, the **DBQUERY** function can be used along with the **RUN** function to issue dynamic **SELECT** statements whose results can be used as input to a map.
- When using other SQL statements such as **INSERT**, **UPDATE**, **DELETE**, and so on.

For information about functions such as **EXTRACT**, **LOOKUP**, **SEARCHUP**, **SEARCHDOWN**, **GET**, and **PUT**, see the Functions and Expressions documentation.

Using bind values in database functions

For information about the availability and usage of the bind facility for your specific database and platform, see the database-specific adapter reference guides.

When the Database Management System (DBMS) receives an SQL request, the request is cached because many applications repeatedly issue the same SQL statement. If the SQL statement differs from one that the DBMS has recently processed, the statement is reevaluated. (The DBMS performs parsing, derives an execution plan, and so on.)

Similarly, if a **DBLOOKUP** or **DBQUERY** function repeatedly issues the same statement, the second and subsequent executions of the statement execute much faster than the first execution. However, if any element of the statement varies, the DBMS considers the statement to be new and does not take advantage of caching. For example, the two following statements are distinct to a DBMS:

```
SELECT * FROM MyTable WHERE CorrelationID=123  
SELECT * FROM MyTable WHERE CorrelationID=124
```

Use the bind facility for **DBLOOKUP** and **DBQUERY** functions to submit such statements to the DBMS so that the statements are syntactically identical. By binding a value to a placeholder in the SQL statement, the actual syntax of the statement can be made static.

The syntax for specifying a value in the SQL statement as a bind value is:

```
:bind(  
value  
)
```

For example, to use a bind variable in the statement above, the SQL statement would be:

```
SELECT * FROM MyTable WHERE CorrelationID=:bind(123)
```

The database adapter strips out the **:bind** keyword and binds the value 123 to a placeholder in the statement.

The value in the parentheses is always a text item. Single quotation marks should not be specified around string literals. For example, if you had the statement:

```
SELECT Artist FROM CDList WHERE Title = 'Goodbye'
```

and you want to bind the value for the title, the syntax would be:

```
SELECT Artist FROM CDList WHERE Title=:bind(Goodbye)
```

Within the context of a DBLOOKUP or DBQUERY function, the elements of the statement to be bound are dynamic elements. For example, if the following call to DBLOOKUP is in a map:

```
DBLOOKUP      ("SELECT Name FROM MyTable WHERE ID="+ Item1:Row +
    "and CorrelationID= '" + Item2:Row + "'",
    "DB.mdq",
    "MyDB")
```

The call could be modified to benefit from binding values as follows:

```
DBLOOKUP      ("SELECT Name FROM MyTable WHERE ID=:bind("+ Item1:Row +")
    and CorrelationID=:bind(" + Item2:Row + ")",
    "DB.mdq",
    "MyDB")
```

There is no performance benefit unless *all* values that change from one invocation of the statement to the next are bound. For example, if the ID value is bound and *not* the CorrelationID value, the statement will vary because the CorrelationID value varies.

Using stored procedures

This topic describes the various mechanisms for using stored procedures to access all types of parameters and return values from stored functions. You can call stored procedures when using DBQUERY and DBLOOKUP functions and when defining a query in the Database Interface Designer for a map data source. When defining a database as the target for an output card, you can also output to a stored procedure.

For information about the availability and usage of calling stored procedures, including the correct native syntax for these calls, refer to each database-specific adapter reference guide.

- [Calling stored procedures](#)
- [Examples using stored procedures](#)
- [Using a stored procedure as an input](#)
- [Using a stored procedure as an output](#)
- [Stored procedures with object type parameters](#)

Calling stored procedures

When used as a source of data in one of the database functions (DBQUERY or DBLOOKUP), in a GET function, or in a query defined in the Database Interface Designer, there are two ways to call stored procedures:

- Use the database-independent syntax for calls.
This provides a means of accessing the output parameters and return values from stored functions.
- Use the native syntax for the database.
Using this method, you cannot access output parameters or return values from stored functions.

In addition to the above methods, when using Oracle object types as parameters in stored procedures, there is a special syntax that must be used. For more information about this, see [Stored Procedures with Object Type Parameters](#).

- [Database-independent syntax for calls](#)

Database-independent syntax for calls

The database-independent syntax for calling stored procedures is:

```
CALL [?=?] procedure_name [(argument_list)]
```

The arguments are described below.

Option	Description
?=	Indicates that the return value from a stored function should be returned.
<i>procedure_name</i>	The name of the stored procedure or function. To invoke a stored procedure in an Oracle package, fully qualify the stored procedure name. For example:

```
schema_name.package_name.stored_procedure_name
```

argument_list

A comma-separated list of arguments in which each argument is one of the following:

Argument	Description
----------	-------------

value	This is the value to be passed to an input parameter. If the value contains spaces, it must be surrounded by single quotation marks (for example, 'city of'). The quotation mark characters are not passed as part of the parameter.
?	Return the value from an output parameter.
X	Do not return the value from an output parameter.
?/value	This is the value to be passed to an In / Out parameter and the value to be returned from the parameter.

Examples using stored procedures

In the following example, there is a stored procedure named **DoSalaryIncrease** with the following parameters:

Employee ID -	parm1 - In
Merit Increase (%) -	parm2 - Out
Salary -	parm3 - In / Out
Effective Date -	parm4 - Out

Using the DBLOOKUP function, an example of the syntax used to call **DoSalaryIncrease** would be:

```
DBLOOKUP
("call DoSalaryIncrease (
+ EmpID::PayrollFile
+ ?,?/?"
+ Salary::PayrollFile + ?,?)", "AdminDb.mdq", "HR_DB")
```

If **EmpID** has a value of **SM01930** and **Salary** has a value of **42,750**, the call syntax would expand to:

```
call DoSalaryIncrease (SM01930, ?, ?/42750, ?)
```

The output from this call is a single text item in which each field is delimited by the pipe character (|). In this example, there will be three fields in the output-one for each question mark character (?) placeholder. If you do not want to use all of the output parameters, you can use any other character in place of the question mark character. For example, if you did not use the **EffectiveDate** (parm4), the call could be changed to:

```
DBLOOKUP
("call DoSalaryIncrease (" + EmpID::PayrollFile
+ ?,?/?" + Salary::PayrollFile + ",X)",
"AdminDb.mdq", "HR_DB")
```

Once again, if **EmpID** has a value of **SM01930** and **Salary** has a value of **42,750**, the call syntax would expand to:

```
call DoSalaryIncrease (SM01930, ?, ?/42750, X)
```

In this example, the **EffectiveDate** (parm4) would not be returned.

- [Returning the Value from a stored function](#)

Returning the Value from a stored function

If you want the value from a stored function, prefix the procedure or function name with **?=**. For example:

```
DBLOOKUP("call ?= MyFunction('cat') , "My.mdq" , "MyDB")
```

Using a stored procedure as an input

Stored procedures can be used in input cards by specifying the call in the **Query** field in the New Query dialog of the Database Interface Designer.

After the stored procedure call is entered in the New Query dialog or the Edit/View Query dialog (if you are editing an existing query), you can generate a type tree for the stored procedure.

Generated type trees for stored procedures adhere to the same format as type trees for queries and will contain a **Row** group, the components of which correspond to the ? placeholders in the CALL statement. Return values from stored functions will typically have the field name **RETURN_VALUE** unless the database returns a specific name.

The call syntax for a stored procedure can be used effectively in input cards in combination with substitution variables to provide values to input parameters. For example, to call **GetPaymentInfo** in an input card, because **GetPaymentInfo** takes a single input parameter, first define the text in the **Query** field.

Next, provide the value on the command line for **parm1** at execution time as follows:

```
dtx MyMap.mmc -ID1 '-VAR parm1=2000-03-11'
```

- [Using a query to execute a stored procedure](#)

Using a query to execute a stored procedure

If your database permits the execution of a SELECT statement in a stored procedure or function and can return values through subsequent row fetches, you can specify a procedure call using the native database syntax in the **Query** field of the **New Query** or Edit/View Query dialog using the Database Interface Designer.

For example, to call a stored procedure by means of ODBC using the native syntax, the query text you enter in the **New Query** or Edit/View Query dialog might be:

```
{call MyProc(-1)}
```

The query text for a call to a stored procedure must be in the native database syntax. For more information about the correct syntax of the procedure call using your particular database adapter, see the database-specific adapter reference guide.

To define a query using a stored procedure:

When you use a stored procedure to define a query, follow the same steps as when you use a SELECT or other statement:

1. Define the query in the **New Query** or Edit/View Query dialog of the Database Interface Designer.
2. Generate a type tree from the query.
3. In the Map Designer, specify the query when defining the data source for the executable map input card for the stored procedure.

Using a stored procedure as an output

Using the database adapters, you can call stored procedures in output cards.

Type trees generated for stored procedures contain an item type for each input argument. Instead of a **Row** type, these type trees have a **ProcedureCall** type that represents the set of arguments passed to the stored procedure for each execution of that procedure. The **DBProcedure** type consists of a series of **ProcedureCalls**. The stored procedure is called once for each **ProcedureCall** in the **DBProcedure** output. This information is highlighted in the following example.

There are two ways to call stored procedures in output cards:

- In the output card dialog in the Map Designer, specify `-PROC procedure_name` in the PUT> Target > Command setting. For more information, refer to [Using a database as a target](#).
or
- When overriding an output card using database adapter commands on the command line, use the `-PROC` adapter command and specify the stored procedure name.
For more information, see the Resource Adapters documentation.

The values for each parameter are passed to the stored procedure with the stored procedure being called for each row of data.

The types of the parameters may be IN, OUT, or IN/OUT. However, there is no mechanism to return values from output parameters. Any values passed to an OUT parameter will be ignored.

Stored procedures with object type parameters

The Oracle adapter provides full support for Oracle object types to be used as parameters to stored procedures or functions. Mapping to a stored procedure call in an output card is no different than mapping to a table; object types as parameters are fully supported.

Similarly, invoking stored procedures with object type parameters using the 'call' syntax is possible. For output parameters, there is no special syntax required. Using a question mark character (?) will result in the entire object being returned from the stored procedure call. However, for input parameters, a special syntax is required to specify the objects. The syntax rules are as follows:

- The object must be contained within square brackets. An example of this is: "[.....]"
- Each element of the type is separated from other elements of the type by the pipe (|) delimiter character.
- Spaces are not allowed unless they are contained within the data itself.

see the following example. The type 'outer' is defined by the following 'create type' statements:

```
create type inner as object (
  a_char varchar(10),
  b_int number(10,0));
create type outer as object (
  x_inner inner,
  y_date date);
```

Assume that there is a table named 'object_holder' and a stored function 'insert_object' defined to insert an object of type 'outer' and to return the number of objects in the table. The SQL required to create this follows:

```
create table object_holder (
  myobj outer);
create or replace function insert_object (obj in outer) return
number is
row_count number;
begin
  insert into object_holder values (obj);
  select count(*) into row_count from object_holder;
  return row_count;
end;
```

To provide an object with the following attributes:

```
x_inner.a_char = 'hello'
x_inner.b_int = 23
y_date = 2000-10-12 04:59:23
```

use the following query:

```
call ?= insert_object([[hello|23]2000-10-12 04:59:23])
```

Note that the inner object is also delimited by square brackets.

Database triggers

Data sources using database adapters can serve as input event triggers that are defined in the Database Interface Designer, enabled in the Integration Flow Designer, and executed by an Launcher.

For information about the availability and usage of triggering for your specific database and platform, see the database-specific adapter reference guide.

- [Database triggers overview](#)
- [Using a database as a map trigger](#)
- [Specifying a combination of different event classes](#)
- [Specifying triggers on the command line](#)
- [Using the Integration Flow Designer to enable triggers](#)

Database triggers overview

This introductory section provides information about the following topics:

- [Database Support](#)
This topic discusses those databases supporting triggering and the types of triggering supported.
- [Installation Requirements](#)
This topic discusses the database-specific scripts required to be run to enable database triggering.
- [Tables Created for Triggering](#)
This topic discusses the four tables created as a result of running the installation scripts for triggering.
- [Maintaining Triggering Tables](#)
This topic discusses table maintenance required in unusual situations such as unexpected shutdown of Launchers and working with truncated tables.
- [Database support](#)
- [Installation requirements](#)
- [Tables created for triggering](#)
- [Maintaining triggering tables](#)
- [Table-based triggering](#)
- [Row-based triggering](#)
- [Issues for both row- and table-based triggering](#)
- [Issues for row-based triggering only](#)
- [Defining a trigger using a database source](#)

Database support

The event(s) that occur causing a trigger to run a map may be the result of a map or some other application.

The following databases support triggering:

- Oracle client and server (for Windows and UNIX)
- Microsoft SQL Server (for Windows only)
For information about the versions of these databases that are supported in this release, see the [system requirements](#).

The Database Interface Designer allows two different triggering actions during event-based map execution:

- [Table-based](#) triggering
- [Row-based](#) triggering
 - [Column-based](#) triggering (an enhancement to row-based)

Installation requirements

Before you can take advantage of the database triggering functionality, either one of three database-specific installation scripts must be run by a system administrator:

Note: This is a one-time only operation except for a possible unexpected Launcher shutdown. For more information about that scenario, refer to [Handling Unexpected Shutdowns](#).

- [m4ora.sql](#) (for Oracle)
- [m4ora_col.sql](#) (for Oracle)
- [m4sqlsvr.sql](#) (for Microsoft SQL Server)

Executing the respective script installs the database objects required for database triggering:

- tables that track "watch" events Four tables are added to your database. These are required for the triggering functionality. For more information about these tables, refer to [Tables created for triggering](#).
 - stored procedures that interface to the tables
 - (for Microsoft SQL Server only) extended stored procedures that contain signaling logic
 - (for Oracle only) public synonyms for tables and stored procedures
 - (for Oracle only) sequences that generate unique trigger IDs
Certain privileges must be granted to the user running the database card triggers. The specific details for this and additional information are presented at the beginning of each script.
 - [Column-based triggering](#)
-

Column-based triggering

To use column-based triggering (for Oracle only), run either of the following scripts:

Script

Use
m4ora_col.sql

if you are upgrading from a release prior to IBM Transformation Extender 8.0, and had been using Oracle database triggering

m4ora.sql

to re-install the database objects required for column-based triggering

For more information, refer to ["Column-Based Triggering"](#).

Tables created for triggering

See the following table for information about the four tables that are created by executing the SQL script.

Table

Description

Trigger_Server

Used at startup, this table tracks the Launchers that are accessing this database. The Launchers must have unique machine name and TCP/IP address combinations. (In other words, triggering is only supported for one Launcher per machine.)

Trigger_Catalog

Used at startup, this table tracks all triggers for all tables that have been defined on this database. This functionality allows table "watches" to be reused across multi-user/Launcher environments.

Trigger_Registry

Used during processing, this table registers every "watched" table for each Launcher. The "watches" on each card are placed here. In this registry is every map on every machine that is being "watched".

Trigger_Events

Used during processing, this table records all events that have occurred as a result of the table "watches" defined in the Trigger_Registry table.

Note: For Oracle only. If an Oracle table is truncated or dropped while having unprocessed row-based table entries, there may be map execution problems. To avoid these problems, you may have to perform some maintenance on this table. For information about how to do this, refer to [Handling truncated tables](#).

Maintaining triggering tables

The current implementation of the triggering functionality should be self-maintaining. However, there are unusual situations in which some user maintenance might need to be performed as described in the following sections:

- [Handling unexpected shutdowns](#)
 - [Handling truncated tables](#)
 - [Handling unexpected shutdowns](#)
 - [Handling truncated tables](#)
-

Handling unexpected shutdowns

Note: Make sure that there are no other Launcher systems running on the target DBMS before running the maintenance operations listed below.

If an Launcher system (containing database triggers) has encountered an unexpected shutdown and cannot be re-started and subsequently shut down in a normal sequence, you must re-run the triggering installation script (specific to your database) to clean up any triggering resources that have been left behind on the target DBMS. This is because when an Launcher is prematurely shut down, any defined database triggers will remain in operation on the backend DBMS (for example, Oracle) until the same system is re-started and then properly shut down.

The database triggers will continue to monitor for events while the Launcher is shut down, thus enabling the system to be fault-tolerant with respect to any database changes that occur during an unexpected downtime. This fault-tolerant behavior requires that a normal system shutdown eventually take place. Otherwise, the database triggers will continually remain in operation, taking up processing and space resources on the target DBMS.

If the triggering installation script cannot be run, a temporary solution would be to run the following SQL statements on the target DBMS:

1. DELETE FROM Trigger_Events;
2. DELETE FROM Trigger_Registry;

3. COMMIT;

Handling truncated tables

Note: For Oracle only.

If an Oracle table is truncated or dropped while having unprocessed row-based table entries, there may be map execution problems. To avoid these problems, you may have to perform some maintenance on the Trigger_Events table as shown in the following procedure.

Make sure you only delete those rows in the Trigger_Events table associated with the truncated table. Also, you can perform this procedure after dropping and recreating a table.

To delete table-specific truncated rows:

1. Enter the following SQL statement:

```
DELETE from Trigger_Events WHERE ID IN (
    SELECT ID FROM Trigger_Registry WHERE TriggerName IN (
        SELECT TriggerName FROM Trigger_Catalog
        WHERE UPPER(SourceSchema) = UPPER('schema_name') AND
        UPPER(SourceTable) = UPPER('table_name')))
```

where *schema_name* is the name of your schema and *table_name* is the name of the truncated table.

2. Commit the transaction (for example, `COMMIT;`).
-

Table-based triggering

A typical usage for table-based triggering would be to set up a trigger that will execute a map to run after another map has completed processing and has inserted rows into a table.

For information about the Source > Transaction > Scope setting, see [Database sources and targets](#). For information about using the Commit by Statement adapter command (`-CSTMTC`), see the Resource Adapters documentation.

To see how to construct the WHEN expression for table-based triggering, see the [Specifying when](#) topic.

Row-based triggering

The row-based triggering design enables a fault-tolerant, multi-server-aware triggering mechanism that can enable maps to selectively process those rows associated with a triggered watch event. In the preceding sentence, fault-tolerant means that data is not lost if a process fails, a connection is dropped, an Launcher stops, or some other unforeseen interruption occurs. Multi-server-aware means that Launchers on different machines can connect to and "watch" the same table.

The main difference between row-based and table-based triggering is that with row-based triggering, the query executes on only those rows that have been updated or inserted, not on the entire table. Additionally, batch-like processing is possible if the When clause is used to control the time and/or date at/upon which processing should occur.

When using column-based triggering, batch processing does not occur.

To see how to construct the WHEN expression for row-based triggering, refer to the example in [SELECT 1 FROM Format](#).

- [Column-based triggering](#)
-

Column-based triggering

An enhancement to the row-based triggering functionality is column-based triggering. It enables you to trigger an event to occur on a row when a particular column condition is met. This functionality is available in both the **m4ora.sql** and the **m4ora_col.sql** scripts. To use this functionality to trigger an Oracle database watch event for a map when a column condition is met, supply the column condition extension of the SQL WHEN expression in the Trigger Specification dialog of the Database Interface Designer. The portion of the WHEN expression that appears after **column condition** is the SQL clause that is passed to the Oracle database for processing.

Refer to Oracle documentation for the WHEN clause syntax when using it in a trigger definition.

For information on installing the **m4ora.sql** and the **m4ora_col.sql** scripts, refer to ["Installation Requirements"](#).

To see how to construct the WHEN expression for column-based triggering, see the example in the [Format of the When Expression](#) section.

Issues for both row- and table-based triggering

The following list represents what is and is not supported in row- or table-based triggering:

- The appropriate database must be used (supported versions of either Oracle client and server [for Windows and UNIX] or Microsoft SQL Server [for Windows only]).
- The respective SQL file (refer back to ["Installation requirements"](#)) must be installed and executed by your system administrator.
- SELECT statements containing Union or Intersect clauses are not supported.

- Case sensitivity for either column or table names is not supported.
- Only one Launcher per machine is supported.

Issues for row-based triggering only

The following list represents what is and is not supported in row-based triggering only:

- For Microsoft SQL Server, each table defined in the query must contain either an identity column or one numeric primary key.
- Queries that reference views or public synonyms are not supported.

Defining a trigger using a database source

About this task

Specify that you want a database source to be a trigger for a map when using a database adapter that supports triggering and an Launcher.

To define a trigger:

Procedure

1. Use the Database Interface Designer to create an MDQ file containing the desired query.
2. From the Trigger Specification dialog in the Database Interface Designer, define the conditions under which changes in database tables will trigger a map. The trigger you define is associated with a query and is saved in the MDQ file. For more information about this, refer to [Defining a trigger for a query](#).
3. Use the Map Designer to create an executable map with an input card that uses the MDQ file containing the trigger specification. For more information, see the Map Designer documentation.
Make sure that the input card corresponding to the database trigger is set to integral mode, not burst.
4. Use the Integration Flow Designer to create a system with the map component containing the trigger specification. Enable the Input(s) > GET > Source setting in the Launcher Settings dialog. For information about how to do this, refer to [Using the Integration Flow Designer to enable triggers](#).
The Integration Flow Designer does not perform any validation of a database source used as a trigger. Ensure that the trigger has been defined using the Database Interface Designer prior to specifying it as an input event trigger.
5. Generate the Launcher system file (.msl) on the Launcher as appropriate. For more information about how to do this, see the Integration Flow Designer documentation.

Using a database as a map trigger

Database sources can be used as input events for the Launcher. Insertions, deletions (for table-based triggering only), or updates to database tables can be the trigger mechanism that will run a map.

A trigger specification is defined in the Database Interface Designer for an individual query and is stored with the query in the MDQ file. When a database source is specified as an input event in the Integration Flow Designer, the trigger specification is evaluated by the Launcher and is run accordingly.

- [Defining a trigger for a query](#)
- [Defining events](#)

Defining a trigger for a query

About this task

After you have defined a query in the Database Interface Designer, you can define a trigger specification that can be used to launch a map using that same query as a data source.

To define a trigger specification:

Procedure

1. In the Database Interface Designer, select the query for which you want to define a trigger specification.
2. From the Query menu, select Define Trigger.
The Trigger Specification dialog appears. When initially displayed, the lists on the left show all of the tables referenced by the SELECT statement of the selected query.
3. Determine whether you can define row-based triggering for this query as determined by the availability of the Row-based triggering check box.
If this is a new query and the table supports it, this check box will be enabled as the default value. (For old queries, this check box will be cleared as the default value, which means that you could use the functionality by enabling it. In another scenario, the entire check box could be disabled because this functionality is not available for the query and table being used.)
4. To specify the events, select a table name from the Insert into or Delete from lists.
or
Select a table name from the Update of list.

The name of the table you select will be either the destination into which data will be inserted, from which data will be deleted, or in which data will be updated when the specified event occurs.

Note: Delete from cannot be used with row-based triggering.

5. To move the table name, in the text box area corresponding to the selected table name (either Insert into, Delete from, or Update of), click the arrow button. The table name moves into the corresponding list.
6. Select as many names as necessary to define the event(s) that must occur so that conditions can be met for the trigger specification.
7. If more than one table is added to a list, you can define conditions that must be met. Select either the AND or OR radio button located directly above each list. For more information, refer to "[Specifying a combination of different event classes](#)".
- The AND option dictates that the condition is not met until the event occurs for all tables in the list when data is either inserted, deleted, or updated. The OR option dictates that the condition is met when the specified event occurs in only one table in the list.
8. To define an additional condition that will be evaluated only after the other specified event(s) has/have occurred, enter an expression in the When field. For more information, refer to "[Specifying when](#)".
9. After you have finished, click OK to save your trigger specification.

The query with the trigger specification is represented in the Navigator with an icon displayed next to the name.

Note: To modify or delete an event, use the same procedure as indicated above. Select the table name in the list on the right and click the corresponding left arrow button. The When expression can also be edited or deleted as required.

Defining events

About this task

Use the Trigger Specification dialog to define a trigger specification for an individual query that will be stored with the query in the MDQ file. As you add and remove the table names, the lists on the right display the tables for which an **Insert into**, **Delete from**, or **Update of** event comprises the condition(s) that must be met for the trigger specification. Additionally, you can specify whether row-based triggering will be used. The different classes of events that you can specify are:

- **Insert into**
The insertion of rows into the specified table serves as an input event trigger to the map that uses this query as a data source.
- **Delete from**
The deletion of rows from the specified table serves as an input event trigger to the map that uses this query as a data source.
Note: This functionality cannot be used with row-based triggering. As soon as you move a table to the right, the Row-based triggering check box is disabled.
- **Update of**
The update of rows in the specified table will serve as an input event trigger to the map that uses this query as a data source.

Specifying a combination of different event classes

About this task

If you define your trigger specification using a combination of event classes (**Insert into**, **Delete from** or **Update of**), there is an implicit OR between the different event classes.

For example, if you defined events in all three event classes, the implied condition to be met for the trigger specification would be:

```
Insert into TableA  
OR  
Delete from TableB  
OR  
Update of TableC
```

When all events have occurred within only one of the specified event classes, the condition(s) has/have been met for the trigger specification and the map is run.

- [Specifying AND or OR](#)
- [Specifying when](#)

Specifying AND or OR

Within the **Insert into** and **Delete from** event classes, you can define multiple insert and delete events by specifying multiple tables. Similarly, you can define multiple **Update of** events by specifying multiple table names.

Using the **Delete from** event class disables row-based triggering. However, you can still define multiple **Insert Into** and **Update of** events using row-based triggering.

When you specify multiple table names within an event class, you must also specify how you want the condition within the event class to be met-either when all of the events occur for all of the specified tables or when one event occurs on any one entry in the list.

The options that dictate the condition(s) to be met when you set up multiple events are:

Option	Description
AND	This option dictates that all of the specified events must occur (for example, TableA AND TableB) for the condition to be met.
OR	This option dictates that conditions are met when at least one event occurs (for example, TableA OR TableB).

Specifying when

After specifying at least one **Insert into**, **Delete from**, or **Update of** event, you can create an expression that must evaluate to true to satisfy the conditions of the trigger specification. Enter an expression in the **When** field that will be evaluated after the other events have occurred. If the **When** expression evaluates to true, the conditions of the trigger specification are met and the map is run. If the **When** expression is not true, the state is restored to what it was prior to the occurrence of any events. When row-based triggering is used, all of the changed rows will be batched together for subsequent processing after the event is re-triggered and the **When** clause has been satisfied.

When using column-based triggering, batch processing does not occur.

- [Format of the when expression](#)

Format of the when expression

There are three basic formats that can be used for the **When** expression as specified in the **Trigger Specification** dialog:

- Clauses referencing table columns ([Table column format](#))
- Clauses using the SELECT 1 FROM format to establish conditions of execution ([SELECT 1 FROM format](#))
- Clauses using the column condition ([Column condition format](#))

Table column format

The **When** expression in the **Trigger Specification** dialog can contain any SQL expressions that are valid for the database. If database columns are referenced in the expression, the column name must be qualified with the `tablename` and the `tablename.column_name` enclosed in square brackets ([]).

For example, if a map should be triggered only when there is a row in the **MyTable** table having a column entitled **Status** with a value of **Ready**, specify the **Insert into**, **Delete from**, and **Update of** events and enter the following expression in the **When** field:

```
[MyTable.Status] = 'Ready'
```

SELECT 1 FROM format

The **When** expression can support any valid SQL statement that begins with a **SELECT 1 FROM** clause. After a database event is detected on the DBMS, the entire statement (as it appears in the Trigger Specification dialog) is executed.

For example, if a database input card should be triggered for execution only during a certain time of day, the following statement could be entered:

Note: This example only applies to versions of the Oracle DBMS supported in this release.

```
select 1 from dual where  
TO_CHAR(SYSDATE, 'HH24') > '00' AND  
TO_CHAR(SYSDATE, 'HH24') < '06'
```

This **When** clause would restrict processing of any database "watch" events to the timeframe of between midnight and 6AM.

Column condition format

The **When** expression can support column-based triggering.

An example of the syntax of the column condition that you would specify in the Trigger Specification dialog of the Database Interface Designer is presented below:

```
column condition new.part_number = 'S'
```

Because column-based triggering is based on row-based triggering, the **Row-based triggering** check box must be enabled. You would enter the column condition `new.part_number = 'S'` clause into the **When** pane. The portion, `new.part_number = 'S'`, specified after column condition, is the SQL clause that the Oracle database will process.

Specifying triggers on the command line

If a trigger specification for a query has not been defined in the Database Interface Designer or if you want to override conditions that are already defined in a trigger specification associated with a query, use the command line.

For more information about using the command line and specifying the Trigger adapter command (-TR), see the Resource Adapters documentation.

Using the Integration Flow Designer to enable triggers

About this task

After you have defined the trigger using the Database Interface Designer and have created an executable map using the Map Designer, use the Integration Flow Designer to define a system containing the associated map component and to enable the trigger for execution by the Launcher. For more information, see the Integration Flow Designer documentation.

To set the database source as a trigger:

Procedure

1. In the Integration Flow Designer, display the Launcher Settings dialog for the map you want to trigger.
2. Set the SourceEvent setting value to ON.
3. Click OK.
A trigger icon appears on the map component in the system diagram. When the map component appears in expanded state, a trigger icon also appears on the input card.

The trigger icon provides a visual cue showing the inputs that serve as triggers.

Debugging and viewing results

This topic explains various troubleshooting tools available when you encounter problems using database objects as data sources or targets for a map or when using the Database Interface Designer to define databases and queries. Also presented are various methods for viewing data extracted from a database or loaded into a database.

- [Troubleshooting tools](#)
 - [Database trace files](#)
 - [Viewing database source and target data](#)
 - [Database audit files](#)
 - [DBMS trace utilities and SQL command tools](#)
-

Troubleshooting tools

If you receive an error while attempting to generate a type tree in the Database Interface Designer or if you run a map that uses database sources and/or targets and receive a runtime error or do not get the expected output, use any or all of the following troubleshooting tools:

- Map audit log (either `Mer_mapname_processkey_mapcounter_hostname.log` for unique audit logs or `mapname.log` for audit logs that do not use the Unique setting)
For information about the map audit log and related settings, see the Map Designer documentation.
 - Database Interface Designer trace (`mdq_filename.dbl`)
 - Database execution trace file (`mapname.dbl`)
 - Database source and target data
 - Database audit file (`audit.dbl`)
 - DBMS trace utilities and SQL command tools
-

Database trace files

Use the information contained in database trace files (**.dbl**) as one of the primary tools to assist in troubleshooting. These files contain detailed information generated during Database Interface Designer activity and also during map execution. For example:

- The trace file recorded for a Database Interface Designer trace contains information about the activities taking place when generating type trees such as database connections, SQL statements executed, and so on.
 - The database trace file produced at map execution time records detailed information about the database adapter activity such as records retrieved, data source and target activity, and so on.
 - [Format of database trace files](#)
 - [Producing the database trace in the Database Interface Designer](#)
 - [Producing the database trace during map execution](#)
 - [Tracing database errors only](#)
-

Format of database trace files

Information displayed in the database trace file varies depending upon the database generating the trace file. Database adapter trace files contain what appears to be a range of numbers at the beginning of each line in the file. These numbers represent:

- the process ID
This is the number representing the process that is running on the machine. If you were watching the processes running on your machine (viewing the **Processes** tab in the Task Manager window), the value displayed in the **PID** (process ID) column would match the value displayed in the database trace file produced as a result of this process.
- the thread ID
This ID distinguishes each map that is running concurrently. Each running map has its own thread.

Producing the database trace in the Database Interface Designer

About this task

Click the **Trace** tool or select Trace from the File menu to enable a database trace file (.dbi). If trace is enabled, a database trace file is automatically created when you generate a type tree. This file is placed in the same directory as the currently open MDQ file. The newly created database trace file is named using the full name of the MDQ file plus a .dbi extension. For example, if your MDQ file is named **Orders.mdq**, the trace file is named **Orders.dbi** and is located in the same directory. If your MDQ file is not yet named, the trace file is named **Database_QueryFile 1.dbi** and resides in the same directory, typically the default installation directory.

Most problems encountered in the Database Interface Designer are relayed to the user in message dialogs. For example, if an incorrect user-ID or password is specified for a database, a dialog appears when attempting to generate type trees for tables in that database. The following example dialog reports an Oracle error ORA-01017 with the following message as returned by the database driver to the database adapter:

```
invalid username/password; logon denied
```

If trace is enabled when the message in this dialog appears, a corresponding message is also written to the database trace file (**.mdq_file_name.dbi**).

The following is a sample of a database trace file when generating a type tree that describes two tables in an Oracle database.

The contents of any trace file are database platform-specific.

```
<1776-940>: Datalink: bocadb2\\Northwind
<1776-940>: UserId : test
<1776-940>: Password:*****
<1776-940>: No existing connection was found.
<1776-940>: Local transaction usage: Transaction ID 0x019287F4
<1776-940>: Transaction started - ISOLATIONLEVEL_READCOMMITTED
<1776-940>: Connection to SQL Server bocadb2 has been established.
<1776-940>: Retrieving 1 rows per fetch.
<1776-940>: The columns are of the following types:
<1776-940>: Column 1 (CustomerID) type is nchar(5) [DBTYPE_WSTR].
<1776-940>: Column 2 (CompanyName) type is nvarchar(40) [DBTYPE_WSTR].
<1776-940>: Column 3 (ContactName) type is nvarchar(30) [DBTYPE_WSTR].
<1776-940>: Column 4 (ContactTitle) type is nvarchar(30) [DBTYPE_WSTR].
<1776-940>: Column 5 (Address) type is nvarchar(60) [DBTYPE_WSTR].
<1776-940>: Column 6 (City) type is nvarchar(15) [DBTYPE_WSTR].
<1776-940>: Column 7 (Region) type is nvarchar(15) [DBTYPE_WSTR].
<1776-940>: Column 8 (PostalCode) type is nvarchar(10) [DBTYPE_WSTR].
<1776-940>: Column 9 (Country) type is nvarchar(15) [DBTYPE_WSTR].
<1776-940>: Column 10 (Phone) type is nvarchar(24) [DBTYPE_WSTR].
<1776-940>: Column 11 (Fax) type is nvarchar(24) [DBTYPE_WSTR].
```

The following example was received when attempting to run a map to retrieve data from a table in an SQL Server database.

```
<1324-3020>: Validating the adapter command...
<1324-3020>: Database type is MS SQL Server 7
<1324-472>: Connecting...
<1324-472>: Datalink: MY_2000_SERVER\\test
<1324-472>: UserId : test
<1324-472>: Password:*****
<1324-472>: OLE DB Error code: 0x80004005
<1324-472>: [DBNMPNTW]Specified SQL server not found.
<1324-472>: Returned status: (-3) No error text found
```

In this example, the following lines:

```
<1324-472>: OLE DB Error code: 0x80004005
<1324-472>: [DBNMPNTW]Specified SQL server not found.
```

indicate the OLE DB provider-specific error code and the corresponding error description. The last line (beginning with `Returned status:`) indicates the error code returned by the adapter that caused the map to fail.

This information can be used, along with the SQL Server documentation, to resolve the problem. In this particular example, the error was caused by typing the incorrect server name in the SQL Server **Server** settings in the Database Definition dialog, rather than by selecting the name from the list of servers. In this example, the server name was incorrectly entered as `MY_2000_SERVER`, instead of its actual name (`MY_2000_SRVR`).

Producing the database trace during map execution

There are several different ways to enable the database trace for reporting database-related information during map execution as discussed in the following sections:

- Using the [Trace adapter](#) command
- Source usage:
 - for a [valid source](#)
 - for a [source with errors](#)
- Target usage:
 - for a [valid target](#)
 - for a target with a [missing required value](#)
 - for a target using the [Bad Data](#) adapter command
 - for a target with [-UPDATE off](#)
 - for a target using the [DBLOOKUP/DBQUERY](#) functions
- [Using the Trace adapter command](#)
- [Database trace for a valid source](#)
- [Database trace for a source with errors](#)
- [Database trace for a valid target](#)
- [Database trace for a target: missing required value](#)
- [Database trace for a target - using the bad data adapter command \(-BADDATA\)](#)

- [Database trace for a target with -UPDATE off](#)
- [Database trace for a target: DBLOOKUP/DBQUERY functions](#)

Using the Trace adapter command

About this task

To produce database trace information for specific database data sources or targets, use the Trace adapter command (-TRACE). For information about the syntax of this command, see the Resource Adapters documentation.

To produce the database trace file when using the DBQUERY or DBLOOKUP functions, use the Syntax2 format to call the function. For example, if output card 3 contains a DBLOOKUP function, call the function as

```
DBLOOKUP ( "SELECT ...", "-DBTYPE DB2 -SOURCE LAMBIN
-USER ARL97IN -TRACE") .
```

Database trace for a valid source

To produce the following database trace file example, we want to produce a database trace for input card 2 (which is a database). To do this, you must include the Trace adapter command (-TRACE) in the GET > Source > Command setting. Upon execution, database trace information is generated for input card 2; the example follows.

Note: Line numbers are for reference purposes only.

```
01 Database type is Oracle
02 Status returned to engine: (0) Success
03 No existing connection was found.
04 Connection to Oracle has been established.
05 Interface library version 6.0(140)
06 Data being retrieved for input card 2.
07 Database adapter version 6.0(140)
08 Starting a database unload...
09 Host string:
10 Userid      : demo
11 Password    : ****
12 Query       : SELECT I.* , P.LIST_PRICE, P.MIN_PRICE, P.START_DATE, P.END_DATE
13   FROM ITEM I, PRICE P, PRODUCT PR
14   WHERE I.PRODUCT_ID = P.PRODUCT_ID and PR.PRODUCT_ID = 15  I.PRODUCT_ID
15   ORDER BY PR.PRODUCT_ID
16 Query size : 189
17 Output is to a buffer.
18 Statement execution succeeded.
19 The columns are of the following types:
20   Column 1 (ORDER_ID) type is NUMBER(4) .
21   Column 2 (ITEM_ID) type is NUMBER(4) .
22   Column 3 (PRODUCT_ID) type is NUMBER(6) .
23   Column 4 (ACTUAL_PRICE) type is NUMBER(8,2) .
24   Column 5 (QUANTITY) type is NUMBER(8) .
25   Column 6 (TOTAL) type is NUMBER(8,2) .
26   Column 7 (LIST_PRICE) type is NUMBER(8,2) .
27   Column 8 (MIN_PRICE) type is NUMBER(8,2) .
28   Column 9 (START_DATE) type is DATE.
29   Column 10 (END_DATE) type is DATE.
30 Number of buffers in fetch array = 574
31 Writing results to a buffer.
32 Retrieved 543 records (34451 bytes).
33 Status returned to engine: (0) Success
34 Cleaning up and closing the transaction...
35 The transaction was successfully committed.
36 Status returned to engine: (0) Success
37 Commit was successful.
38 Database disconnect succeeded.
```

This sample database trace file (`map_name .dbl`) reveals important information, examples of which are described below.

- Lines 1-5 show information about the connection made, identifying the database type as Oracle as well as the version number of the interface library. In this example, there was no existing database connection and a new connection was successfully established.
- Line 6 indicates that the data is being retrieved for input card number 2.
- Line 7 identifies the version of the database adapter for Oracle. Lines 8-11 identify the information used to make the connection with the Oracle database: the host string, user ID, and password. Because this information is for an input card, there is a message indicating that a database unload is being started.
- Next, the database trace file indicates that the query successfully executed (as indicated by the following text on Line 18: `Statement execution succeeded`) and includes descriptions of the ten columns to be retrieved.
- The results of the query are written to the buffer. 543 records (rows) were retrieved using this query.

Use the Trace adapter command (-TRACE) for as many database source or targets as desired. Note that the information for later cards is appended to the default database trace file unless a file name is specified using the -TRACE filename option as described in the Resource Adapters documentation.

The exact information in the database trace file varies, depending upon the information returned by different entities including the database driver, database source versus target, and so on.

Database trace for a source with errors

The example in the preceding section provided database trace information for a database source with no problems. The following is an example of information you may see when there are errors while accessing the database source.

```
Database type is Oracle
Status returned to engine: (0) Success
No existing connection was found.
Connection to Oracle has been established.
Interface library version 6.0(140)
Data being retrieved for input card 1.
Database adapter version 6.0(140)
Starting a database unload...
Host string:
Userid      : demo
Password    : *****
Query       : SELECT * FROM BONUSS
Query size  : 20
Output is to a buffer.
Error in: oparse

        Message : ORA-00942: table or view does not exist

        Retrieved 0 records (0 bytes).

        Error returned to engine: (-17) Failed to parse SQL statement
Cleaning up and closing the transaction...
The transaction was successfully committed.
Status returned to engine: (0) Success
Commit was successful.
Database disconnect succeeded.
```

The key information in the database trace is in the line defining the query (beginning with `Query`) and the four lines beginning with the `Error in:` line. In this example, the attempt to execute the query failed because the table specified in the query listed does not exist. This would result in a map return code of 12 and a message of:

Source not available

Upon receiving this error, verify that the query is correct and that the table referenced in the query exists using the Database Interface Designer or the SQL command tool provided with your database.

Database trace for a valid target

The information included in the database trace for an output (data target) is similar to that for a database source. The following example shows the PUT > Target settings for the first output card (which is a database) in a map called **UpdateMembershipDB**.

The Update adapter command (`-UPDATE`) specifies that the rows produced by the map should update existing rows or should insert new rows, based upon the update keys configured for the table in the Database Interface Designer. The Trace adapter command (`-TRACE`) generates the database trace information for this output card.

An example of the database trace information produced for this map follows.

```
Database type is Oracle
Status returned to engine: (0) Success
No existing connection was found.
Connection to Oracle has been established.
Interface library version 6.0(140)
Loading data for output card 1.
Database adapter version 6.0(140)
Starting database load...
Host string:
Userid      : eventmgt
Password    : *****
Update mode is on.
The columns are of the following types:
Column 1 (MEMBERID) type is VARCHAR(10).
Column 2 (ATTENDEEFIRSTNAME) type is VARCHAR(30).
Column 3 (ATTENDEELASTNAME) type is VARCHAR(50).
Column 4 (TITLE) type is VARCHAR(50).
Column 5 (COMPANYNAME) type is VARCHAR(50).
Column 6 (ADDRESS) type is VARCHAR(255).
Column 7 (CITY) type is VARCHAR(50).
Column 8 (STATEORPROVINCE) type is VARCHAR(20).
Column 9 (POSTALCODE) type is VARCHAR(20).
Column 10 (COUNTRY) type is VARCHAR(50).
Column 11 (PHONENUMBER) type is VARCHAR(30).
Column 12 (FAXNUMBER) type is VARCHAR(30).
Column 13 (EMAILADDR) type is VARCHAR(50).
Column 14 (MEMBERSINCE) type is DATE.
The insert statement to be executed is:
INSERT INTO Membership VALUES
(:a00,:a01,:a02,:a03,:a04,:a05,:a06,:a07,:a08,:a09,:a10,:a11,:a12,:a13)
The update statement to be executed is:
UPDATE Membership SET ATTENDEEFIRSTNAME=:a01,ATTENDEELASTNAME=:a02,TITLE=:a03,
COMPANYNAME=:a04,ADDRESS=:a05,CITY=:a06,STATEORPROVINCE=:a07,
POSTALCODE=:a08,COUNTRY=:a09,PHONENUMBER=:a10,FAXNUMBER=:a11,EMAILADDR=:a12
WHERE (MEMBERID=:a00)5 rows inserted.

        2 rows updated.
Database load complete.
Status returned to engine: (0) Success
Cleaning up and closing the transaction...
The transaction was successfully committed.
Status returned to engine: (0) Success
```

```
Commit was successful.  
Database disconnect succeeded.
```

This sample database trace file (**map_name .dbt**) reveals important information that is highlighted in **bold** type above and some of which is described below.

- After the logon information in the sample, a message indicates that **Update mode is on**. This will affect how the rows produced are handled. Because update mode is on (enabled by the **-UPDATE** adapter command), rows in the table are inserted or updated based upon the update keys defined in the Database Interface Designer.
- After the connection is made, the database trace shows the column definitions for the output table.
- Next, the database trace file displays the actual SQL statements to be executed using the data produced for the output card. Because update mode is enabled, the database trace file displays both an **INSERT** statement and an **UPDATE** statement. The **UPDATE** statement is executed for each row in the output for which a corresponding row is found in the database table, using the update key defined (which, in this example, is the **MemberID** column). The **INSERT** statement is executed for all rows in the output for which a corresponding row does not exist in the table.
- After the SQL statements in the sample, the database trace file indicates the number of rows that were both inserted (5) and updated (2).
- Finally, the database trace file indicates that database load was executed successfully (**Database load complete**) and that the database changes were committed (**The transaction was successfully committed**).

Database trace for a target: missing required value

The following database trace file example was produced by using almost the same map as in the preceding example except for the usage of a different input data file. This database trace file illustrates the information you might see if a database error occurred while attempting to insert or update rows in a table.

```
Database type is Oracle  
Status returned to engine: (0) Success  
No existing connection was found.  
Connection to Oracle has been established.  
Interface library version 6.0(140)  
Loading data for output card 1.  
Database adapter version 6.0(140)  
Starting database load...  
Host string:  
Userid      : eventmgt  
Password    : *****  
Update mode is on.  
The columns are of the following types:  
Column 1 (MEMBERID) type is VARCHAR(10).  
Column 2 (FIRSTNAME) type is VARCHAR(30).  
Column 3 (LASTNAME) type is VARCHAR(50).  
Column 4 (TITLE) type is VARCHAR(50).  
Column 5 (COMPANYNAME) type is VARCHAR(50).  
Column 6 (ADDRESS) type is VARCHAR(255).  
Column 7 (CITY) type is VARCHAR(50).  
Column 8 (STATEORPROVINCE) type is VARCHAR(20).  
Column 9 (POSTALCODE) type is VARCHAR(20).  
Column 10 (COUNTRY) type is VARCHAR(50).  
Column 11 (PHONENUMBER) type is VARCHAR(30).  
Column 12 (FAXNUMBER) type is VARCHAR(30).  
Column 13 (EMAILADDR) type is VARCHAR(50).  
Column 14 (MEMBERSINCE) type is DATE.  
The insert statement to be executed is:  
INSERT INTO Membership VALUES  
(:a00,:a01,:a02,:a03,:a04,:a05,:a06,:a07,:a08,:a09,:a10,:a11,:a12,:a13)  
The update statement to be executed is:  
UPDATE Membership SET FIRSTNAME=:a01,LASTNAME=:a02,TITLE=:a03, COMPANYNAME=:a04,  
ADDRESS=:a05,CITY=:a06,STATEORPROVINCE=:a07, POSTALCODE=:a08,COUNTRY=:a09,  
PHONENUMBER=:a10,FAXNUMBER=:a11,EMAILADDR=:a12 WHERE (MEMBERID=:a00)  
Error in: oexec  
  
Message : ORA-01400: cannot insert NULL into  
("EVENTMGT"."MEMBERSHIP"."LASTNAME")  
  
The following values were being inserted:  
Column 1 MEMBERID : D190-0002  
Column 2 FIRSTNAME : Leverling  
Column 3 LASTNAME : NULL  
Column 4 TITLE : Vice President-New Products  
Column 5 COMPANYNAME : Northwind Traders  
Column 6 ADDRESS : 722 Moss Bay Blvd.  
Column 7 CITY : Kirkland  
Column 8 STATEORPROVINCE : WA  
Column 9 POSTALCODE : 98033  
Column 10 COUNTRY : USA  
Column 11 PHONENUMBER : (206) 555-3412  
Column 12 FAXNUMBER : (206) 555-3413  
Column 13 EMAILADDR : jleverling@northwind.com
```

```

Column 14 MEMBERSINCE : 1999-07-09 22:03:03

Failed to insert a row (rc = -9).

Failed after 1 rows inserted.

Database load complete.

Error returned to engine: (-9) Failed to execute the SQL statement

Cleaning up and closing the transaction...

Transaction rollback was successful.

Status returned to engine: (0) Success

Commit was successful.

Database disconnect succeeded.

```

In this example, the **bold** text is information that can be provided when an error occurs. The first lines of this example provide the same information as was in the database trace file with no errors: connection parameters, update mode indicator, table column descriptions, SQL statements to be used, and so on.

However, after the UPDATE statement, the database trace file provides details to assist in determining the problem. The Message line indicates that an attempt was made to insert a row with a NULL value for the **EVENT.MEMBERSHIP.LASTNAME** column that cannot contain a NULL. To further identify the row in the output data causing the error, the database trace file lists the values for all of the columns in the row causing the error.

The remaining lines in the database trace file display information about the disposition of the entire database card transaction. The transaction failed after one row was inserted. The database adapter returns an error code of -9 to the Launcher with a corresponding error message of Failed to execute the SQL statement. If you produced the audit log, you would see the following line in the execution summary section:

```

<TargetReport card="1" adapter="DB" bytes="1218" adapterreturn="-9">
  <Message>Failed to execute the SQL statement</Message>
  <TimeStamp>22:07:32 January 8, 2004</TimeStamp>
</TargetReport>

```

Subsequently, the database trace file communicates that the database adapter is cleaning up and closing the transaction. Because the **OnFailure** setting was set to **Rollback** for this output card, the final entry in the database trace reveals that the transaction rollback was successful.

Database trace for a target - using the bad data adapter command (-BADDATA)

About this task

Use the Bad Data adapter command (-BADDATA) for a target (or in a PUT function). If any inserts, updates, or procedure calls fail to execute, the data that could not be processed is written to a file that you specify and processing continues.

The following database trace example was produced using the same map and data as in the preceding example, now additionally using -BADDATA.

```

.
.
Error in: oexec
Message : ORA-01400: cannot insert NULL into
("EVENTMGT"."MEMBERSHIP"."LASTNAME")
The following values were being inserted:
Column 1 MEMBERID : D190-0002
Column 2 FIRSTNAME : Leverling
Column 3 LASTNAME : NULL
Column 4 TITLE : Vice President-New Products
Column 5 COMPANYNAME : Northwind Traders
Column 6 ADDRESS : 722 Moss Bay Blvd.
Column 7 CITY : Kirkland Column 8 STATEORPROVINCE : WA
Column 9 POSTALCODE : 98033
Column 10 COUNTRY : USA
Column 11 PHONENUMBER : (206) 555-3412
Column 12 FAXNUMBER : (206) 555-3413
Column 13 EMAILADDR : jleverling@northwind.com
Column 14 MEMBERSINCE : 1999-07-09 22:03:03
Failed to insert a row (rc = -9).
4 rows inserted.
2 rows updated.
1 rows were rejected.
Database load complete.
Warning returned to engine: (1) One or more records could not be processed
Cleaning up and closing the transaction...
The transaction was successfully committed.
Status returned to engine: (0)
SuccessCommit was successful.
Database disconnect succeeded.

```

All of the information in this trace file example is the same as the previous example except for the bold lines of text. In this example, because -BADDATA was used, the database adapter goes on to process all of the other rows produced for the target. Upon completion, four rows were successfully inserted, two rows were successfully updated, and one row was rejected. The rejected record was saved in the file specified with the Bad Data adapter command (-BADDATA). In this example, the rejected record was saved to a file called badstuff.txt.

The remaining lines in the database trace file indicate information about the disposition of the entire database card transaction. Notice that the use of -BADDATA allows the card to successfully complete. The map successfully completes and the transaction is committed.

If you produced the audit log, you would see the following line in the execution summary section:

```

<TargetReport card="1" adapter="DB" bytes="1218" adapterreturn="1">
  <Message>One or more records could not be processed</Message>
  <TimeStamp>22:07:32 January 8, 2004</TimeStamp>
</TargetReport>

```

Database trace for a target with -UPDATE off

The following example illustrates the database trace that can result from a common error encountered when developing maps have database targets.

```

Database type is ODBC
Status returned to engine: (0) Success
No existing connection was found.
Connection to datasource OracleProd has been established.
Interface library version 6.0(140)
Loading data for output card 1.
Database adapter version 6.0(140)
Starting database load...
Datasource: OracleProd
Userid   : EVENTMGT
Password : *****
Update mode is off.
The columns are of the following types:
Column 1 (MEMBERID) type is VARCHAR, precision is 10.
Column 2 (ATTENDEEFIRSTNAME) type is VARCHAR, precision is 30.
Column 3 (ATTENDEELASTNAME) type is VARCHAR, precision is 50.
Column 4 (TITLE) type is VARCHAR, precision is 50.
Column 5 (COMPANYNAME) type is VARCHAR, precision is 50.
Column 6 (ADDRESS) type is VARCHAR, precision is 255.
Column 7 (CITY) type is VARCHAR, precision is 50.
Column 8 (STATEORPROVINCE) type is VARCHAR, precision is 20.
Column 9 (POSTALCODE) type is VARCHAR, precision is 20.
Column 10 (COUNTRY) type is VARCHAR, precision is 50.
Column 11 (PHONENUMBER) type is VARCHAR, precision is 30.
Column 12 (FAXNUMBER) type is VARCHAR, precision is 30.
Column 13 (EMAILADDR) type is VARCHAR, precision is 50.
Column 14 (MEMBERSINCE) type is TIMESTAMP, precision is 19.

The insert statement to be executed is:
INSERT INTO Membership VALUES (?, ?, ?, ?, ?, ?, ?, ?, ?, ?, ?, ?, ?, ?)
Error in SQLExecute
Message: ORA-00001: unique constraint (SYSTEM.UNIQUE_MEMBER_ID) violated
SQL State: 23000
The following values were being inserted:
Column 1 MEMBERID : 1978-1964
Column 2 ATTENDEEFIRSTNAME : Jean
Column 3 ATTENDEELASTNAME : Fresnière
Column 4 TITLE : Marketing Assistant
Column 5 COMPANYNAME : Mère Paillarde
Column 6 ADDRESS : 43 rue St. Laurent
Column 7 CITY : Montréal
Column 8 STATEORPROVINCE : Québec
Column 9 POSTALCODE : H1J 1C3
Column 10 COUNTRY : Canada
Column 11 PHONENUMBER : (514) 555-8054

Failed to insert a row (rc = -9).

Failed after 2 rows inserted.

Database load complete.

Error returned to engine: (-9) Failed to execute the SQL statement

Cleaning up and closing the transaction...

Transaction rollback was successful.

Status returned to engine: (0) Success

Commit was successful.

Database disconnect succeeded.

```

If you forget to specify the usage of the update setting (using **-UPDATE** either in the PUT > Target > Command setting in the Map Designer or Integration Flow Designer or in the command line), you may receive a database error resulting from the attempt to insert a row with a duplicate index.

The first entry in this example highlighted in **bold** type indicates that update mode is off. Because update mode is off, the database adapter attempts to insert a row into the database table for each row produced by the map. The **Message** entry contains the message returned by the database driver to the database adapter describing the cause of the error. In this example, the row in error would violate the **UNIQUE_MEMBER_ID** constraint defined for the table. The next lines show the column values for the row in which the error occurred and the final result of the database operation.

There are several possible methods for resolving this problem. Depending upon the desired behavior, you might:

- Enable update mode when executing the map by using the **-UPDATE ON** or **-UPDATE ONLY** adapter command.
- Use the Delete adapter command (**-DELETE**) to remove all rows from the output database table before inserting the rows resulting from map execution.
- Build logic into your map to ensure that there is no existing row in the table prior to generating an output row to be inserted. This might be accomplished by either defining a query for the table being used as an input against which a **LOOKUP** or **SEARCHUP** function is performed or by using the **DBLOOKUP** function to check for an

existing row.

- Use -BADDATA so that all rows with a unique **MEMBERID** are inserted. Those rows that would result in duplicate rows are then saved to a specified file.

Database trace for a target: DBLOOKUP/DBQUERY functions

The following is a selection from a database trace file (**map_name dbl**) for an output card using the GET function to execute a DELETE statement based upon a value in the input.

```
..Starting a database unload...
Host string:
Userid      : eventmgt
Password    : *****
Query       : DELETE FROM REGISTRATION WHERE REGISTRATIONSTATUS = 'Overflow'
Query size : 71Output is to a buffer.
Statement execution succeeded.
Retrieved 0 records (0 bytes).
Size of DBLOOKUP data is 0.
Warning returned to engine: (2) No data found
Cleaning up and closing the transaction.....
```

The following SQL statement to be executed:

```
DELETE FROM REGISTRATION WHERE REGISTRATIONSTATUS = 'Overflow'
```

and the resulting successful execution statement:

```
Statement execution succeeded
```

are included in this trace file as shown in the example above. Note that no records were retrieved because the DELETE statement does not return data.

The next series of statements are produced for an output card using a DBQUERY function to obtain several columns from a database table based upon specified values in the **MEMBERID** column in the input data.

```
..Starting a database unload...
Host string:
Userid      : eventmgt
Password    : *****
Query       : SELECT FIRSTNAME, LASTNAME , EMAILADDR FROM EVENTMGT.MEMBERSHIP
              WHERE MEMBERID = 'D191-0001'
Query size : 108
Output is to a buffer.
Statement execution succeeded.
The columns are of the following types:
  Column 1 (FIRSTNAME) type is VARCHAR(30).
  Column 2 (LASTNAME) type is VARCHAR(50).
  Column 3 (EMAILADDR) type is VARCHAR(50).
Number of buffers in fetch array = 492
Writing results to a buffer.
Retrieved 1 records (40 bytes).
Size of DBQUERY data is 40.
The following data was returned from a DBQUERY:
```

```
Nancy|Davolio|nancyd@cascadecoffee.com
```

```
Status returned to engine: (0) Success
Status returned to engine: (0) Success
Interface library version 6.0(140)
Data being retrieved for DBQUERY function.
Database adapter version 6.0(140)
Starting a database unload...
Host string: Userid      : eventmgt
Password    : *****
Query       : SELECT FIRSTNAME, LASTNAME , EMAILADDR FROM EVENTMGT.MEMBERSHIP
              WHERE MEMBERID = 'D191-0002'
Query size : 108
Output is to a buffer.
Statement execution succeeded.
The columns are of the following types:
  Column 1 (FIRSTNAME) type is VARCHAR(30).
  Column 2 (LASTNAME) type is VARCHAR(50).
  Column 3 (EMAILADDR) type is VARCHAR(50).
Number of buffers in fetch array = 492
Writing results to a buffer.
Retrieved 1 records (42 bytes).
```

```
Size of DBQUERY data is 42.
```

```
The following data was returned from a DBQUERY:
```

```
Janet|Leverling|jleverling@northwind.com
```

In this example, as in the previous one, the database trace file reports the actual query to be executed. In this example, each DBQUERY returns a single row containing the three columns from the **Membership** table for the specified **MEMBERID**. The data returned by the DBQUERY function conforms to the **Delimited Row group format** type tree definition, meaning that there will be a pipe character (|) delimiter between columns and a carriage return/line feed terminator for each row of data.

The size of the data returned by the DBQUERY is also listed. Note that the size of the DBQUERY data is specified as 42. This value represents the length of the data, including the carriage return/line feed that follows the row of data. There will be a similar set of entries in the database trace file for each DBQUERY executed.

Tracing database errors only

Depending upon the number of database sources and targets, the volume of database functions that are executed, and the database trace settings that are used, the database trace file can contain a large amount of data. Even when no database errors occur, the database trace file can become very large.

Use the Trace Error adapter command (-TRACEERR) to minimize the amount of information contained in the database trace file (**map_name.dbt**). This file contains only the database errors occurring during the map execution.

When -TRACEERR is specified, the database trace file is produced using the full name of the MDQ with a **.dbt** file name extension instead of the usual trace (**.mtr**) extension. It is created in the directory in which the map is located. Use the -TRACEERR *filename* syntax as described in the *Resource Adapters documentation* to specify the name for the database trace file.

A full database trace is most beneficial during map development; however, it is preferable to use -TRACEERR in a production environment because only the database errors are reported.

For example, if you generate the full database trace for a map called **DBUpdate** that has three database input cards, it would produce the following 88-line **MultiDB's.dbt** file.

```
Database type is MS SQL Server
Status returned to engine: (0) Success
No existing connection was found.
Error in: dbopen
Error   : 5701
State   : 2
Message : Changed database context to 'master'.

Status returned to engine: (0) Success
Interface library version 6.0(140)
Data being retrieved for input card 3.
Database adapter version 6.0(140)
Starting a database unload...
Server\\Database: HP_NT\\pubs
Userid      : sa
```

```

Password      :
Query         : SELECT * FROM Title
Query size    : 19
Output is to a buffer.
Error in: dbsqlexec

        Error   : 208
        State   : 1
        Message : Invalid object name 'Title'.
        Error in: dbsqlexec

        Error   : 10007
        Message : General SQL Server error: Check messages from the SQL Server.

        Failed to execute statement.

        Invalid object name 'Title'.
Retrieved 0 records (0 bytes).
Error returned to engine: (-9) Failed to execute the SQL statement
Cleaning up and closing the transaction...
The transaction was successfully committed.
A transaction was started.
Status returned to engine: (0) Success

```

After reviewing this file, notice that the query for input card number 3 (SELECT * FROM Title) failed because it references an object name (the table name **Title**) that does not exist. Alternatively, you could use the Trace Error adapter command (-TRACEERR) for each of the three input cards and produce the following database trace file:

```
Invalid object name 'Title'.
```

This file can be used along with the following execution audit log information:

```

<SourceReport card="1" adapter="DB" bytes="1810" adapterreturn="0">
  <Message>Success</Message>
  <TimeStamp>01:02:00 January 9, 2004</TimeStamp>
</SourceReport>

<SourceReport card="2" adapter="DB" bytes="305" adapterreturn="0">
  <Message>Success</Message>
  <TimeStamp>01:02:00 January 9, 2004</TimeStamp>
</SourceReport>

<SourceReport card="3" adapter="DB" bytes="0" adapterreturn="-9">
  <Message>Failed to execute the SQL statement</Message>
  <TimeStamp>01:02:00 January 9, 2004</TimeStamp>
</SourceReport>

```

Use this information to determine whether the query defined for input card 3 references a table or view that does not exist.

Viewing database source and target data

When debugging a map that uses database sources or targets, you cannot view the database source or target data in the Map Designer by selecting Run Results from the View menu. Because the data retrieved from a database for an input or written to a database as an output is a snapshot of the data at a given time, it is not available to the Map Designer after the map runs.

However, you can use **Backup** settings to capture the data retrieved from or written to the database for debugging purposes.

- [Using backup settings](#)
- [Capturing data not processed](#)

Using backup settings

Backup settings are used to determine when, where, and how the data for a specific card should be copied to a specified backup file. These settings are configured in the **Input Card** and **Output Card** settings in the Map Designer and the Launcher or in Command Settings for the Integration Flow Designer. For more information about these settings, see the Map Designer documentation.

Capturing data not processed

The Bad Data adapter command (-BADDATA) can be used for a target (or in a **PUT** function). If any inserts, updates, or procedure calls fail to execute, the data that could not be processed is written to a file you specify and processing continues.

The -BADDATA command can be specified:

- as part of the **PUT** Target > Command setting for a card target
- as part of the command line for a database target referenced in a **RUN** or **PUT** function
- on the command line or in a command file.

The rejected record(s) is/are saved in the file specified with the -BADDATA adapter command.

When the `-BADDATA` adapter command is used and one or more rows are rejected, the database adapter returns an adapter return code of 1 with a message of One or more records could not be processed as shown in the following TargetReport excerpt in the execution summary section:

```
<TargetReport card="1" adapter="DB" bytes="1218" adapterreturn="1">
  <Message>One or more records could not be processed</Message>
  <TimeStamp>22:07:32 January 9, 2004</TimeStamp>
</TargetReport>
```

Database audit files

Additional troubleshooting and diagnostic information is available in the database adapter audit. Use the Audit adapter command (`-AUDIT`) to create a file that records the adapter activity for each specified database activity. This command can be used for a source or target, or in a `DBLOOKUP`, `DBQUERY`, `GET`, or `PUT` function. This adapter command can be specified for individual input and output cards on a card-by-card basis or, optionally, as a global audit that encompasses all database activity for the entire map.

The default is to produce a file named `audit.dbl` in the directory in which the map is located. Optionally, you can append the audit information to an existing file or specify a name or the full path for the file. For more information, see the Resource Adapters documentation.

The database adapter audit file provides the following details for each database access:

- **Execution Time (Audit Time)**
This is the amount of clock time (in seconds) the database adapter takes to execute the database action (for example, the retrieval of all rows for a data source, a single instance of `ADBLOOKUP` function, and so on).
- **Adapter Return Code (AC)**
This is the adapter return code as a result of executing the database action.
- **Connection**
This information identifies the connection used for each database action. This can be helpful in determining ways to configure your map to minimize the number of database connections that must be made.
- **Map Name (Map)**
This is name of the compiled map file.
- **Access Type (Input Card, Function, or Output Card)**
This information identifies the type of database action (for example, whether the type is for an input card, output card, or for a `DBLOOKUP`, `DBQUERY`, `GET`, or `PUT` function).
- **Additional Information**
This information is provided (when appropriate) for each database action such as the SQL statement associated with an input card, the name of the table or stored procedure for a database target, or the SQL statement executed by any of the functions for interfacing with data in a database (for example, `DBLOOKUP`, `DBQUERY`, `PUT`, and `GET`).

DBMS trace utilities and SQL command tools

The utilities and tools that are part of your relational database management system (RDBMS) will also be helpful during the troubleshooting process. For example, a map fails at runtime because a table name was invalid in an input that is a database source. Try to execute that same query using the tools included with your database to determine whether the query will run natively.

- [Trace utilities](#)
- [SQL command tools](#)

Trace utilities

For example, when using ODBC data sources on a Windows platform, enable ODBC tracing from the ODBC Data Source Administrator window. This creates a log of the calls to ODBC drivers as you use the Database Interface Designer to define databases and queries, and when you use a Launcher to run maps that have database sources or targets. Similar tracing tools are available for most of the other database systems. For information about the tracing capabilities available for your database system, see the documentation for your RDBMS.

SQL command tools

Each database management system includes some form of an SQL command tool. For example, ODBC data sources can be accessed using tools such as Microsoft Query to test queries and view information about your tables, views, and stored procedures. Oracle databases can be accessed using SQL Plus; Microsoft SQL Server data sources can be accessed with ISQL.

These tools provide the ability to determine the problem by testing your queries against the database using the same drivers being accessed by the database adapters.

For example, if you run a map that executes a query for a data source and it fails because one or more of the column names was invalid, you could copy the query text from the Database Interface Designer and test it using the SQL command tool for your database. Then, you could modify the query as necessary to get it to work correctly. When you achieve the expected results, copy the SQL statement back to the query defined in the Database Interface Designer.

Similarly, if a database insert or update operation fails, you could try entering the corresponding INSERT or UPDATE statement into your database system's SQL command tool to help determine the cause of the failure.

REST API V2.0

- **[Deployment APIs](#)**

Deployment in v2 uses SQLite files generated by tx-server during deployment. These files contain all the objects (flows, maps, and files) defined in the definition of the package being deployed.

- **[Map and Flow run APIs](#)**

These APIs allow you to run maps or flows that have URLs specified for them in the package definition.

- **[Flow Schedule APIs](#)**

Flow Schedule APIs allow you to control the scheduler properties for a flow.

Deployment APIs

Deployment in v2 uses SQLite files generated by tx-server during deployment. These files contain all the objects (flows, maps, and files) defined in the definition of the package being deployed.

After the file has been sent to the tx-rest server, it is merged into the master SQLite file for that server which can be found at the location specified for the rest.persistence.catalog property in config.yaml.

Packages can be started, paused, and stopped. They are automatically started when they are deployed. After they are started, the flows, maps, and files within the SQLite file are unpacked to the file system under a directory named after the package located inside the directory specified for the property rest.persistence.maps in config.yaml. If multiple locations are specified, the first one is used.

When stopped, the files are removed from the file system and the flows and maps cannot be run until it is started again.

If the package is paused, maps and flows can still be invoked through the REST API but listeners are paused until the package is un-paused.

These APIs in this table can be called:

API	Description
GET /v2/packages/{package_name}	Returns detailed information about the specified package.
DELETE /v2/packages/{package_name}	Deletes the specified package. This API has a Boolean query parameter stop that if set to true will allow you to delete a package that has been started, otherwise the package must first be stopped.
GET /v2/packages	Returns basic information about each deployed package. Has a Boolean query parameter details . If set to true will return more detailed information for each package.
POST /v2/packages	Deploys a package. Takes an SQLite file containing a package as the request body. Has a Boolean query parameter start which will cause the package to automatically start after it is deployed
PUT /v2/{package_name}/actions/start	Starts the specified package if it is stopped or paused.
PUT /v2/{package_name}/actions/stop	Stops the specified package if it is started or paused.
PUT /v2/{package_name}/actions/pause	Pauses the specified package if it is started.
PUT /v2/{package_name}/actions/resume	Un-pauses the specified package if it is paused.

Map and Flow run APIs

These APIs allow you to run maps or flows that have URLs specified for them in the package definition.

- **[PUT /v2/run/url](#)**

Synchronously run a map or flow whose package has been started. The result contains the data of each output card that was set as a REST output for a map, or each flow output terminal defined for a flow.

- **[POST /v2/run/url](#)**

This API asynchronously runs a map or flow whose package has been started.

PUT /v2/run/url

Synchronously run a map or flow whose package has been started. The result contains the data of each output card that was set as a REST output for a map, or each flow output terminal defined for a flow.

If there is only one, it will be returned as a stream of bytes, otherwise, the multiple outputs will be joined into a multipart/form-data response. These requests will timeout after a timeout length specified in the synchronousTimeout property in config.yaml.

The status and log can also be specified as values for the return query parameter for both maps and flows, which return a status message about the run and the audit for a map, respectively.

For a flow, status and log both just return a status message, but with log specified, that status message contains the flow audit. Maps can also use the value trace which returns the map trace. Multiple values for the return parameter can be specified at one time.

POST /v2/run/url

This API asynchronously runs a map or flow whose package has been started.

The result contains an href that gives information on the status of the run when a GET request is sent to it and an id for a run instance which can be used with the map and flow instance APIs defined in this table:

Map and flow APIs	Description
GET /v2/instances/{id}	Get the status of an asynchronous map or flow run. The id is the one returned from running a map or flow asynchronously.
DELETE /v2/instances/{id}	Delete the instance of an asynchronous map or flow run, these instances will persist until this API is invoked. The id is the one returned from running a map or flow asynchronously
GET /v2/instances/{id}/outputs/{output_number}	Get the data for an output card or output flow terminal of an asynchronous map or flow run. The id is the one returned from running a map or flow asynchronously, and the output_number is the number of the output to get the data for.
/v2/instances/{id}/log	Get the log of an asynchronous map or flow run. The id is the one returned from running a map or flow asynchronously
/v2/instances/{id}/trace	Get the trace of an asynchronous map run. The id is the one returned from running a map asynchronously

It is important to note that status and log can also be specified as values for the return query parameter for both maps and flows, which return a status message about the run and the audit for a map, respectively.

For a flow, status and log both return a status message, but with log specified, that status message contains the flow audit. Maps can also use the value trace which returns the map trace. Multiple values for the return parameter can be specified at the same time.

Each REST input and output for maps or flow input and output terminal for flows, can be overridden by specifying the input and output query parameters. The accepted values for these parameters are in the form <card/terminal-number>;<adapter-name>;<adapter-cmd>. Multiple overrides can be provided by separating each with a comma.

Flow Schedule APIs

Flow Schedule APIs allow you to control the scheduler properties for a flow.

- [POST /v2/schedule/url](#)
Set scheduler properties for a flow. Any flow variables that the flow should use can be passed in the flow_vars query parameter which takes flow variables as a JSON string.
- [DELETE /v2/schedule/url](#)
Unschedule a flow. When this is invoked on a flow with a schedule, it no longer runs according to its schedule until new schedule properties are set to it.

POST /v2/schedule/url

Set scheduler properties for a flow. Any flow variables that the flow should use can be passed in the flow_vars query parameter which takes flow variables as a JSON string.

For example, {"myVariable":"sampleValue","otherVariable":"otherValue"}

The request body should contain a JSON object specifying the desired scheduler properties to be set. These properties are listed below:

- start – A string representing the time of day that the flow should start being executed which should be a string in the form "HH:MM". If specified, 'end' must also be specified.
- end – A string representing the time of day that the flow should stop being executed. This is a string in the form HH:MM. If specified, start must also be specified.
- days – An array of integers between 1 and 7 which represent the days on which the flow should be run, with Monday being a 1 and Sunday being a 7. If not specified, the flow will run every day.
- unit - The unit of time for the scheduler. Can be hours, minutes, or seconds. If specified, interval must also be specified.
- interval – An integer that together with unit determines how often the flow will execute. If specified, unit must also be specified.
- skipifbusy – A Boolean expression, which is treated as true by default, which determines whether the flow should execute if an instance of it is already being executed.
- timezone – A string representing the timezone of the start and end times.

DELETE /v2/schedule/url

Unschedule a flow. When this is invoked on a flow with a schedule, it no longer runs according to its schedule until new schedule properties are set to it.

Flow functions

Using the Flow functions, you can specify a value for each of the flow variables defined for a flow, and additionally, alter an already-specified value for a flow variable, if required. Flow variables act as an alternative means to pass information through and through a flow instance—thereby eliminating the limitations and cumbersomeness of nodes being the only gateway for passage of information.

Flow variables are name-value pairs that persist until the flow-instance that is using these variables is executed. Flow variables are case-sensitive. So, you need to be particular about the case you are using while defining a flow variable. Flow variables are also instance-specific; that is, no two flow-instances that are running simultaneously can share the same set of variables. However, a set of flow variables defined for one flow instance can be used by another as long as the other instance is not executed during the runtime of the instance for which the variables are originally defined.

See the Flow variables documentation contained in the Functions and Expressions sections of this online documentation.

Using a Command Server

To use the Command Server to execute a map, you will prepare the maps for execution.

For installation information, see the [release notes](#). Before using the Command Server after you have installed it, test your installation by running an example map. To see how to test your installation on a specific platform, see the platform-specific topic.

- [Command Server Overview](#)
- [Executing a map](#)
- [Troubleshooting tools](#)
- [External interfaces for applications, EXIT and RUN](#)

Maps can interface with other maps, functions in libraries, or programs using the `EXIT` function, the `RUN` function or an adapter as a data source or target.

Command Server Overview

The Command Server is used to develop, test, and execute maps in development environments. It can also be used to execute commands in production environments.

Maps are developed and tested using the Design Studio software on a Windows system-based development computer. When a map's development is complete, the compiled map file (`.mmc`) is, by default, ready to be executed by a Windows system-based Command Server. For example, you can run a map from the Map Designer interface or a Windows system-based Command Server, a Launcher, or the Platform API that has the same byte-order and character set.

The following list summarizes the steps you will do to run maps with the Command Server.

1. Create your map
2. Build or build for specific platform
3. Transfer if necessary
4. Execute with the Command Server

To account for environmental differences, some platforms require the map to be compiled or built for that specific platform. The **Build for Specific Platform** command is available from the Map menu in the Map Designer. After a map is built, it can be transferred to any destination computer hosting the Command Server. Using your preferred file transfer method, the file must be transferred in BINARY mode to ensure that the content of the compiled map arrives in its proper format on the destination platform.

Maps already transferred to their destination platform can be executed:

- from the command line
- as part of a series of maps in a command file
- from a program that runs an external program
- using a batch file or shell script
- as a task within a scheduler
- [Building a platform-specific map](#)

Building a platform-specific map

After creating a map in Map Designer, you can build a map for a specific execution platform. Select a specific platform under Map > Build for Specific Platform.

When a map is built for a specific platform, the name of the compiled map file has a platform-specific file name extension that indicates the execution platform for the map. The following table lists each platform and the corresponding platform-specific filename extension.

Platform	Map File Name Extension
HP-UX (Itanium processor)	.hpi
IBM® AIX® (RS/6000® processor)	.aix
IBM z/OS®	.mvs
Linux® (Intel processor)	.lnx

```
Microsoft Windows  
  .mmc  
pLinux  
  .pnx  
Sun Solaris (SPARC processor)  
  .sun  
zLinux  
  .znx
```

After transferring a platform-specific built map, it is strongly recommended that you rename the compiled map by using the .mmc file extension. Renaming it is not necessary; however, it is helpful because an .mmc extension identifies the file name in mapping functions and the renamed map can be executed without specifying the extension.

Executing a map

After a map has been built for a specific execution platform and transferred, the map can be executed using a Command Server.

- [Using execution commands](#)
 - [Input data validation](#)
 - [Output objects built](#)
-

Using execution commands

Using the execution commands and options, you have precise control over how a map executes. For example, you can override sources and targets specified in the map, create trace and audit log files, and control a variety of characteristics of the run-time environment.

Some execution commands are not available on all platforms. For information about execution commands and their syntax, see the *Execution Commands* documentation.

Input data validation

When a map begins execution, the input data must first be validated to ensure that the data for each input conforms to the definition of the corresponding input card. If it does conform, the data is valid. If the data does not conform, it is invalid. If data is determined to be invalid, a run-time return code and corresponding message is issued.

If invalid data is encountered, you may still want the map to continue processing or you may even want to map the invalid data. This can be accomplished during map development by using the **Restart** attribute when defining the input data and using the **REJECT** function when mapping the output data. In addition, functions are available to test for the presence of errors. For information about using the **Restart** attribute, see the *Type Designer* documentation. For information about using the error-related functions, see the *Functions and Expressions* documentation.

The validation process assumes that source data is a data stream. To find data objects in the input stream, type tree definitions are used including information about syntax items, data patterns, restrictions, component rules, and size. To process your input, the data must be able to be accessed at a designated position, for a specified length.

As data is validated, information about the data is recorded into workspace in memory or work files that guide the output process. The workspace information controls the data objects appearing in the data stream, whether they are related to other data objects, and what (if any) the relationship is. This enables you to specify any input within a map rule regardless of where the data appears in the input stream. It also enables you to use rules about the presence of data so that, for example, you can count objects or test their presence.

Output objects built

After all the input data has been validated and the input data is valid, output objects are generated based on each output card specification, including the map rules. If the output has an initiator defined, it is built first. Then, each output is built, one rule at a time, beginning with the first rule of the first output card. The entire first rule is evaluated, even if it refers to other maps and functions. When the first output is built, it is a complete data object, identified and treated as any other input data object is identified and treated. This enables you to refer to earlier outputs in a map rule.

As outputs are built, syntax objects are inserted—such as a delimiter, initiator, terminator, or release character—according to the type definition, and whatever remaining bytes of a fixed-length item are filled with pad characters. The execution process continues as the rules are evaluated and output data is built through the completion of the last rule of the last card.

Troubleshooting tools

When a map begins to run, the first thing that occurs is the validation of the input data—performed by comparing the data to the type tree definition. After data validation completes, the map rules are evaluated for the output cards and output objects are built.

When a map executes, invalid or unknown input data may be encountered and you may want to analyze what happened during the validation process. You may also want to analyze the output data if the map did not produce the expected results.

Many debugging aids are available to assist you through the troubleshooting process including:

- A Command Server display of ongoing execution information

- Command Server return codes and messages
 - Map audit log files, including data audit, execution audit, map settings, and card settings information
 - Map trace files
 - If an adapter is used, adapter-specific return codes and messages, audit log files, and trace files
- [Command Server display](#)**
- [Command Server return codes and messages](#)**
- [Map audit logs and trace files](#)**
-

Command Server display

Unless suppressed using execution commands, the Command Server displays several pieces of information when you run a map including the Command Server name, number of input objects found, number of output objects built, map execution time and a message indicating the map status. This information displays using a Command Server window on all Windows operating systems or using a console display on UNIX operating systems.

Ongoing feedback is shown during map execution and upon map completion. The messages that result (each message has a corresponding return code) indicate whether the map has completed and display the mapping results.

Command Server return codes and messages

After a map completes, a message indicates the execution results. These messages are also recorded in the appropriate audit logs.

Some return codes are only warnings indicating that the map did complete, but some problems occurred. You can change the default behavior for the warning codes by specifying **Fail on Warnings** or **Ignore Warnings** through the map settings or by using the **-F** or **-Z** execution command.

Map audit logs and trace files

Audit logs and trace files provide information that can be used effectively for debugging and troubleshooting purposes. There are many situations that occur during map execution in which you would want the activities associated with the processing of your data to be recorded in an audit log file or trace file. The auditing and tracing of the map execution process can be accomplished at various levels by specifying that the appropriate audit logs and trace files be enabled for maps, input cards, output cards, or particular adapters. These audit log and trace files may also be defined further to include summary or detail information about execution statistics, data information, or adapter activity.

For information about map audit logs and trace files, see the *Map Designer* documentation.

For information about audit log and trace files for an adapter, see the adapter-specific documentation about enabling and viewing these adapter-specific log files.

- [Map audit log](#)
 - [Map trace files](#)
-

Map audit log

When the **MapAudit Log Switch** setting is set to **ON**, you can select to have either execution information or data information recorded. You can also specify to have both execution and data information recorded for a complete picture of what transpired during the execution of a map. The map audit logs can be enabled from the Map Settings window in the Map Designer, Integration Flow Designer, Command Server for Windows, or on any platform using execution commands on the command line.

The default name for an audit log that is not unique is the full name of the map with the .log extension. The default name for a unique audit log is `Mer_mapname_processkey_mapcounter_hostname.log`. The default audit log directory is the directory of the compiled map file.

The **MapAudit** log can contain three different sections: **BurstAudit**, **SummaryAudit**, and **SettingsAudit**. The sections produced depend on the settings for **MapAudit**.

BurstAudit

The information in the **BurstAudit** section of the **MapAudit** setting is configurable using the Data Audit Settings tab in the Organizer. See the *Map Designer* documentation for information about configuring these options and interpreting the information in the **BurstAudit** section.

SummaryAudit

When the **SummaryAudit's Execution** setting is **Always**, **OnError**, or **OnWarningsOrError**, an **ExecutionSummary** section is included in the log file. The **ExecutionSummary** section of the audit log file provides a summary of the return codes, sources, targets, and work areas for the map. This execution information also includes:

- The command string to use if you were running the map from the command prompt.
- The number of input and output objects.
- Information about data and work files.
- Execution time

See the *Map Designer* documentation for more information.

An ExecutionLog per burst

When the **BurstAudit Execution** setting is **Always**, **OnBurstError**, or **OnBurstWarningOrError**, the log file will contain a section for each burst within the map. If all inputs have a **CardMode** of **Integral**, there will be a single **Burst** section. The following excerpt is from the **tryaudit.log** file, created from running the **tryaudit.mmc** compiled map, which is included in the *install_dir\examples\general\audit* folder and presents the **Burst** section:

```
<Burst count="1">

<DataLog>

<input card="1">
  <object index="1" level="1" size="10113" status="E00">
    DTX_MapAudit General Element
  </object>
  <object index="1" level="0" size="10113" status="V01">
    Audit_Log
  </object>
</input>

</DataLog>

<ExecutionLog burstreturn="28" ElapsedSec="3.9280">

<inputstatus card="1" bytes="10113" adapterreturn="0" contentreturn="28"/>
<inputstatus card="2" bytes="1067" adapterreturn="0" contentreturn="0"/>
<outputstatus card="1" bytes="610" adapterreturn="0" contentreturn="0"/>
<outputstatus card="2" bytes="1055" adapterreturn="0" contentreturn="0"/>
<outputstatus card="3" bytes="10938" adapterreturn="0" contentreturn="0"/>
<outputstatus card="4" bytes="0" adapterreturn="0" contentreturn="0"/>

</ExecutionLog>

</Burst>
```

The **ExecutionLog** section identifies the return code and elapsed time for the burst, as well as the status of each input or output, including both an adapter return code, if applicable, and a content return code.

ExecutionSummary per map

The **ExecutionSummary** section provides information at the map level. The following excerpt presents the **ExecutionSummary** section:

```
<ExecutionSummary MapStatus="Valid" mapreturn="0" ElapsedSec="3.9610"
  BurstRestartCount="0">
  <Message>Input type contains errors</Message>

  <CommandLine>'C:\install_dir\examples\general\audit\tryaudit.mmc'</CommandLine>
  <ObjectsFound>111</ObjectsFound>
  <ObjectsBuilt>10</ObjectsBuilt>

  <SourceReport card="1" adapter="File" bytes="10113" adapterreturn="0">
    <Message>Data read successfully</Message>
    <Settings>C:\install_dir\examples\general\audit\goodaud.log</Settings>
    <TimeStamp>07:03:10 December 11, 2003</TimeStamp>
  </SourceReport>

  <SourceReport card="2" adapter="File" bytes="1067" adapterreturn="0">
    <Message>Data read successfully</Message>
    <Settings>C:\install_dir\examples\general\audit\maperrcd.dat</Settings>
    <TimeStamp>06:11:46 May 29, 2003</TimeStamp>
  </SourceReport>

  <TargetReport card="1" adapter="File" bytes="610" adapterreturn="0">
    <Message>Data written successfully</Message>
    <Settings>C:\install_dir\examples\general\audit\result.txt</Settings>
    <TimeStamp>09:27:11 January 23, 2004</TimeStamp>
  </TargetReport>
  .
  .
  <WorkArea type="File">
    <inputarea card="1" Path="C:\install_dir\examples\general\audit\tryaudit.I01"
     TimeStamp="09:27:11 January 23, 2004" bytes="67522"/>
    <inputarea card="2" Path="C:\install_dir\examples\general\audit\tryaudit.I02"
     TimeStamp="09:27:11 January 23, 2004" bytes="67522"/>
    <outputarea card="1" Path="C:\install_dir\examples\general\audit\tryaudit.001"
     TimeStamp="09:27:11 January 23, 2004" bytes="65536"/>
    <outputarea card="2" Path="C:\install_dir\examples\general\audit\tryaudit.002"
     TimeStamp="09:27:11 January 23, 2004" bytes="65536"/>
    <outputarea card="3" Path="C:\install_dir\examples\general\audit\tryaudit.003"
     TimeStamp="09:27:11 January 23, 2004" bytes="65536"/>
    <outputarea card="4" Path="C:\install_dir\examples\general\audit\tryaudit.004"
     TimeStamp="09:27:11 January 23, 2004" bytes="65536"/>
  </WorkArea>
</ExecutionSummary>
```

As shown above, the execution log can provide some high-level debugging information, such as:

- **Map return code and message.** The map return code and message indicate how the mapping operation completed and whether there were any problems. For example, a map return code of 0 and message of **Map completed successfully** indicate that no execution errors were encountered. This information helps in

analyzing the source information in the log.

- **SourceReport and TargetReport.** For each source or target, the **ExecutionSummary** includes information indicating the adapter, the size of the data for the source or target, the adapter return code and message, and so on. For example, if using a database adapter, a return code of -17 and a message of Failed to parse SQL statement for an input would indicate that some error occurred when the adapter attempted to execute the appropriate SQL statement to fetch the data from the database.
- **WorkArea.** For each input or output for which a WorkArea is created, the **ExecutionSummary** includes information, such as the location and size.

The **ExecutionSummary** is a good place to start when diagnosing map execution problems because you can quickly determine the sources or targets in error. Using the information in the **ExecutionSummary**, you can produce more detailed troubleshooting information for only those sources or targets that experienced problems.

MapSettings section

The **MapSettings** section contains a list of all map settings, including the settings for **MapAudit**, **MapTrace**, **WorkSpace**, **Century (SlidingCentury)**, **Validation (CustomValidation)**, **Retry (MapRetry)**, and **Warnings**. The following excerpt presents the **MapSettings** section:

```
<MapSettings>

<MapAudit switch="ON">
    <Log executionsummary="Always" databurst="Always"
        database_sizevalidation="WrongSize" executionburst="Always"
        mapsettings="Always" datasettings="OnError"/>
    <Location type="File" action="Create">
        <Directory type="Map">C:\install_dir\examples\general\audit</Directory>
        <FileName type="Default" prefix="MapName">tryaudit.log</FileName>
    </Location>
</MapAudit>

<MapTrace switch="OFF"></MapTrace>

<WorkSpace>
    <Location type="File" action="Delete">
        <Directory type="Map">C:\install_dir\examples\general\audit</Directory>
        <FileName type="Default" prefix="MapName"></FileName>
    </Location>
    <Paging>
        <PageSize>64</PageSize>
        <PageCount>8</PageCount>
    </Paging>
</WorkSpace>

<SlidingCentury switch="OFF"></SlidingCentury>

<CustomValidation switch="ON">
    <OnValidationError>Continue</OnValidationError>
    <RestrictionError>Validate</RestrictionError>
    <SizeError>Validate</SizeError>
    <PresentationError>Validate</PresentationError>
</CustomValidation>

<Retry switch="OFF"></Retry>

<BurstRestart switch="OFF"></BurstRestart>

<Warnings type="Every" action="Warn"></Warnings>

</MapSettings>
```

This information can be useful during debugging to determine why execution occurred in a certain way.

DataSettings section

The DataSettings section contains a list of all **InputData** and **OutputData** settings depending on the adapter used, including the **FetchAs (CardMode)**, **WorkArea**, **Backup**, **Command (SourceAdapterCommand or TargetAdapterCommand)**, **OnSuccess**, **OnFailure**, **Retry (AdapterRetry)**, **Scope (AdapterScope)**, and so on. The following excerpt presents the DataSettings section:

```
<DataSettings>

<InputData card="1" CardMode="Integral" WorkArea="!Reuse">
    <Backup switch="ON" when="Always" action="Create">
        <Path>C:\install_dir\examples\general\audit\Mer_tryaudit_10441074864820_5.ll.bak
    </Path>
    </Backup>
    <Source adapter="File" OnSuccess="Keep" OnFailure="Rollback" Scope="Map"
        Warnings="Ignore">
        <Resource>C:\install_dir\examples\general\audit\goodaud.log</Resource>
        <Retry switch="OFF"></Retry>
    </Source>
</InputData>
.

.

<OutputData card="1">
    <Backup switch="OFF"></Backup>
    <Target adapter="File" OnSuccess="Create" OnFailure="Rollback" Scope="Map"
        Warnings="Ignore">
        <Resource>C:\install_dir\examples\general\audit\result.txt</Resource>
        <Retry switch="OFF"></Retry>
    </Target>
</OutputData>
```

```

</Target>
</OutputData>
.
.
</DataSettings>
```

This information can be useful during debugging to identify whether data should be copied to a backup file, whether the changes to a database target should be committed if the map fails, and so on.

Map trace files

Map trace files can be used for diagnosing invalid data or incorrect type definitions. When the MapTrace Switch setting is set to **ON**, you can specify the location and file name and select to have information captured for inputs and outputs including what level of detail you want recorded.

When you enable the **InputContentTrace** setting to trace your input data, the log file provides information about the data objects found, why data was found to be invalid, sizes and counts of data objects and their position in the data stream. When **OutputTrace** is enabled, the information recorded in the trace file reflects which output objects were built and which output objects evaluate to **NONE**.

You can choose to trace the input data, the output data or both. For additional information about map trace files, see the *Map Designer* documentation.

Note: You should enable the trace for debugging purposes only because enabling a map trace may affect execution performance.

External interfaces for applications, EXIT and RUN

Maps can interface with other maps, functions in libraries, or programs using the **EXIT** function, the **RUN** function or an adapter as a data source or target.

You can implement an adapter or **EXIT** function through a:

- library interface using a function in a library
- program passing a command line

You can invoke a user exit by specifying the **EXIT** function on a map rule, or by specifying an external library or application on a source or target card.

Platform-specific limitations can determine the availability and usage of these interface methods on a particular platform.

For example, the following table summarizes by platform the availability (Y) of the **RUN** function, the library interface, and program interface.

Table 1. External interfaces for user exits and RUN function

Platform	User Exit: External Library	User Exit: Application	RUN Function
HP-UX (PA-RISC)			Y
RS/6000 AIX	Y		Y
Windows			Y
z/OS Batch	Y	Y	Y
z/OS CICS		Y	Y

For information about the **RUN** and **EXIT** functions, see the *Functions and Expressions* documentation.

Windows platforms

There are several activities you can do with the Command Server that you have installed on your Windows environment.

You can:

- test your Windows Command Server installation by running the sample map provided
- use the Command Server to run your maps
- [Running the map examples](#)
After successfully installing the software, you can run the map examples included in the installation to test the installation to ensure the Command Server is functioning properly.
- [Using the Command Server](#)
The Command Server provides a window that shows ongoing information during map execution.
- [Help](#)

Running the map examples

After successfully installing the software, you can run the map examples included in the installation to test the installation to ensure the Command Server is functioning properly.

To run the map example

1. Run the setup script.
2. Execute the map:

- Go to `install_dir/examples/general/map/sinkmap`
- From the command line, type:

```
dtx sinkmap
```

The Command Server updates the screen while the map executes. If the map ran successfully, the following message is displayed:

```
Map completed successfully
```

If the map does not complete successfully, see [Using a Command Server](#) for troubleshooting information.

Using the Command Server

The Command Server provides a window that shows ongoing information during map execution.

To use the Command Server to run a map

When you open the Command Server application, a window opens indicating that the Command Server is ready to be run; however, no maps are currently loaded:

1. From the Map menu, select Run.
2. Choose a compiled map.

The Command Server window displays status information such as the number of objects found and built, as well as execution time.

Note: If the map does not complete successfully, see [Using a Command Server](#) for troubleshooting information.

To override map settings, right-click an executable map in Design Studio and edit the map settings. The map is ready to be run according to the newly entered override settings. The values entered in the Map Settings do not update the compiled map file, and are only recognized for this one-time execution. To permanently change any values for map settings, use the Map Designer to modify the settings and recompile the map.

Help

Help is available for the Command Server to provide access to descriptions and procedures including information about execution commands, return codes, functions, and so on. You can access Help by selecting Contents from the Help menu.

When using the command line, Help for Command Server is available by typing:

```
DTX -?
```

Note: Ensure your current directory is where the Command Server is located or specify the relative path or full path as applicable when entering the Help command.

z/OS Batch

There are several activities you can do with the Command Server that you have installed on your z/OS Batch environment.

You can:

- Test your z/OS Batch Command Server installation by running the sample map provided
- Use the Command Server to run your maps

- [Running the map examples](#)

After successfully installing the software, you can run the map examples included in the installation to test the installation to ensure the Command Server is functioning properly.

- [Using the Command Server](#)

- [z/OS Batch execution commands](#)

- [Troubleshooting](#)

There are three files that are essential to troubleshooting efforts.

- [VSAM considerations](#)

- [Using the EXIT function](#)

The EXIT function calls a user-written program to return data that is mapped to an item.

- [Using the RUN function](#)

The first argument to the RUN function is the name of the map to be executed.

- [Reusing work files](#)

- [Output file same as input file](#)

- [Appended output](#)

- [Resource names](#)

Running the map examples

After successfully installing the software, you can run the map examples included in the installation to test the installation to ensure the Command Server is functioning properly.

Using the Command Server

The Command Server for z/OS Batch requires JCL coding to execute as a batch job.

Note: Maps must always be built for z/OS Batch and transferred as BINARY for execution on the z/OS platform. **The file transfer must not use the CRLF option because map corruption may result.**

- [Execution command line \(JCL PARM statement\)](#)

- [Identifying data sources and targets](#)

On z/OS, data sources and targets that exist as datasets are identified by DDNAME. Sources and targets must be defined by DD statements in the execution JCL before a map can be executed.

- [Names to avoid](#)

- [Temporary datasets](#)

- [JCL](#)

The following sample JCL can be used as a guide to help develop JCL for your maps meeting your mapping requirements and the standards at your z/OS site.

- [Overriding Language Environment \(LE\) runtime options](#)

You can set the Language Environment (LE) runtime options in the executable DTXCMDSV program.

Execution command line (JCL PARM statement)

The execution command line is coded in the PARM statement of the JCL. The command line comprises the DDNAME of at least one map followed by one or more commands that affect the execution of that same map. The map DDNAME is required; execution commands are optional.

The first argument in a command line string is always the DDNAME that identifies the map to be executed. The map DDNAME may indicate a sequential dataset that contains the z/OS Batch-specific map (Example 1), a PDS member that contains the z/OS Batch-specific map (Example 2), or a member name (Example 3).

- [Example 1](#)

- [Example 2](#)

- [Example 3](#)

- [Example 4](#)

Example 1

```
//STEP1 EXEC PGM=DTXCMDSV,PARM='MYMAP -TS'  
//MYMAP DD DSN=USER.MAP1,DISP=SHR
```

Example 2

```
//STEP1 EXEC PGM=DTXCMDSV,PARM='MYMAPPDSDS(MAP1) -TS'  
//MYMAPPDSDS DD DSN=USER.MAPPDS,DISP=SHR
```

Example 3

```
//STEP1 EXEC PGM=DTXCMDSV,PARM='MYMAP -TS'  
//MYMAP DD DSN=USER.MAPPDS(MAP1),DISP=SHR
```

You can control the execution of a map by specifying one or more of the execution commands described below in [z/OS Batch Execution Commands](#). These commands must follow the map whose execution they affect.

You can execute multiple maps in one job step. Example 4 shows the syntax.

Example 4

```
//STEP1 EXEC PGM=DTXCMDSV,  
// PARM='MAP1DD -<opt1> -<opt2> MAP2DD -<opt1> -<opt2>'
```

The PARM statement may be continued onto multiple lines; however JCL syntax limits it to a total of 100 characters. However, this JCL limitation can be overcome by using the Command Dataset execution command (-@).

During execution, the map is loaded once and is removed from storage only when the task ends or when the map being executed is different than the last executed map. This means that when maps are executed repeatedly, they are not reloaded each time.

Identifying data sources and targets

On z/OS, data sources and targets that exist as datasets are identified by DDNAME. Sources and targets must be defined by DD statements in the execution JCL before a map can be executed.

When you create a map to be run using the Command Server for z/OS Batch, define source and target names associated with input and output cards. If a map is tested on a Windows platform before being executed on a z/OS platform, data source and target names typically use the Windows file naming convention of *drive:\path\filename.extension*. When a map executes on z/OS Batch, source and target names are converted to valid z/OS DDNAMES by removing *drive*, *path*, and *extension*, converting *_* characters to *#* characters, and translating the remaining characters to uppercase.

Consider the following example. A map is to be executed on z/OS Batch. It has one input and one output-both of them sequential datasets. The map was developed on a Windows platform; for testing purposes the data source was initially defined as C:\My\Data\In_file.txt and the data target was defined as F:\Outfile.dat. When the map executes on z/OS Batch, source and target names are converted to DDNAMES. The data source name becomes IN#FILE and the data target name becomes OUTFILE. The execution JCL must contain the following DD statements:

```
//IN#FILE DD DSN=MY.INPUT,...  
//OUTFILE DD DSN=MY.OUTFILE,...
```

The DDNAME associated with a data source or target may be changed at run time using a card override on the command line passed in the PARM statement. Input and output card override commands are discussed in [z/OS Batch Execution Commands](#).

The use of instream datasets for data sources is supported. If an instream dataset is used, ensure that no sequence numbers exist in columns 73 through 80; sequence numbers will be interpreted as data by the map. The **GETANDSET** function may not be used with instream datasets.

Note: If you are testing a map on a computer that is targeted to z/OS Batch, the process can be simplified by specifying data source and target names that, when converted, will resolve to the expected z/OS DDNAMES.

Names to avoid

When defining data sources and targets in the Design Studio, use names that resolve to unique DDNAMES upon conversion. You should also ensure that a converted name is not reserved. The following DDNAMES are reserved for use on z/OS:

DDNAME	Description
DTXDEBG	Aid in problem resolution
DTXAUD	Audit Log
DTXLOG	Execution log
DTXTRCE	Trace output
DBTRACE	DB adapter trace output
MQTRACE	WebSphere MQ adapter trace output
DTXMRN	Fixed DDNAME for the .mrn file.
SYSTMP <i>n</i>	where <i>n</i> is a number between 01 and 99. Reserved for statically allocated temporary datasets.
STEPLIB	Reserved by the operating system or Language Environment or both
SYSPRINT	Reserved by the operating system or Language Environment or both
SYSOUT	Reserved by the operating system or Language Environment or both
CEEDUMP	Reserved by the operating system or Language Environment or both

Temporary datasets

During mapping, temporary datasets are allocated as needed, depending on two factors:

- how the map is constructed
- the record format (RECFM) of the map's input and output files

One temporary dataset is allocated in all cases, which is a general use work file. One temporary dataset is also allocated for each input. Depending on how the map is constructed, it may create a temporary dataset for each output to serve as its work file.

In addition, one temporary dataset is always allocated for each input or output defined with an RECFM that is not F (fixed unblocked) or FBS (fixed blocked standard).

Because you can develop a map with no inputs, and output work files may not be used in some situations, the minimum number of possible temporary files for a map execution is 1. The maximum possible number is $1 + (2 * \text{number of inputs}) + (2 * \text{number of outputs})$. Temporary files will be allocated using this formula where you have specified in the map to create output work files during its execution and all the inputs and outputs are formatted with a RECFM other than F or FBS.

By default, temporary datasets are dynamically allocated on disk. Dynamically allocated datasets require no DD statements in the JCL and can store up to approximately 3.1 MB of data. This is based on the settings specified in the **ALLOCxx** PARMLIB member. These datasets are deleted at the end of mapping and have system-generated dataset names with low-level qualifiers of **CTMFnnn**, where *nnn* is a number indicating the sequence in which the dataset was created. For example, the first temporary dataset created during a mapping has a qualifier of **CTMF000**; the second, **CTMF001**, and so on.

If the space allocation for a dynamic temporary dataset is insufficient, override it with a static allocation in the JCL. Use the following DD statement as a template:

```
//SYSTMP<nn> DD DSN=&&TEMP<nn>,
//                      DISP=(NEW,DELETE,DELETE),
//                      DCB=(RECFM=FBS,LRECL=<lrecl>),
//                      UNIT=<unit>,
//                      SPACE=(<space>)
```

The DDNAME for a statically allocated temporary dataset must use the form, **SYSTMPnn**, where *nn* is a number between 01 and 99 corresponding to the sequence number of the temporary dataset. For example, if the third temporary dataset created by a map (the system-generated dataset name with a low-level qualifier of **CTMF002**) runs out of space (this will be indicated by an **IEC030I x37** message in JES log), override the dynamic allocation with a **SYSTMP03** DD statement that provides sufficient space.

The dataset name for a static allocation must begin with **&&** which indicates a temporary dataset. The disposition must be (NEW,DELETE,DELETE). The RECFM should be FBS (fixed blocked standard) although F (fixed unblocked) can be used. You can choose the logical record length, although larger record lengths may increase IO efficiency. Do not use the BUFNO parameter.

To statically allocate all the temporary datasets that can possibly be used by a map, code DD statements **SYSTMP01** through **SYSTMPnn**, where *nn* is equal to $1 + (2 * \text{number of inputs}) + (2 * \text{number of outputs})$. This will provide adequate space.

Note: Statically allocating temporary datasets may increase map performance.

Static temporary dataset allocations are reused when multiple maps are executed from the command line. Consider the following scenario: the command line executes MAPA followed by MAPB and MAPC. MAPA uses seven temporary files, MAPB nine, and MAPC four. In this example, you must statically allocate not 20 temporary datasets ($7 + 9 + 4$), but nine temporary datasets, the maximum number needed by any map in the series. Each successive map execution reuses the existing static temporary file allocations beginning with SYSTMP01.

The resulting execution log reports complete temporary dataset usage information including DDNAME, dataset name, DCB, and size.

JCL

The following sample JCL can be used as a guide to help develop JCL for your maps meeting your mapping requirements and the standards at your z/OS site.

The z/OS Batch Command Server is called DTXCMDSV.

```
/** The program to be executed is DTXCMDSV. The command line is passed in the
/** PARM statement. The map to be executed is MYMAP, which has one input,
/** MYINPUT and one output, MYOUTPUT. The map and all its datasets are
/** accessed through ddnames.
*/
//STEP1 EXEC PGM=DTXCMDSV,PARM='MAPPDS (MYMAP) /P256:12 /TS'
/*
/** The ddname MAPPDS identifies the partitioned dataset
/** where IBM Transformation Extender maps are stored. MYMAP is the member.
*/
//MAPPDS DD DSN=MY.MAPPDS,DISP=SHR
//DTXLOG DD SYSOUT=* Execution log
//DTXAUD DD SYSOUT=* Audit
//DTXTRACE DD SYSOUT=* Map Trace
//DTXDEBUG DD SYSOUT=* Map Debug listing
//DTXMRN DD DSN=USER.TEST(RES1MRN),DISP=SHR
//SYSPRINT DD SYSOUT=* Used by LE
//SYSOUT DD SYSOUT=* Used by LE
//CEEDUMP DD SYSOUT=* Used by LE
/*
/** STEPLIB identifies the load library where IBM Transformation Extender was
/** installed.
/** It identifies the Language Environment library if it is not in the link list.
*/
//STEPLIB DD DSN=MY.LOADLIB,DISP=SHR
//          DD DSN=CEE.SCEERUN,DISP=SHR
/*
/** The map's output.
*/
//MYOUTPUT DD DSN=MY.OUTPUT,
//                      DCB=(RECFM=VB,LRECL=256),
//                      UNIT=SYSDA,SPACE=(TRK,(5,1)),
//                      DISP=(NEW,CATLG,DELETE)
/*
/** The map's input.
*/
//MYINPUT DD DSN=MY.INPUT,DISP=SHR
/*
/** Static temporary dataset allocations.
*/
//SYSTMP01 DD DSN=&&TEMP01,DISP=(NEW,DELETE,DELETE),
//                      DCB=(RECFM=FBS,LRECL=23476),
//                      UNIT=VIO,SPACE=(TRK,(5,1))
//SYSTMP02 DD DSN=&&TEMP02,DISP=(NEW,DELETE,DELETE),
//                      DCB=(RECFM=FBS,LRECL=23476),
//                      UNIT=VIO,SPACE=(TRK,(5,1))
//SYSTMP03 DD DSN=&&TEMP03,DISP=(NEW,DELETE,DELETE),
```

```

//          DCB=(RECFM=FB5,LRECL=23476),
//          UNIT=VIO,SPACE=(TRK,(5,1))
//SYSTMP04 DD DSN=&#39;TEMP04',DISP=(NEW,DELETE,DELETE),
//          DCB=(RECFM=FB5,LRECL=23476),
//          UNIT=VIO,SPACE=(TRK,(5,1))
//SYSTMP05 DD DSN=&#39;TEMP05',DISP=(NEW,DELETE,DELETE),
//          DCB=(RECFM=FB5,LRECL=23476),
//          UNIT=VIO,SPACE=(TRK,(5,1))
//
```

Overriding Language Environment (LE) runtime options

You can set the Language Environment (LE) runtime options in the executable DTXCMDSV program.

Use the **PARM** field or the **CEEOPTS DD** statement in your JCL to set the LE options.

For information about how to use the LE runtime options, see the following publications:

- SA22-7561-0X z/OS Language Environment Programming Guide
- SA22-7562-0X z/OS Language Environment Programming Reference

The LE options that you specify on either the **PARM** field or the **CEEOPTS DD** override both the system and program-defined options. A common use of these LE runtime options with IBM Transformation Extender is to override the **STACK** and **HEAP** runtime options.

As an example, if you specify the following LE options on the **CEEOPTS DD** statement of your JCL, it produces both an LE Options and Storage report. These reports can assist you in tuning the product's interaction with LE. The reports are directed to the **SYSOUT DD** statement.

```

//CEEOPTS DD *
  RPTOPT(ON)
  RPTSTG(ON)
/*

```

To use the DTXCMDSV executable program, specify it in your JCL as shown in the following example:

```

//DTX EXEC PGM=DTXCMDSV,REGION=0M,
//      PARM='REVERSEB /VX0D,X0A REVERSEI /VX0D,X0A REVERSEO'

```

z/OS Batch execution commands

To properly enter the z/OS Batch execution commands, you must observe the command syntax as well as the following general rules:

- Each command must begin with a hyphen (-) or a forward slash (/).
- At least one space between commands is required (for example: -A -v).
- Do not put spaces within commands, except for -I, -O and -V, which require a space before the source or target name.
- Execution commands are not case sensitive.
- When specifying commands, the entire command string (the map name and its associated commands and options) may be on one line or several lines if the -@ command is used.

Only the execution commands listed in the following table are supported under z/OS Batch. The majority of these commands are described in the *Execution Commands* documentation. If there is a difference in how the command is used for z/OS Batch, the exception is noted in the Syntax column. Commands only used by z/OS Batch are marked "Unique to z/OS Batch" in the Syntax column. z/OS Batch-specific commands are not listed in the *Execution Commands* documentation, so are described here.

The Syntax displayed is for z/OS Batch usage.

Command	Syntax
MapAudit	-A[D[R W]] [E[R W]] [B[R W]] [C[R W]] [P[R W]] [[M][S]]
Sliding Century	-D [ccyy 0]
	Exception: None
Fail on Warnings	-F[!][warning_code[:warning_code...]]
	Exception: None
Ignore Validation Options	-G[R] [S] [B]
	Exception: None
Input Dataset Override (-I)	-I[F]card_num[W !W][B] ddbname
	Unique to z/OS Batch
Input Echo Override	-IEcard_num[Ssize]
	Exception: For z/OS Batch, this command cannot be used to designate the source (source) or change the specification for using workfiles (W !W)
List	-L
	Exception: None

[No DTXLOG \(-NL\) or \(/NL\)](#)

-NL|/NL
Unique to z/OS Batch

[Output Dataset Override \(-O\)](#)

-O[F] *card_num* [+|!+] [B] *ddname*
Unique to z/OS Batch

Output Echo Override

-OE *card_num* [S]
Exception: For z/OS Batch, the X option is not available to exclude this card from echo.

WorkSpace Paging

-P*size:count*
Exception: None

MapTrace

-T[I|C*card_num*|I_{from}[:*to*]||O|OC*card_num*][S]
Exception: For z/OS Batch, the =dir option is not available to change from the default the location in which the trace file is created.

Stop Validation

-V
Exception: None

[Workfiles in Memory \(-WM\)](#)

-WM
Exception: None

Ignore Warnings

-Z[!][warning_code[:warning_code...]]
Exception: None

[Print Uppercase \(-+\)](#)

-+
Unique to z/OS Batch

[Command Dataset \(-@\)](#)

-@*ddname*
Unique to z/OS Batch

[Problem Resolution \(-\\$\)](#)

-\$
Unique to z/OS Batch

[Record Separators \(/V\)](#)

/V[separator_list...] *ddname*
Unique to z/OS Batch

The following commands are unique to z/OS Batch.

- [Input Dataset Override \(-I\)](#)
- [No DTXLOG \(-NL\) or \(/NL\)](#)
- [Output Dataset Override \(-O\)](#)
- [Workfiles in Memory \(-WM\)](#)
- [Print Uppercase \(-+\)](#)
- [Command Dataset \(-@\)](#)
- [Problem Resolution \(-\\$\)](#)

Use the Problem Resolution execution command (-\$) only under the direction of Customer Support.

- [Record Separators \(/V\)](#)

Input Dataset Override (-I)

Use the Input Dataset Override execution command (-I) to override the specified input card source with a dataset only for this execution.

-I [F] *card_num*[W|!W] [B] *ddname*

Option

Description

F

Optional for compatibility with previous versions.

card_num

The number of the input card to override.

W

Reuse the existing work file for this data source. If the work file does not exist at execution time, create it.

!W

Do not use the existing work file, but create a new work file each time the map is run.

B

If map execution is **not** successful, roll back any changes made to the dataset and reinstate the dataset to the original state prior to map execution.

ddname

Specify the DDNAME of the dataset used as the input source.

No DTXLOG (-NL) or (/NL)

Use the No DTXLOG execution command (-NL) to suppress the creation of a **DTXLOG**. When you use it, no informational data will be produced from **DD DTXLOG**. If you pass the -NL command on the command line through the **RunMap()** function, **DD RUNLOG01 (RUNLOG02 and so forth)** information will be suppressed.

-NL | /NL

Output Dataset Override (-O)

Use the Output Dataset Override execution command (-O) to override the specified output card target with a dataset for this execution only.

-O [F] *card_num*[+|!+] [B] *ddname*

Option

Option	Description
F	Optional for compatibility with previous versions
<i>card_num</i>	The number of the output card to override
+	Append the data for the current map execution to an existing dataset.
!+	Do not append to an existing dataset, but create a dataset each time the map is run.
B	If map execution is not successful, rollback any changes made to the dataset and reinstate the dataset to the original state prior to map execution.
<i>ddname</i>	Specify the DDNAME of the dataset used as the output target.

Workfiles in Memory (-WM)

Use the Workfiles in Memory execution command (-WM) to override the default allocation of work files on disk and to allocate them as memory files.

-WM

Print Uppercase (+)

Use the Print Uppercase execution command (+) to cause all printed output, execution logs, audit logs, and trace logs to be written in uppercase.

-+

Command Dataset (-@)

Use the Command Dataset execution command (-@) to specify a DDNAME defining a dataset that contains map names and execution commands. This command is unique to z/OS Batch. If this command is used, it can only appear in the PARM statement and it must be the only command coded in the parm statement (for example: EXEC PGM=DTXCMDSV, PARM='-@DTXPARM'). Using the command dataset eliminates the 100-byte limitation of the JCL PARM statement. Within the command dataset, map names and execution commands may be coded free-form. The command dataset may reside on disk or it may be defined instream in the JCL. If defined instream, ensure that there are no sequence numbers in columns 73 through 80. A sequence number, because it does not begin with the switch indicator (- or /), is interpreted by the command parsing logic as a map name.

-@ *ddname*

Option	Description
<i>ddname</i>	The DDNAME of the command file dataset.

Problem Resolution (-\$)

Use the Problem Resolution execution command (-\$) only under the direction of Customer Support.

This command produces output that is unintelligible to the user but is required by Customer Support for debugging.

Ensure you use the hexadecimal value **0x5B** for the '\$' character on US EBCDIC systems. Regardless of the character displayed in the JCL, using Hex **0x5B** is essential to make this option work and produce the debug output if Support requests it.

Record Separators (/V)

Use the Record Separators execution command (/V) to enable special handling of datasets with variable length records (datasets defined with RECFM=V).

/V[separator_list...] ddname

Option	Description
separator_list	Specify a comma-delimited string of separator bytes that can be expressed in hex format (for example: /VX5B,X6C,X7C) or character format (for example: /V\$,%,@). The default record separator if none is indicated on the /V command as a single byte, hex15.
ddname	The DDNAME of the input or output dataset

This command functions differently for data sources and targets. If specified for an input dataset, the indicated (or default) record separator string is appended to each variable record after it has been read. If specified for an output dataset, the record separator string is interpreted as marking the end of a variable length record in the output.

For inputs, this command causes a string of one or more record separator bytes to be appended to each variable record to ensure that the data maps properly on z/OS Batch. For example, suppose you are mapping an input file on Windows that consists of lines of text delimited by carriage-return/line-feed (0D 0A) pairs. Even though you cannot see them in a text editor, these delimiters are embedded in the data and the map expects them to be there.

Now you need to run this same map on z/OS Batch. However, when you upload the input file to a z/OS dataset of variable length records using the CRLF option, the record separators embedded in the data are removed during the transfer. Consequently, when the file is read in for mapping under z/OS Batch, the record separators must be reinstated or the data will not map correctly. The solution is to use the command /VX0D, X0A to append a hex 0D 0A record separator string to the end of each variable record.

If a dataset of variable length records already contains the separators defined to the map embedded in the data, this option should not be used.

For outputs, this command specifies that the indicated (or default) record separator byte or bytes are used to mark the ends of variable length records in the output. When this command is used, the map must embed record separator strings in the output data. These separator strings indicate the places where variable length record boundaries are to occur in the final output. The record separator strings are removed when the variable records are created. They do not appear in the output in its final form.

Output variable records wrap at the maximum record length defined for the dataset. If an output dataset is defined in the JCL with DCB=(RECFM=VB, LRECL=80) and either by accident or design a map produces an output record which is actually 120 bytes in length, two variable records are produced in the output dataset—one that is 80 bytes in length and one that is 40 bytes in length.

Troubleshooting

There are three files that are essential to troubleshooting efforts.

These files have DDNAMES as indicated in the following table:

DDNAME	File	Description
DTXTRCE	Trace File	Produced as a result of specifying the Trace execution command (-T)
DTXAUD	Map Audit Log	Produced as a result of enabling the Map Audit settings for a map and running the map with the Audit execution command (-A)
DTXDEBG	Problem Resolution	Produced as a result of specifying the Problem Resolution execution command (-S) as instructed by Customer Support.

- EBCDIC-encoded XML trace files**

The IBM Transformation Extender batch command server can generate trace log files in EBCDIC encoding. You can display EBCDIC-encoded trace files by using the vi editor or the ISPF application of the IBM® Time Sharing Option/Extensions (TSO) facility.

EBCDIC-encoded XML trace files

The IBM Transformation Extender batch command server can generate trace log files in EBCDIC encoding. You can display EBCDIC-encoded trace files by using the vi editor or the ISPF application of the IBM® Time Sharing Option/Extensions (TSO) facility.

To configure EBCDIC-encoded trace log files, add the following DD statement to the JCL step that invokes IBM Transformation Extender:

```
//CEEOPDS DD *  
ENVAR ("DTX_XML_LOG_ENCODING_IBM1047=TRUE")  
/*
```

VSAM considerations

The z/OS Batch Command Server supports the use of VSAM keyed-sequenced (KSDS), entry-sequenced (ESDS) and relative-record (RRDS) datasets for both inputs and outputs subject to the following conditions:

- VSAM datasets must be pre-defined and, if used for input, pre-loaded using IDCAMS or some other utility.
- The z/OS Batch Command Server opens input and output VSAM files for both reading and writing.
- When used as input, all VSAM datasets are processed sequentially; as output, KSDS files are updated and ESDS and RRDS files are appended.
- The use of SHAREOPTIONS 3 or 4 is not recommended. The library IO routines supplied by Language Environment do not check SHAREOPTIONS at dataset open time and do not provide support for read and write integrity for shared VSAM files.

Using the EXIT function

The **EXIT** function calls a user-written program to return data that is mapped to an item.

The **EXIT** function is documented in your *Functions and Expressions* documentation. However there are special considerations when using this function with the z/OS Batch Command Server.

A user exit is invoked by calling the **EXIT** function in a mapping rule. The **EXIT** function expects three arguments:

```
EXIT ("DLL_load_module_or_non_null",
      "DLL_function_or_load_module", "parameters")
```

If the user exit program is a DLL, the first argument must contain the name of the DLL load module and the second argument must contain the name of the function within the DLL.

If the user exit program is not a DLL, the first argument must contain some value that is not a null string ("")-for example, one or more spaces-and the second argument must contain the name of the load module.

The third argument is a text item that contains parameter information passed to the exit program.

Your user exit programs must reside in one of the load libraries referenced by the STEPLIB DDNAME in the JCL used to run the z/OS Batch Command Server. Any static data areas declared within an exit program, such as COBOL working-storage or C static variables, persist across multiple calls to the exit.

For non-C language (for example, COBOL) exits, four arguments are passed that contain the address of:

- A full word that contains the length of the parameter text item
- A space-padded 64K buffer that contains the parameter text item
- A full word that will contain the length of the resulting text item
- A 64K buffer where the resulting text item will be placed

For C language exits, a single argument is passed, which is the address of the EXITPARAM structure as described in the *Functions and Expressions* documentation.

User exits must support the conventions of z/OS Batch standard linkage and be link-edited in 31-bit addressing mode. DLL exits must be compiled as DLL code.

For an example of a C language and COBOL user exit program, see DTXEXRME in the DTX.SDTXSAMP PDS included in the IBM Transformation Extender with Command Server installation.

Using the RUN function

The first argument to the **RUN** function is the name of the map to be executed.

On z/OS, this must be the DDNAME that identifies the deployed map. To ensure this, the z/OS Batch Command Server converts the map name to a legal z/OS DDNAME by removing drive, path, and file extension information if it exists, converting _ characters to # characters and translating the remaining characters to uppercase. For example, the map rule **RUN ("install_dir \mymaps\map_10.mmc")** executes the map identified by the DDNAME **MAP#10**.

When using the **RUN** function, the z/OS Batch Command Server execution log, audit log, trace and problem resolution output must be written to individual datasets for each level of recursion; otherwise the output from different recursion levels are mixed together and will be unintelligible. By default, output from a map executed with the **RUN** function is directed to dynamically-allocated print datasets assigned to the default SYSOUT class for the job. This may be overridden by coding additional DD statements in the JCL. For each level of recursion, four DD statements should be added to your execution JCL:

- **RUNLOG nn** z/OS Batch execution log file
- **RUNAUDnn** Data audit log file
- **RUNTRCnn** Trace file
- **RUNDBGnn** z/OS Batch problem resolution file (used with Customer Support)

where *nn* is the level of recursion (always two positions, zero-filled).

For example, if an executed map issues a **RUN** function and the map to be run does not execute any other maps, one level of recursion exists and the following statements should be added to the JCL step:

```
//RUNLOG01 DD SYSOUT=B  
//RUNAUD01 DD SYSOUT=B  
//RUNTRC01 DD SYSOUT=B  
//RUNDBG01 DD SYSOUT=B
```

A map executed using the **RUN** function is loaded once and is removed from storage when the task ends or when the map executed is different from the last map executed. Maps repeatedly executed are not reloaded each time.

Statically allocated temporary datasets are reused when a map is executed repeatedly using the **RUN** function. For example, consider the following scenario: MAPA calls MAPB 100 times in succession using the **RUN** function. MAPA uses seven temporary files and MAPB uses three. In this example it is necessary to statically allocate, not 307 temporary datasets ($7 + (100 * 3)$), but 10 temporary datasets. MAPA will use SYSTMP01 through SYSTMP07 and MAPB will reuse SYSTMP08 through SYSTMP10 each time it is executed.

Reusing work files

To reuse a work file in the z/OS Batch Command Server, you must code a DD statement in the JCL, allocating the work file as a cataloged dataset. Only input work files can be reused.

The DDNAME for the work file to be reused must be a concatenation of up to five characters of the map name, followed by the `IW` string, followed by the number of the work file. The number of the work file corresponds to the number of the input card. For example, if you are executing a map called **MYMAP** and you want to reuse the work file for input card number three, code a DD statement with the following DDNAME:**MYMAPI3**.

Work file DCB parameters should define a file with fixed-blocked standard (FBS) records. The disposition should be (MOD,CATLG,DELETE). Using MOD will ensure that if the file does not exist, it will be created. Using CATLG may cause the message NOT RECATLGD 2 to appear in the output JES log, but this message can be safely ignored. The BUFNO parameter should not be used.

The following example DD statement demonstrates how you can reuse the work file for input card number 1 of a map named **MYMAP**:

```
//MYMAPI1 DD DSN=name,  
//          DISP=(MOD,CATLG,DELETE),  
//          DCB=(LRECL=23476,RECFM=FBS),  
//          UNIT=unit,  
//          SPACE=(space)
```

Output file same as input file

There are no special z/OS Batch considerations when the file named in the output card a map is the same as the file named in its input card. Code one DD statement for both files with a disposition of `OLD` or `SHR`. If you are mapping your output back to the input, be careful using card overrides.

The following example will not work:

```
//STEP1 EXEC PGM=DTXCMDSV,PARM='MAP -IF1 INFILE -OF1 OUTFILE'  
//INFILE DD DSN=MY.IOFILE,DISP=SHR  
//OUTFILE DD DSN=MY.IOFILE,DISP=SHR
```

Instead, the JCL should read:

```
//STEP1 EXEC PGM=DTXCMDSV,PARM='MAP -IF1 IOFILE -OF1 IOFILE'  
//IOFILE DD DSN=MY.IOFILE,DISP=SHR
```

Appended output

When an output card for a map specifies that the output be appended to a file, the target file MUST previously exist. Use a disposition of `OLD` or `SHR`.

Resource names

For information about creating resource names for use on the Command Server for the z/OS Batch platform, see [Resource Names for z/OS Platform](#).

z/OS CICS

There are several activities you can do with the CICS Execution Option that you have installed on your z/OS CICS environment.

You can:

- Test your CICS Execution Option installation by running the sample maps provided in the installation.
- Use the CICS Execution Option to run your maps.

Note: The IBM Transformation Extender includes the CICS Execution Option through which you can run maps in your CICS environments. Prior to IBM Transformation Extender version 8.1, this functionality was provided in the CICS Command Server product.

- [Running the map examples](#)

After successfully installing the software, you can run the map examples included in the installation to test the installation to ensure the CICS Execution Option is functioning properly.

- [Using the CICS Execution Option](#)

The CICS Execution Option can be invoked in several ways.

- [z/OS CICS execution commands](#)

- [Specifying storage medium](#)

The z/OS CICS Execution Option can map from or to any of six different storage media.

- [Using EXEC CICS LINK passing storage buffers](#)

When the z/OS CICS Execution Option is called by an EXEC CICS LINK, it is often because you want to pass to the CICS Execution Option the address of one or more storage buffers containing input data or the address of one or more storage buffers that will contain mapped output data or both address types.

- [Using the EXIT function](#)

The EXIT function is available when entering mapping rules for fields using the Map Designer on your PC.

- [Using the RUN function](#)

- [Preloading IBM Transformation Extender maps and .mdq files in a z/OS CICS environment](#)

The CICS® preloader utility preloads IBM Transformation Extender maps and database query (.mdq) files into memory. When maps and .mdq files run frequently,

you can reduce processing by preloading them into memory. Preloaded files do not require I/O processing.

- **Abnormal termination**

If a task terminates abnormally with an internal error, the return code 16 and an error message are passed back to the calling program.

- **The DTXMPULD utility**

In addition to loading maps into the KSDS, where maps are stored for use in the z/OS CICS region as described above, the DTXMPULD utility has the capability of listing and deleting maps from the **KSDS** map.

- **Resource names**

- **Multiple IBM Transformation Extender versions**

This section presents information about running multiple versions of the IBM Transformation Extender CICS Execution Option concurrently in a single CICS region.

Running the map examples

After successfully installing the software, you can run the map examples included in the installation to test the installation to ensure the CICS Execution Option is functioning properly.

For information about the examples, see the example readme files in the DTX.SDTXSAMP PDS, as well as the IBM Transformation Extender for z/OS [release notes](#).

Using the CICS Execution Option

The CICS Execution Option can be invoked in several ways.

It can be invoked:

- From a clear terminal, enter the **DTXI** transaction and follow it with a command string containing the name of at least one map and any execution commands required for the execution of that map. Command arguments must be separated by spaces. For example, to run the map **MYMAP** from a terminal with commands specifying input and output card overrides, type:

```
DTXI MYMAP -I1 MYINPUT -O1 MYOUTPUT
```

Note: The **MYMAP** file must have been built for z/OS CICS, file transferred to z/OS, and loaded into the z/OS CICS map **KSDS**.

- Start the **DTXI** transaction from a user program by passing the transaction name **DTXI** followed by the command string containing the map name and any required execution commands in the **FROM** option of the **EXEC CICS START** command.
- Automatically initiate the **DTXI** transaction from a trigger transient data queue. The first record in the queue must contain the transaction name **DTXI** followed by the command string.
- Invoke the **DTXI** program using an **EXEC CICS LINK** and pass the link control blocks. (Use the **DTXSCTST** sample program as a guide.) These control blocks define areas for the command string, optional data buffers, and a return code and message.

Note: When **DTXI** is invoked using an **EXEC CICS LINK**, the command string supplied must be null terminated. If the calling program is COBOL, this means that the command string must be followed, in working storage, by at least one byte containing LOW-VALUES.

To run a map using the CICS Execution Option for z/OS CICS

1. Build the map for z/OS CICS. From the Map Designer select Map > Build for Specific Platform and select IBM(TM) z/OS from the drop-down list.
2. File transfer the platform-specific map to z/OS CICS as BINARY with no ASCII to EBCDIC translation and no elimination of carriage returns (CRs) and line feeds (LFs).
Note: Transfer the file exactly as it is, without any changes.
3. Modify and execute the **DTXCMJCL** JCL to load the map into the z/OS CICS VSAM map dataset see [Running the Map Examples](#).
Note: It is possible to execute multiple maps from one command line. The syntax is:

```
map1 map1_execution_commands map2 map2_execution_commands
```

... Maps are loaded once and removed from storage when the task ends or when the map executed is different from the last map executed. This means that maps repeatedly executed are not reloaded each time.

z/OS CICS execution commands

To properly enter the z/OS CICS execution commands, you must observe the command syntax as well as the following general rules:

- Each command must begin with a hyphen (-) or a forward slash (/).
- At least one space between commands is required (for example: **-A -V**).
- Do not put spaces within commands, except for **-I**, **-O** and **-V**, which require a space before the source or target name.
- Execution commands are not case sensitive.

Only the execution commands listed in the following table are supported under z/OS CICS. The majority of these commands are described in the *Execution Commands* documentation. If there is a difference in how the command is used for z/OS CICS, the exception is noted in the Syntax column. Commands only used by z/OS CICS are marked "Unique to z/OS CICS" in the Syntax column. z/OS CICS-specific commands are not listed in the *Execution Commands* documentation, so are described in this section. The Syntax displayed is for z/OS CICS usage.

Command	Syntax
<u>Audit (-A)</u>	<pre>-A [D R W]][E R W]][B R W]][C R W]][P R W]][M S][@storage_codeName]</pre>
SlidingCentury	<pre>-D [ccyy 0]</pre>
	Exception: None.

- [Eliminate AICA \(ICVR Timeout\) Abends \(-In\)](#)

Audit (-A)

Use the Audit execution command (-A) to control the creation of audit log information. When used with other specified options, the **Audit** settings specified with the Audit command (-A) override all **Audit** settings compiled into the map. When used without other specified options, no audit log is produced. For information about the audit log files, see the *Map Designer* documentation. The default is to write the audit information to a temporary storage queue named **DTXAUD**. You can override the default by specifying the storage medium to be used and the name. See [Specifying Storage Medium](#) for details.

```
-A [D|R|W] [E|R|W] [B|R|W] [C|R|W] [P|R|W] [[M] [S]]  
[@storage_codeName]
```

Options

Description

@storage_code

Specify one of the following codes, which represents the storage medium to be used for the audit report
T = Specify a temporary storage queue
D = Specify a transient data queue
R = Specify VSAM relative-record dataset
K = Specify VSAM key-sequenced dataset
E = Specify VSAM entry-sequenced dataset

Name

Specify the queue name or VSAM dataset name for the audit report

Name must not be preceded by any spaces.

Input Dataset Override (-I)

Use the Input Dataset Override execution command (-I) to override the specified input card source with a dataset for this execution only. Use this command to override data source specifications that are in the compiled map file for a single execution of a map.

Use this command to override the name for a specific input data source, work file behavior, or rollback.

You can also specify storage medium, record separator delimiters, behavior for data with variable length records, and so on. See [Specifying Storage Medium](#) and [Variable Length Records](#) for more information about specifying these options.

```
-I[F]card_num[W|!W][B][[@storage_code][:{W|P[delimiter_list]}]] [name]
```

Option

Description

F

Optional for compatibility with previous versions

card_num

The number of the input card to override

W

Reuse the existing work file for this data source. If the work file does not exist at execution time, a work file is created.

!W

Do not use the existing work file but create a new work file each time the map is run.

B

If map execution is **not** successful, roll back any changes made to the file and reinstate the file to the original state prior to map execution.

storage_code

Specify one of the following codes, which represent the type of storage medium to be used for input data. The default is a temporary storage queue with the name defined for the input card with the path and file extension removed.

T = Specify a temporary storage queue.

D = Specify a transient data queue.

R = Specify VSAM relative-record dataset.

K = Specify VSAM key-sequenced dataset.

E = Specify VSAM entry-sequenced dataset.

B = Specify storage buffer.

Note: If the storage buffer option (B) is selected, then specifying an override name is not applicable.

:W

Specify for a file consisting of variable length records to copy data from the input file into fixed format workspace before mapping begins. The map will take its input not from the file but from workspace. For details see [The :W Option](#).

:P

Specify that the data will be *profiled*, that is, a table will be built in memory which cross-references record identifiers to corresponding file offsets. For details, see [The :P Option](#).

Delimiter_list

Specify a comma-delimited list of character or hex values. (Xnn is the syntax for indicating a hexadecimal value.) The default delimiter is a single byte with the value hex 15, decimal 21.

name

Specify the name of the storage entity (source) containing the data for the specified input card. If *name* is omitted, the name used is the name defined for the input card with the PC-based path information and file extension removed.

Note: *name* must be preceded by one or more spaces.

Execution Log (-L)

Use the Execution Log execution command (-L) to specify that an execution log is produced. The default is to write the execution information to a temporary storage queue name **DTXLOG**. You can override the default by specifying the storage medium to be used and the name of the log. See [Specifying Storage Medium](#) for details.

-I[@storage_codeName]

Options

Description
<i>storage_code</i>
One of the following codes, which represent the type of storage medium used for the execution log
T = Specify a temporary storage queue.
D = Specify a transient data queue.
R = Specify VSAM relative-record dataset.
K = Specify VSAM key-sequenced dataset.
E = Specify VSAM entry-sequenced dataset.
<i>Name</i>
The name for the execution log
Note: <i>name</i> must not be preceded by any spaces.

Output Dataset Override (-O)

Use the Output Dataset Override (-O) execution command to override the specified output card target with a dataset for this execution of the map only. For example, use this command to override the name for a specific output data target or to specify the appending of data files, file deletion, or rollback.

You can also specify the storage medium, record length, delimiters to use for record separators, and so on. See [Specifying Storage Medium](#), [Specifying Output Fixed Format Record Length](#) and [Variable Length Records](#) for more information about specifying these options.

When using an input or output override execution command (-I) or (-O), the source or target name must be preceded by one or more spaces. If the override specifies a storage buffer, using an override name is not applicable. Names for the data and execution audit, trace, and problem resolution information are not separated from the command by spaces.

**-O[F]card_num[+|!+][B][[@storage_code][#record_length]
[:{W|P[delimiter_list]}]] [name]**

Option

Description
F
Optional for compatibility with previous versions.
<i>card_num</i>
The number of the output card to override.
+
Append the current map execution data to an existing data file.
!+
Do not append the data to an existing data file, but create a file each time the map is run.
B
If map execution is not successful, rollback any changes made to the file and reinstate the file to the original state prior to map execution.
@ <i>storage_code</i>
One of the following codes that represent the type of storage medium to be used for output data. The default is a temporary storage queue with the output card name defined without its path and file extension.
T = Specify a temporary storage queue.
D = Specify a transient data queue.
R = Specify VSAM relative-record dataset.
K = Specify VSAM key-sequenced dataset.
E = Specify VSAM entry-sequenced dataset.
B = Specify storage buffer.
If the storage buffer option (B) is specified, then specifying an override name is not applicable.
<i>record_length</i>
The fixed output record length specified for writing the data that is less than or equal to 32768. The default is to write the data as 4096-byte fixed length records. For VSAM, the record length is the record length defined for the dataset.
:W
The data is mapped into workspace and then copied from workspace to its final target after mapping completes. Variable length records are separated out during the copy operation based on a defined record separator. See The :W Option .
:P
The data <i>profiled</i> , that is, a table is built in memory that cross-references record identifiers to corresponding file offsets. For details, see The :P Option .
<i>delimiter_list</i>
A comma-delimited list of character or hex values. (Xnn is the syntax for indicating a hexadecimal value.) The default delimiter is a single byte with the value hex 15, decimal 21.
<i>name</i>
The name for the temporary storage entity (target) where data for the specified output card will be written. If <i>name</i> is omitted, the name used will be the name defined for the output card without the PC-based path information and file extension.
<i>name</i> must be preceded by one or more spaces.

Enqueuing on Data Files (-Q)

Use the Enqueuing on Data Files execution command (-Q) to specify this execution command to enable enqueueing on data sources and targets for maps that run concurrently in a z/OS CICS region and share inputs or outputs or both inputs and outputs. By default, I/O calls to and from input and output files are not serialized.

-Q

Trace (-T)

Use the Trace execution command (-T) to turn off tracing or to specify a particular card or a range of input or output data objects or both input and output data objects to trace. When the -T command is used without other options specified, no trace log is produced. You can also produce a trace summary and specify the storage medium to use for the trace report. The default is to write the trace information to temporary storage queue DTXTRCE. You can override the default by specifying the storage medium to be used and the name. See [Specifying Storage Medium](#) for details.

**-T[I|ICcard_num|Ifrom[:to]|
[O|OCcard_num][S][@storage_codeName]**

Option	Description
I	Produce detailed trace information for all output cards
ICcard_num	Produce detailed trace information for a single input card. For example, the command -TIC3 only produces detailed trace information for input card 3.
Ifrom:to	Produce detailed trace information for a range of input objects. For example, to produce trace information for objects 1000 to 1320, the option could be specified as -TI1000:1320 . The upper limit of the object range is optional such that to trace from input object 1000 to the end of the file, the option could be specified as -TI1000 .
O	Produces detailed trace information for all output cards
OCcard_num	Produce detailed trace information for a single output card. For example, the command -TOC2 produces detailed trace information only for output card 2.
S	Produce summary trace information for input and output cards as specified, providing a message for each card. For example, the message for a particular card may be Input 1 was valid, but 34 bytes of unknown data found or Output 2 built successfully .
storage_code	One of the following codes that represent the type of storage medium used for the trace report. The default storage medium is transient data queue CSML. T = Specify a temporary storage queue. D = Specify a transient data queue. R = Specify VSAM relative-record dataset. K = Specify VSAM key-sequenced dataset. E = Specify VSAM entry-sequenced dataset.
name	The name for the trace report. <i>name</i> must not be preceded by any spaces.

Workfiles in Memory (-WM)

Use the Workfiles in Memory execution command (-WM) to override the default allocation of work files on disk and allocate them as memory files.

-WM

Problem Resolution (-\$)

Use the Problem Resolution execution command (-\$) only under the direction of Customer Support.

This command produces output that is unintelligible to the user but is required by Customer Support for debugging.

-\$

Ensure you use the hexadecimal value 0x5B for the '\$' character on US EBCDIC systems. Regardless of the character displayed in the JCL, using Hex 0x5B is essential to make this option work and produce the debug output if Support requests it.

Print Uppercase (+)

Use the Print Output to Uppercase execution command (+) to cause all printed output, execution logs, audit logs, and trace logs to be written in uppercase.

+*

Eliminate AICA (ICVR Timeout) Abends (-!n)

Use the Eliminate AICA (ICVR Timeout) Abends execution command (-!n) to issue an EXEC CICS SUSPEND being issued after every *n* objects found or built by the map. The EXEC CICS SUSPEND resets the ICVR timer and eliminates AICA abends caused by long-running maps that do a large amount of processing in CPU. Be aware that

using this command could adversely affect map performance if other tasks with higher priority are executing in the z/OS CICS region at the same time as the map.

-!n

Specifying storage medium

The z/OS CICS Execution Option can map from or to any of six different storage media.

You would specify the storage media by using the following codes:

- **T** = Specify a temporary storage queue.
- **D** = Specify a transient data queue.
- **R** = Specify VSAM pre-defined relative-record dataset.
- **K** = Specify VSAM pre-defined key-sequenced dataset.
- **E** = Specify VSAM pre-defined entry-sequenced dataset.
- **B** = Specify storage buffer.

Storage media can be specified for data sources and targets as well as execution log, trace, and audit output. For a data source or target, the default storage medium is a temporary storage queue with the input or output card name defined without the PC-based path and file extension.

A particular storage medium can also be specified for data audit, execution log, trace, and problem resolution information:

**This temporary storage queue
is the default medium for the...**

DTXLOG
 execution log
DTXAUD
 audit log
DTXTRCE
 trace
DTXDEBG
 debug listing

The following examples demonstrate how to specify the storage medium option with the applicable execution commands. In these examples, it is assumed that the storage medium for input and output data files comprises one or more records of a consistent, fixed length.

Example

Example	Description
-I1@D INPQ	Specifies data for input card 1 resides in a TDQ called INPQ
-O1 OUTPUTQ	Specifies data for output card 1 is written to a TSQ named OUTPUTQ
-I3@B	Specifies data for input card 3 resides in a storage buffer
-I2@K MYKSDSIN	Specifies input 2 is a VSAM KSDS named MYKSDSIN
-O2@E MYESDSOU	Specifies output 2 is a VSAM ESDS named MYESDSOU
-O2@R	Specifies output 2 is written to a VSAM RRDS named without a PC path or file extension
-L@TDTXLOG	Specifies that an execution log is written to a TSQ named DTXLOG
-A@DDTXAUD	Specifies that an audit log file is written to a TDQ named DTXAUD
-TI@TDTXTRCE	Specifies that an input trace file is written to a TSQ named DTXTRCE
-\$@TDTXDEBG	Specifies that a debug listing is written to a TSQ named DTXDEBG

Note: When using an input or output override execution command (-I) or (-O), the source or target name must be preceded by one or more spaces. If the override specifies a storage buffer, using an override name is not applicable. Names for the data and execution audit, trace, and problem resolution information are not separated from the command by spaces.

- [Specifying output fixed format record length](#)
- [Variable length records](#)

The z/OS CICS Execution Option views inputs and outputs as byte stream files rather than as collections of records.

Specifying output fixed format record length

Output data to transient data queues and temporary storage queues is, by default, written as 80-byte fixed length records. Use the Output File Override execution command (-O) to override the default and specify a different fixed output record length that is less than or equal to 32768.

The following examples demonstrate how to specify the fixed output record length using the Output File Override (-O) execution command:

Example

Example	Description
-O2@D#72 OUTQ	

Data is written to a transient data queue named **OUTQ** in 72-byte fixed-length records.
-01#256 MYTSQ
Data is written to a temporary storage queue named **MYTSQ** in 256-byte fixed-length records.

Note: Fixed format record length cannot be specified for input cards and storage buffers. For VSAM, the record length is the record length defined for the dataset.

Variable length records

The z/OS CICS Execution Option views inputs and outputs as byte stream files rather than as collections of records.

The CICS Execution Option requires support for random positioning to any byte offset within an input or output file. Random positioning is easily implemented for fixed length records, because any file offset can be easily converted to a record number and a byte offset from the start of the record; however, it is more difficult for variable length records.

In the CICS Execution Option, variable length records are handled either by copying the data to or from fixed format workspace or by building a table to cross-reference record identifiers to file offsets. You can designate the method to be used by specifying the :W or :P options when using the Input File Override (-I) and Output File Override (-O) execution commands.

- **The :W option**

When the :W option is specified using the Input File Override (-I) execution command, variable length records are reformatted by copying them from the input file into fixed format workspace before mapping begins and the map will take its input not from the input file but from workspace.

- **The :P option**

The :W option

When the :W option is specified using the Input File Override (-I) execution command, variable length records are reformatted by copying them from the input file into fixed format workspace before mapping begins and the map will take its input not from the input file but from workspace.

When this option is specified using the Output File Override (-O) execution command, data is mapped into fixed format workspace and then copied to its final target after mapping completes. Variable length records are separated out during the copy operation based on a defined record separator.

The following examples demonstrate how to specify the :W option using the Input File Override (-I) and Output File Override (-O) execution commands:

Example

Description

-I1:W MYINPUT

Input 1, **MYINPUT**, is a TSQ of variable length records; copy it to fixed format workspace before mapping it.

-O1:W MYOUTPUT

Output 1, **MYOUTPUT**, is a TSQ that will contain variable length records. Data is mapped to fixed format workspace and after mapping completes, variable length records are separated out and written to the queue.

Output files of variable length records must have a delimiter or delimiters at the end of each record so that the copy operation can detect where one record ends and the next begins. Output record separators are defined in and built by the map. The default delimiter expected is a single byte with the value hex 15, decimal 21. Optionally, you can use different delimiters by specifying them as a comma-delimited list of character or hex values. (*Xnn* is the syntax for indicating a hexadecimal value.)

The following example demonstrates how to specify a delimiter list using the Input File Override (-I) and Output File Override (-O) execution commands:

Example

Description

-O1:WXOD,XOA

Output data is mapped to fixed format workspace and records are copied to a TSQ of variable length records using the delimiter list of hex 0D 0A as record separators. In other words, when a 0D 0A byte pair is sensed in the output stream, it is understood that it indicates the end of a record. Record separators are removed.

Because reads against transient data queues are destructive and multiple passes may need to be made against them, data mapped to and from TDQs take place in workspace, regardless of the record format.

The :P option

When the :P option is specified using the Input File Override (-I) or Output File Override (-O) execution command, the data is *profiled*, that is, a table will be built in memory that cross-references record identifiers to corresponding file offsets. It is the responsibility of the map to place record separators in the output data so that the profiling operation can interpret where one record ends and the next begins.

The following examples demonstrate how to specify the :P option using the Input File Override (-I) and Output File Override (-O) execution commands:

Example

Description

-I1:P MYINPUT

Input 1 is a TSQ of variable length records; it will be profiled.

-O1@K:PX25 MYKSDS

Output 1, VSAM KSDS **MYKSDS**, contains variable length records; build a profile of the output using hex 25 as a record separator.

When using the :W or :P options, a delimiter list can also be specified for record separators to be used for input cards.

This can be useful in a situation in which you defined a map on the PC that reads a text file as input. A text file, by definition, consists of lines delimited by carriage-return/line-feed pairs (0D 0A). If you transfer this data to a z/OS environment as TEXT, the record separators are removed and variable length records are created. Mapping this data is a problem because the map as defined expects each record to be terminated by a carriage-return/line-feed pair that no longer exists. You can specify the following command string:

```
-I1:PX0D,X0A MYINPUT
```

This example command string would result in the bytes 0D 0A being added to the end of each record at the time it is read in.

Using EXEC CICS LINK passing storage buffers

When the z/OS CICS Execution Option is called by an EXEC CICS LINK, it is often because you want to pass to the CICS Execution Option the address of one or more storage buffers containing input data or the address of one or more storage buffers that will contain mapped output data or both address types.

Suppose that you want to call the CICS Execution Option from a z/OS CICS COBOL program using an EXEC CICS LINK and execute a map named **MAPA**. This map has one input and one output, both of which exist as storage buffers. To do this, the COMMAREA passed to the CICS Execution Option should be defined as:

```
01 DTX-LINK-BLOCK-B.
  05 MRLB-VERSION          PIC X(04) VALUE 'B002'.
  05 MRLB-PARM-COUNT       PIC 9(08) COMP VALUE 0.
  05 MRLB-PARM-LIST-ADDRESS    POINTER VALUE NULL.
  05 MRLB-RETURN-CODE      PIC 9(04) COMP VALUE 0.
  88 MRLB-NORMAL-RETURN    VALUE 0.
  05 MRLB-RETURN-MESSAGE    PIC X(80) VALUE SPACE.
  05 MRLB-MAPPING-RETURN-CODE PIC 9(04) COMP VALUE 0.
  88 MRLB-NORMAL-MAP-RETURN VALUE 0.
```

Next, code a working-storage area similar to the following example to hold the command line. The command line has card overrides for input 1 and output 1 indicates that the source and target exist as storage buffers.

```
01 MAP-COMMAND-LINE
  05 MAP-COMMAND-STRING   PIC X(16) VALUE 'MAPA -I1@B -O1@B'.
  05 FILLER               PIC X(01) VALUE LOW-VALUE.
```

MRLB-PARM-LIST-ADDRESS in DTX-LINK-BLOCK-B should contain the address of a parameter list such as the following example. The parameters need not be in this exact order but the command line must be the first parameter in the list.

```
01 PL00-PARM-LIST.
  05 PL01-MAP-COMMAND     POINTER.
  05 PL02-I1-BUFFER-PARM  POINTER.
  05 PL03-O1-BUFFER-PARM  POINTER.
```

PL01-MAP-COMMAND should contain the address of the null-terminated Command Line, MAP-COMMAND-LINE, defined above. PL02-I1-BUFFER-PARM should contain the address of the following working storage area:

```
01   DTX-DATA-BUFFER.
  05 MRDB-DATA-LENGTH        PIC S9(8) COMP.
  05 MRDB-DATA-ADDRESS       POINTER.
  05 MRDB-DATA-NAME-AREA    PIC X(04).
  05 FILLER REDEFINES MRDB-DATA-NAME-AREA.
    10 MRDB-DATA-NAME-L2      PIC X(02).
    10 MRDB-NULL-TERMINATOR-L2 PIC X(01).
    10 FILLER                 PIC X(01).
  05 FILLER REDEFINES MRDB-DATA-NAME-AREA.
    10 MRDB-DATA-NAME-L3      PIC X(03).
    10 MRDB-NULL-TERMINATOR-L3 PIC X(01).
```

MRDB-DATA-LENGTH should contain the actual length of the data in the buffer for input 1. MRDB-DATA-ADDRESS should contain the address of the buffer for input 1. MRDB-DATA-NAME-AREA should contain the null-terminated string "I1", indicating that this buffer is to be used as input 1.

PL02-O1-BUFFER-PARM should contain the address of an identical working storage area initialized as follows: MRDB-DATA-LENGTH should contain the full size of the buffer allocated for output 1. MRDB-DATA-ADDRESS should contain the address of the output buffer. MRDB-DATA-NAME-AREA should contain the null-terminated string "O1", indicating that this buffer will hold the mapped data for output 1.

MAPLB-PARM-COUNT should be set to 3 (1 for the command line + 1 for the input buffer + 1 for the output buffer). If more or fewer parameters are to be passed, make sure that you adjust the value of MAPLB-PARM-COUNT accordingly. See the **DTXSCTST** sample program.

Using the EXIT function

The **EXIT** function is available when entering mapping rules for fields using the Map Designer on your PC.

Use this function to exit to a user-written program to get data for mapping to a field. See the *Functions and Expressions* documentation. However, there are special considerations when using this function in conjunction with the z/OS CICS Execution Option.

A user exit is invoked by calling the **EXIT** function in a mapping rule using the Map Designer. The **EXIT** function expects three arguments, as seen in the following example:

```
EXIT ("non_null_value", "load_module_name", "parameters")
```

When using the CICS Execution Option:

- The first argument contains a value that is not a null string (a single space is sufficient).
- The second argument contains the name of the exit program (the load module name).
- The third argument is a text item containing parameter information for the exit program. This parameter text item may be up to 64K bytes in length, and the EXIT function returns a resulting text item, which also may be up to 64K bytes in length. Execution of this mapping rule causes the text item returned by the program *exit-name* to be placed in the field to which you are mapping data.

Exit programs must be defined as z/OS CICS programs. Any static data areas declared within an exit program, such as COBOL working storage, do not persist across multiple calls to the exit. Four arguments are passed to the user exit program in the COMMAREA:

- The address of a full word that contains the length of the parameter text item.
- The address of a space-padded buffer of up to 64K bytes that contains the parameter text item.
- The address of a full word that contains the length of the resulting text item.
- The address of a buffer of up to 64K bytes into which the resulting text item will be placed.

For an example of source code for a COBOL user exit program, see DTXSCXIT in the DTX.SDTXSAMP PDS included in the IBM Transformation Extender installation.

Using the RUN function

The first argument of the **RUN** function is the name of the map to be executed. Under z/OS CICS this must be the name of the map as it exists in the map KSDS. At run-time, the CICS Execution Option converts the map name specified in the **RUN** function by removing any drive, path, and file extension information if it exists. For example, the following map rule will execute the map **MAP_10**:

```
RUN ("install_dir\mymaps\map_10.mmc")
```

When using the **RUN** function, by default, the CICS Execution Option execution log, audit log, trace, and problem resolution output are written to temporary storage queues **RUNLOGnn**, **RUNAUDnn**, **RUNTRCnn**, and **RUNDBGnn**, respectively, where *nn* is the recursion level of the map greater than or equal to 01. You can override these targets as described above.

A map executed using the **RUN** function is loaded once and is removed from storage when the task ends or when the map executed is different from the last map executed. This means that maps repeatedly executed are not reloaded each time.

Preloading IBM Transformation Extender maps and .mdq files in a z/OS CICS environment

The CICS® preloader utility preloads IBM Transformation Extender maps and database query (.mdq) files into memory. When maps and .mdq files run frequently, you can reduce processing by preloading them into memory. Preloaded files do not require I/O processing.

The CICS preloader loads maps and .mdq files from a partitioned data set (PDS or PDSE) or from a z/OS® flat file.

- [Configuring the CICS preloader utility](#)
- [Map and .mdq file DD statements in the CICS startup JCL](#)
The CICS preloader loads maps and .mdq files from a partitioned data set (PDS or PDSE) or from a z/OS® flat file.
- [Running the IBM Transformation Extender CICS preloader utility](#)
The name of the preloader utility is DTXnnnLD, where *nnn* is the IBM Transformation Extender version. For example, the name of the preloader for IBM Transformation Extender V8.4.1 is DTX841LD.

Configuring the CICS preloader utility

To configure the CICS® preloader utility:

1. Create a preloader control file.
2. In the preloader control file, identify the maps and .mdq files that you want to load.
3. Add DD statements to the CICS startup JCL for:
 - The preloader control file
 - The maps and .mdq files that you want to load

These steps are described in detail in the topics that follow.

- [The preloader control file](#)
A control file identifies the IBM Transformation Extender maps and database query (.mdq) files that the IBM Transformation Extender CICS preloader utility loads into memory. You allocate the DTXnnnIN preloader control file in the CICS startup JCL.
- [Identifying the maps and .mdq files in the DTXnnnIN preloader control file](#)
In the DTXnnnIN CICS preloader control file, identify the IBM Transformation Extender maps and database query (.mdq) files that you want to preload into memory.

The preloader control file

A control file identifies the IBM Transformation Extender maps and database query (.mdq) files that the IBM Transformation Extender CICS preloader utility loads into memory. You allocate the DTXnnnIN preloader control file in the CICS startup JCL.

The *ddname* of the preloader control file resource must be DTX*nnn*IN, where *nnn* is the IBM Transformation Extender version, for example DTX841IN. The preloader control file must have a fixed-block record format (**RECFM=FB**).

For example, the following DD statement allocates a preloader control file that is named KEYWORD.MAP in the CICS startup JCL:

```
//DTX841IN DD DSN=KEYWORD.MAP DISP=SHR
```

The preloader control file cannot be the D*nnn*MAP VSAM file (where *nnn* is the IBM Transformation Extender version).

Identifying the maps and .mdq files in the DTX*nnn*IN preloader control file

In the DTX*nnn*IN CICS preloader control file, identify the IBM Transformation Extender maps and database query (.mdq) files that you want to preload into memory.

1. Edit the DTX*nnn*IN preloader control file.
2. Specify each map file and .mdq file in the format:

```
MAPNAME=MAP_TO_LOAD  
MDQNAME=MDQ_FILE_TO_LOAD
```

where *MAP_TO_LOAD* or *MDQ_FILE_TO_LOAD* is the name of the map or .mdq file. The contents of the preloader control file must be in uppercase. You can specify multiple *KEYWORD=FILE_NAME* pairs in the preloader control file. Specify multiple pairs on separate records or lines, or as a single space-delimited or comma-delimited record. For example:

```
MAPNAME=MAP_TO_LOAD,MDQNAME=MDQ_FILE_TO_LOAD,MAPNAME=MAP_TO_LOAD
```

Map and .mdq file DD statements in the CICS startup JCL

The CICS preloader loads maps and .mdq files from a partitioned data set (PDS or PDSE) or from a z/OS® flat file.

- **Map or .mdq files in a z/OS flat file**

The name of the map or .mdq file must be the *ddname* of the DD statement that allocates the resource in the CICS startup JCL. The data set name (DSN parameter) is the name of the z/OS flat file that contains the map.

- **Map or .mdq files in a PDS or PDSE**

When a map or .mdq file is a partitioned data set (PDS or PDSE), its DD statement determines how you specify it in the preloader control file.

Map or .mdq files in a z/OS flat file

The name of the map or .mdq file must be the *ddname* of the DD statement that allocates the resource in the CICS startup JCL. The data set name (DSN parameter) is the name of the z/OS flat file that contains the map.

For example, the PORDER.MAP file is a native z/OS flat file that contains the POMAP.MVS map. The SKUDB.MDQ file is a native z/OS flat file that contains the SKUMDQ.MDQ file. Use the following DD statements in the CICS startup JCL:

```
//POMAP DD DSN=PORDER.MAP, DISP=SHR  
//SKUMDQ DD DSN=SKUDB.MDQ, DISP=SHR
```

In the preloader control file, specify the map and .mdq files to preload:

```
MAPNAME=POMAP  
MDQNAME=SKUMDQ
```

Map or .mdq files in a PDS or PDSE

When a map or .mdq file is a partitioned data set (PDS or PDSE), its DD statement determines how you specify it in the preloader control file.

- If the *ddname* of the DD statement is the map or .mdq file name, the preloader control file specifies only the map or .mdq file name. For example, the following DD statement loads the TEST1 map from the TX.MAPS PDS:

```
//TEST1 DD DSN=TX.MAPS(TEST1),DISP=SHR
```

The preloader control file must specify the following MAPNAME:

```
MAPNAME=TEST1
```

- If the *ddname* of the DD statement is not the map or .mdq file name, the preloader control file specifies both the *ddname* and the map or .mdq file name. For example, the following DD statement loads the TEST1 map from the TX.MAPS PDS:

```
//MAPLIB DD DSN=TX.MAPS,DISP=SHR
```

In this case, the preloader control file must specify both the MAPLIB *ddname* and the TEST1 map name:

```
MAPNAME=MAPLIB(TEST1)
```

Running the IBM Transformation Extender CICS preloader utility

The name of the preloader utility is DTX nnn LD, where nnn is the IBM Transformation Extender version. For example, the name of the preloader for IBM Transformation Extender V8.4.1 is DTX841LD.

You can run the utility only when no other mapping process is active. The DTX nnn IC and the DTX nnn IK programs must have a RESCOUNT of 0. If a mapping process is active, the DTX nnn LD utility fails and writes a message to SYSPRINT DD.

You can execute the DTX nnn LD utility:

- As a transaction (DTLD)
- By linking to the DTX nnn LD program
- By adding the DTX nnn LD program as a second-phase initialization PLTPI

You can run the CICS preloader utility multiple times. Each time it runs, it frees the maps from memory and reloads them from disk.

If you do not preload a map, load it into the D nnn MAP VSAM file (where nnn is the IBM Transformation Extender version) to run it.

Abnormal termination

If a task terminates abnormally with an internal error, the return code 16 and an error message are passed back to the calling program.

Diagnostic information is written to the execution log if one is being produced or to the system transient data queue **CSML** if there is no execution log. Diagnostic information for a task can be identified by the task ID that occupies the first eight bytes of each line of output. All temporary files in workspace are deleted before the task ends.

The DTXMPULD utility

In addition to loading maps into the KSDS, where maps are stored for use in the z/OS CICS region as described above, the DTXMPULD utility has the capability of listing and deleting maps from the **KSDS** map.

The command syntax is as follows:

```
DELETE=map_name_or_mask  
LIST=map_name_or_mask
```

Either or both of these can be used in combination with the INPUT command that specifies maps to be loaded into the VSAM **KSDS**.

The parameter *map_name_or_mask* can be used to specify a single map or a collection of maps if you use the wildcard character *. For example, DELETE=MAPA will delete only MAPA from the **KSDS** map. DELETE=MAPA* deletes all maps with names beginning with MAPA. LIST=* lists all maps stored in the VSAM dataset. DELETE=* deletes all maps.

To use either the DELETE or LIST, the DDNAME MAPKSDS must identify the map **KSDS**:

```
//MAPKSDS DD DSN=map_KSDS,DISP=SHR
```

If the INPUT command is not used, no output is generated for loading into the map **KSDS**. Consequently, the SORT and REPRO steps of the **DTXCI** JCL should not be executed.

Resource names

For information about creating resource names for use on the CICS Execution Option for the z/OS CICS platform, see [Resource Names for z/OS Platform](#).

Multiple IBM Transformation Extender versions

This section presents information about running multiple versions of the IBM Transformation Extender CICS Execution Option concurrently in a single CICS region.

This feature will help you migrate to additional releases of the CICS Execution Option without the need to define and configure additional CICS regions. You will also be able to do a staged migration, or phase-approach, to a new release while your existing release is running in that same CICS region.

- [Enabling the multiple IBM Transformation Extender feature](#)

This feature is enabled by making the names of the files and programs you are currently installing unique to the names used in other releases you have installed previously.

- [Using the multiple installations](#)

After the new release of the CICS Execution Option has been installed, you need to be able to distinguish between the multiple installations and then invoke them.

Enabling the multiple IBM Transformation Extender feature

This feature is enabled by making the names of the files and programs you are currently installing unique to the names used in other releases you have installed previously.

It is done by embedding the product version number, *nnn*, in the resource name, D*nnn*MAP. An example is to specify D810MAP as the resource name you are currently installing, while MERCMAP is the resource name used in your previous install.

With this resource naming convention, you must update the CICS resource definitions for each release of CICS Execution Option and duplicate the associated VSAM datasets.

The result is that a completely separate copy of the product is installed and none of its resources are shared with any other version of the product that exists in the same CICS region. The user Dynamic Storage Area used by CICS Execution Option components will effectively be doubled.

Using the multiple installations

After the new release of the CICS Execution Option has been installed, you need to be able to distinguish between the multiple installations and then invoke them.

There are two ways to identify and run multiple installations of the CICS Execution Option depending on which method you use to invoke the CICS Execution Option.

- If you invoke the CICS Execution Option through the EXEC CICS START command, Transient Data Queue trigger, or by entering the transaction ID at a terminal
 - use the transaction ID **D_{nnn}** (where *nnn* is the version of the release you have installed) and **MERC** or **DSTX** depending on the specific release you currently have installed.
- If you invoke the CICS Execution Option through the EXEC CICS LINK command
 - use the DTX*nnn*KI (used with XPLINK) or DTX*nnn*CI program names (where *nnn* is the version of the release you have installed) for the new version of the CICS Execution Option and MERCCICS or DSTXCICS depending on the specific release you currently have installed.
Note: If you do not need to use the multiple CICS Execution Option feature, you can use the alias name, **MERCCICS** for the program name for backward compatibility.

Resource names for z/OS platform

These are the details for creating resource names for use on z/OS Batch and CICS platforms.

Resource names created in the Resource Registry can be used in maps running on z/OS platforms. However, there are a few things to take into consideration:

- Resource values must conform to z/OS rules for their types, such as DDNAMES and Database names.
- Virtual server defined for the z/OS platform must be named **MVS SERVER**
- Resource name file (**.mrn**) must be copied to z/OS platform
- Name and location of resource name file are specified in either **DTXMRN** DDNAME for Batch region or **DTXMRN** VSAM dataset definition for CICS region
- Resource configuration file (**.mrc**) is not required
- **Resource name aliases**
Because the z/OS platform does not recognize file path information, the IBM Transformation Extender automatically truncates the path specified in input and output cards when the map is executed.
- **Virtual server names**
When creating virtual servers to represent the z/OS deployment environment, **MVS SERVER** (case-sensitive) must be defined as the virtual server name.
- **Specifying resource name file for batch**
- **Specifying resource name file for CICS**
- **Resource configuration files**

Resource name aliases

Because the z/OS platform does not recognize file path information, the IBM Transformation Extender automatically truncates the path specified in input and output cards when the map is executed.

Therefore, it is not necessary to create a resource name that has a value defined for a file path.

- **Resource name limitations for files and DDNAMES**
To conform to z/OS conventions, the IBM Transformation Extender truncates file and resource names to 8 characters when a map is executed.

Resource name limitations for files and DDNAMES

To conform to z/OS conventions, the IBM Transformation Extender truncates file and resource names to 8 characters when a map is executed.

Therefore, resource names and their values have an 8-character limitation. Because this includes the percent (%) symbols that enclose the resource name when using it in a source or target resource, the resource name must not be longer than 6 characters. For example, the resource name **MyFile** is specified as **%MyFile%** when used in the **Command** setting of an input or output card.

The resolved resource value is actually a DDNAME that is defined on the z/OS Batch platform. The resolved value must conform to the rules for DDNAMES.

See "[DDNAMES](#)" for more information about defining DDNAMES for resolved resource values.

Virtual server names

When creating virtual servers to represent the z/OS deployment environment, **MVSSERVER** (case-sensitive) must be defined as the virtual server name.

MVSSERVER is the only server name the IBM Transformation Extender recognizes.

Even if other virtual servers are also defined in the same **.mrn** file, **MVSSERVER** is the only name recognized by the z/OS version of the IBM Transformation Extender as being the active server.

Specifying resource name file for batch

When associating a resource name file for the z/OS Batch version of the Command Server, the name and location of the **.mrn** file are specified in the **DTXMRN** DDNAME definition in a JCL (Job Control Language) file.

- [**DDNAMES**](#)

DDNAMES

DTXMRN is the only DDNAME recognized by the Command Server that contains the **.mrn** file specifications. A DD statement specifies the file name or path of the **.mrn** file.

To specify a resource name file for Batch

1. Create the resource name **.mrn** file in the Resource Registry.
2. Copy the **.mrn** file to the z/OS platform.
3. Update the JCL file.
 - Specify the **DTXMRN** DDNAME definition.
 - Include a DDNAME definition for each resolved resource value used.

Specifying resource name file for CICS

When associating a resource name file for the z/OS CICS version of the IBM Transformation Extender, the name and location of the resource name file are specified in the **DTXMRN** Virtual Storage Access Method (VSAM) dataset.

- [**VSAM**](#)

VSAM

JCL files are used when executing the IBM Transformation Extender in the CICS region just as they are for Batch. However, instead of specifying the **.mrn** file in a **DTXMRN** DDNAME definition in the same JCL file in which the job steps that invoke the IBM Transformation Extender are also specified, the **.mrn** file is specified in a **DTXMRN** VSAM dataset definition submitted in a separate JCL file. The **DTXMRN** VSAM dataset definition includes the name and location of the **.mrn** file.

To specify a resource name file for CICS

1. Create the resource name **.mrn** file in the Resource Registry.
2. Copy the **.mrn** file to the z/OS CICS platform and then load it into a VSAM dataset.
3. Update the separate JCL file.
 - Specify the **DTXMRN** DDNAME definition to define this VSAM dataset to the CICS region.
 - Include a CICS resource definition for each resolved resource value used.

Only one **DTXMRN** VSAM dataset can be used while the CICS region is running, therefore, only one resource name file can be referenced during this duration. Because of this, it is suggested that you define all resource names and their associated values that will be used on the z/OS CICS version of the IBM Transformation Extender in one resource name file.

Resource configuration files

A resource configuration file (**.mrc**) is not used by the z/OS version of IBM Transformation Extender to determine which **.mrn** file to use and what server is active. Instead, the **.mrn** file is specified in either a DD statement for the **DTXMRN** DDNAME or in the **DTXMRN** VSAM dataset definition, and **MVSSERVER** is recognized as the only active server for the z/OS version of IBM Transformation Extender.

Because a resource configuration file is not required, it is not necessary to specify an **.mrc** file in the Map Designer or the **config.yaml** file.

Launcher introduction

The Launcher automates the execution of systems of maps and can control multiple systems.

On Windows platforms, the Launcher runs as a multi-threaded service. On UNIX platforms, the Launcher runs as a multi-threaded *daemon*. For platform and version-specific information, see the [Release Notes](#).

Note: When running the Launcher on z/OS® through z/OS UNIX System Services (z/OS UNIX), follow the instructions for UNIX. The z/OS environment is treated as another UNIX system. Any differences between the standard UNIX and z/OS usages are noted where appropriate.

- **[Installation considerations](#)**

See the [release notes](#) for installation details.

- **[Optional local z/OS administration interfaces](#)**

There are optional local z/OS administration interfaces available for configuring and managing the Launcher on z/OS operating systems.

- **[Launcher overview](#)**

The Launcher runs systems of maps that are created and generated using the Integration Flow Designer (IFD).

- **[Using the Launcher](#)**

To use the Launcher, you must complete a series of steps.

Installation considerations

See the [release notes](#) for installation details.

Note: Ensure that the hostname 'localhost' resolves to 127.0.0.1 or Launcher execution (**launcher.sh**) will produce unexpected results.

Note: <install_dir> refers to the directory where your product is installed.

Optional local z/OS administration interfaces

There are optional local z/OS® administration interfaces available for configuring and managing the Launcher on z/OS operating systems.

The two optional local z/OS administration interfaces ("[Local z/OS Administration Interfaces](#)") are:

Launcher overview

The Launcher runs systems of maps that are created and generated using the Integration Flow Designer (IFD).

These systems of maps that are generated specifically to run in the Launcher are called system files (**.mst**), sometimes referred to as Launcher control files.

When the Launcher starts running, it is initialized with **.mst** files in the deployment directory.

The new HTTP Listener component of the Launcher provides secure, two-way communication between external clients and the Launcher. An external HTTP client can trigger a map in a Launcher system by sending a request to the Launcher HTTP Listener. Regardless of whether it runs successfully, the map returns a response through the HTTP Listener to the external HTTP client. If the map fails or the output card does not return a response to the client, the input card automatically returns a response. For more information on the HTTP Listener, see [Launcher HTTP Listener overview](#).

You can specify a deployment directory from the Launcher Administration interface. (For more information about this, see "[Launcher Administration](#)".)

Note: When using the z/OS® local administration interfaces, the deployment directory defaults to *install_dir/systems*.

- **[Launcher HTTP Listener overview](#)**

The HTTP Listener component of the Launcher provides secure, two-way communication between external clients and the Launcher. The HTTP Listener is included in the Design Studio installation. The HTTP Listener can automatically recognize an MTOM message and store the attachments in a user-designated location.

Launcher HTTP Listener overview

The HTTP Listener component of the Launcher provides secure, two-way communication between external clients and the Launcher. The HTTP Listener is included in the Design Studio installation. The HTTP Listener can automatically recognize an MTOM message and store the attachments in a user-designated location.

An external HTTP client can trigger a map in a Launcher system by sending a request to the Launcher HTTP Listener. Regardless of whether it runs successfully, the map returns a response through the HTTP Listener to the external HTTP client. If the map fails or the output card does not return a response to the client, the input card automatically returns a response.

The HTTP Listener executable name is **httpslsnr**. This functionality supports the following features:

- Allows you to configure HTTP Listeners in Launcher Administration.
 - Add a new HTTP Listener
 - Remove an existing HTTP Listener
 - Update an existing HTTP Listener configuration
- Runs HTTP Listeners that are enabled during the start up of the Java Launcher.
 1. The Java Launcher spawns HTTP Listener processes.
 2. The HTTP Listener process listens for client requests based on user settings.
 3. The HTTP Listener provides status information to clients.
 4. The HTTP Listener allows clients to configure non-start up settings.
 5. The Java Launcher restarts HTTP Listener if they terminates abruptly.
- Allows you to monitor the HTTP Listeners from Management Console.
 - Monitor only those HTTP Listeners that are of interest to you
 - Provide Summary, Status, and Configuration statistics
 - Provide a manual refresh for status statistics, in addition to the automatic refresh
- Provides command line interface support for HTTP Listeners.

- Define HTTP Listeners with Launcher Administration command line utility
- List HTTP Listeners defined by the user
- Export and import HTTP Listener definitions in XML format
 - Note: The Java Launcher can start HTTP Listeners with Launcher Administration XML.
- Report the status of the HTTP Listener using Java Launcher command line utility
- List HTTP Listeners running under Java Launcher
- Provides status and configuration information updates for clients through the Management Console and web browsers.
 - View status and configuration updates
 - Audit HTTP Listener activity
- Provides command line execution.
 - Includes many command line options for easy configuration and fast startup
 - Provides monitoring, auditing, and tracing from the command line console
 - Registers HTTP Client requests quickly regardless of the volume of requests
- Provides remote control access.
 - Handles updates and real-time monitoring from a browser on a remote machine
 - Refreshes the web browser automatically in custom intervals depending on the window visibility
- Allows real-time monitoring of activity.
 - Reports the total number of HTTP client requests and the type of Launcher response
 - Reports the average map execution times per HTTP Adapter watch
 - Tracks the total number of connections and averages the elapsed time for the establishment of sessions
 - Reports the names and sizes of the audit and trace files
 - Displays statistics on command line console, web browser, and Management Console
- Auditing
 - Reports each HTTP Client request and Launcher response in a XML schema format
 - Logs individual map completion times
 - Tracks each connection type and the elapsed time for session establishment
 - Activates on-demand and can be periodically archived once auditing is disabled
- Expanded Tracing
 - Provides unique names for the standard and verbose trace files
 - Tracks regular events in standard trace file and socket activity in verbose trace file
 - Activates on-demand and can be periodically archived once tracing is disabled
- Enhanced Triggering
 - Provides 2-way communication between the HTTP Adapter Input Card and HTTP Listener for added functionality and fast response times
 - Allows configurable HTTP response codes and messages based on map return code
 - Enables boilerplate and customized HTTP data responses that can include runtime map information
 - Guarantees timely HTTP Responses upon map failure

Using the Launcher

To use the Launcher, you must complete a series of steps.

The list below provides a high-level overview of the steps to follow after installing WebSphere® Transformation Extender.

Note: When running the Launcher daemon under z/OS® UNIX System Services (z/OS UNIX), by default, the Launcher daemon uses the value calculated by subtracting 1 from the starting listening port to stop, resume or pause the Launcher daemon. The starting listening port is configured under the General tab in the Launcher Administration interface.

Note: When using the z/OS local administration interfaces, see "[z/OS Launcher](#)" for more information.

- [**Basic steps**](#)

Basic steps

The following steps summarize the process flow of using the Launcher with the Management Tools.

1. From the Launcher Administration interface, configure the Launcher by setting up users, port numbers, and deployment directories.
2. Use the Integration Flow Designer to create a system and then generate the system (.msl) file to the deployment directory. For help on creating or generating a system file, see the *Integration Flow Designer* documentation.
3. Start the Launcher service or daemon.
4. Open a connection to the Launcher from the Management Console and begin viewing statistical data from the process that is running. From there you can also control the compound system that is running.
5. Open a connection to the Launcher from the Launcher Monitor to view watches that are running dynamically and to take snapshots.
6. Open the Snapshot Viewer to view snapshots taken by the Monitor.

Launcher architecture

The Launcher is an event-driven software model for linking and executing maps. Systems contain maps with the system workflow you specify by using the Integration Flow Designer.

A Launcher runs on a server platform and manages one or more Launcher processes (comprised of one or more systems) concurrently. Systems are asynchronous multi-threaded processes, whose atomic units are transactional maps. Systems can execute in a distributed environment where a Launcher resides on each server. When events occur, the Launcher is notified and starts maps based on that notification. Distributed data is received or routed during map execution.

Launcher functionality is based on the following premises:

- An event manager controls the initiation of maps based on sources to which a map subscribes.
 - A resource manager synchronizes shared data and timing interfaces among heterogeneous sources and targets.
 - Maps publish data that result from the content transformation of source data.
 - Maps are transactional processes with each map having its own error detection and recovery procedures.
 - The Launcher runs as a single process with multiple threads.
- [Triggers: Asynchronous communication](#)
 - [Synchronous coordination](#)
 - [System execution consistency](#)
 - [Map function and requirements](#)
 - [Defining a system](#)

Triggers: Asynchronous communication

The Launcher starts maps based on *triggers* that you identify using the IFD. Triggers are asynchronous events and time or source state changes. In some cases, there might be multiple triggers that must collectively exist before a map is initiated. The Launcher manages the coordination of these events to ensure that the correct set of circumstances have occurred before a map is initiated.

Although each instance of a map is considered a separate *watch*, the Launcher must also manage the resource interfaces used by other maps and other instances of the same map to properly synchronize these asynchronous events.

Synchronous coordination

Situations exist where synchronous interaction between maps is required. For example, you might not want to complete a transaction until you receive an acknowledgment of a particular action. Or you might want to communicate with a program or function to receive input data or send output data. Synchronous interaction can be performed in different ways:

- Communicate with other maps from a map rule during the data transformation process. Using a map rule in this manner with the Launcher manages coordination among maps to assure deadlock situations are avoided and shared resources are reliably accessed or deleted
- Synchronize coordination to interact with other applications using a resource adapter for a data source or target. For example, if you send a message by using the e-mail adapter, receipt notification might occur before the mapping process completes. When using resource adapters, you can configure recovery procedures for errors that occur during communication.

System execution consistency

System execution consistency implies data resources get to the right place at the right time with the right priority and that resources are manageable so that data or timing interfaces do not interfere with each other.

The smallest unit in a system configuration is a map. The definition of a map requires you to identify logical source and target data objects and rules for transforming source content to target content. For example, a logical data object can be an order, a ship notice, a news report, or a point-of-sale transaction. In this case, content transformation rules determine how an order and inventory schedule produces a ship notice.

If the transformation is consistent, the result is predictable. If the transformation is consistent, the same rules can execute on a variety of computing platforms; different sources and targets can be applied to the same logical data. For example, orders might be in a distributed database, inventory schedules might appear as messages, and ship notices might need to be contained in files.

Maps communicate when data can flow among them. To visualize that transaction data flow, the architecture of map interaction is defined as a system using the IFD. From a graphical diagram of system components, you can generate consistent control information to distribute maps and subsystems across different servers and execute all *atomic* maps in a system as an integrated whole with an Launcher.

Map function and requirements

The primary function of a map is to transform and route data from source formats to target formats. Sources and targets are independent objects, with respect to the metadata that specifies the content, the applications to which they might link, and the transport mechanisms used to obtain or deliver the content.

Defining a system

Using the IFD, you can define a system as a set of distributed subsystems, a set of maps, or a combination of maps and subsystems. You can create these definitions because a system is an isolated set of components whose interfaces are as explicit as the interfaces for an atomic map.

For example, this isolation enables the Launcher to manage a system as easily as it manages a map.

To complete successfully, a map needs the proper resources to be in place. For example:

- Every data source must be accessible.
- Every output must be routable to its assigned target.
- The server-required resources to perform the transformation (work files and audit logs, for example) must not be in use by any other process during the transformation process.

To accomplish this reliably, the transformation must be able to succeed or fail as a whole. That is, when a map does not complete successfully, the original data must persist in a form that is recoverable and partial results can be rolled back and made inaccessible to other maps or applications.

You can use a single map to simplify logical connections between multiple heterogeneous applications; direct links using application adapters; and indirect links using file, messaging, and database adapters.

Getting started

In this documentation, you will learn how to set up and start using the Launcher.

- [Creating systems](#)
To create Launcher processes (.msl system files) that run on your Launcher platform, you must use the Integration Flow Designer (IFD).
- [Launcher Administration](#)
- [Preparing to execute defined systems](#)

Creating systems

To create Launcher processes (.msl system files) that run on your Launcher platform, you must use the Integration Flow Designer (IFD).

Additionally, you can use the IFD to:

- Define systems and Launcher settings.
- Build maps for a target platform, if required.
- Move all files that are required for system execution (that is, ported map files, Launcher system files, and so on) to a target platform in a designated deployment directory. For example, generate the system file (.msl) to the deployment directory.

See *Integration Flow Designer* documentation for more information about systems.

Note: When using the z/OS® native administration interfaces, see "[z/OS Launcher](#)" for more information. The remainder of this topic does not apply.

Launcher Administration

The Launcher Administration is the interface to the Launcher from which you can do the following configuration tasks:

- Choose the deployment directories from which systems run.
 - Set up users and user access rights.
 - Select a listening port and port range.
 - Select a resource configuration file (.mrc).
 - Specify system properties for the Java™ Remote Method Invocation (RMI)
 - Configure automatic restart parameters.
- [Accessing Launcher Administration](#)
The Launcher Administration is included with the WebSphere® Transformation Extender package and runs on both Windows and UNIX platforms.
- [Using Launcher Administration](#)

Accessing Launcher Administration

The Launcher Administration is included with the WebSphere® Transformation Extender package and runs on both Windows and UNIX platforms.

To start the Launcher Administration (Windows)

Select Start > Programs > Transformation Extender > Launcher > Launcher Administration.

To start the Launcher Administration application (UNIX)

1. From the installation directory, type:

```
. setup
```

2. At the command prompt type:

```
launcheradmin.sh
```

Using Launcher Administration

Before starting the Launcher, it is recommended that you confirm the default settings. If you do not change settings in the Launcher Administration before starting the Launcher, the Launcher Administration uses the following default values:

- Automatic startup option is enabled.
- Automatic restart is enabled.
- Launcher service listening ports are 5015 and 5016.
- Port range is 7000 - 8000.
- There are no user profiles.
- The deployment directory is:
 - *install_dir\System* on Windows platforms
 - *install_dir/System* on UNIX platforms

At the minimum, you must set up at least one user profile before using the Launcher. The documentation describes all of the options.

Note: When you configure the Launcher to run with the multiple-processes feature enabled, you can edit some of the settings while it is running as described in "[Multiple Processes](#)".

When you configure the Launcher to run as a single Launcher process (Compound System), you cannot edit settings.

- [Automatic startup option](#)
- [Configuring automatic restart](#)

On distributed platforms, the Launcher restarts automatically when it fails. This option can reduce downtime in production environments. You can configure how long and how many times the Launcher attempts to restart, or you can disable automatic restart. Automatic restart is not supported on Enterprise (USS) platforms.

- [Connection ports](#)

- [User profiles](#)

- [Deployment directories](#)

- [Resource resolution](#)

- [Cluster support](#)

- [Firewall configuration](#)

- [HTTP Listener startup configuration](#)

An HTTP Listener routes HTTP requests from external clients to maps in the Launcher and returns a response to the external client. Use the Launcher Administration utility Options page and select Listeners to add, remove, and update HTTP Listeners.

- [Automatic restart for launchers and HTTP Listeners](#)

Launchers and HTTP Listeners can automatically restart when they unexpectedly stop running. Use the Launcher Administration utility Options page to enable automatic restart and to limit the number and duration of restart attempts.

- [About multiple Launchers](#)

Automatic startup option

In the Launcher Administration, the **Automatic startup** option is enabled by default. The **Automatic startup** option triggers the **.msl** system files located in the deployment directory to start running automatically upon starting the Launcher service or daemon.

Note: One or more system files appear in the Management Console as one "CompoundSystem". See "[Multiple Processes](#)" for additional information when using the multiple-processes feature.

If you disable the **Automatic Startup** option and then start the Launcher service, you must manually start the system from the Management Console. See "[Management Console](#)" for more information about the Management Console.

Configuring automatic restart

On distributed platforms, the Launcher restarts automatically when it fails. This option can reduce downtime in production environments. You can configure how long and how many times the Launcher attempts to restart, or you can disable automatic restart. Automatic restart is not supported on Enterprise (USS) platforms.

1. In the Options tab of Launcher Administration, select Restart.
2. Click Enable Configuration to enable or disable automatic restart. Restart is enabled by default.
3. In the Retry Attempts field, specify the maximum number of times the Launcher is to attempt to restart after a failure.
The default value is two restart attempts. If the specified number of restart attempts has not occurred when the Retry timeout period elapses, the Launcher continues to retry until it reaches the specified number of attempts.
4. In the Retry Timeout field, specify the maximum amount of time, in minutes, that the Launcher is to attempt to restart after a failure.
The default value is 10 minutes. There are five minutes between each restart attempt.

Related reference

- [Launcher Administration command line syntax](#)

Connection ports

A **Listening Port** is a network port that listens for incoming requests. The default listening ports are **5015** and **5016**. The second listening port is reserved for communicating with the Launcher Monitor and is displayed in a read-only field. The Launcher Administration application uses an increment of 1 to determine the second listening port number. The system-generated number for this port is based on the **Listening Port** value plus **1**. For example, if you change the listening port to **3050**, the second listening port number automatically changes to **3051**.

Note: When running the Java™ Launcher on UNIX platforms and using the stop, pause or restart command with the **launcher.sh** shell script command, the Java Launcher internally uses a port setting that is 1 less than the first **Listening Port** value. The default internal **Port** is **5014**, which is **1** less than the first **Listening Port**, **5015**.

The **Port Range** values determine the port range that is used for systems running in the Launcher. There are *three* ports used for each Launcher running. The default range is **7000-8000**. You can change the port range to any value except the **Listening Port** number plus 1 (for example, **5016**), which is reserved for communication with the

Launcher monitor.

Note: When using WebSphere® Transformation Extender for z/OS®, the specified **Listening Port** and **Port Range** ports should be added to the **TCPIP.ETC.SERVICES** file. These ports cannot be currently in use by another application. The purpose of specifying them in the file is to document that these ports are reserved and should not be used by another application. It does not prevent other applications from using them.

This is true for all platforms, although the services file name is different.

For more details, see the *IBM® z/OS Communications Server: IP Configuration Reference* documentation.

Note: See "[Multiple Processes](#)" for additional information about connection ports when using the multiple-processes feature.

Note: When running the Java Launcher on UNIX and LINUX platforms, the specified **Listening Port** and **Port Range** ports should be added to the etc/services file.

User profiles

Before starting the Launcher, you must create at least one user profile for Launcher authentication.

To add a user profile

- From the Access tab, click Add.

The User Properties window opens.

- Complete each field:

- User Name** - the user's name (up to 32 alphanumeric characters).
- Login Name** - the user's login ID for the network (up to 9 alphanumeric characters).
- Password** - the password for the **Login Name** (up to 12 alphanumeric characters).

By default, each action category (**Start/Stop; Pause/Resume; Monitor**) is set to **Revoke**, which means that this user does not have any access rights.

Note: The access rights that you grant to a user apply to all systems running in the Launcher.

- Under each action category (**Start/Stop; Pause/Resume; Monitor**), click **Revoke** to view a drop-down menu that contains the two options: **Grant** or **Revoke**.

- After you select the security level for each category, click OK to save changes.

The new user appears in the profiles list on the Access tab.

Note: You must set up users with the appropriate access rights in the Launcher Administration interface to view systems running in the Management Console.

About Access Permission

By default, the Launcher process has Local System account privileges on Windows platforms because it is run as a service. However, Local System account privileges are insufficient for performing tasks associated with mapped network drives.

If you have an issue with access permission on mapped network drives, the solution is to configure the Launcher service to log on using a specific account.

To configure user account information

- Open the Windows **Computer Management** console.
- Locate **Services** and double-click **WebSphere® Transformation Extender Launcher**.

The Properties window is displayed, from which you can make account changes.

Deployment directories

The deployment directories are where the **.msl** files are placed to run in the Launcher. The default deployment directory (**Systems**) is located in the **WebSphere® Transformation Extender** installation directory; however, you can modify the default path or add new deployment directories as needed.

Note: You can create several deployment directories, however all systems will run simultaneously. The statistics that are displayed in the Management Console ("Management Console") will include all systems running.

To add a deployment directory

- From the Deployment Directories tab, click Add.
The Select window opens.
- Navigate to the deployment directory.
- Click once on the directory and click Select.
The new directory is displayed in the directory list.

To remove a deployment directory

From the Deployment Directories tab, select a path from the directory list and click Remove.

The path is removed from the directory list.

Resource resolution

In the Launcher Administration, you can choose a resource configuration file (**.mrc**) that contains specifications for the Launcher. For example, the file can contain information such as an active virtual server and its associated resource name file (**.mrn**).

For more information about resource configuration files, see the *Resource Registry* documentation.

Cluster support

The Launcher service uses the Java™ Remote Method Invocation (RMI) to communicate with clients. When the Launcher service is running in a cluster environment or if there are machines with multiple network interface cards (NIC), you must manually specify the RMI system properties. You can do so from the Launcher Administration application Advanced tab.

The Launcher service sets these properties before running the RMI server. In a cluster environment, you must enter `java.rmi.server.hostname` in the Property column and the Launcher service host name in the Value column.

For example, `java.rmi.server.hostname` can be the Property. The host name **mycluster.fl.company.com** (under Value) can be the "value" of the property, which indicates where the Launcher service is running.

Firewall configuration

To use a firewall, settings in both the Launcher Administration and Management Console must be configured. Configuration for assigning port numbers for the firewall must be enabled for both.

By default, the Launcher opens anonymous ports for 2-way communication with the Management Console. If there is a firewall in place, fixed port numbers are required. To assign specific port numbers for the Launcher, you must enable the **Enable Configuration** option and either accept the default port numbers or enter specific ones.

To assign fixed port numbers in the Launcher Administration for firewall use

1. From the Launcher Administration Options tab, select the **Firewall** option.
Firewall configuration options appear.
2. Enable the **Enable Configuration** option.
The **Server Port** and **Client Port** fields become active.
3. Enter specific port numbers in the **Server Port** and **Client Port** fields, or accept the default values (**4634** and **4635**).

Firewall Option

Value

Enable Configuration

This option is turned off by default.

Select the check box to configure firewall ports.

When this option is enabled, the **Server Port** and **Client Port** fields become active.

Server Port

Enter a server port number or accept the default value of **4634**.

Client Port

Enter the client port number or accept the default value of **4635**.

4. Click OK to save the changes.

Note: If you are using a firewall, ensure that the Enable Configuration firewall option is also enabled in the Management Console.

To assign fixed port numbers in the Management Console for firewall use

1. From the Management Console, select Tools->Options.
The Options window opens.
2. From the **Options** list, select Firewall.
The override configuration options appear.
3. Enable the **Enable Configuration** option.
The **Client Port** field becomes active.
4. Enter the client port number in the **Client Port** field, or accept the default value (**7777**).

Firewall Option

Value

Enable Configuration

This option is turned off by default.

Select the check box to configure firewall ports.

When this option is enabled, the **Client Port** field becomes active.

Client Port

Enter the client port number or accept the default value of **7777**.

5. Click OK to save the changes.

HTTP Listener startup configuration

An HTTP Listener routes HTTP requests from external clients to maps in the Launcher and returns a response to the external client. Use the Launcher Administration utility Options page and select Listeners to add, remove, and update HTTP Listeners.

HTTP Listener settings

Name

A unique name of up to 25 characters to represent a listener.

Mode

When enabled, the listener starts automatically when the Launcher starts. By default, the listener is disabled.

HTTP port

The port that the listener uses to communicate with external clients. The listener monitors the HTTP port for incoming HTTP requests and responds to the external client through the HTTP port. Each listener must use a unique HTTP port. If you configure multiple listeners to use the same HTTP port, only one listener starts when the Launcher starts. The default HTTP port is 5017.

Launcher port

The port that the listener uses to communicate with the Launcher. Each listener must use a unique Launcher port. If you configure multiple listeners to use the same Launcher port, only one listener starts when the Launcher starts. The default Launcher port is 5018.

HTTP certificate

Specifies the server certificate used for SSL communication with external HTTP clients on the client port. If you omit it, SSL communication between the HTTP Listener and external HTTP clients is disabled.

Launcher certificate

Specifies the server certificate used for SSL communication with HTTP adapters on the Launcher port. If you omit it, SSL communication between the HTTP Listener and maps is disabled.

Log level

The trace setting for the HTTP Listener. The Launcher creates a unique trace file name by appending the current date, timestamp, and computer host name to the HTTP Listener name (for example, lsnr_a_socket07-06-16-02-11-14-PM_myhostname.log). Logs are created in the installation directory on Windows systems and in the \bin directory on UNIX systems.

None

Tracing is not enabled for the HTTP Listener. This is the default setting.

Standard

Logs the HTTP Listener activity. The log file name is *listenername_timestamp_hostname.log*.

Verbose

Logs the HTTP Listener activity and socket activity. The log file name is *listenername_socket_timestamp_hostname.log*.

Audit

Enables or disables an audit log of Transformation Extender map executions and each adapter connection and external client connection to the listener. The audit log is in XML format that can be queried with XSLT transformations. The audit log schema is LHL-Audit.xsd, installed in the Transformation Extender installation directory on Windows systems or the /bin directory on UNIX systems. Auditing is disabled by default. There is one audit log per listener.

Automatic restart for launchers and HTTP Listeners

Launchers and HTTP Listeners can automatically restart when they unexpectedly stop running. Use the Launcher Administration utility Options page to enable automatic restart and to limit the number and duration of restart attempts.

About multiple Launchers

For all supported Windows or UNIX platforms, multiple Launcher services or Launcher daemons that run on the same machine must run on different listening ports and have different port ranges. If this condition is violated, the Launcher services (or daemons) might not work as intended.

Run multiple Launcher services (or daemons) on separate installations of Launcher. Do not run more than one Launcher service (or daemon) on a single Launcher installation.

Preparing to execute defined systems

After you generate .msl files to the deployment directory, prepare the Launcher to execute the maps defined in those systems by performing one of the following actions:

- If the Launcher service or daemon is not currently started, start the Launcher.
- If the Launcher service or daemon is running, stop and then restart the Launcher.

To run a Launcher process (comprised of one or more systems) using the Launcher:

- The Launcher system files must be located in the designated deployment directory.
- All maps and source event gateways specified for system components defined within the system must be available.
- [Starting and stopping the Launcher](#)
- [Modifying systems while the Launcher is running](#)

Starting and stopping the Launcher

The following procedure describes the control functionality for running services on Windows platforms.

See the related reference topics for details about stopping the Launcher on a UNIX system.

Related reference

- [Starting, stopping, pausing, and resuming the Launcher service](#)

To start the Launcher service (Windows)

1. From your desktop, right-click My Computer and select Manage.
2. From the Computer Management window, expand the **Services and Applications** list and select Services.
3. In the **Computer Management** window, right-click **WebSphere® Transformation Extender Launcher** and select Properties. The Properties window opens.
4. Click Start.

To stop or restart the Launcher service (Windows)

From the **Computer Management** window, right-click **WebSphere Transformation Extender Launcher** and select **Stop** or **Restart** from the context menu.

Modifying systems while the Launcher is running

You can make changes to a Launcher system file (**.msl**) while the Launcher is running, however, you can only see the changes if the system is restarted from the Management Console. To add a new system, both the Launcher service or daemon and the Management Console need to be restarted.

The procedures in each of the following scenarios assume that a system is currently running in the Management Console.

Related reference

- [Benefits of using separate Launcher processes](#)

To modify an .msl file

If the changes are only to the contents of one particular **.msl** file that is already part of the **CompoundSystem** for a Launcher process (see ["Multiple Processes"](#) for additional information when using the multiple-processes feature), and the name of the system file is the same, then you must do the following actions:

1. Stop the **CompoundSystem** from the Management Console.
2. Overwrite the existing file in the deployment directory with the updated **.msl** file.
3. Restart the system from the Management Console.

To add or delete files

1. Stop the **CompoundSystem** from the Management Console.
2. Disconnect the Management Console from the relevant Launcher.
3. Stop the Launcher service.
4. After the service has stopped, make additions or deletions as necessary.
5. Restart the Launcher service.
6. In the Management Console, reconnect to the Launcher and restart the **CompoundSystem**.

Configuration parameters

The **config.yaml** file is the configuration file for **WebSphere® Transformation Extender** and contains specific settings for the Launcher. The **config.yaml** file is created in the <data directory>/config directory during the installation of **WebSphere Transformation Extender**. You can use a text editor to edit option values as needed.

- [HTTP Listener settings in config.yaml](#)
The HTTP Listener can automatically recognize an MTOM message and store the attachments in a user-designated location. You configure HTTP Listener settings in the config.yaml file.
- [Trace and log files naming conventions](#)
The Launcher trace and log files are located in the logs directory under *install_dir*, which is the directory where your product is installed.
- [Result codes in log files](#)

HTTP Listener settings in config.yaml

The HTTP Listener can automatically recognize an MTOM message and store the attachments in a user-designated location. You configure HTTP Listener settings in the config.yaml file.

The /runtime/HTTP Listener key of the config.yaml file is used by the Launcher HTTP Listener. You configure these settings as appropriate for your business needs.

RefreshInterval:

The time (in seconds) that the HTTP Listener Status interface automatically refreshes in a browser window (unless the page is already reloading from a prior refresh attempt). Set this parameter to 0 to disable the refresh interval.

RefreshIntervalIfHidden:

The time (in seconds) for automatic updates to occur if the sHTTP Listener Status interface is minimized or hidden behind another tabbed window.

mtomMode:

Configures the storage of MTOM attachments. If this parameter is enabled, the attachments for a MIME message that uses the XOP type are saved to the MTOM directory. For example, for this HTTP header

```
Content-Type: multipart/related; type="application/xop"
```

, any data following the `xop` is irrelevant. Set this parameter to 0 to disable it. Set this parameter to 1 to enable the storage of MTOM attachments.

mtomDir:

This is the directory in which all extracted attachments are stored. The default directory is the WebSphere® Transformation Extender logs subdirectory.

Important: Directory delimiters are substituted appropriately, depending on runtime and platform. On the UNIX platform, the drive letter and subsequent colon (for example, C:) are removed.

mtomExt:

This is the extension used for the MTOM file. The default file extension is MTOM. The file name format is: <HTTP Listener Cfg Name>-<date-time-stamp>-<session id>. <mtom_ext>

- [Enabling or disabling settings](#)
- [M4File](#)
- [Launcher](#)
- [Resource Manager](#)
- [Connection Manager](#)
- [Configuring Java-based adapters](#)

Enabling or disabling settings

If the config.yaml setting is commented out, or set to empty value, the default value is used. The default value is the value set in the original config.yaml file.

In the original config.yaml file, /runtime/Connections Manager/keep: 0 means that the default value of /runtime/Connections Manager/keep is 0. Therefore, the following three lines setting keep option are equal:

```
/runtime
  Connections Manager:
    keep: 0
    # keep: 0
    keep:
```

M4File

In the config.yaml file, the settings listed under the **runtime/m4file** key heading pertain to the file listener in the Launcher.

- [Logging](#)
- [FileListenCount](#)
- [ListenSleepTime](#)

Logging

Use the **/runtime/launcher/log** keys to define the file listener logging. See "[Troubleshooting Tip](#)" for details.

FileListenCount

This setting is the number of files to process at a time for each directory (0 meaning all). The default value for this setting is 25 (**FileListenCount=25**). For trigger uniformity, decrease this value as more directory watches are added.

ListenSleepTime

This setting is the time in milliseconds between directory processing. The default value is 50 (**ListenSleepTime=50**). If the CPU level is high when Launcher is idle, you should increase this value.

Launcher

In the config.yaml file, the Launcher settings are listed under **/runtime/launcher** key.

- [Logging categories descriptions](#)

- [ResourceCfgFile](#)
- [LoadPDH](#)
- [MaxThreads](#)
- [TriggerTime](#)
- [Launcher logging](#)
- [InitPendingHigh](#)
- [InitPendingLow](#)
- [WatchMaxThreads](#)
- [DisableMaxThreads](#)
- [InitPendingIdleMS](#)
- [RunMapCacheMaxNum](#)
- [LogFilePermissions](#)

You can use the LogFilePermissions setting in the runtime/launcher section of the **config.yaml** file to change the file permissions of the logs that are generated by the Launcher logging option.

- [MapAdapterTraceOff](#)

Enable this setting to turn off all adapter tracing for all watches, overriding any trace option that is configured on the adapter command line. When this setting is disabled, adapter tracing is controlled by the adapter command line.

- [CircularLogSize](#)

Use this option to specify the maximum size of the *system_name_timestamp_host_name.log* file.

- [CircularLogFileNum](#)

Use this option to specify the maximum number of *system_name_timestamp_host_name.log* files to keep before the oldest, non-startup log file is deleted.

Logging categories descriptions

Logging Category	Value	Description
trace	false	Disabled (default)
debug	false	Disabled (default)
info	false	Disabled (default)
warning	true	Enabled
error	true	Enabled
fatal	true	Enabled

If you turn on logging (["Logging Option"](#)) from the Management Console or the **config.yaml** file, the resulting files are created in the **runtime/launcher/log** subdirectory of the **WebSphere® Transformation Extender** installation directory.

ResourceCfgFile

A default resource configuration file for the Launcher is specified in the /runtime/launcher/ResourceCfgFile key section of the **config.yaml** file:

```
/runtime:
  launcher:
    ResourceCfgFile: resource.mrc
```

You can specify a resource configuration file for the Launcher by modifying the default file name (**resource.mrc**) to the resource configuration file that you want to use.

For more information about the resource configuration file, see the *Resource Registry* documentation.

LoadPDH

This setting disables the central processing unit (CPU) and memory counters (Windows only).

If the setting is commented out (indicated by a semicolon at the beginning of the line), or uncommented and set to **1**, the CPU and memory counters are loaded.

If you uncomment the line and set the value to **0** by a hash sign #, the function is disabled. Setting LoadPDH to **0** is generally not necessary; however, some adapters might require the disabling of counters.

LoadPDH: {0 | 1}

Option

Description

0

Disables CPU and memory counter loading.

1

Enables CPU and memory counter loading.

MaxThreads

The **MaxThreads** value is used to limit the number of map threads for all watches in an environment, provided that no other settings have conflicting values. If the following settings are not set to 0, then the **MaxThreads** value will be impacted:

- **WatchMaxThreads**
- **DisableMaxThreads**
- **Max Concurrent Map Instances** (a setting in the IFD).

MaxThreads: *n*

Option

Description

n

Maximum number of maps (threads) that the Launcher can execute concurrently. Range is 0 to 32,000. Default value is 20.

Note: For performance reasons, on the z/OS® operating system, *n* should be less than or equal to 400.

TriggerTime

Use the **TriggerTime** setting to specify file time granularity in seconds.

TriggerTime: *n*

Option

Description

n

Minimum trigger time in seconds for files. This is the minimum time that must elapse in a file's timestamp before it can cause a new event. Default value is 1.

Note: The **TriggerTime** setting can be used for files that reside in the Hierarchical File System (HFS) on the z/OS® operating system; it is not available for use with native data sets.

Launcher logging

In the `/runtime/launcher` key of the **config.yaml** file, you can specify the settings for a Launcher log file. See [Trace and Log Files Naming Conventions](#) for the specific naming conventions.

The `/runtime/launcher/LauncherLog` is set to empty value by default and the launcher log file is not created by default. To make sure that a log file is created, you must set one of the available options in the **config.yaml** file.

For example:

LauncherLog: `ewsc`

This will create a file that contains error, warning, startup, and configuration information, and will be created in the product installation directory by default.

The default syntax is:

LauncherLog: `[E] [W] [S] [C]`

Each option is described in the following table.

Option

Description

`E`

Logs map errors

`W`

Logs map warnings

`S`

Logs Launcher startup statistics

`C`

Logs configuration information

Configuration option

If you specify `c` for configuration, the following example displays how each watch is configured:

```
*** CONFIGURATION:

Time: Thu Nov 21 10:53:05 2002
-----
Watch: 1
MSL File: C:\mapdev.nn\mercntsv\systems\single-mq-to-file.msl
System: single-mq-to-file
Component: fromqueuetofile
Map: C:\testing\n.n\15010\fromqueuetofile.mmc

Map Delay: <none>
Pending Exp.: <none>
```

```

Retries:          10 every 5 seconds
Paging:          8 X 64K
Trace:           Summary
Validation:      Ignore: <none>
                  Stop On First Error: Yes
Work Area:       Default
Init High:       100
Init Low:        50
Time Trigger:    <none>
Input 1 (T):     IBM WebSphereMQ: -QMN QM1 -QN QA.QUEUE5
-MID * -QTY 1
                  Rollback: Yes, Delete: No, Reuse Work File: No
                  Retries: <none>
Output 1:         File: C:\testing\n.n\15010\output*.txt
                  Rollback: Yes, Delete: If empty, Append: No
                  Retries: <none>
Audit File:      Burst Data           Never
                  Burst Execution      Always
                  Summary Execution     Always
                  Data Settings         Never
                  Map Settings          Never

```

Startup option

If you specify **s** for startup, you will see an entry on whether the startup of the Launcher was successful. If successful, something similar to the following entry is displayed:

```
*** STARTUP:
Status:          Successful
Time:            Thu Nov 21 10:53:11 2002
```

If not successful, it might pinpoint where the startup problem is:

```
*** STARTUP:
Status:          Failure
Time:            Thu Nov 21 18:49:58 2002
Errors:          No systems to run
```

Error option

If you specify **e**, the file lists all maps that have an error status after being run:

```
*** ERROR:
System:          single-mq-to-file
Component:       fromqueueToFile
Map:             C:\testing\n.n\15010\fromqueueToFile.mmc
Start Time:      Thu Nov 21 10:54:06 2002
Instance:        1
Run Time:        0.1957 seconds
Return Code:     8 - One or more inputs was invalid
Input 1:         IBM WebSphereMQ: -QMN QM1 -QN QA.QUEUE5
-MID AMQ0 -QTY 1
Output 1:        File: C:\testing\n.n\15010\outputAMQ.txt
Audit File:      C:\testing\n.n\15010\fileAMQ.log
```

Warning option

If you specify **w**, the file lists all maps that have a warning status after being run.

```
System:          single-mq-to-file
Component:       fromqueueToFile
Map:             C:\testing\n.n\15010\fromqueueToFile.mmc
Start Time:      Thu Nov 21 11:23:54 2002
Instance:        1
Run Time:        0.0923 seconds
Return Code:     21 - Input valid but unknown data found
Input 1:         IBM WebSphereMQ: -QMN QM1 -QN QA.QUEUE5
-MID AMQ1 -QTY 1

Audit File:      C:\testing\n.n\15010\fileAMQ.log
```

InitPendingHigh

Use `InitPendingHigh` to pause the listener threads if too many initialized pendings occur.

`InitPendingHigh: n`

Option

Description

`n`

Any integer value; modification not recommended.

Default setting of `0` specifies that an unlimited number of `InitPendings` might occur. For example, if you change this value to `10`, the listener thread pauses when the number of `InitPendings` reaches the limit of `10`.

InitPendingLow

Use `InitPendingLow` to resume the listener threads if paused from `InitPendingHigh`.

`InitPendingLow: n`

Option

Description

`n`

Any integer value; modification not recommended.

Default setting is `0`. The listener thread resumes when the number of occurring `InitPendings` is equal to this setting. For example, if `InitPendingHigh` is set to `10` and `InitPendingLow` is set to `5`, the listener thread pauses processing when the number of occurring `InitPendings` reaches `10` and resumes processing when the number reaches `5`.

WatchMaxThreads

The `WatchMaxThreads` option is also known as Global Max Threads per Watch.

`WatchMaxThreads: n`

Option

Description

`n`

Global limit on the number of concurrent mappings for each (*any individual*) watch.

This number cannot exceed the `MaxThreads` value, which is the total number of concurrent mappings overall.

Range is `0` to `32,000`.

Default setting is `0`.

Note: The `Max Concurrent Map Instances` setting in the IFD overrides the `MaxThreads`, `WatchMaxThreads`, and `DisableMaxThreads` Launcher settings.

DisableMaxThreads

Use the `DisableMaxThreads` setting to disable the `MaxThreads` option.

`DisableMaxThreads: {0|1}`

Option

Description

`0`

Setting is off (default)

`1`

Setting is on.

If set to `1`, the `MaxThreads` value is disabled and the `WatchMaxThreads` value is used to place a global limit on the number of concurrent map executions for each watch.

Note: The `Max Concurrent Map Instances` setting in the IFD overrides the `MaxThreads`, `WatchMaxThreads`, and `DisableMaxThreads` Launcher settings.

InitPendingIdleMS

This entry controls how often the Launcher checks to see if initialization-pending maps can be executed. This reduces waiting time, and improves performance on most platforms.

The default value is **1**. Higher values cause the Launcher to check less frequently for initialization-pending maps, which can decrease CPU usage but might introduce latency to the map execution.

InitPendingIdleMS: *n*

Option

Description

n

Time (in milliseconds) that initiation-pending threads should remain idle between mapping attempts.
Valid values are 1-10000 (one millisecond - 10 seconds).

RunMapCacheMaxNum

Use the `RunMapCacheMaxNum` setting to define the maximum number of RUN maps to be cached in memory.

To disable RUN map caching, set the value to **-1**.

RunMapCacheMaxNum: *n*

Option

Description

n

Maximum number of RUN maps to be cached in memory.
Default value is 300; the minimum value is 10.

LogFilePermissions

You can use the `LogFilePermissions` setting in the runtime/launcher section of the `config.yaml` file to change the file permissions of the logs that are generated by the Launcher logging option.

LogFilePermissions: *value*

Where *value* is one of the following:

Value	File Permissions
666	<code>rw-rw-rw-</code> This is the default file permission.
664	<code>rw-rw-r--</code>
644	<code>rw-r--r--</code>

MapAdapterTraceOff

Enable this setting to turn off all adapter tracing for all watches, overriding any trace option that is configured on the adapter command line. When this setting is disabled, adapter tracing is controlled by the adapter command line.

MapAdapterTraceOff: {0 | 1}

Option

Description

0

Disables the `MaxAdapterTraceOff` setting. This is the equivalent of commenting out the option with a preceding semicolon (;). When this option is disabled, the adapter command line controls tracing.

1

Turns off all adapter tracing for all watches, overriding any trace option that is configured on the adapter command line.

Related reference

- [Dynamic adapter tracing](#)

CircularLogSize

Use this option to specify the maximum size of the `system_name_timestamp_host_name.log` file.

When the log file reaches the maximum size, the Launcher service closes it, appends an index number to the timestamp in the log file name (`LauncherLog_timestamp_index.log`), and begins logging to a new file.

CircularLogSize: *n*

Option

Description

n

The maximum log file size. The maximum size is 100 MB. A value of 0 specifies an unlimited log file size. The default minimum size is 10 MB. If you specify a smaller size than 10 MB, the Launcher service creates a 10 MB log file.

Related reference

- [Launcher log file](#)
-

CircularLogFileNum

Use this option to specify the maximum number of *system_name_timestamp_host_name.log* files to keep before the oldest, non-startup log file is deleted.

CircularLogFileNum: *n*

Option	Description
<i>n</i>	Specifies the maximum number of non-startup log files to keep before deleting the oldest. The minimum is two log files, and the default maximum is five log files.

Related reference

- [Launcher log file](#)
-

Resource Manager

The config.yaml file contains the default Launcher startup setting values for the Resource Manager. The Resource Manager synchronizes shared data and timing interfaces among heterogeneous sources and targets. You can edit the values as needed using a text editor.

- [Logging categories](#)
 - [Disable](#)
 - [TransManager](#)
 - [Stream configuration options](#)
-

Logging categories

The logging categories provide a variety of debugging information for the Resource Manager. The Launcher uses them to determine which severity levels and components to debug.

/runtime/Resource Manager/log

For descriptions and examples of the logging categories, see [Logging Category Descriptions](#).

Disable

Use this option to enable or disable resource management. If the Resource Manager is disabled, the file access protection scheme is deactivated. This allows you to have concurrent maps writing to the same file at the same time. If you choose to disable the Resource Manager and your system relies on the file access protection, data can become corrupt. However, if you do not need resource management, disabling this option boosts performance.

Disable: *0*

Option	Description
0	Enables resource management. This is the default setting.
1	Disables resource management.

TransManager

See the *Global Transaction Management* documentation.

Stream configuration options

When the data that is passed to or from an adapter exceeds the size specified by Stream Maximum Memory Limit value, a file is created in a temporary directory for paged data. This limits the memory consumption of the process.

```
/runtime/stream/MaxMemLimit: n
```

Option

Description

n

Data size in megabytes.

If the size of data is exceeded, the data is paged to a temporary file.

Default value is 500.

```
/runtime/stream/MaxMemDirectory: /tmp
```

By default, the temporary directory is designated by the operating system.

For Windows this is typically what the environment variable **TEMP** is set to (such as **C:\TEMP**); for UNIX, this is typically **/tmp**.

Note: Ensure that the path points to a directory with sufficient file space.

Connection Manager

The **config.yaml** file contains the default product startup setting values for the Connection Manager. You can use a text editor to edit the values as needed. A value of 0 means disabled or off. A setting that is commented out is disabled.

- [How the Connection Manager works](#)
- [Connection Manager settings](#)
- [Logging categories](#)

How the Connection Manager works

The Connection Manager works in conjunction with adapters to maintain connections. To reduce overall run time and increase efficiency, the Connection Manager keeps a pool of connections to reduce the total number of connect or disconnect operations that have to be done. This means that a connection will not be disconnected when a map is complete, but sometime after that.

When a connection is needed, the Connection Manager searches its pool until it finds a connection that the adapter finds suitable (using the adapter's **CompareConnections** function). A suitable connection means that it must be connected to the appropriate resource, such as a database, message queue, and so forth.

If a suitable connection is found, Connection Manager then tries to verify that the connection is still valid. This is done by calling **ValidateConnection**. If the adapter does not implement **ValidateConnection**, the test will fail.

Connection Manager settings

The Connection Manager settings include:

- [Logging Categories](#)
- [IgnoreGPFs](#)
- [ShareConnectionThreads](#)
- [Idle](#)
- [Soft Limit \(SLim\)](#)
- [Hard Limit \(HLim\)](#)
- [Min](#)
- [Keep](#)
- [HSleep](#)
- [HLimTimeout](#)
- [PollWaitTimeMin](#)
- [PollWaitTimeMax](#)

Each setting is described here.

Logging categories

The logging categories defined in **config.yaml** using **/runtime/Connection Manager/log** provide a variety of debugging information for the Connection Manager. The runtime components uses them to determine which severity levels and components to debug.

For descriptions and examples of the logging categories, see [Logging Category Descriptions](#).

IgnoreGPFs

Use this setting to ignore system exceptions during processing so that only the map fails as opposed to the system.

IgnoreGPFs: false

Option

Description

false

Disables the option, which means the system will fail upon encountering an exception.

true

Enables the option so that exceptions are ignored on connection threads and therefore a map failure occurs instead of a system failure.

This is the default setting.

ShareConnectionThreads

The **ShareConnectionThreads** setting allows multiple connections on the same thread. There are three levels of sharing to specify the criteria used for sharing threads. Each value is described in the following table. This setting is disabled by default.

ShareConnectionThreads: n

Option

Description

0

Disables the sharing option, which means each connection gets its own thread.

1

Enables sharing for GTX only. Only connections with GTX will get combined to the same thread.

idle

Use this setting to specify global default settings for all adapters or specify settings for individual adapters.

The idle setting creates a background map thread with the purpose of periodically searching the connection pools, locating connections with idle time greater than the value specified by idle, and then removing them. This allows connections to be disconnected even when no map is running.

The Connection Manager shuts down the idle thread gracefully when running under a Launcher or Command Server. In an API environment that invokes maps that use Java-based adapters (such as JMS, Java™ Class, and JALE), you might wait additional idle seconds after a shutdown request. This delay occurs only when the custom application does not explicitly shut down WebSphere® Transformation Extender by using the Java-based terminateAPI routine or the C-based mpiTermAPI routine.

- To specify default settings for all adapters, use `idle: n`
- To specify settings for individual adapters, use `/runtime/Connections Manager/xxx/idle`

Option

Description

0

Disables the use of idle settings for adapters.

n

Number of seconds to allow a connection to be idle before automatically disconnecting.

xxx

Adapter type where xxx represents the command line alias for the adapter. Example values for typical adapters include:

DB

Database Adapters

MQS

IBM® WebSphere MQ (server) Adapters

MQSC

IBM WebSphere MQ (client) Adapters

ALE

ALE Adapters

FTP

FTP Adapters

For example, `/runtime/Connections Manager/MQS/idle: 30` sets the connection idle limit for IBM WebSphere MQ adapters to 30 seconds.

See the Resource Adapters documentation for more information.

Soft Limit (sLim)

Most servers place a limit on the number of clients that can be connected. WebSphere Transformation Extender generally shares a server with other clients, and therefore should not be able to use all available connections. The Resource Manager provides two limit parameters: sLim (soft limit) and hLim (hard limit). Either or both of these parameters can be used to specify a maximum number of connections. Existing connections are only removed when a new one is required.

The sLim setting is a soft (advisory) limit. This number can be exceeded at peak load, but sLim tries to limit the number of idle connections at all other times. Limits are only checked when opening a connection, so it is possible to have a greater number of idle connections.

The global sLim value is by default set to **4** and is used if any other limit for the number of connections is not set.

- To specify global default settings for all adapters, use `sLim: n`
- To specify settings for individual adapters, use `/runtime/Connections Manager/xxx/sLim`

Option

Description

n

	Number of idle connections. Default is 4.
xxx	Adapter type where xxx represents the command line alias for the adapter. Example values for typical adapters include:
DB	Database Adapters
MQS	IBM WebSphere MQ (server) Adapters
MQSC	IBM WebSphere MQ (client) Adapters
ALE	ALE Adapters
FTP	FTP Adapters

For example, `/runtime/Connections Manager/MQS/slIm: 30` sets the soft limit for IBM WebSphere MQ adapters to 30 idle connections.

See the *Resource Adapters Library* for adapter documentation.

Hard Limit (hLim)

The hLim setting is a hard (mandatory) limit. This number will not be exceeded. Connections are placed in a pending state rather than exceed this number.

- To specify global default settings for all adapters, use: `hLim: n`
- To specify settings for individual adapters, use: `/runtime/Connections Manager/xxx/hLim`

Option	Description
n	Maximum number of connections. Default is 0 (unlimited).
xxx	Adapter type where xxx represents the command line alias for the adapter. Example values for typical adapters include:
DB	Database Adapters
MQS	IBM WebSphere MQ (server) Adapters
MQSC	IBM WebSphere MQ (client) Adapters
ALE	ALE Adapters
FTP	FTP Adapters

For example, `/runtime/Connections Manager/MQS/hLim: 30` sets the hard limit for IBM WebSphere MQ adapters to 30 connections.

min

The min setting specifies a minimum number of connections to keep. When a limit (slim or hlim) is exceeded, idle connections will be removed until no more than this value remains (if possible).

- To specify default settings for all adapters, use `min: n`
- To specify settings for individual adapters, use `/runtime/Connections Manager/xxx/min`

Option	Description
n	Minimum number of connections to keep. The default setting is 0, which means there is no limit set.
xxx	Adapter type where xxx represents the command line alias for the adapter. Example values for typical adapters include:
DB	Database Adapters
MQS	IBM WebSphere MQ (server) Adapters
MQSC	IBM WebSphere MQ (client) Adapters
ALE	ALE Adapters
FTP	FTP Adapters

keep

Use this setting to specify the time, in seconds, an idle connection is expected to remain valid. Connections that idle longer than this are tested prior to being used. If the test fails or is not supported, the connection is not reused.

The keep setting is an efficiency measure and represents some amount of time to assume that the connection is valid without a test. If the idle time of the connection (amount of time since it was last used) is less than the keep value, then the Resource Manager does not attempt to verify connection validity.

Last used refers to the timestamp when the connection was last assigned to a map. Whether it was used successfully or not is not considered because it is assumed that an unsuccessful attempt is a temporary condition, not a permanent failure.

This setting should only be used for adapters that implement ValidateConnection.

Do **not** use the KEEP setting with the FTP adapter. When used with the FTP adapter, the KEEP setting causes unpredictable results.

- To specify global default settings for all adapters, use: `keep: n`
- To specify settings for individual adapters, use: `/runtime/Connections Manager/xxx/keep`

Option

Description

`n`

Specify how many seconds an idle connection is expected to remain valid. Default is **0**, which disables connection testing. A value of **-1** will force a test every time, but this is not recommended.

`xxx`

Adapter type where `xxx` represents the command line alias for the adapter. Example values for typical adapters include:

`DB`

Database Adapters

`MQS`

IBM WebSphere MQ (server) Adapters

`MQSC`

IBM WebSphere MQ (client) Adapters

`ALE`

ALE Adapters

`FTP`

FTP Adapters

For example, `/runtime/Connections Manager/MQS/keep: 30` sets the keep period for IBM WebSphere MQ adapters to wait 30 seconds for idle connections.

Note: As an example, if you are executing maps using an IBM WebSphere MQ (server) adapter at least once every 10 seconds, a setting of `/runtime/Connections Manager/MQS/keep: 10` results in the connection not being tested because they are used before they expire.

See the *Resource Adapters Library* for adapter documentation.

HSleep

The HSleep setting is the specified polling interval used to check resource availability. The value is the cycle time (in seconds) for checking connection availability. The default value is **2** and if specified should be as follows: $0 < \text{HSleep} < \text{HLimTimeout}$.

Note: No validation of this value is performed. Unexpected values for this setting can cause unpredictable results.

HSleep: n

Option

Description

`n`

Number of cycle time seconds for checking connection availability.

Default value is **2** seconds.

Note: The number of retries is the HLimTimeout value divided by the HSleep value.

HLimTimeout

The HLimTimeout setting specifies a maximum amount of time (in seconds) that a map waits for a new connection to become available before failing the map. If not specified, HLimTimeout defaults to infinite.

HLimTimeout: n

Option

Description

`n`

Number of seconds that a map waits for a new connection to become available before failing the map.

Default value is infinite.

PollWaitTimeMin

The PollWaitTimeMax and PollWaitTimeMin parameters enable you to configure a polling interval that is used by adapters to detect events. If the interval is not specified, the default value is used.

Note: If this value is too small, such as below 50 milliseconds, CPU usage can go up during the idle time when the Launcher is waiting for an event.

PollWaitTimeMin: n

Option

Description

`n`

Minimal polling interval in milliseconds.

Default setting is 2000.

PollWaitTimeMax

The PollWaitTimeMax and PollWaitTimeMin parameters enable you to configure a polling interval that is used by adapters to detect events. If the interval is not specified, the default value is used.

PollWaitTimeMax: *n*

Option	Description
<i>n</i>	Maximal polling interval in milliseconds. Default setting is 10000.

Configuring Java-based adapters

From the **config.yaml** file, you can add **.jar** files to the CLASSPATH variable. To do this, you must add an **/runtime/External Jar Files/jarN** key to **config.yaml** and list the applicable jar files, similar to the following example:

```
/runtime/External Jar Files:  
  jar1: c:\J2EE\lib\j2ee.jar  
  jar2: c:\mypath\myjar.jar
```

For more information, see the *Resource Adapters* documentation.

Trace and log files naming conventions

The Launcher trace and log files are located in the logs directory under *install_dir*, which is the directory where your product is installed.

The naming convention for the Launcher trace files, previously named launcher.txt, is the following:

Trace File Naming Convention	Description
CompoundSystem_date_time_hostname.txt	For all systems in a single Launcher process
<i>unique-name</i> _date_time_hostname.txt	For one or more systems run in separate Launcher processes. <unique_name> is the name configured in the Launcher Administration.

The naming convention for the Launcher log files, previously named mercntsv.log on Windows platforms and debug.log on UNIX platforms, is shown in the following table:

Log File Naming Convention	Description
CompoundSystem<date><time><hostname>.log	For all systems in a single Launcher process
<unique_name><date><time><hostname>.log	For one or more systems run in separate Launcher processes. <unique_name> is the name configured in the Launcher Administration.

The name and location of these log files within the initialization file are not used. The content of the log files from the resource manager and connections manager, previously named dtxrsmgr.log, are written to the Launcher log for each process.

Result codes in log files

The Launcher log files contain result codes from processes run by the Launcher. These codes are returned from the operating system and do not have the same meaning as the codes returned after issuing command line options.

Launcher settings

This documentation describes the settings that are configured in the IFD for maps to be run by the Launcher. These map settings, when configured from the IFD, are called *Launcher settings*.

Map settings are originally set during map creation in the Map Designer. When you change the map settings using the IFD, you are overriding the map settings. However, the overrides from the IFD only affect the map during the generation of Launcher system files (**.msl**)-the settings in the original map source file are not affected.

See the *Integration Flow Designer* documentation for information about how to configure all settings.

Note: The UNIX operating systems are case sensitive. Systems created using the IFD to be executed by a UNIX Launcher must observe the proper case for path names, map names, and so on.

- [Accessing Launcher settings](#)
- [Launcher settings window](#)

- [Trigger event settings](#)
 - [Source and target settings](#)
 - [Adapter classes](#)
 - [Adapters that support event triggers](#)
 - [Connection testing adapters](#)
 - [Subsystem component execution settings](#)
-

Accessing Launcher settings

Systems defined in the IFD contain source map components, compiled map components, and Launcher settings configured to control map execution. Systems can include options such as time and source event triggers to initiate maps and source and target settings for inputs and outputs.

The following procedure assumes that execution mode for the open system is **Launcher**.

To view Launcher settings:

From the IFD, do one of the following actions to view Launcher settings for a map component:

- Right-click on a map component and select Edit Launcher Settings.
 - Click the execution settings button of the map component icon.
- The Launcher Settings window appears.
-

Launcher settings window

The Launcher Settings window shows a collapsed tree view of the settings that can be specified for a map component in a system that has the Launcher mode.

The settings provide specific information needed by the Launcher.

- [MapServerLocation](#)
Use the Launcher settings in the Integration Flow Designer to set the MapServerLocation. The MapServerLocation setting identifies the path to the executable map on the server. The default value is the path of the selected map.
- [MapSettings > MapAudit](#)
- [MapSettings > WorkSpace](#)
- [MapDelay](#)
- [PendingExpiration](#)
- [Max concurrent map instances](#)
- [TimeEvent](#)
- [Pending instance thresholds](#)
- [MapInstance Timeout](#)
The MapInstance Timeout setting is the length of time that a map instance can run before a warning or an error is logged in the compound system log. You can specify the time limit in hours, minutes, or seconds.

MapServerLocation

Use the Launcher settings in the Integration Flow Designer to set the MapServerLocation. The MapServerLocation setting identifies the path to the executable map on the server. The default value is the path of the selected map.

When using the z/OS® Launcher, see "[z/OS Launcher](#)" for more information about specifying the location of the compiled map file as a native file system object.

Choose one of the following methods to change the default MapServerLocation setting:

- Enter the path and file name of the compiled map.
 - Click the browse button and navigate to the compiled map file.
 - Enter a resource alias that represents the path and file name of the compiled map. Enclose the alias in percent symbols (for example, %map_loc%). In the Integration Flow Designer, use Tools > Options > Miscellaneous to set the resource configuration file. See the Resource Registry documentation for details about resource aliases.
-

MapSettings > MapAudit

You can use the **MapAudit** settings to create and store map audit logs. The audit logs contain information about data audit, execution audit, map settings, and data settings.

MapAudit settings are compiled (as overrides) into the **.msl** file, which is run by the Launcher.

To enable the audit log

From the Launcher Settings window, under MapSettings > MapAudit > Switch, choose **ON**.

The audit log is created in a file in the map directory or to a location that you specify using the **AuditLocation** settings.

When you choose **Custom** for **Directory** under the **AuditLocation** setting, enter a file path in **Value**. The value you enter in **FileName** determines the audit log file name.

There are three options from which to choose for the audit log filename (AuditLocation.>.FileName): **Default**, **Unique**, and **Custom**. The following table displays the filename outcome of each option.

Value

Description

Default

The file is automatically assigned an audit log file name (based on the compiled map name) with a .log file name extension.

Unique

Generates a unique audit log name in the following format:

Mer_mapname_processkey_mapcounter_hostname.log

Run_mapname_processkey_mapcounter_hostname.log

The prefix "Mer" is used with top-level maps while "Run" is used for run maps.

mapname

The executable map name.

processkey

Unique value for each process.

mapcounter

Unique value for each map instance (within the same process)

hostname

The host name of the computer where Transformation Extender is running.

Custom

A custom filename. Enter the name in the FileName Value field.

Note: Wildcards can be used as long as an input trigger resolves them.

Note: For detailed information about map settings, see the *Map Designer* documentation.

Note: If you are using a map stored in a z/OS® dataset, see the documentation about the three data file location options DEFAULT (["DEFAULT"](#)), CUSTOM (["CUSTOM"](#)), and UNIQUE (["UNIQUE"](#)), for the format of the audit log filename generated in the HFS.

- [Unique names for audit log files](#)

Unique names for audit log files

If the log files produced for one map trigger another map, use AuditLocation.>.FileName.>Unique to select unique names for the log files. Each log file will then trigger another instance of the other map.

For the AuditLocation.>.FileName setting, the following option results apply:

- The **Unique** option produces a file in the following format:
Mer_mapname_processKey_mapCounter_hostname.log
- The **MapName** option produces a log file in the following format:
mapname.log

If you use this **MapName** option, the general **Retry** option is used to determine when one map instance will not interfere with another. If you use multiple maps that generate unique log file names and you want to use log files to trigger different maps, be sure to specify different directories for those log files.

MapSettings > WorkSpace

When a map runs, the software creates or reuses a workspace that it uses during the mapping process to find data that it needs to transform.

The **Unique** value of the **WorkFilePrefix** setting enables you to select globally-unique work file names for a map. If you want multiple instances of the same map to run at the same time, use this option. If you do not use the unique work files option, multiple instances of the same map will run sequentially.

If you do not use unique work files, the general retry setting is used (MapSettings.>.MapRetry.>.Switch = ON) when one map instance interferes with another.

Note: Selecting the **Memory** option for the **AuditLocation** setting also allows multiple instances of the same map executing simultaneously.

Unique filename format for work files:

Mer_mapname_processkey_mapcounter_hostname[I|O].cardnumber

MapDelay

The **MapDelay** setting defines the amount of time in milliseconds that the Launcher waits, after all triggers are satisfied, before running the map. The default value for the **MapDelay** setting is **0**.

Value

Description

n

Time, in milliseconds, to wait before starting the map.

Valid entries are integers 0 to 9999.

PendingExpiration

The **PendingExpiration** setting specifies the amount of time that a map can stay in an initiation pending state before expiring (running without all of its input events). The default value for the **PendingExpiration** setting is **Hour**.

Setting Value

Description

Hour

Measures the value of the **PendingExpiration** period in hours

Minute

Measures the value of the **PendingExpiration** period in minutes

Second

Measures the value of the **PendingExpiration** period in seconds

The **PendingExpiration_Value** setting specifies how many units (in hours, minutes, or seconds) to use for measuring the waiting period. Enter the number of units in the **Value** field. The default value for the **Value** setting is **0**.

If the map associated with a given watch has multiple triggers and at least one trigger occurs, the map is placed in an *initiation pending* state until all triggers occur. Maps in an initiation pending state are reevaluated each time another trigger occurs.

The initiation pending state occurs when any of the following conditions are true:

- The map is defined as single-threaded and one occurrence of the map is already running.
- The map requires an event that has not yet occurred. (This is the only initiation pending condition in which **PendingExpiration** can occur.)
- The maximum number of concurrent maps are already running.

If all preceding conditions are eliminated, the initiation pending state can be removed from the map; if the **PendingExpiration** period has not elapsed, the map can run.

Max concurrent map instances

Specifies the maximum number of concurrent mappings for each watch. In the IFD, this setting overrides the **MaxThreads**, **WatchMaxThreads**, and **DisableMaxThreads** Launcher settings.

TimeEvent

The **TimeEvent** settings initiate (or trigger) map components of a system based on time. Each map component is run based on a time event, a source event, or a combination of multiple events. If a map component is not assigned an event trigger, the Launcher will not initiate that map to run.

Note: When you analyze a system on the IFD and your system is set to Launcher mode, a warning is registered for any source or compiled map component that has no associated event triggers.

- [TimeEvent > Switch](#)
- [TimeEvent > BeginAfter](#)
- [TimeEvent > Trigger](#)
- [Trigger > Interval](#)
- [Interval > OmitDays](#)
- [Interval > OmitHours](#)
- [TimeEvent > SkipIfBusy](#)
- [TimeEvent > EventCoordination](#)

TimeEvent > Switch

The **Switch** setting enables or disables **TimeEvent** options. The default value for the **Switch** setting is **OFF**.

Value

Description

OFF

Disables **TimeEvent** options

ON

Enables **TimeEvent** options

TimeEvent > BeginAfter

The **BeginAfter** settings specify the period of time in hours, minutes, or seconds to wait (from the time the Launcher starts) before enabling the time trigger.

BeginAfter > Hour

The **Hour** setting is used to specify how many hours to wait to begin the map. The default value for the **Hour** setting is **0**.

Value	Description
<i>n</i>	Enter a number to represent the time in hours to wait to begin the map. Valid entries are integers 0 to 23.

BeginAfter > Minute

The **Minute** setting is used to specify how many minutes to wait to begin the map. The default value for the **Minute** setting is **0**.

Value	Description
<i>n</i>	Enter a number to represent the time in minutes to wait to begin the map. Valid entries are integers 0 to 59.

BeginAfter > Second

The **Second** setting is used to specify how many seconds to wait to begin the map. The default value for the **Second** setting is **0**.

Value	Description
<i>n</i>	Enter a number to represent the time in seconds to wait to begin the map. Valid entries are integers 0 to 59.

TimeEvent > Trigger

The **Trigger** setting is used to define the type of time event. You can trigger a map based on a singular time event or cycle, according to a specified time increment. The default value for the **Trigger** setting is **Once**.

Value	Description
Once	The trigger is a non-repeating, one-time-only event.
Every	The trigger occurs once for every interval defined using the Interval settings.

Trigger > Interval

Use the **Interval** setting to describe the recurring period to use for the trigger. The **Interval** setting is available only if the value of the **Trigger** setting is **Every**. The default value for the **Interval** setting is **1 Day(s)**.

Interval > At

Use the **At** settings to set a specific time for the trigger to start after the start of the interval defined in **Interval** settings. The **At** settings are only available if the value of the **Trigger** setting is **Every**. The time periods specified in the **Hour**, **Minute**, and **Second** settings describe a time based on a 24-hour clock set to system time.

At > Hour

The **Hour** setting specifies the hour in which to run the map. The default value for the **Hour** setting is **0**.

Value	Description
<i>n</i>	Enter a number representing the time in hours in which to run the map. Valid entries are integers 0 to 23.

At > Minute

The **Minute** setting specifies the minute in which to run the map. The default value for the **Minute** setting is **0**.

Value	Description
<i>n</i>	Enter a number representing the time in minutes in which to run the map. Valid entries are integers 0 to 59.

At > Second

The **Second** setting specifies the second in which to run the map. The default value for the **Second** setting is **0**.

Value	Description
<i>n</i>	Enter a number representing the time in seconds in which to run the map. Valid entries are integers 0 to 59.

Interval > OmitDays

Use the **OmitDays** setting to set the days to omit.

OmitDays > Monday

The **Monday** setting is used to omit Mondays from the time trigger schedule. The default value for the **Monday** setting is **No**.

Value

Description

No

Do not omit Mondays.

Yes

Omit Mondays.

OmitDays > Tuesday through Sunday

These settings work the same way as the **Monday** setting.

Interval > OmitHours

Use the **OmitHours** setting to set the hours to omit.

OmitHours > 0

The **0** setting is used to omit the 0 hour (midnight to 1:00 am). The default value for the **0** setting is **No**.

Value

Description

No

Do not omit this hour.

Yes

Omit this hour.

OmitHours > 1 through 23

These settings work the same way as the **0** setting (above).

TimeEvent > SkipIfBusy

The **SkipIfBusy** setting is used to ignore the time trigger if it occurs when a watch instance is already in process. The default value for the **SkipIfBusy** setting is **Yes**.

Value

Description

Yes

Ignore time trigger if a watch is in process.

No

Do not ignore time trigger if a watch is in process; initiate another watch instance.

TimeEvent > EventCoordination

The **EventCoordination** setting is used to control the coordination of time and input events. The **EventCoordination** setting is available only if the map has both a time trigger and one or more input triggers: the **SourceEvent** setting for one of the input cards is **ON**. The source trigger might have wildcard values. The default value for the **EventCoordination** setting is **All or None**.

Value

Description

All or None

If no source trigger exists when the time trigger occurs: this time trigger interval is skipped and nothing is run.

If one source trigger exists when the time trigger occurs: the map is run.

When the time trigger occurs, if multiple source events exist that satisfy a wildcard: multiple instances of the map are run for all event sets that exist.

FirstAvailable

If no source trigger exists when the time trigger occurs: then the map goes into pending state and waits for the first source trigger to appear, then the map runs.

If one source trigger exists when the time trigger occurs: the map is run.

When the time trigger occurs, if multiple source events exist that satisfy a wildcard: the map is run with the first known source event.

Pending instance thresholds

The **Pending Instance Thresholds** setting enables a listener to pause or resume for a specific watch. This setting allows high and low initialization-pending maps for any given watch to turn listeners on or off for that particular watch only.

The use of this setting can improve performance by enabling watches to run that could not run previously because of other watches monopolizing system resources.

If two watches share the same event (what an adapter is triggering), the two watches must have the same values for high and low pending instance thresholds. Otherwise, an error occurs, preventing the Launcher from starting.

During initialization, properties of the watch, including high and low parameters, are written to the debug trace (.txt) file (see [Trace and Log Files Naming Conventions](#) for the specific naming conventions).

Note: The global **InitPendingHigh** and **InitPendingLow** settings in **config.yaml** regulate all listeners and events. The **Pending Instance Thresholds** Launcher setting regulates listeners for a specific watch (or watches) based on individual watch settings for high and low pending maps. If the **InitPendingHigh** and **InitPendingLow** settings in the runtime/launcher section of the **config.yaml** file are also set, the **Pending Instance Thresholds** Launcher settings will take precedence.

Setting	Description
Hi	Value (no limit) for the watch to pause the event or events for that watch. The default value is 0 .
Low	Value (no limit) for the watch to resume the event or events for that watch. The default value is 0 .

MapInstance Timeout

The MapInstance Timeout setting is the length of time that a map instance can run before a warning or an error is logged in the compound system log. You can specify the time limit in hours, minutes, or seconds.

The map does not fail when it runs longer than specified by the MapInstance Timeout setting.

To log warnings and errors, you also must enable the LogWarning and.LogError logging options in the runtime/launcher section of the config.yaml file.

The following table shows the logging settings and sample log messages for a map instance that runs for 15 seconds:

MapInstance Timeout Setting	config.yaml File Setting	Logged Message
Warning = 10 seconds	warning=true	Map Warning: TIMEOUT watch num/card num: 15s > 10s
Error = 10 seconds	rror=true	Map Error: TIMEOUT watch num/card num: 15s > 10s

Trigger event settings

Event settings initiate map components of a system. Each map component is run based on a time event, source event, or combination of multiple events. A source event can be a file, message, or database event. If a map component is not assigned an event trigger, the Launcher does not initiate that map to run.

Note: When you analyze a system on the IFD and your system is configured for Launcher mode, a warning for a source or compiled map component that has no associated event triggers results.

A *watch* consists of the map and the set of events that initiate that map. Each event that contributes to the initiation of a map is called a *trigger*. Whenever the Launcher detects a new event trigger, the watches associated with that trigger are either initiated, placed in an initiation pending state, or maintained in an initiation pending state until all specified event triggers have occurred.

The same map can appear in different watches. For more information on this situation, see [Same Map in Different Watches](#).

- [Time events](#)
- [Source events](#)

A source event is the change in state of an input that you designate as a trigger. A source event can be associated with a file, database, or message source. A source event can trigger a map component with or without a time trigger.
- [Time and source event coordination](#)
- [Launcher input trigger files](#)

Time events

A time event is the occurrence of a specific time that you designate to initiate a watch. You can select to trigger a map based on a singular time event or cycle according to a specified time increment.

To specify an event based on time, select the **TimeEvent** setting in the **Launcher** Settings window in the IFD. See ["TimeEvent"](#) for information about how to configure these settings.

Source events

A **source event** is the change in state of an input that you designate as a trigger. A source event can be associated with a file, database, or message source. A source event can trigger a map component with or without a time trigger.

When the **SourceEvent** setting for a map input card is **ON** and the map has a time trigger, the **TimeEvent...>EventCoordination** setting is available. This setting controls the coordination of time and input events.

The following table describes the file, message, and database source events.

Event	Description
File Event	A change in state of that file, its creation, or a change in the time stamp for an existing file. If you use file triggers, you can enter the full path name for that file as the source name. You can also enter a path name relative to where the compiled map resides (that is, the .mmc file). The file name can also include wildcards, as described in Wildcards in Adapter Names .
Message Event	The occurrence of a new message in a messaging system
Database Event	Database modification that triggers a map. Database sources for certain database types can be used as source events for the Launcher, which allow insertions, deletions, or updates to database tables as the trigger mechanism that launches a map. The specific database trigger activities (that is, insertions, updates or deletions) are defined for the query in the Database Interface Designer. The event or events might be the result of a map or another application. A typical use is to configure a trigger that launch a map to run when another map has completed and modified a table. Note: For more information about database triggering, and the specific databases that support it, see <i>Database Triggers</i> in the <i>Database Interface Designer</i> documentation. For platform and version-specific information, see the release notes .

Time and source event coordination

When a map has a time trigger and one or more source triggers, use the Launcher settings to coordinate these different events. You specify how these events are coordinated using the **EventCoordination** setting under **TimeEvent** in the **Launcher Settings** window. This setting specifies how the Launcher executes when a map has both a time trigger and at least one source trigger (which may include wildcard values). The two options for **EventCoordination** are **FirstAvailable** or **All or NONE**.

The following table describes the conditions that might exist at execution time and the result for each Event Coordination option.

Condition	FirstAvailable	All or NONE
No source trigger exists when the time trigger occurs.	Map goes into pending state and waits for the first source trigger to appear, then the map runs.	This time trigger interval is skipped and nothing is run.
One source trigger exists when the time trigger occurs.	Map is run.	Map is run.
When the time trigger occurs, multiple source events exist that satisfy a wildcard.	Map is run with the first set that appeared, instances of the same map are run sequentially with each set at successive time trigger intervals, based on the order that the event set appeared.	Multiple instances of the map are run for all event sets that exist.

Launcher input trigger files

These are recommendations for creating Launcher input trigger files if you experience the following issues:

- Multiple triggering of the same file.
- Unexpected EOF (end of file) during map processing, which is reported with the following error message: Input type contains errors.

If you have experienced the above issues, the following command usage is recommended:

- Use the `rename` system call or `mv` shell command to create input files on UNIX platforms.
- Use the `rename` or `ren` command on Windows platforms to create input files.
- Do not use the `copy` command or similar non-atomic commands or functions (such as FTP) because the Launcher file adapter can detect a file before it is fully copied.

This is applicable for both Windows and UNIX platforms.

Note: To avoid the potential problems listed above, you should use a **.tmp** filename extension during file creation and rename the file afterward.

- [How to prevent Launcher from triggering multiple times on same input file](#)

Source and target settings

When you compile a map from the Map Designer, you supply a default set of sources and targets. From the IFD, you can override those sources and targets to adapt a map to the system in which that map is used.

These source and target setting options enable you to treat a map as a transaction for mission critical applications. The option settings are important when you use multiple target adapters. For example, if one output inserts data to a database correctly, but the next output fails to produce a related message, you can rollback the database insert.

Source adapters are used to read input data from a file, query a database, get a message from a queue, or receive the results of a call to an application. Target adapters are used to write output data to a file, insert or update data into a database, put a message on a queue, or call an application to send data to it.

From the **Launcher Settings** window, you can select source adapters for inputs and target adapters for outputs. Select the adapter type from the **Source** or **Target** drop-down list and then enter specific settings for the selected adapter type.

Adapter classes

The source and target adapters are organized into four adapter *classes*. Each adapter class has an icon that appears in the system diagrams in the IFD that indicates the Launcher properties of that adapter. The following table shows the Launcher properties for each adapter class. It also shows the properties available in all Server modes (Command Server, Launcher, and SDK) and those properties that are available only on the Launcher.

n

Table 1. Properties available in all server modes (Launcher, Command Server, SDK)

Properties	Application Adapters	Database Adapters	File Adapters	Message Adapters
OnSuccess action	Yes	Yes	Yes	Yes
OnFailure option	Yes	Yes	Yes	Yes
Retry option	Yes	Yes	Yes	Yes
Override option for compiled adapters	Yes	Yes	Yes	Yes

Table 2. Properties available only in the Launcher

Properties	Application Adapters	Database Adapters	File Adapters	Message Adapters
Event management	No	Yes	Yes	Yes
Resource management	No	Yes	Yes	Yes
Wildcard instantiation based on source events	No	No	Yes	Yes
Wildcard coordination with source events	Yes	No	Yes	Yes

- [Wildcards in adapter names](#)
- [File adapters](#)
- [Database adapters](#)
- [Application adapters](#)
- [Message adapters](#)

Wildcards in adapter names

Use wildcard notation to identify a source or target to coordinate data threads in the same map or among many maps. The **Launcher Settings** window allows only valid source and target names. Inconsistencies are analyzed from the IFD and only valid names are accepted. In the following list, wildcard notation refers to a name with asterisks or question marks in it.

General rules for using wildcards in adapter names:

- Directories *cannot* have wildcard notation in their names.
- A database source name *cannot* contain wildcard notation.
- If wildcards are used as sources or targets, at least one source trigger must have a wildcard.
- Question marks *cannot* be used in target file names.
- Multiple wildcards can be used in a source trigger name of a map, as long as there are no other source triggers.
- If more than one source file name contains a wildcard, that wildcard must be the same wildcard.
- Sources that are not event triggers and target names can contain at most one asterisk.

File adapters

When you select a file adapter, you supply the name of a specific file or a file name that contains a wildcard. If a source adapter is a file, you can specify that the file be a source trigger. If you use an input file with a wildcard in its name, the Launcher initiates a watch for any file that matches that name. If more than one source for the same watch has a wildcard, the first one to change state is used as the value for the other input sources and output sources that have that wildcard in its name.

Use watch directories only for trigger files to avoid the overhead caused by polling non-trigger files and to ensure the best performance of the Launcher file adapter listener. For example, if the watch directory is FULLPATH/WatchDir and the watch wildcard is set to trigger from *.txt files, do not keep configuration files (*.conf) in the watch directory.

Files used as sources or targets have the following characteristics:

- [Event triggers](#)
- [Wildcards](#)
- [File names, path names, directories, and overrides](#)
- [OnFailure and Retry settings](#)
- [Effect of OnSuccess card setting on file event triggers](#)
The OnSuccess card setting can affect performance when an input file is a source event in a Launcher system.
- [Troubleshooting tip](#)

Event triggers

- A file can be used as a source event trigger for a map
- Files used as triggers cannot have a **.tmp** extension. The Launcher uses this extension for temporary files. For example, temporary files are created when rollback options are selected.

Wildcards

- Can be used within a file name
- Cannot be used for directory names
- Can be used in Audit Log file names providing the input that a trigger has the necessary wildcards to resolve the name for resource coordination

See the *Resource Adapters* documentation for more information about wildcards.

File names, path names, directories, and overrides

- File names can be specified with a full path name or a relative path name. Relative path names are relative to the path of the compiled map.
- File names can be coordinated with other sources and destinations.
- Files can be used as an override for any source or destination type.
- If the directory for a file source that is an input trigger for a map becomes disconnected while the Launcher is running, the Launcher will attempt to reconnect to that watch directory every 10 seconds.

OnFailure and Retry settings

An **OnFailure** setting can be specified for a file that a map writes to in case the map does not run successfully. If an **OnFailure** setting of **Commit** is specified, the changes to the file remain intact, even if the map does not complete successfully. If an **OnFailure** setting of **Rollback** is specified and a map does not complete successfully, the file remains in its original state. That is, if a file originally exists, it is not updated. If a file does not originally exist, it is not created.

When the Launcher settings specify **OnFailure=Rollback**, the File adapter can move the source-event file to an error directory when a map fails. A default error directory is always available when cooperative file listening is enabled in the config.yaml file. When cooperative file listening is disabled, an error directory is available only if you configure it in the Launcher settings.

The **Retry** option applies to files that exist. **Retry** is used for files that exist, but might be in use by applications unknown to the Launcher and cause a resource conflict. For example, a file to be opened is already open for write or a file to be opened for write is already opened for read or write.

Effect of OnSuccess card setting on file event triggers

The OnSuccess card setting can affect performance when an input file is a source event in a Launcher system.

The Launcher file listener maintains and monitors a list of the files that have triggered the Launcher to run a map. Each time the file listener receives an input file candidate for the Launcher, it compares the input file's name and timestamp against the list before it notifies the Launcher of the file.

- Files that have the **OnSuccess=Keep** card setting remain on the list after triggering an event.
- Files that have the **OnSuccess=KeepOnContent** card setting remain on the list after triggering an event if the file is not empty.
- Files that have the **OnSuccess=Delete** card setting are removed from the list after triggering an event.

Over time, files that have the **OnSuccess=Keep** card setting cause the list to grow. A longer file list takes the file listener longer to traverse and maintain, which affects the performance of the Launcher. In production environments that use the Launcher, either set the **OnSuccess** card setting to **Delete**, or configure a keep directory.

When the Launcher **OnSuccess** setting specifies **Keep** or **KeepOnContent**, the File adapter can move the source-event file to a keep directory when a map succeeds. A default keep directory is always available when cooperative file listening is enabled in the config.yaml file. When cooperative file listening is disabled, a keep directory is available only if you configure it in the Launcher settings. By using a keep directory, you can retain a source-event file without affecting the performance of the file listener.

Related reference

- [Keep directory configuration](#)

Related information

- [Cooperative file listening: Multiple watches monitor a single trigger directory](#)

Troubleshooting tip

To enable trace (logging) functionality for the file listener, you must enable the option in the **config.yaml** file.

To enable logging for the file listener

1. Open **config.yaml**, which is located in the product installation directory.
2. Scroll down to the **runtime/m4file** heading and locate the following text:

```
; used to enable logging for the file listener -- it should  
; be a valid complete path (directory and filename)  
;Logging=
```

3. Uncomment the `Logging` line by removing the semicolon in front of it.
4. Enter a complete path and filename for the log file. For example:
`Logging=install_dir \m4trace.log`
5. Save and close the file.

Database adapters

Database source adapters enable you to query a database and use the results of that query as input data. Target adapters enable you to insert or update data to a database. Connections to a particular database are generally made once for each map instance. However, if one database resource uses a rollback option and another does not, the database adapter will use a separate connection for the rollback option.

Before you specify the database to be used by the Launcher, you must first define and configure connections to the selected database. For example, before you specify the Oracle **Connect String** (in the Database Interface Designer) to be used by the Launcher on a computer installed with Oracle client, you must ensure that the value you provide for the **Connect String** matches the Oracle service name definition on that client.

Note: For more information about how to define or configure connections to a database, see the documentation for your specific operating system and database.

- [Characteristics of database adapters](#)

Characteristics of database adapters

Event triggers

Database sources can be used as source event triggers.

Wildcards

Wildcards cannot be used for database sources and targets.

Overrides

Database adapters can be used as an override for any source or target type.

Database connections

- Database connections are coordinated across sources, targets, and database functions used in a single map instance. For example, if one database target is specified with a rollback option and that database is accessed by a `DBLOOKUP` function within any output, the connection will apply for data accessed in that function.
- A connection to a database is specified for each unique combination of data-source name, user ID, password, rollback option and map instance. You can force a new connection, for example, by using different user IDs or data source names. You can take advantage of single connections for a particular map instance by keeping all the database specific parameters the same.

OnSuccess, OnFailure, and Retry settings

- The **OnFailure** setting applies to modifications made to a database source or target within a particular map, burst or card instance (depending on the setting for **Scope**). For example, an **OnFailure** setting of **Rollback** specified for a source query applies only when that query references a stored procedure, which modifies the database
- A database transaction is synonymous with a connection for the purposes of **OnFailure** and **OnSuccess** settings. The database transaction begins when the connection is established and ends when the map completes. If the map does not complete successfully and a rollback is associated with that transaction, the database transaction is rolled back. This means, for example, that if multiple sources and targets of the same map share the same connection and all have an adapter rollback specified, any modification made to any one of these sources or targets are part of the same database transaction

- If a map does not complete successfully, all DBQUERY and DBLOOKUP functions used in that map always rollback. If a DBQUERY or DBLOOKUP function fails and the map succeeds, the function returns NONE, but any modifications to a database specified in the function will rollback.
 - The **Retry** option applies when attempting to connect to a database.
 - The **OnSuccess** option for a source or target is not supported. However, SQL delete statements and stored procedures used as sources can be used for deletion purposes.
- Note: If more than one map instance deletes the same data, the first map instance that completes will delete that data. Deleted database data is not coordinated among map instances.

Application adapters

Application adapters are programs or functions called by the Launcher after a map instance has been initiated. The use and availability of both program and library function application adapters is platform dependent. If an application adapter is a function, that function must conform to a specific prototype. Its prototype, or interface syntax and semantics are defined in the *TX Programming Interface* documentation.

- [Characteristics of application adapters](#)

Characteristics of application adapters

Event triggers

Application adapters cannot be used as source event triggers, they are client applications within a map instance.

Wildcards

Wildcards can be used in an application adapter override command to coordinate trigger events with adapter arguments.

OnSuccess, OnFailure, and Retry settings

- Custom adapters can make use of the **OnFailure** and **Retry** options. The Launcher passes the information to the adapter. The adapter is responsible for responding to the rollback and retry.
- **OnSuccess** options are passed to application adapters.
- **Retry** options apply only if an adapter can be found and if applicable to that adapter. If not available on the server where the Launcher is installed, you will get a source not available or a target not available message.

Note: If you use your own application adapter, you are responsible for including functions for **OnFailure** and **Retry** options. For more information about using your own application adapter, see the *TX Programming Interface* documentation.

Message adapters

Message adapters allow you to send or receive discrete units of information, typically identified by a unique name. The naming conventions are adapter specific. For example, IBM® WebSphere® MQ names or *message identifiers* are 24-byte text items. SAP R/3 message names are called *transaction identifiers*. The storage mechanism for a message is also adapter-specific. For example, IBM WebSphere MQ uses queues to store messages.

When a source message adapter is used with an Launcher, the adapter notifies the Launcher when specific source event messages are available.

To use message adapters, you must have message adapters for the server where the Launcher is installed. For information about command options, see the Resource Adapters documentation.

- [Characteristics of message adapters](#)

Characteristics of message adapters

Event triggers

Messages can be used as source event triggers for a map.

Wildcards

Wildcards can be used for message identifiers. If the message identifier is specified as a wildcard, the value of that wildcard is derived from the value of the message identifier of a message event trigger or from a file source with a wildcard in its name.

OnFailure, and Retry settings

- The **OnFailure** option for a source or target depends on the specific messaging adapters. For example, for IBM® WebSphere® MQ the source rollback option includes an option to place the source message on an error queue.
- The **Retry** option for a source or target depends on the specific messaging adapters. In general, the command option for the adapter must be valid on the computer where the Launcher is installed. If a connection to a queue cannot be made because the specified queue is not available, you will get a source not available

message or a target not available message. If connection parameters are valid, but the message is unavailable due to, for example, a connection limit that has been reached or the message is locked, the retry will be attempted.

Adapters that support event triggers

The following list displays the adapters that can be used as event triggers by the Launcher.

Note: For platform and version-specific information, see the [release notes](#).

- BW Staging BAPI
- Connect:Direct
- Database (See note below.)
- File
- HL7 MLLP
- HTTP
- IBM® IMS TM Resource Adapter
- IBM WebSphere® MQ (client)
- IBM WebSphere MQ (server)
- JMS
- MSMQ
- Oracle AQ
- R/3 ALE
- R/3 BAPI
- R/3 BDC
- Socket
- TIB/RVTX

Note: For information about the specific databases that support event triggers, see the *Database Triggers* in the *Database Interface Designer* documentation.

Connection testing adapters

The following list of adapters supports connection testing.

Note: See the [release notes](#) for platform- and version-specific information.

• BW Staging BAPI	• MSMQ	• R/3 ALE
• DB2®	• ODBC	• Socket
• HTTP	• OLE DB/MS SQL Server	• Sybase
• IBM® WebSphere® MQ (client)	• Oracle	
• IBM WebSphere MQ (server)	• Oracle AQ	
• Informix®	• R/3 BAPI	
• JMS	• R/3 BDC	
• MS SQL Server		

Subsystem component execution settings

A subsystem component references another system that you have defined. As such, a subsystem is an executable unit. You use the IFD to specify the execution settings of subsystem components. Because the IFD treats each subsystem component as a unique instance, these execution settings are maintained separately with each component.

A subsystem component has a defined set of interfaces based on the sources and targets of the various maps that it contains. The inputs and outputs of a subsystem are derived according to the following rules:

- An input of a subsystem is a source that is not internally produced by one of its components.
- An output of a subsystem is a target that is internally produced by one of its components, and is not deleted.

You define execution settings for each subsystem component in your system by accessing the **Launcher Settings** window. To display the **Launcher Settings** window in the IFD, click the **Execution Settings** button of the subsystem component icon with the assigned server displayed.

You can also access this window by selecting the **Edit Execution Settings** command from the context menu for a subsystem component.

- [Launcher settings dialog](#)

Launcher settings dialog

Use the **Launcher Settings** window to configure the settings for the subsystem component.

- [Server](#)
- [ExecutionType](#)
- [Inputs and outputs](#)

Server

The **Server** setting is used to specify the server on which the system will be deployed. The default value for the **Server** setting is **None**.

Value	Description
Local Server	A system is going to run on the local workstation, usually where the IFD is installed. You might want to assign Local Server to systems to use your workstation as a test environment to verify execution. Or, you can plan to use Local Server as a part of your production environment for system execution.
Distributed	Distributed server; a system is composed of subsystems that are assigned to run on different servers in a coordinated manner to distribute the processing. Components in a distributed system must be subsystems, not maps.
None	No server selected; no server is assigned. The system is not executable. Systems that have an assigned server of None do not appear in the Component view in the Navigator. They can be used as subsystems within a system that has a server assigned. A subsystem with an assigned server of None derives its server from its parent system that has a server assigned. Subsystems always display in the Navigator hierarchical view unless the parent system also has a server of None .
Custom	User-defined server

ExecutionType

The **ExecutionType** setting is used to specify the execution mode for the system. The default value for the **ExecutionType** setting is **Launcher**.

Value	Description
Launcher	System will be deployed for execution by the Launcher.
Command	System will be deployed for execution by the Command Server.

Inputs and outputs

Expanding the **Input(s)** and **Output(s)** settings shows the map cards associated with the maps in the subsystem. The values shown are based on the settings specified in the map but the **Launcher Settings** window enables you to override these values. The values you can override are:

- **FetchAs** (for input cards)
- **WorkArea**
- **Backup**
- **Source** (for input cards)
- **Target** (for output cards)

See the *Map Designer* documentation for more information about card settings.

Map initiation scenarios

This documentation describes map initiation scenarios and coordination.

- [Coordinating and using wildcards](#)
- [Multiple map instances in the same watch](#)
- [Same map in different watches](#)
- [Cooperative file listening: Multiple watches monitor a single trigger directory](#)

With cooperative file listening, you can scale your solution to the volume of input files. Multiple watches can run on multiple Launchers and monitor the same trigger directory for arriving source-event files. The File adapter ensures that only one watch triggers on a particular source event. As the volume of incoming source events increases, you can add Launchers to the same computer or to different computers.

- [Different maps that use the same source](#)
- [Different maps use the same target](#)
- [One map's target is another map's source](#)
- [HTTP requests trigger maps](#)

An external HTTP client can trigger a map in a Launcher system by sending a request to the Launcher HTTP Listener. The HTTP Listener provides secure, two-way communication between external clients and the Launcher.

- [Map initiation states](#)

Coordinating and using wildcards

You can use wildcard notation to specify sources or targets that have varying names. To determine the value of a wildcard, the Launcher requires that at least one wildcard-using source is specified as a trigger event.

- [Single source name](#)
- [Matching multiple source names](#)
- [Matching source to target names](#)
- [Multiple wildcards in a source name](#)
- [Threading wildcards across multiple maps](#)

Single source name

If you want a map to run each time a file appears in a particular directory, use a wildcard as part of the source name. An example is `install_dir\receive*.any`.

In this example, each file in the `install_dir\receive` directory with an extension of `.any` starts an instance of the **Run All** map. Depending on other Launcher settings, instances of the **Run All** map can be concurrent or sequential.

For some adapters, an implicit wildcard can be used. For example, if you use the IBM® WebSphere® MQ source adapter, the message identifier is an option. In this case, if no message identifier is specified, any message on a particular queue will initiate a map. An example is `-QMN MyManager -QN MyQueue`.

If you require all message identifiers that end in `XYZ` to run the map, use a specification that is such as `-QMN MyManager -QN MyQueue -MID *.XYZ`.

Depending on other Launcher settings, instances of the **Run All** map can be concurrent or sequential.

Matching multiple source names

If more than one source name for a map has a wildcard, you can use the first source with that wildcard to set the wildcard value for the other sources required by the same map instance.

For example, consider a business using an order system that requires a credit check for all orders. Orders that pass the credit check need to be confirmed; the business does not want to mismatch an order with the wrong credit check.

In this example, the order message is a source trigger. When a new order arrives, its message identifier is used as the value of the wildcard and **CreditCheck** will not run until a credit report message with the same message identifier arrives.

Matching source to target names

If a source has a wildcard, any target that contains an asterisk is assigned the source wildcard value. Modify the credit check example used previously to include an asterisk in the target message's identifier:

The value of the Order message identifier wildcard is assigned to the **CreditStatus** message identifier wildcard. For example, if the value of Order's message identifier is `AAA1212TW`, the **CreditStatus** message identifier is assigned the value, `STATAAA1212TW`.

Multiple wildcards in a source name

If a source name has multiple wildcards and the target name has a single asterisk wildcard, the target name asterisk is replaced with the first wildcard value, next wildcard value, and any characters that exist between the wildcards.

For example, with a source name of `*a??b.c` and a target name of `*.d`, if the source file name instance is:

`xyazzzb.c`

the target name assigned by the Launcher is:

`xyazzz.d`

Threading wildcards across multiple maps

You can track a data object and other objects produced as a result of its existence. These related objects can be produced asynchronously and feed yet other transformation steps that produce more objects.

You can tag each related object to distinguish the thread of actions taken as a result of the event of the first object that started.

For example, suppose there is a travel reservation system. One component of the travel reservation system accepts travel requests with a proposed itinerary. That component sends out request messages to airlines and hotels for availability. After there is a response from an airline and hotel for that itinerary, a response is produced

so that a reservation can be made.

To track a travel request to match it to a reservation as described previously, you can design an example system to have an **Availability** map component with an input event trigger that accepts the travel requests represented by the **-QMN MyManager -QN Itinerary -MID.*** input card. The **Availability** map can send out request messages represented by the **1: AirlineRequest** and **2: HotelRequest** output cards. The responses can be represented by the **-QMN MyManager -QN Airline -MID Air*** output card from the airline and the **-QMN MyManager -QN Hotel -Htl*** output card from the hotel, which can be used as input by the **Reservation** map component with an input event trigger to produce the **-QMN MyManager -QN Response -MID *** output card.

Using wildcards, each Itinerary message identifier can be tracked by the same identifier on the Hotel queue, the Airline queue, and the Response queue.

Multiple map instances in the same watch

The same map might be initiated more than once by the same watch. For example, a map configured to run once every minute will run multiple times. You might, or might not, want multiple instances of the same map running at the same time. How Launcher settings are specified determine specific Launcher actions.

- [Using time events](#)
- [Using source events](#)

Using time events

In this scenario, a map is configured to run every minute. The map starts at 3:00 P.M. and takes over one minute to run. Another instance of that same map could be initiated at 3:01 P.M., and you could have two instances of the same map running at the same time. You can design an example **AppToApp** map with a time event trigger, **1: OrderAppln_In** input card and **1: OrderAppln_Out** output card. The map takes a minute-and-a-half to run on average. Each time it runs, it uses an application adapter to get data expected from some communication session, transforms it to its output form, and puts it in a file. Assume that this map is the only one controlled by the Launcher. Here are the different ways the map could run in real-time.

- [Case 1: Different map instances can run at the same time](#)
- [Case 2: Different map instances can run sequentially](#)
- [Case 3: Skip if Busy can be used to omit map instances from starting](#)

Case 1: Different map instances can run at the same time

If you select unique work files, different map instances can run at the same time.

Unique work files on their own do not guarantee map instances will run at the same time. For example, if the output file is appended, the resource manager will not let multiple map instances run at the same time because the result of one map instance is dependent on another.

Case 2: Different map instances can run sequentially

If unique work file names are not selected, different map instances will *always* run sequentially. A second map instance will begin running after the first map instance has completed running.

There are other situations for which maps run sequentially. For examples, see [Using Source Events](#).

Case 3: Skip if Busy can be used to omit map instances from starting

The Skip if Busy Option can be used to omit map instances from starting when another instance is in process.

In this case, it might not matter what options you select for work files and log files because map instances always run sequentially.

Note: If you want multiple instances of the same map to be able to run at the same time, be sure to select unique work files and unique log file run options. These options create different work files and log files for each map instance so that one map instance will not interfere with another. If you do not select these options, the Launcher will keep the second instance in a pending state until the first instance has completed.

Using source events

In this scenario, a map is configured to run each time a new file appears in a specified directory. A map instance starts when the first file appears and takes over a second to run. Another file appears a half a second after the first file. There could be two instances of the same map running at the same time. You can create an example **AppToApp** map with an event trigger, *install_dir\MQS\APPLN*.TXT* input card and **1: OrderAppln_Out** output card.

Assume that this map is the only one controlled by the Launcher. The following case describes different ways the map could run in real-time.

- [Case 1: Different map instances run at the same time, if all sources and targets are different](#)
- [Case 2: Different map instances run at same time or sequentially based on source and target settings](#)

Case 1: Different map instances run at the same time, if all sources and targets are different.

How run options are selected might affect the length of time a map instance is in process. Assume run options are set as one of the following combinations:

- Select unique work file names or work area in memory and select no log file.
- Select unique work file names or work area in memory and select unique log file names.

In this case, each map instance is independent and the length of time each map instance runs depends only on the amount of processing time associated with the size of the data and the mapping rules used.

If sources and targets are independent, and unique work files are used, but map instances share log files or other map system resources, you might see map instances in process run longer than expected. This occurs because the Launcher will initiate an instance based on available event triggers and then waits for map system resources to become available.

Note: Sources can be the same if they do not have the potential of a map writing data to it. See [Different Maps That Use the Same Source](#).

Note: If you use work files with the WorkFilePrefix setting of MapName (available under the Workspace setting; see [MapSettings > WorkSpace](#)), be sure to use the retry option if multiple map instances can run at the same time. If a retry is not set, the map will fail to run if these resources are in use.

You might also see this same effect if a source or target resource is required, it cannot be shared, and it is in use by an application unknown to the Launcher. In this case, be sure to use the source or target retry option, or the map instance will fail to run.

Case 2: Different map instances run at same time or sequentially based on source and target settings

Unique log file names and unique work file names do *not* guarantee map instances will run at the same time. For example, if the same input file is used each time a map runs, and it is updated by a map rule, the resource manager will not let multiple map instances run at the same time because the result of one map instance is dependent on another.

Map instances will run sequentially under the following conditions:

- If a map uses the same file or message as both a source and target
- If a source is the same file each time a map runs and a map rule is used to update it
- If a target is a file and that file is appended

If any of the previous conditions apply, you will not see two instances of the same map running at the same time.

Same map in different watches

You can have the same map in different watches. The initiations of map instances of one watch can be configured to be independent from the initiation of map instances of other watches.

For example, you want to process orders based on priority. All orders look alike before processing and are converted to the same output form. Priority orders are placed on one message queue. Normal orders are placed on another queue. This is the same map with different component names and different sources.

You want **Priority Orders** to run as fast as possible and (if more than one priority order appears at the same time) you want to process them all at the same time. Normal orders can be processed at the same time, as long as there are enough computer resources available to do so. In this case, you configure **Priority Orders** to have a higher priority than **Normal Orders**.

You also set unique work files and unique log files, so that **Priority Orders** will not need to wait for map system resources. If you just keep work files for each map in a different directory, **Priority Orders** and **Normal Orders** could run at the same time. However, this would limit **Priority Orders** instances to run sequentially. It would also limit **Normal Orders** instances to run sequentially.

Note: If you are using the log file options and are doing this for more than one map, you might want to keep these files for each watch in a separate directory. Although unique log file names are globally unique, they do not contain the name of the map. For example, if you use log files to trigger other maps, keeping these in a separate directory will make sure the logs trigger the correct map instance.

Cooperative file listening: Multiple watches monitor a single trigger directory

With cooperative file listening, you can scale your solution to the volume of input files. Multiple watches can run on multiple Launchers and monitor the same trigger directory for arriving source-event files. The File adapter ensures that only one watch triggers on a particular source event. As the volume of incoming source events increases, you can add Launchers to the same computer or to different computers.

- [Horizontal scaling](#)

Cooperative file listening scales a solution horizontally, by adding more Launchers. It is designed to address performance bottlenecks that are due to maximum CPU utilization or excessive local I/O.

- [Cooperative file listening and fault tolerance](#)

With cooperative file listening, source-event files are retained when a Launcher or a map fails.

- [Cooperative file listening and load balancing](#)

By implementing the cooperative file listening load-balancing guidelines, multiple launchers that poll the same trigger directory for the same files can process a similar number of files to ensure that uniform triggering occurs.

- [Cooperative file listening configuration](#)

- [Balance the workload across watches and scale for large data](#)

With cooperative file listening, a single watch runs on multiple Launchers. On each Launcher where the watch runs, the file listener monitors the same trigger directory for the same files. Use the Pending Instance Thresholds and the Max Concurrent Map Instances Launcher settings in the Integration Flow Designer to help to balance the workload among Launchers.

Horizontal scaling

Cooperative file listening scales a solution horizontally, by adding more Launchers. It is designed to address performance bottlenecks that are due to maximum CPU utilization or excessive local I/O.

Cooperative file listening is of limited benefit if CPU utilization on the existing computer is not maximized. Instead, scale the system vertically by adding more Launcher processes or more threads within the same Launcher process.

Similarly, Cooperative file listening does not address performance bottlenecks that are caused by contention for a shared external resource, such as an NFS file system or database.

Cooperative file listening and fault tolerance

With cooperative file listening, source-event files are retained when a Launcher or a map fails.

When a Launcher fails and cooperative file listening is enabled, the File adapter automatically saves the source-event files of the failed Launcher. Other Launchers continue to process source-event files as they arrive, so the failure of one or more Launchers or maps causes minimal processing delays.

The File adapter saves the source-event files of the failed Launcher in a subdirectory of the trigger directory. The subdirectory is WTX_port_num_hostname, where port_num and hostname are the control port and host name of the Launcher.

When the failed Launcher restarts, the File adapter automatically returns the Launcher's source-event files to the trigger directory, where any Launcher that is listening can process them.

If the failed Launcher cannot restart, you can manually move its source-event files to the trigger directory.

When a map fails and cooperative file listening is enabled, the File adapter automatically saves the source-event files to an error directory. You can use the error directory as the trigger directory for an error-processing map.

File listener messages are logged in the Launcher log file.

Cooperative file listening and load balancing

By implementing the cooperative file listening load-balancing guidelines, multiple launchers that poll the same trigger directory for the same files can process a similar number of files to ensure that uniform triggering occurs.

Cooperative file listening configuration

- [Cooperative file listening requirements](#)

Cooperative file listening requires single source-event watches and source-event files that are created by atomic operation. It supports the GPFS and NFS shared network file systems as well as POSIX-compliant local file systems.

- [Cooperative file listening config.yaml file and Launcher settings](#)

You enable cooperative file listening in the config.yaml configuration file and in the /runtime/launcherSettings.

- [Error directory configuration](#)

When cooperative file listening is enabled and the output card specifies OnFailure=Rollback, the File adapter moves the source-event file to an error directory when a map fails. The error directory is a subdirectory of the trigger directory. You can use the default error directory, or specify the error directory as an absolute file path, a relative file path, or an alias that is defined in the Resource Registry.

- [Keep directory configuration](#)

A keep directory stores source-event files after a map successfully processes them. A keep directory is always available when cooperative file listening is enabled in the config.yaml file. When cooperative file listening is not enabled, a keep directory is available if you explicitly configure its directory path in the Launcher settings. The OnSuccess setting of the input card must be Keep or KeepOnContent to save source-event files in a keep directory.

Cooperative file listening requirements

Cooperative file listening requires single source-event watches and source-event files that are created by atomic operation. It supports the GPFS and NFS shared network file systems as well as POSIX-compliant local file systems.

Single source-event watches

Cooperative file listening supports only watches that trigger on a single source-event card. Multiple source-event cards are not supported. If two Launchers use multiple source-event cards and monitor the same directory, one Launcher can process the first source-event file and another Launcher can process the second source-event file, preventing the watch from triggering.

Source-event file creation

Source-event files must be created by atomic operation. When a file is created with a non-atomic operation, its timestamp can change as the file is written, which can cause the Launcher to trigger more than once on the same file.

File system requirements

Cooperative file listening supports the General Parallel File System (GPFS) and Network File System (NFS) shared network file systems, as well as POSIX-compliant local file systems.

On Windows platforms, cooperative file listening supports file triggering on Samba-mapped UNIX drives. It does not support local or mapped NTFS or FAT drives.

- [How to prevent Launcher from triggering multiple times on same input file](#)

Cooperative file listening config.yaml file and Launcher settings

You enable cooperative file listening in the config.yaml configuration file and in the /runtime/launcherSettings.

The config.yaml configuration file setting

To enable cooperative file listening, edit the `[runtime/m4file]` section of the config.yaml configuration file and set `FileListenCooperativeListener=true`.

Launcher settings

Use the Integration Flow Designer to set the required Launcher settings for cooperative file listening. If `FileListenCooperativeListener=true` but the required Launcher settings are not configured, the Launcher does not start.

Table 1. Required Launcher settings for cooperative file listening

Option	Value
Input(s) > card_name > GET > Source	File
Input(s) > card_name > SourceEvent	On

Error directory configuration

When cooperative file listening is enabled and the output card specifies `OnFailure=Rollback`, the File adapter moves the source-event file to an error directory when a map fails. The error directory is a subdirectory of the trigger directory. You can use the default error directory, or specify the error directory as an absolute file path, a relative file path, or an alias that is defined in the Resource Registry.

Specify the error directory in the `Input(s) > card_name > SourceEvent > ErrorDirectory` field of the Launcher settings. If the fully qualified path to the error directory exceeds 260 bytes, the Launcher does not start.

If a map fails when cooperative file listening is enabled in the config.yaml file but no error directory is specified in the Launcher settings, the File adapter saves the source-event files in the default `WTX_ERRDOCS` subdirectory of the trigger directory. If the default `WTX_ERRDOCS` directory does not exist, the launcher creates it. The permissions of the default `WTX_ERRDOCS` directory are the same as the parent trigger directory.

The following table illustrates how the error directory paths resolve, relative to the `C:\myInput` trigger directory.

Table 1. Resolution of error subdirectory paths in `C:\myInput`

Specified path in ErrorDirectory field	Fully-qualified path
errors	<code>C:\myInput\errors</code>
<code>C:\errors</code>	<code>C:\errors</code>
<code>..\myErrors</code>	<code>C:\myInput\..\myErrors</code>
No directory specified	<code>C:\myInput\WTX_ERRDOCS</code>

If you disable cooperative file listening and you specify an error directory in the Launcher settings, the File adapter moves the source-event file to the error directory if a map fails and `OnFailure` is set to `Rollback`.

If cooperative file listening is disabled and you do not specify an error directory, the processing of the source-event file depends on the `OnFailure` setting.

Keep directory configuration

A `keep` directory stores source-event files after a map successfully processes them. A `keep` directory is always available when cooperative file listening is enabled in the config.yaml file. When cooperative file listening is not enabled, a `keep` directory is available if you explicitly configure its directory path in the Launcher settings. The `OnSuccess` setting of the input card must be `Keep` or `KeepOnContent` to save source-event files in a `keep` directory.

Configure the keep directory path in the Input(s) `card_name` `SourceEvent` `KeepDirectory` field of the Launcher settings. You can specify the keep directory as an absolute file path, a relative file path, or an alias that is defined in the Resource Registry. If the fully qualified path to the Keep directory exceeds 260 bytes, the Launcher does not start.

If you enable cooperative file listening but do not specify a keep directory in the Launcher settings, the File adapter saves the source-event files in the default `WTX_KEEPDOCS` subdirectory of the trigger directory. If the default `WTX_KEEPDOCS` directory does not exist, the launcher creates it. The permissions of the default `WTX_KEEPDOCS` directory are the same as the parent trigger directory.

The following table illustrates how the keep directory paths resolve, relative to the `C:\myInput` trigger directory.

Table 1. Resolution of keep subdirectory paths in `C:\myInput`

Specified path in ErrorDirectory field	Fully qualified path
backup	<code>C:\myInput\backup</code>
<code>C:\backup</code>	<code>C:\backup</code>
<code>..\myBackup</code>	<code>C:\myInput\..\myBackup</code>
No directory specified	<code>C:\myInput\WTX_KEEPDOCS</code>

To use a keep directory when cooperative file listening is disabled, specify a keep directory in the Launcher settings and set `OnSuccess` to `Keep` or `KeepOnContent`. When the setting is `Keep`, the File adapter saves the source-event file when the map succeeds. When the setting is `KeepOnContent`, the File adapter saves the source-event file when the map succeeds and the source-event file is not empty.

Balance the workload across watches and scale for large data

With cooperative file listening, a single watch runs on multiple Launchers. On each Launcher where the watch runs, the file listener monitors the same trigger directory for the same files. Use the Pending Instance Thresholds and the Max Concurrent Map Instances Launcher settings in the Integration Flow Designer to help to balance the workload among Launchers.

The Pending Instance Thresholds pause and resume the file listener of a watch. The file listener pauses when the watch's backlog of unprocessed source events reaches the high threshold, and resumes when the backlog falls below the low threshold. While the watch is paused on one Launcher, the listeners on other Launchers can process the arriving source events, which balances the workload.

Configure the high and low Pending Instance Thresholds to ensure that maps trigger uniformly across multiple Launchers. Adjust these settings so that each Launcher processes a similar number of source-event files, proportionate to the processing speed of the Launcher's server.

For example, if a watch that typically processes 10000 files runs on three Launchers, set the high Pending Instance Threshold value to 3300 to ensure that a Launcher listener pauses when it acquires a third of the source-event files. While the watch on one Launcher is paused, the listeners on the other Launchers continue to process the incoming source-event files. Set the low Pending Instance Threshold value to 1000 to resume the paused listener when the Launcher processes most of the source-event files.

Also consider the average transformation time as you adjust the Pending Instance Thresholds. In general, faster transformation needs higher Pending Instance Thresholds for optimal throughput.

- If the high and low Pending Instance Thresholds values are too low, stopping and starting the listeners frequently can impact performance.
- If the high and low Pending Instance Thresholds values are too high, one watch can accumulate the inputs while the others remain idle.

With very large data and CPU-intensive transformation, low values for the Pending Instance Thresholds can achieve scalability and load balancing. Low thresholds limit the number of source-event files that each Launcher can acquire and resume the listener only when a Launcher has CPU power available to process them.

You can accommodate CPU-intensive maps and large data by tuning the Max Concurrent Map Instances Launcher setting in the Integration Flow Designer. The Max Concurrent Map Instances setting limits the number of map instances that can run simultaneously within a Launcher process.

When you configure the Max Concurrent Map Instances setting and the Pending Instance Thresholds, take into consideration:

- Average input volume per hour
- Average time per transformation
- Number of cooperative Launchers
- Number of processors per Launcher per computer
- CPU utilization during peak load

For example, consider a system that processes very large data. Each map takes approximately 60 seconds to run and utilizes nearly 100% of one CPU. The system has three Launchers (L1, L2, and L3) that are deployed on three different host computers (H1, H2, and H3). The Launchers trigger on the same directory.

Host	Number of CPUs
H1	4
H2	2
H3	1

You might configure the Max Concurrent Map Instances and Pending Instance Thresholds as follows to balance the load and achieve optimal throughput:

Launcher on host computer	Max Concurrent Map Instances	High Pending Instance Threshold	Low Pending Instance Threshold
L1 on H1	4	8	4
L2 on H2	2	4	2
L3 on H3	1	2	1

- [Pending instance thresholds](#)

Related information

- [Max concurrent map instances](#)

Different maps that use the same source

Different maps that use the same source can run at the same time, as long as that source is not updated by one of those maps.

For example, a patient is admitted to a hospital. The admitting department produces an admitting message. Various other departments in the hospital use the admitting message. The medical records department needs to update the patient record. The accounting department needs to track the patient's charges. The nurses' station on the floor where the patient will be staying needs to be notified. Other departments might have a need to know.

Each department uses a separate system for its internal processing. And none of these understands how to process the admitting message. The same message must be converted to many different forms, one for each department.

You could create one map and do all the conversions in one step, but some departments need the information faster than others. You therefore decide to configure a different map for each department.

For example, create an **Admit** system in the IFD with a different map for each department, **Pharmacy**, **Medical Records**, **Accounting** and **Nurses**.

In this example, each map uses the same trigger source as input. An example input trigger source is **-QMN MyManager -QN ADMIT**. Each map has different targets. Example targets are **1:HL7_Style** for the **Admit To Pharmacy** map, **1:MedicalRecord** for the **Admit To Medical Records** map, **2:InsuranceBilling** and **1:PatientCharges** for the **Admit To Accounting** map and **1:FAX** for the **Admit To Nurses** map. Each map is independent from the other; each can run at the same time. Also, more than one instance of each map could run at the same time.

- [Impact of Delete settings](#)

Impact of Delete settings

All maps that share the same source and have no Delete action specified are run first. When these maps complete, a map that specifies the Delete action for that shared resource can be initiated. Only one map should use the delete action for this type of resource to avoid a **Source not available** message.

Different maps use the same target

If different maps use the same target, the type of target influences how maps are run:

- If the target is a file or a message, the resource manager will prevent different maps that use the *same* file or message from running at the same time.
- If the target is an application, the Launcher relies on the application adapter to be multi-threaded and assumes resources for different instances of that adapter are independent.
- If the target is a database, the database adapter communicating with the specific database handles shared resources.

One map's target is another map's source

When the target of one map is used as a trigger source for another, the Launcher does not start any map until that trigger occurs. However, if a file or message source is not a trigger, the Launcher initiates a map based on other event criteria.

HTTP requests trigger maps

An external HTTP client can trigger a map in a Launcher system by sending a request to the Launcher HTTP Listener. The HTTP Listener provides secure, two-way communication between external clients and the Launcher.

You configure the HTTP Listener to monitor its ports for an incoming HTTP request for a specific URL. You design a map in a Launcher system to use the HTTP request as an input trigger. The listener sends the request to the map's HTTP adapter input card and returns a response to the external client. The response is either the output from the map's HTTP adapter output card, or the status of the map execution from the HTTP input card.

The HTTP Listener example is installed in the *tx_install_dir\examples\httplsnr* directory.

- [HTTP Listener map execution results overview](#)
Regardless of whether it runs successfully, a map returns a response through the HTTP listener to the external HTTP client. If the map fails or the output card does not return a response to the client, the input card automatically returns a response.
- [HTTP Listener map performance and throughput](#)
You can analyze the HTTP Listener status information to tune the performance of Launcher systems. The status information includes response time details for URL watches that can indicate bottlenecks during peak load periods. It also displays details about connections, responses to the HTTP client, and logging.
- [HTTP Listener connection performance](#)
The HTTP Listener status provides details about the connections between the listener and its external clients and HTTP adapters. The data can indicate the need to adjust connection settings.
- [HTTP Listener browser access](#)
You can display map execution status and configure HTTP Listener settings through a local or remote browser, as well as through the Launcher Management

- Console.
 - [HTTP Listener logging](#)
HTTP Listener trace and audit logs capture details about listener events, socket activity, connections, and HTTP communications.
 - [Supported cryptographic protocols for the HTTP Listener](#)
You can configure the cryptographic strength that the Launcher uses to communicate with its Secure Sockets Layer (SSL) clients. The Launcher supports encryption protocols that range from SSL V2.0 to Transport Layer Security V1.2 (TLS V1.2). Other supported protocols include SSL V3.0, TLS V1.0, and TLS V1.1. Also available is a NIST Special Publication (SP) 800-131A-compliant mode that selects a TLS protocol version based on the cryptographic and certificate strength that is used by the SSL client.
-

HTTP Listener map execution results overview

Regardless of whether it runs successfully, a map returns a response through the HTTP listener to the external HTTP client. If the map fails or the output card does not return a response to the client, the input card automatically returns a response.

The response from the input card can include customized HTTP status codes and a customized text page that describe the map execution results. A default set of status codes and default status page ensures that the HTTP client always receives a response from the map.

- [Status code command \(-STATUS_CODE\)](#)
When the HTTP adapter **-STATUS_CODE** command is used on a map input card, it associates one or more map error codes with an HTTP status code.
 - [Status page commands \(-STATUS_PAGE and -STATUS_PAGE_DEFAULT\)](#)
When a map or card fails, the HTTP Listener sends the external HTTP client a text file that describes the status of the map execution results.
-

Status code command (-STATUS_CODE)

When the HTTP adapter **-STATUS_CODE** command is used on a map input card, it associates one or more map error codes with an HTTP status code.

If the map fails or its output card does not produce a response, the **-STATUS_CODE** command on the input card returns the HTTP status code to the HTTP client. The `/runtime/M4HTTP` section of the `tx_install_dir\config.yaml` configuration file defines default HTTP status codes that the listener returns to the client (if the input card does not override them with the **-STATUS_CODE** command).

Related reference

- [Map execution error and warning messages](#)
 - [Status Code \(-SC or -STATUS_CODE\)](#)
-

Status page commands (-STATUS_PAGE and -STATUS_PAGE_DEFAULT)

When a map or card fails, the HTTP Listener sends the external HTTP client a text file that describes the status of the map execution results.

The HTTP adapter **-STATUS_PAGE** command sends map execution results to the external HTTP client in a text file. A map input card can use the command to create a uniquely named file that's specific to an HTTP request. The map can dynamically create the file contents by using pre-defined variables that resolve when the map runs.

The HTTP adapter **-STATUS_PAGE_DEFAULT** command returns a customized default file to the external HTTP client when the input card or map fails. When an HTTP adapter input card does not use the **-STATUS_PAGE** or **-STATUS_PAGE_DEFAULT** commands, an HTTP failure returns the generic `m4http_statuspage.html` file specified in the `/runtime/M4HTTP` section of the `config.yaml` configuration file.

HTTP Listener map performance and throughput

You can analyze the HTTP Listener status information to tune the performance of Launcher systems. The status information includes response time details for URL watches that can indicate bottlenecks during peak load periods. It also displays details about connections, responses to the HTTP client, and logging.

The HTTP Listener status displays metrics that can be used to tune the Launcher performance.

Response time

The overall time to process an HTTP request for a particular URL.

Register time

The overall time to match an HTTP request with an available URL watch.

Map time

The average time to run the map and return a response to the HTTP Listener. Response time is approximately the sum of register time and map time.

The URL watch information displayed in the listener status is similar to the information in this table.:

Table 1. Example URL watch information provided as part of the HTTP Listener status

Watch #	Busy	Map Return	HTTP Response	Response Time	Register Time	Map Time	URL
0	0	0	0	0.000	0.000	0.000	/admin

Watch #	Busy	Map Return	HTTP Response	Response Time	Register Time	Map Time	URL
1	0	0	0	0.000	0.000	0.000	/admin/update

12	0	1	1	0.531	0.001	0.528	/example

A significant increase in register time during peak load periods can indicate a backlog of HTTP requests. You can address a backlog by adding more copies of the map to the system (.msl) or by adding another Launcher to load-balance the HTTP requests.

The HTTP Listener status also includes the total number of success, failure, and unavailable responses that the HTTP Listener returned to the external HTTP client.

The Management Console displays this information in the Status page. You can also display it in a browser by entering the `http://Launcher_host_address:http_port/admin/status` URL. The config.yaml configuration file controls the refresh interval of the information in the browser Status page. The Launcher refresh interval controls the refresh interval of the Management Console Status page.

Related tasks

- [To set up an instance of a Launcher](#)

HTTP Listener connection performance

The HTTP Listener status provides details about the connections between the listener and its external clients and HTTP adapters. The data can indicate the need to adjust connection settings.

The Connection Information provides the total number of active and inactive connections that occurred since the listener was started. The HTTP adapter shuts down an idle connection when it exceeds the timeout limit. You can adjust adapter timeouts with the HTTP adapter **-KEEPALIVE** command and the **IdleHTTP** setting in the tx_install_dir/config.yaml configuration file.

The Connection Time indicates the total amount of time required for the HTTP Listener to connect with the external HTTP client or with the HTTP adapter.

The Management Console displays the connection information in the Status page. You can also display it in a browser by entering the `http://Launcher_host_address:http_port/admin/status` URL. The config.yaml configuration file controls the refresh interval of the information in the browser Status page. The Launcher refresh interval controls the refresh interval of the Management Console Status page.

Related reference

- [KEEPALIVE \(-KEEPALIVE\)](#)

HTTP Listener browser access

You can display map execution status and configure HTTP Listener settings through a local or remote browser, as well as through the Launcher Management Console.

To view or change the settings of a running HTTP Listener, you can use the `http://Launcher_host_address:http_port/admin` URL (for example, `http://localhost:5017/admin`). Changes that you make through the browser take effect immediately, but they only persist when the listener has been started with the **httplsnr** command. Use the Launcher Management Console to change the settings of a listener that was started with the Launcher.

HTTP Listener logging

HTTP Listener trace and audit logs capture details about listener events, socket activity, connections, and HTTP communications.

You can enable HTTP Listener tracing and audit logs through the listener Status browser or Management Console interface, the Launcher Administration utility or command, or the **httplsnr** command.

Note: Binary data is not logged.

The following table describes HTTP Listener logging.

Table 1. Listener logging details

Logging type	Logged information	Log name
Standard	HTTP Listener events such as client requests	<i>listenernname_timestamp_hostname.log</i>
Verbose	Socket activity	<i>listenernname_socket_timestamp_hostname.log</i>
Audit	Details about individual connections and map executions	<i>listenernname_audit_timestamp_hostname.log</i>

Each listener has one audit log. The audit log is in XML format that can be queried with XSLT transformations. The audit log schema is LHL-Audit.xsd, installed in the Transformation Extender installation directory on Windows systems or the /bin directory on UNIX systems.

The location of the log files depends on how you start the listener:

- When you start the listener by using Launcher Administration or the Management Console, the listener creates the log files in the `tx_install_dir/logs` directory.
- When you start the listener from the command line and specify a fully qualified log file name, the listener creates the log files in specified path. If you omit the log file name or specify a relative path to the log file, the listener creates the log in the current working directory.

Supported cryptographic protocols for the HTTP Listener

You can configure the cryptographic strength that the Launcher uses to communicate with its Secure Sockets Layer (SSL) clients. The Launcher supports encryption protocols that range from SSL V2.0 to Transport Layer Security V1.2 (TLS V1.2). Other supported protocols include SSL V3.0, TLS V1.0, and TLS V1.1. Also available is a NIST Special Publication (SP) 800-131A-compliant mode that selects a TLS protocol version based on the cryptographic and certificate strength that is used by the SSL client.

The cryptographic strength that the Launcher uses to communicate with SSL clients depends on the following factors:

- The digital certificates that are obtained.
The SSL and TLS protocols use X.509 certificates to encrypt communication between the Launcher and its SSL clients.
 - When you do not use X.509 certificates, no encryption is in effect in the TCP/IP session layer.
 - SSL encryption without NIST SP 800-131A compliance is in effect when:
 - You obtain digital certificates.
 - You do not install IBM Global Security Kit (GSKit).
- Configuring the SSL security mode (`SECURE_MODE`) setting in the config.yaml configuration file
The [SSL_SERVER] section of the config.yaml configuration file controls the level of security that the Launcher requires to communicate with SSL and TLS clients. The default setting is `SECURE_MODE=0`.

Table 1. Cryptographic strength. This table describes the levels cryptographic strength and the factors that control this strength.

Cryptographic Strength	Digital Certificates	SSL Module in Effect	SSL Security Mode Setting (config.yaml)	SSL Secure Mode Displayed in the HTTP Listener Configuration:
None	undefined	N/A	0	N/A
SSL encryption without NIST SP 800-131A compliance	defined	mercssl	0	unavailable
NIST SP 800-131A and TLS V1.2 are attempted, but the SSL client and SSL server might negotiate a less secure protocol	defined	m4gskssl	0	available
NIST SP 800-131A required	defined	m4gskssl	1	NIST SP 800-131A required
NIST SP 800-131A and TLS V1.2 are required	defined	m4gskssl	2	TLS V1.2 and NIST SP 800-131A required

Map initiation states

To be initiated, a map might require multiple events to occur and multiple resources to be available. The Launcher coordinates these events and resources for maps based on the Launcher settings established during the system creation process in the IFD.

A map is ready to run when all its triggers have occurred and all required resources known to the Launcher are available. After the map is initiated, if a source, target, work file, map file, or log file exists but is in use, the retry values set in `Source>.Retry` and `Target>.Retry` are used to determine whether to continue or complete the processing of that map instance.

- [Initiation pending state](#)
- [Resource pending state](#)
- [Map initiation tip](#)

Initiation pending state

If the map associated with a watch has multiple triggers and at least one trigger occurs, the map is placed in an initiation pending state until all triggers occur. Maps in an initiation pending state are reevaluated each time another trigger occurs.

Resource pending state

The resource pending state refers to source and target resources shared by other map instances known to the Launcher. If you are using the Launcher Status, the resource pending status count is non-zero when all triggers for a map have occurred but the resource manager has not yet released that map for initiation. In this case, at least one source or target updates or replaces a resource used by a map in process.

Map initiation tip

- If a single multi-threaded map is triggered 100 times, the map is read up front during initialization, and kept in memory for all runs. Thus, the map is only read once.

Management Tools

This documentation describes how to configure and use the Management Tools for the Launcher.

The Management Tools are a component of WebSphere® Transformation Extender.

Note: When using the z/OS® local administration interfaces, see "[z/OS Launcher](#)" for more information. The following information does not apply.

- [Overview](#)
- [Unique keys in the Launcher Management Tools](#)
There are some unique key combinations available in the Launcher Management Tools in addition to the standard Java™ navigation keys.
- [HTTP Listener default port settings](#)
- [Automatically-generated log files](#)
The Launcher automatically generates log files in the logs subdirectory of the *install_dir* during processing.
- [Management Console](#)
- [Dynamic adapter tracing](#)
- [Dynamic logging](#)
- [Logging option](#)
- [System and watch status in JSON format](#)
The Launcher heartbeat file summarizes the status of Launcher systems and watches in a JSON-formatted log file that an external program can read to automatically monitor Launcher status.
- [Launcher Monitor](#)
- [Snapshot Viewer](#)

Overview

The Management Tools provide a means to manage and view Launcher processes running in the Launcher. The Management Tools are automatically installed with WebSphere® Transformation Extender and can also be installed separately on multiple machines to allow multiple users to monitor Launcher activity remotely. You can view both Windows and UNIX Launcher activities from one station.

Note: A large number of instances of the Management Tools running will adversely affect the performance of the Launcher.

- [Management Tools for Windows platforms](#)
- [Management Tools for UNIX platforms](#)

Management Tools for Windows platforms

You can install the Management Tools separate from WebSphere® Transformation Extender on your client machines. The Management Tools installation for Windows includes the following applications:

- Management Console ("[Management Console](#)")
- Launcher Monitor ("[Launcher Monitor](#)")
- Snapshot Viewer ("[Snapshot Viewer](#)")

Management Tools for UNIX platforms

You can install the Management Tools separate from WebSphere® Transformation Extender on your client machines. The Management Tools installation for UNIX includes only the Management Console application.

Note: If you are using Native Window Manager and experience symptoms such as no title bar, no insertion point, or no pop-ups, you can work around this by reconfiguring the X Window Manager (Exceed settings).

Unique keys in the Launcher Management Tools

There are some unique key combinations available in the Launcher Management Tools in addition to the standard Java™ navigation keys.

For enhanced accessibility, the following key combinations are available in the Launcher Management Tools applications.

Application name	Navigation description	Key combination
Launcher Administration	To navigate the tabs in the Deployment Directories panel.	Shift+F2
Management Console	To navigate between panes.	Shift+F2
	To navigate the status panel tabs.	Tab

HTTP Listener default port settings

The Launcher Administration, Launcher service, Launcher, and Management Tools applications work collectively and must communicate by means of ports. Each application has default port settings, which can be changed. From the Launcher Administration interface you can configure startup, connection user security, firewall, and deployment options for the Launcher. The following list displays the default port settings for each application, and the interrelated structure of the applications.

- The Launcher process relays monitoring information over port 7001 to the Monitor.

- The Launcher process relays status information over port 7000 to the Management Console.
- The Launcher service sends control information (start, stop, pause, resume) to the Launcher process that is running over port 7002.
- The Management Console commands (start, stop, pause, resume, disconnect) are relayed to the Launcher service over port 5015 (also known as the listening port). Note: On UNIX systems, Management Console commands require both port 5015 and port 5014.
- Communications between the Monitor and the Launcher service are relayed over port 5016 (also known as the listening port).
- The Launcher HTTP Listener communicates with an external client over port 5017 and with Launcher maps over port 5018.

If you run multiple Launcher processes on one computer, they must run on different listening ports and must have different port ranges. If this condition is violated, the Launcher service might not work as intended. Also, export the display to a server that supports X Window systems for that same environment.

When you run the Launcher service through Telnet or on Transformation Extender for z/OS®, ensure that the *DISPLAY* variable points to the machine that you are using. The value of the *DISPLAY* variable can be checked by typing `echo $DISPLAY` at the Telnet prompt and can be set using the `export` command. Otherwise, if the listening port is already in use, an exception is raised instead of the regular message that indicates the listening port is in use. In all cases, an entry in the log file indicates which listening port *number* is in use.

Automatically-generated log files

The Launcher automatically generates log files in the logs subdirectory of the *install_dir* during processing.

- **[Launcher log file](#)**

When it is started, the Launcher service (or daemon) begins to write to the `LauncherLog_timestamp_hostname.log` file. The Launcher Admin process starts Launcher processes to execute launcher systems. Launcher processes write trace messages to the `system_name_timestamp_hostname.log` file. The `LauncherLog_timestamp_hostname.log` file contains session-related logging information, such as initialization settings from the Launcher Administration. The `system_name_timestamp_hostname.log` file contains system processing information such as system command lines, system commands from the Management Console, map execution status, I/O related messages, system status, and any exceptions.

- **[Management Console log file](#)**

The Launcher service (or daemon) generates the `MgmtConsoleLog_timestamp_hostname.log` to log exceptions in communication between the Management Console and the Launcher service.

- **[Communication log file](#)**

The `Communication_timestamp_hostname.log` file is the Management Console log file that the Launcher generates to log exceptions that occur when the Management Console is interacting with the Launcher.

- **[Java Management Tool log file permissions](#)**

Log files that are created by the Java™ Management Tools have the default file permissions `rwx-rw-rw-`. You can change the log file permissions by using the operating system's `umask` command before you run the Java components.

Launcher log file

When it is started, the Launcher service (or daemon) begins to write to the `LauncherLog_timestamp_hostname.log` file. The Launcher Admin process starts Launcher processes to execute launcher systems. Launcher processes write trace messages to the `system_name_timestamp_hostname.log` file. The `LauncherLog_timestamp_hostname.log` file contains session-related logging information, such as initialization settings from the Launcher Administration. The `system_name_timestamp_hostname.log` file contains system processing information such as system command lines, system commands from the Management Console, map execution status, I/O related messages, system status, and any exceptions.

When the `system_name_timestamp_hostname.log` file reaches a maximum size, the Launcher process closes it, appends an index number to log file name (`system_name_timestamp_hostname_index.log`), and begins logging to a new file. You can specify the maximum size of the `system_name_timestamp_hostname.log` file size on the `CircularLogSize` option in the `config.yaml` configuration file. The default maximum size is 100 MB, and the minimum size is 10 MB.

You also can specify the maximum number of `system_name_timestamp_hostname.log` files to keep before the oldest log file is deleted. The `CircularLogFileNum` option in the `config.yaml` file controls the maximum number of log files. The minimum is two log files, and the default maximum is five log files.

The initial `LauncherLog_timestamp_hostname.log` file that is created at Launcher service startup is never deleted. When the Launcher service restarts, it creates a log file with a new timestamp.

- **[UNIX signal-generated codes in the Launcher log file](#)**

Launcher result codes that are higher than 128 occur when the operating system sends a UNIX signal to the Launcher. The value of the Launcher result code is the UNIX signal value plus 128.

Related reference

- [CircularLogSize](#)
- [CircularLogFileNum](#)

UNIX signal-generated codes in the Launcher log file

Launcher result codes that are higher than 128 occur when the operating system sends a UNIX signal to the Launcher. The value of the Launcher result code is the UNIX signal value plus 128.

To determine the UNIX signal value, subtract 128 from the Launcher result code. For example, Launcher result code 139 corresponds to the UNIX signal value 11 (`139 - 128 = 11`). UNIX signal value 11 represents the POSIX SIGSEGV signal.

See your operating system documentation for the list UNIX signals and signal values.

Management Console log file

The Launcher service (or daemon) generates the MgmtConsoleLog_timestamp_hostname.log to log exceptions in communication between the Management Console and the Launcher service.

The log file contains the Management Console and Launcher service session-related logging information including information about Launcher service connection-related failures and Graphical User Interface (GUI) update-related exceptions.

Communication log file

The Communication_timestamp_hostname.log file is the Management Console log file that the Launcher generates to log exceptions that occur when the Management Console is interacting with the Launcher.

The Launcher populates the statistic fields in the Management Console screen directly through Communication Layer that acts as a bridge between the Management Console and the Launcher after the Launcher is running.

Java Management Tool log file permissions

Log files that are created by the Java™ Management Tools have the default file permissions **rw-rw-rw-**. You can change the log file permissions by using the operating system's **umask** command before you run the Java components.

For example, you can use the **umask** command to change the file permissions as follows:

Command	Java Log File Permission
umask 2	rw-rw-r--
umask 22	rw-r--r--

To change the file permissions for all three logs, put the umask command in the DTX_HOME_DIR/bin/common.sh shell script.

Management Console

The Management Console allows you to control and view the status of Launcher processes (.msl system files) running in the Launcher. From the Management Console you can start, stop, and pause a compound system, which is the combination of all .msl files in the deployment directory. See "[Multiple Processes](#)" for additional information when using the multiple-processes feature.

The Management Console provides a variety of figures about the maps being run by the Launcher, such as how long the Launcher has been running, how many maps have been processed, and so on.

- [Features of the Management Console](#)
- [Using the Management Console](#)
- [Monitor option](#)
All systems and compound systems are monitored by default. When you no longer need to monitor a system, you can reduce network traffic by disabling monitoring for that system.
- [Retry option](#)
- [Snapshot option](#)
- [Launcher options](#)
- [Management Console statistics](#)

Features of the Management Console

- Provides internal information for statistical analysis and troubleshooting.
- Runs on all platforms that Transformation Extender supports.
- Displays data in an easy-to-read format.
- Provides debugging information.
- Monitors the current state of an HTTP Listener or a compound system process.
- Starts, stops, and pauses a compound system without stopping the service.
- Provides both real-time and historical statistical information from the compound system running in the Launcher.
- Displays statistics for HTTP Listeners and changes HTTP Listener settings that don't affect listener start up.

Using the Management Console

The Management Console is used to display run-time statistics of the Launcher. You must complete the following steps before using the Management Console.

- [Management Console quick start list](#)
- [Management Console icon descriptions](#)
- [Required steps to perform outside of the Management Console](#)
- [Getting started](#)

- [Controlling systems](#)

Management Console quick start list

After you complete required steps outside of the Management Console, there are three main tasks to complete in the Management Console before you can begin viewing run-time statistics of the Launcher:

To prepare to view Launcher run-time statistics

1. Set up an instance of a Launcher. (See [To set up an instance of a Launcher](#).)
2. Connect to a Launcher. (See [To connect to the Launcher](#).)
3. Start the system or systems. (See [To start the system\(s\)](#).)

The procedures for each task are described in the following topics.

Management Console icon descriptions

The following icons appear in the Management Console navigation pane:

Icon	Description
	Management Console in connection mode
	Management Console in disconnection mode
	Management Console is in retry mode. (The icons periodically fluctuate)
	system stopped
	system running
	statistics
	system paused
	system stopping

Required steps to perform outside of the Management Console

- Generate a system file (**.msl**) and add it to either the **install_dir\systems** directory (which is the default) or to a deployment directory of your choice.
- Using the Launcher Administration interface, do the following activities:
 - Create a user profile with the appropriate access rights.
 - Set up the deployment directory path from where the Launcher will access the system file (**.msl**).
- Start the Launcher.

After you complete the required steps, you are ready to begin using the Management Console. Follow the steps in the following topics to quickly get started using the Management Console.

Getting started

To open the Management Console (Windows)

Select Start > Programs > Transformation Extender > Launcher > Management Console.

To open the Management Console (UNIX)

1. From the command prompt, enter the following command:

```
. setup
```

2. From the same command prompt, enter the following command:

```
mgmtconsole.sh
```

After you open the Management Console, the first thing you need to do is set up an instance of the Launcher that you're going to monitor. After the Launcher is set up, the next step is to connect to the Launcher and begin monitoring.

To set up an instance of a Launcher

Note: You must set up users with the appropriate access rights in the Launcher Administration interface to view systems running in the Management Console. If you add a new user after the Launcher service is running, you must close the Management Console and restart the Launcher before the user is recognized.

1. From the **Launcher** menu, select New to add a Launcher.
The New Launcher window appears.
2. In the **Name** field, type a unique name of up to 20 alphanumeric characters.
Note: Although the name must be unique, it can be arbitrary because it is only a label that appears on its own tab in the Management Console navigation pane.
3. In the **Host Name** field, enter the host name or IP address. An IP address can be in IPv4 (for example, 1.2.3.4) or IPv6 (for example, a:b:c:d:0:1:2:3) format.
4. In the **Port** field, enter the port number for the Launcher. Port 5015 is the default setting.
Note: Each host name must have a separate port number.
5. In the **Refresh Interval (sec)** field, type an interval time in seconds. The minimum value is 1 second, meaning that the Launcher will check for new data every second. The default setting is 5 seconds.
6. Under **Security**, type a **Login Name** and **Password** that permits access to the host. This information must correspond to a user profile set up in the Launcher Administration interface ([Launcher Administration](#)).
7. Click OK.

The New Launcher window closes and the new Launcher name is listed in the navigation pane of the Management Console window.

To connect to the Launcher

Before you create the connection to the Launcher, the Launcher must be running. (See [Starting and Stopping the Launcher](#) for instructions on starting the Launcher service). See [Multiple Processes](#) for additional information when using the multiple-processes feature.

From the navigation pane, right-click on the Launcher and select Connect.

The connection is established. The **CompoundSystem** icon is displayed in the navigation pane for a single process.

The system is labeled **CompoundSystem**, which can represent one or more system files (.msl).

To start the system or systems

From the navigation pane, right-click CompoundSystem and select Start from the context menu.

In the navigation pane, if you expand the **CompoundSystem**, you will see the **Status**, **History**, and **Configuration** icons:

Note: If you see this information upon opening the Management Console, it indicates that the **Automatic startup** option in the Launcher Administration is enabled. The statistics display in the main window.

Note: See [Management Console Statistics](#) for a description of each statistic.

Controlling systems

The Management Console enables you to control the systems that are running. If you right-click on **CompoundSystem** in the navigation pane (see ["Multiple Processes"](#) for additional information when using the multiple-processes feature), a context menu appears that has disconnect and stopping options. The following instructions describe how to disconnect from the Launcher and stop the service on a Microsoft Windows system. See the related reference topics for details about stopping the Launcher on a UNIX system.

Related reference

- [Starting, stopping, pausing, and resuming the Launcher service](#)

To stop an instance of the Launcher

1. From the Management Console navigation pane, right-click **CompoundSystem** and select Stop from the context menu.
The status of the system changes from **Running** to **Stopping** to **Stopped**.
2. Go to the **Launcher** menu and select Disconnect.
The connection is terminated and the **CompoundSystem** disappears from the navigation pane.

To stop the Launcher service (Windows)

1. From your desktop, right-click My Computer and select Manage.
2. From the Computer Management window, expand the **Services and Applications** list and select Services.
3. Right-click **WebSphere Transformation Extender Launcher** and select Stop from the context menu.

Monitor option

All systems and compound systems are monitored by default. When you no longer need to monitor a system, you can reduce network traffic by disabling monitoring for that system.

The Monitor option in the Management Console disables system statistics monitoring for a particular system. Use either of these methods to stop monitoring a system:

- In the Management Console menu, click System and deselect Monitor.

- In the system context menu, click Monitor.

Note: This option is not available when the **CompoundSystem** is stopped.

Retry option

The Management Console has a retry mode that automatically attempts to reconnect to the Launcher service in case it becomes unavailable or shuts down. This eliminates the need to manually monitor the Management Console for possible problems.

When the Launcher service fails, the Management Console attempts to reconnect to the server every 20 seconds. When the Management Console attempts to reconnect, the status bar displays the time in seconds.

To enable retry mode

From the Management Console window, select **LauncherRetry if Disconnected**.
A check mark appears next to **Retry if Disconnected**.

When this option is enabled, the Management Console goes into retry mode upon the shutdown of the Launcher service. To assist with troubleshooting, see the Launcher log file. For information about the Launcher log file, see [Launcher activity log files](#).

Because retry mode is an infinite process, you must stop the operation manually if needed.

To manually stop retry mode

From the Management Console window, select **LauncherStop Retry**.
The Management Console stops trying to connect to the Launcher.

To connect to the Launcher again, you must restart the service or daemon.

Snapshot option

The **Snapshot** option in the Management Console provides a means for saving a "snapshot" of Launcher information to a file in XML format. A "snapshot" of Launcher information refers to capturing a moment in time of status, historical, and configuration information that the Management Console provides about a **CompoundSystem** (see ["Multiple Processes"](#) for additional information when using the multiple-processes feature) running under a Launcher.

To create a snapshot file

Note: This option is not available when the **CompoundSystem** is stopped.

1. From the Management Console, select **System > Snapshot**.
The Save As window opens.
2. Specify the name of the XML file to which the Launcher **CompoundSystem** information will be stored and click **Save**.
The file is saved in XML format.

You can accomplish the same task on the command line. For information about using the Snapshot command line options, see [Snapshot commands](#).

Launcher options

In the **Options** list of the Options window, when you select Launchers, the configuration options described below are displayed. These options allow you to manually configure and override connection information for each Launcher connection in the Management Console.

- [Override Configuration options](#)

Override configuration

You can manually configure and override connection information for each Launcher connection in the Management Console. Typically, the Management Console relays control commands (start, stop, pause, resume, disconnect) to a Java-based Launcher service, which in turn executes the commands to the process running. However, you can manually override the typical process so that the Management Console bypasses the Java-based service and communicates directly with the process running. In this case, the Management Console can relay only limited control commands (stop, pause, resume) to the process running. The Launcher itself must be manually started from the CPU where it resides.

The following list describes the communication process that occurs when you use the override configuration option. The port numbers that are referenced are the default numbers.

- Control information including stop, pause, and resume commands, are communicated between the Launcher process that is running and the Management Console over port 7002.
- Status information is communicated between the Launcher process that is running and the Management Console over port 7000.
- Monitoring information is communicated between the Launcher process that is running and the Launcher Monitor over port 7001.

To access override configuration options:

1. In the Management Console, select **Tools > Options**.
The Options window opens.

2. From the **Options** list, select Launchers.
The override configuration options appear.

Override Configuration options

The Launcher override configuration options in the Options dialog are described in the following table:

Override configuration options	Value
Launchers	This field lists each Launcher connection that is configured in the Management Console. You can set override values for each Launcher listed.
Override Configuration	When this option is enabled, you can manually enter connection information for the Launcher selected that overrides the original connection information.
Host Name	Enter the host name or IP address of where the Launcher service will run.
Status Port	Enter the status port number, or accept 7000, which is the default port. This port provides status information about the process running to the Management Console.
Control Port	Enter the control port number, or accept 7000, which is the default port. This port relays stop, pause, and resume information from the process running back to the Launcher service.

Management Console statistics

The statistical information displayed in the Management Console is refreshed periodically based on the refresh interval that you set when creating a new Launcher. Statistical information is derived directly from the process that the Launcher service is running.

The Management Console displays information for systems and HTTP listeners.

- [**System statistics**](#)
The Management Console displays summary, status, history, and configuration information about a running Launcher system.
- [**Launcher HTTP Listener summary, status, and configuration**](#)
The Launcher HTTP Listener provides two-way communication between external HTTP clients and maps in the Launcher.

System statistics

The Management Console displays summary, status, history, and configuration information about a running Launcher system.

- [**Summary statistics**](#)
- [**Status statistics**](#)
- [**Historical information**](#)
- [**Configuration information**](#)

Summary statistics

From the Management Console, statistical data is displayed on the Summary tab in the main window of the Management Console. The statistics are grouped into the following three areas by default: **Performance**, **Status**, and **Historical**.

- [**Performance**](#)
- [**Status**](#)
- [**Historical**](#)

Performance

Statistic	Description
Memory Usage	Current amount of memory usage. (Supported on Windows platforms only.)
CPU Usage	Current percent of total CPU usage. (Supported on Windows platforms only.)

Status

Statistic	Description
System Status	Status of the Launcher process (.msl system file). Options include: Starting, Running, Stopping, Stopped, and Paused.
Active Component Maps	

Active Listeners Up	Current number of component map instances running
Active Listeners Down	Number of listeners running
Active Connections	Number of active connections
Start Time	Time that the Launcher started
Success Time	Cumulative amount of time for maps, which are successful
Failure Time	Cumulative amount of time for maps that failed
Up Time	Total time that the Launcher has been running
Pending Initialization	Number of maps currently waiting to begin execution
Pending Initialization Maximum	Maximum number of maps that have waited to begin execution at any one time
Pending Resource	Number of maps currently waiting for resources, such as a shared data target
Pending Connection	Number of maps waiting to connect
Pending Total Maps	Sum of Pending Initialization, Pending Resource, and Pending Connect

Historical

Statistic	
Description	
History Successes	Number of maps that have succeeded since the Launcher started
History Failures	Number of maps that have failed since the Launcher started
History Total Maps	Total number of all maps that have been executed
History Connection Failures	Total number of connections that failed
History Deadlocks Detected	Number of map failures resulting from deadlocks
History Function Failures	Number of failures in RUN, GET, PUT, DBLOOKUP, and DBQUERY

Status statistics

From the Status tab, you can view information about active components, pending components, and adapter connections.

Active Component tab

Column	
Description	
Component	Component name
Map	Name of compiled map file (.mmc)
System	System name
State	The state of the Launcher. Options include:
	<ul style="list-style-type: none"> • getting input • validating input • building input • running map • GET/PUT adapter • ending output
Card	The card number and I/O indicator
Resource	Adapter command used for this card
	<ul style="list-style-type: none"> • Pending • Adapter connections

Pending

Column	Description
Component	Component name
Map	Name of compiled map file (.mmc)
System	System name
State	Initialization, connect, or resource pending
Card	For connect and resource pending state, which card is pending
Reason	For resource pending state, reason why card is pending
Resource Type	Type of resource or adapter alias for this card
Resource Name	Name of resource (adapter command) for this card

Adapter connections

Column	Description
Adapter	Adapter type, such as database or FTP. Default represents the global default settings.
Open	Number of connections currently open
Active	Number of open connections being used in a map
Idle	Number of open connections not in use
Pending	Number of pending connection requests

Historical information

From the Historical tab, you can view information about:

- [Map Failures](#)
- [Adapter Connections](#)
- [Map Function Failures](#)

The number of rows of data varies dynamically.

- [Map failures](#)
- [Adapter connections](#)
- [Map function failures](#)

Map failures

Column	Description
Component	Component name
Map	Name of compiled map file (.mmc)
System	Name of system containing map failure
Card	Card number and I/O indicator that caused the error
Card Error	Return code and error message from adapter
Map Error	Return code and error message from map

Adapter connections

Column	Description
Adapter	Adapter type, such as database or FTP. Default represents global default settings.
Requests	Number of connection requests
New	Number of requests that required a new connection
Reused	The number of requests that reused an existing connection
Successes	Number of successful operations (GET or PUT) on the adapter
Failures	Number of failing operations (GET or PUT) on the adapter

Map function failures

Column	Description
Component	Name of the map component where the function is contained
Function Name	Name of function that failed
Argument	Map name for RUN; adapter name for GET, PUT, DBLOOKUP, and DBQUERY
Reason	Reason for function failure

Configuration information

From the Configuration tab, you can view global configuration parameters used by the Launcher.

- [System tab](#)
- [Adapter connections tab](#)

System tab

Column	Description
Maximum Concurrent Maps	Maximum number of maps that can run at the same time
Maximum Concurrent Maps Per Watch	Maximum number of maps running at the same time for each watch
Pending Initialization High	A user-defined static amount that serves as the threshold for the number of adapter listeners and time events pending initialization. After this amount is reached, maps can no longer trigger until the Pending Initialization Low amount is reached.
Pending Initialization Low	After the Pending Initialization High amount is reached, the number of items pending must reach this amount before maps can begin triggering again.

Adapter connections tab

Column	Description
Adapter	Adapter type, such as database or FTP. Default represents global default settings.
Idle Time	The period of time after which an idle connection is expected to be disconnected
Keep Time	How long an idle connection is expected to remain valid. Do not use this setting with the FTP adapter.
Keep Minimum	The minimum number of connections allowed
Advisory Limit	The maximum number of connections, but can be exceeded if necessary
Mandatory Limit	The maximum number of connections allowed

Launcher HTTP Listener summary, status, and configuration

The Launcher HTTP Listener provides two-way communication between external HTTP clients and maps in the Launcher.

Overview

To view listener details, click `Launcher > Listeners` in the Management Console and select the HTTP Listeners that you want to monitor. You can display the HTTP Listener startup settings, watch and connection status, and configure HTTP Listener settings and logging options.

Summary page

The Summary page displays the HTTP Listener startup settings defined when you create the listener. Use the Launcher Administration utility to edit these settings.

The Summary is refreshed at the refresh interval that is configured in the `config.yaml` configuration file.

Status page

The Status page displays response totals, connection data, and information about URL watches that you can use to tune the system performance of the Launcher. Also, you can enable and disable trace, socket, and audit logging on the Status.

By default, the Status is refreshed at the Launcher refresh interval. To enable manual refresh, edit the `tx_install_dir\mgmtconsole.properties` file and set `listener.status.manual=1`.

Configuration page

In the Configuration page, you can edit the HTTP Listener settings that are not required for starting the listener. The Configuration is only refreshed when you update the HTTP Listener settings.

HTTP Port

The port that the listener uses to communicate with external clients. The listener monitors the HTTP port for incoming HTTP requests and responds to the external client through the HTTP port. The HTTP port for each listener must be unique. If you configure multiple listeners with the same HTTP port value, only one listener starts. The default HTTP port is 5017.

Launcher Port

The HTTP Listener port used in the URL of HTTP adapters in Launcher systems that are going to process requests handled by this Launcher. The default Launcher port is 5017.

Launcher Policy

The method to use to load-balance HTTP requests among Launchers when there are multiple Launchers on one listener or multiple watches on the same Launcher.

- FCFS (first come first served)
- RR (round robin)
- RND (random)

Response Timeout

Amount of time in minutes and seconds (*mm:ss*) that the HTTP Listener waits for a response from the Launcher. The default value is 90 seconds (01:30).

Launcher User

User ID that the Launcher uses to connect to the HTTP Listener.

Launcher Password

Password that authorizes the User ID for the Launcher.

Admin URL (this form)

URL to access Launcher Administration form.

Admin Page (this form)

Source file name of Launcher Administration form.

Admin User

User ID to authenticate connection to Launcher Administration.

Admin Password

The password for the **Admin User** ID.

Port Monitor Cycle Time

Length of time to listen on a socket before checking for control messages. The format is *mm:ss* (minutes:seconds), where *mm:* is optional. The default value is 45 seconds.

Important: This value affects the time it takes to stop the service.

Launcher Time Limit

Time to wait for the Launcher connection when a request is received. The format is *mm:ss* (minutes:seconds), where *mm:* is optional. The default value is 5 seconds.

Client Retry-After Time

Notifies HTTP clients of the amount of time to wait before resending a request that has not been answered by the Launcher. The default value is 45 seconds.

Authenticate Clients

Globally determines whether browser requests should be authenticated. The default is authentication disabled.

User Administration

Click User Administration to add, modify or delete users for the Launcher.

SSL Status

Indicates whether SSL is available.

SSL Authentication

Indicates whether SSL communication with HTTP clients is enabled.

SSL Secure Mode

Indicates the required level of security for communication between the HTTP Listener and HTTP clients.

None

X.509 certificates are not defined. No encryption is in effect in the TCP/IP session layer.

Unavailable

SSL encryption without NIST SP 800-131A compliance is in effect.

Available

- NIST SP 800-131A and TLS V1.2 are attempted, but the SSL client and SSL server can negotiate a less secure protocol.
- NIST SP 800-131A required
 - Communication between the Launcher and SSL clients must comply with the NIST SP 800-131A standard.
- NIST SP 800-131A and TLS V1.2 required
 - Communication between the Launcher and SSL clients must use the TLS V1.2 protocol and comply with the NIST SP 800-131A standard.

HTTP Certificate

The name in the key store of the certificate from the Certificate Signing Authority that enables SSL communication between the HTTP Listener and external HTTP clients. The key store is set in the config.yaml file in the installation directory.

Launcher Certificate

The name in the key store of the certificate that enables SSL communication between the HTTP listener and the Launcher. The key store is set in the config.yaml file in the installation directory.

Dynamic adapter tracing

Dynamic adapter tracing enables you to dynamically turn on and off adapter tracing for a map running under the Launcher. Through the configuration pane of the Management Console, you can configure adapter tracing dynamically. When you turn adapter tracing on, the result is that the map will write all the trace information to a new trace file or append the trace information to an existing file.

You do not need to enable adapter tracing in the adapter command line of your map to optimize it. If you encounter an issue with the adapter, you can dynamically turn adapter tracing on in the Management Console.

- [Using the dynamic adapter trace feature](#)
- [Enabling dynamic adapter tracing](#)
- [Configuration pane](#)
- [Output files](#)

Related reference

- [MapAdapterTraceOff](#)

Using the dynamic adapter trace feature

This feature is helpful for resolving adapter issues without having to:

- bring the Launcher down to add tracing to the adapter command lines
- having to recompile and redeploy the maps
- having to restart the Launcher

The following procedure assumes you have connected to a Launcher from the Management Console and have selected the Compound System that appears in the navigation pane.

Refer to ["Multiple Processes"](#) for additional information when using the multiple-processes feature.

To use the dynamic adapter trace feature:

- Start the Launcher.

When the Launcher starts, it will initialize all trace settings to default values as configured on the adapter command line. Tracing will be done for all watches according to the adapter command line settings.

The MapAdapterTraceOff INI setting is used to override the default tracing at the startup of the Launcher.

When the MapAdapterTraceOff INI setting is commented or 0, it indicates that the default tracing should be used at the startup of the Launcher.

When the MapAdapterTraceOff INI setting is 1, it indicates that tracing is turned off for all components at the startup of the Launcher, regardless of the command line settings.

- Enable the adapter tracing feature in the Management Console.
- Configure adapter tracing dynamically through the configuration pane.
- Modify adapter tracing configurations.

Note: When you modify the adapter tracing configurations after a Launcher has started, the changes will take affect in the next map that is run for that component.

Enabling dynamic adapter tracing

The configuration pane in the Management Console is used to configure the settings for enabling dynamic adapter tracing. This procedure assumes that the Launcher is running and there is a Launcher system (.msl) file in the deployment directory.

To enable dynamic adapter tracing

1. After highlighting a Launcher system (.msl) file, from the menu bar in the Management Console, select System.
2. Select Trace & Log from the pull-down menu.
A pane opens in which you can configure the dynamic adapter tracing specifications for each map component in each system separately.

Configuration pane

When you have enabled dynamic adapter tracing through the System menu option in the Management Console, you use the configuration pane to configure settings for a watch. For each watch, you can:

- turn off adapter tracing, which overrides the adapter command line that was defined in a map through the Map Designer
- turn on adapter tracing for all adapters including child RUN maps
- use the default tracing configurations in the adapter command line that was defined in a map through the Map Designer

Selecting Trace from the Config pull-down menu in the configuration pane will present the configuration pane elements specific for dynamic adapter tracing.

- [Configuration pane elements](#)
- [Using wildcards](#)

Configuration pane elements

The Configuration pane in the Management Console used for dynamic adapter tracing consists of the elements required to enable tracing and configure the trace specifications. The following table lists the components and provides a description of their use.

Configuration Pane Elements

Description	
Config	The Config pane contains a pull-down menu where you can select either of the following two configuration options: <ul style="list-style-type: none">• Trace The Trace configuration option indicates that you want to configure dynamic adapter tracing. When you select Trace, the trace configuration for the selected Launcher will appear.• Logging The Logging configuration option indicates that you want to configure dynamic logging.
Systems	The Systems pane contains a pull-down menu where you can select the path and system file for the Launcher process.
Components	The Components pane contains all the map components in the Launcher system, which you can configure individually. It is the list of all top-level map components running in that Launcher process for the selected system. When you select a map, only the trace settings for that selected map will appear. When you select a different map, a different set of trace settings will appear. All RUN maps associated with that component will use the same settings. Only information for a running system will be available for configuration, not for a stopped system.
Settings	The Settings pane comprises the Trace and Action panes, which are used to configure trace settings for each of the components in the Components pane.
Trace	The Trace pane contains radio buttons for the following three adapter trace setting options: <ul style="list-style-type: none">• Default The Default adapter trace setting option indicates that the Launcher will use the settings on the adapter command line for a map configured in the Map Designer or the Integration Flow Designer. The Default option is the default adapter trace setting.• ON The ON adapter trace setting option enables adapter tracing for all adapters for a map. This setting overrides any setting on the adapter command line for a map configured in the Map Designer or the Integration Flow Designer.• OFF The OFF adapter trace setting option disables adapter tracing for any adapter. This setting overrides any setting on the adapter command line for a map configured in the Map Designer or the Integration Flow Designer.
Action	The Action pane contains two sub-elements related to the output adapter trace file: Adapter trace file option Allows you to configure how you want the trace content to be written.

There are two radio buttons for the adapter trace file options:

- Create
When the Create option is selected, the map will write all the trace information to a new trace file.
- Append
When the Append option is selected, the map will write all the trace information to a new trace file or append the trace information to an existing file.

File Name

Allows you to configure the trace file name and location.

See "[Using Wildcards](#)" for information about using wildcards in your trace file name.

Apply

The Apply button is used to refresh the Launcher with the settings associated with the component.

The adapter trace configuration changes for the component will be passed to the Launcher process, and will take effect when the next map is initiated for the configured component.

Note: These dynamic adapter trace configurations are not saved anywhere.

Using wildcards

Wildcards in the trace file name can be used to reference map source events. They are specified in the configuration pane of the Management Console when using the dynamic adapter tracing feature.

How wildcards are used

- Used in the trace file name based on source events that also use wildcards.
- Can not be used if the source event does not use wildcards.
- Allow for unique instances of adapter trace files.

Output files

The output of using the dynamic adapter trace feature is a file. It contains the following sections:

- Header
- Trace results for a map instance
- Trailer

The header and trailer sections are written to the trace file before and after each map instance including RUN maps. They both contain the following information:

- map name including full path
- date and time of executed action type
- map instance count, which represents the cumulative number of times the map has been executed

Note: RUN maps will be nested within top map entries to enhance your ability to see the sequence of events.

See the "[File Name:](#)" within the configuration pane element for more detailed information about naming the adapter trace output file.

Dynamic logging

Dynamic logging allows you to configure a Launcher process for logging while the Launcher is running. You can configure the following logging entries in the Management Console:

Logging Entries

- Launcher (ES)
- Resource Manager (RM)
- Connection Manager (CM)

Each logging entry is categorized by the following severity classes and debug components listed from lowest impact to highest:

Logging Categories

- Trace
- Debug
- Info
- Warn
- Error
- Fatal

Without having to stop the Launcher, you can turn each of these logging components (**Trace**, **Debug**, **Info**, **Warn**, **Error** and **Fatal**) for each of the logging entries (**Launcher**, **Resource Manager**, and **Connection Manager**) on and off individually for a Launcher process that you select to configure.

For example, you can run the Launcher with **INFO** settings to track the status of maps. If one of the maps connecting to a database starts to fail, you can dynamically enable the setting (turn on) for the **DEBUG** and **ERROR** components under the **Connection Manager** logging entry for a Launcher process that you have selected. Now you can track what the database connection is reporting without having to stop the Launcher, configure the Launcher with different debug settings, and then restart it.

- [Using the dynamic logging feature](#)
- [Enabling dynamic logging](#)
- [Configuration pane](#)
- [Output files](#)
- [Logging messages for Trace](#)
- [Logging messages for Debug](#)
- [Logging messages for Info](#)
- [Logging messages for Warning](#)
- [Logging messages for Error](#)
- [Logging messages for Fatal](#)

Using the dynamic logging feature

This feature is helpful for resolving Launcher issues *without* having to:

- bring the Launcher down to enable the logging feature
- reconfigure the Launcher with different logging settings
- restart the Launcher

The following procedure assumes you have connected to a Launcher from the Management Console and have selected the Compound System that appears in the navigation pane.

See "[Multiple Processes](#)" for additional information when using the multiple-processes feature.

To use the dynamic logging feature

1. Start the Launcher.
 - When the Launcher starts, it will use the logging category settings configured in the **INI (config.yaml)** file under each logging entry section (**Launcher**, **Resource Manager**, and **Connection Manager**) to determine which severity levels and components to debug.
 - The following logging categories in the **INI** file will be configured to 0 to turn that logging category off or 1 to turn that logging category on:
 - LogTrace
 - LogDebug
 - LogInfo
 - LogWarning
 - LogError
 - LogFatal
2. Enable the logging feature in the Management Console.

Enabling dynamic logging

The configuration pane in the Management Console is used to configure the settings for enabling dynamic logging. This procedure assumes that the Launcher is running and there is a Launcher system file (**.msl**) in the deployment directory.

To enable dynamic logging

1. After highlighting a Launcher system (**.msl** file), from the menu bar in the Management Console, select System.
 2. Select Trace & Log from the pull-down menu.
- A pane opens in which you can configure the dynamic logging specifications for each logging category component for each logging entry.

These logging category settings are not saved anywhere. Changes you make to these logging categories in the Management Console do not update the INI file.

Logging begins recording upon starting the system.

Configuration pane

When you have enabled dynamic logging through the System menu option in the Management Console, you use the configuration pane to configure logging settings for a Launcher process.

Selecting Logging from the Config pull-down menu in the configuration pane will present the configuration pane elements specific for dynamic logging.

- [Configuration pane elements](#)

Configuration pane elements

The configuration pane in the Management Console used for dynamic logging consists of the elements required for you to specify logging and configure the logging specifications.

The following table lists the components and provides a description of their use.

Configuration Pane Elements

Description
Config The Config pane contains a pull-down menu where you can select either of the following two configuration options: <ul style="list-style-type: none">• Trace The Trace configuration option indicates that you want to configure dynamic adapter tracing.• Logging The Logging configuration option indicates that you want to configure dynamic logging. When you select Logging, the Logging configuration for the selected Launcher will appear.
Launcher The Launcher pane contains the list of severity levels and components (logging categories) for the Launcher logging entry that you can enable or disable for the logging of the Launcher process you selected.
Resource Manager The Resource Manager pane contains the list of severity levels and components (logging categories) for the Resource Manager logging entry that you can enable or disable for the logging of the Launcher process you selected.
Connection Manager The Connection Manager pane contains the list of severity levels and components (logging categories) for the Connection Manager logging entry that you can enable or disable for the logging of the Launcher process you selected.
Apply The Apply button is used to: <ul style="list-style-type: none">• trigger the Management Console to pass these logging configuration changes to the Launcher process• refresh the Launcher with the settings associated with each logging category for each logging entry As a result, the Launcher will notify the Management Console to synchronize the logging settings.
Clear All The Clear All button is used to: <ul style="list-style-type: none">• disable all the check boxes under the three logging entries: Launcher, Resource Manager, and Connection Manager The Clear All button is grayed out when there are no check boxes enabled.

Output files

The output of using the dynamic logging feature is a file. It contains the log entries. A log entry is a single line entry for each event that has been logged and is comprised of components in the following format:

```
<msgid><date/time><threadid><instance><msgtext><extra>
```

Log Entry
Component
Description

msgid unique identifier of the log entry
date/time date and time of the executed action type
threadid identifier that distinguishes each map that is running concurrently
instance instance number of a map that is running
msgtext log entry
extra area for additional information (optional)

Logging option

If you select the logging option when you have configured the Launcher to run multiple systems as a compound system in a single Launcher process or as separate Launcher processes and then run the system or systems, there are two log files that are created in the logs subdirectory of the *install_dir*. Both log files have the same name as the system (.msl) file, appended with the current date and time stamp (yyyy-mm-dd-hh-mm-ss) and the host name of the computer where the Launcher is running.

The first log file has a .log filename extension.

The second log file has a .txt filename extension.

See [Trace and Log Files Naming Conventions](#) for the specific naming conventions.

- [Launcher-created log file permissions](#)

The Launcher creates its log files with the default file permissions **rw-rw-rw-**. You can change the log file permissions by changing the LogFilePermissions setting in the **config.yaml** file.

- [Example](#)

- [Log file types](#)

- [Environmental debug \(UNIX\)](#)

Launcher-created log file permissions

The Launcher creates its log files with the default file permissions **rw-rw-rw-**. You can change the log file permissions by changing the LogFilePermissions setting in the **config.yaml** file.

The LogFilePermissions setting is specified in the **[Launcher]** section of the *install_dir\config.yaml* file:

```
; this defines the permissions used to create the
; log files for the Launcher:
; default 666 (rw-rw-rw-)
; rw-rw-r-- is 664
; rw-r--r-- is 644
LogFilePermissions=666
```

To change the log file permissions, change the value of the LogFilePermissions setting:

Value	File Permissions
666	rw-rw-rw- This is the default file permission.
664	rw-rw-r--
644	rw-r--r--

Example

This is an example of file names generated from running a system with logging enabled.

Run a system on a computer with the hostname *mycomputer*, where the system file path is *install_dir\systems\small.msl* and logging is enabled. The date is May 29, 2017 and the time is 10:31:11 AM. The following two files are generated in the logs subdirectory of the *install_dir*:

- small-2017-05-17-10-31-11_mycomputer.log
- small-2017-05-17-10-31-11_mycomputer.txt

With logging enabled, these files are generated with the current date and time stamp every time the system is started.

Log file types

Using the logging option produces files that contain information falling under the following log file types:

- [Launcher Activity Log Files](#)
 - [Debug Log Files](#)
 - [Diagnostic Log Files](#)

 - [Launcher activity log files](#)
 - [Debug log files](#)
 - [Diagnostic log files](#)
-

Launcher activity log files

The text (.txt) Launcher log file produced from the Launcher contains information about Launcher activities including summary and detail information that is useful for analysis, debugging and troubleshooting. Based on default parameters, the log file contains information about:

- Launcher configuration
- Launcher startup
- Map warnings
- Map errors

The default location for the Launcher log file is in the **logs** subdirectory of the *install_dir*. As described in an example (see [Example](#)), the file name is based on the system name and current date.

For more information, see the following documentation:

- [Trace and Log Files Naming Conventions](#) for the specific naming conventions
 - [LauncherLog](#)
-

Debug log files

The text (.txt) debug log file produced from the Launcher contains information about Launcher activities that is helpful for analysis, debugging and troubleshooting. Based on the default parameters, this file contains information about:

- Watch triggers
- Time and input events
- Error messages

The text debug log file is also generated in the logs subdirectory of the *install_dir* and generates upon startup. As described in [Logging Option](#), the file name is based on the system name and current date.

For more information, see the following documentation:

- [Trace and Log Files Naming Conventions](#) for the specific naming conventions
 - [LauncherLog](#)
-

Diagnostic log files

Additional files are created when certain events occur with the Launcher:

- If an unhandled system exception occurs in a map thread that is running, troubleshooting information for technical support purposes is written to a file named **GPFThreadId-TimeStamp.txt** on Windows and **ABORT-pid.txt** on UNIX. You can find this diagnostic log file in the installation directory of WebSphere® Transformation Extender.
- The **dtxAbort.log** file is a UNIX environment-specific log file that indicates when the Launcher, Command Server, Platform API, or Java™ API is attempting to acquire memory from the operating system but does not succeed.
The **dtxAbort.log** file gets created in **\$DTX_TMP_DIR** when the respective application is started. **\$DTX_TMP_DIR** is normally empty, which indicates that there has not been a failed attempt to get additional memory.

If a failure occurs while attempting to obtain additional memory, the message appended to the **dtxAbort.log** file will be similar to one of the following messages:

- Fatal Error: malloc() - Unable to Retrieve Additional New Memory.
 - Fatal Error: realloc() - Unable to Retrieve Additional New Memory.
- The message is prefaced with text indicating the date and time that the failure occurred.
-

Environmental debug (UNIX)

To turn on the environmental debug option for UNIX Launcher, you must set the DTX_DEBUG variable to **TRUE** before you start the Launcher (by using the **launcher.sh -start** command). The environmental debug option does not work unless this action is performed.

To set the option:

```
sh: DTX_DEBUG=TRUE
      export DTX_DEBUG
```

System and watch status in JSON format

The Launcher heartbeat file summarizes the status of Launcher systems and watches in a JSON-formatted log file that an external program can read to automatically monitor Launcher status.

The Launcher logs the following information in the heartbeat file:

- Current time in ISO8601 format
- System statistics:
 - Output equivalent to the **launcher -summary** command
 - Launcher warning, error, and fatal error counts. Informational messages about log file enablement are not counted.
- System deltas:
 - Number of successful maps, map errors, and total number of maps since the last heartbeat interval
 - Number of system warnings, errors, and fatal errors since the last heartbeat interval
- Watch statistics:
 - Watch name
 - Summary:
 - Number of instances triggered
 - Total time of all instances in milliseconds
 - Minimum time for one instance in milliseconds
 - Maximum time for one instance in milliseconds
 - Average time for one instance in milliseconds
- Delta: The change to each of the Summary values since the last heartbeat interval

Configuring the Launcher heartbeat file

Options in the **/runtime/Launcher** section of the config.yaml file enable and configure the Launcher heartbeat file:

HeartbeatTimeInterval

The interval in seconds between heartbeat files. Specifying 0 disables heartbeat monitoring.

HeartbeatFileKeepNum

The number of heartbeat files to keep before the oldest file is deleted.

The most recent heartbeat file has the Launcher log file name and the .json file extension. For example:

CompoundSystem04-11-17-05-45-42-AM_myhost.json

Older heartbeat files have a numeric index appended to the file extension. For example:

CompoundSystem04-11-17-05-45-42-AM_myhost.json.1

Heartbeat file example

The log file format is similar to the following:

```
"Time": "2017-04-11T16:05:23-0400",

```

Launcher Monitor

The Launcher Monitor provides graphical, detailed information about maps that are running in the Launcher. Using the Monitor, you can create, update, delete, and start Launcher connections for monitoring. Although you can set up more than one Launcher, you can only connect to and view one at a time.

The Launcher Monitor provides a dynamic view of watches as they run. A watch is a single map that is running. Watches are sequentially numbered starting with 1. When you start the Launcher Monitor and maps begin to run, a window for each watch appears within the Launcher Monitor window.

- [How the Monitor works](#)
- [Using the Launcher Monitor](#)
- [Configuring the Monitor display](#)
- [Snapshots](#)

How the Monitor works

The Launcher Monitor works with the Launcher by means of Transmission Control Protocol/Internet Protocol (TCP/IP). Because this set of protocols allows for communications over interconnected, dissimilar networks, the Monitor can monitor the Launcher on a Windows or UNIX system.

Interprocess communication (IPC) between the server and client requires:

- An address (or computer name)
- A port number

Using the Launcher Monitor

To use the Monitor to view Launcher processes (systems) that are running in the Launcher, a series of steps must first take place:

- One or more **.msl** files are generated and placed in the deployment directory that you specified in the Launcher Administration interface.
- The Launcher service/daemon is running.
- The Launcher is configured and a process is running in the Management Console.
- From the Launcher Monitor, you must configure the server and port number where the Launcher is running.

To open the Launcher Monitor

Select Launcher Monitor from the Start > Programs menu under **WebSphere® Transformation Extender n.n** (where **n.n** represents the version number). The Launcher Monitor window opens.

To start the Launcher Monitor

1. From the Launcher Monitor window, select Options > Select Launcher.
The Select Launcher window appears.
2. Click Add.
The Add Launcher window appears.
3. Enter a name for the Launcher and click OK.
4. Under **User**, enter the user name and password that corresponds to the server you need to connect to so that you can monitor a Launcher.
5. Under **Connection**, enter the name or IP address of the server where the Launcher is running in the **Server** field.
Note: The **Server** connection is either obtained from network configuration information or can be a TCP/IP address.
6. In the **Port** field, type the port number that you want to use or accept the default port number, which is **5016**.
The port number is always the Launcher port number (configured in the Management Console) plus **1**. The default port for the Launcher is **5015**; therefore, the default port here is **5016**. See [Default Port Settings](#) for more information about default port settings.

On a UNIX server, the default port setting can be changed in the services file located on the machine where the Launcher is installed: /etc/services.

On the z/OS® operating systems, the default port setting can optionally be changed in the TCPIP.ETC.SERVICES or in /etc/services, if installed.

7. Under **Timeout**, enter a value (in seconds) in the **Response** field. This value can range from 30 to 3600 seconds, which is the time that can elapse without an initial response from the Launcher before a timeout occurs. The default setting is 30 seconds.

8. Do one of the following activities:

- To save this Launcher connection and close the Select Launcher window, click OK.
 - To connect to the Launcher and begin monitoring, click Connect.
- The Select System window opens.

Notice that both .msl files are listed under System File Name. This is because if you have more than one .msl file running, all of the data consolidates into one compound system. This is the same functionality as the Management Console.

9. Select CompoundSystem from the list (see [Multiple Processes](#) for additional information when using the multiple-processes feature) and click OK.

10. From the Select Launcher window, click OK.

Each map that is running in the process is displayed in an individual window as a sequentially numbered watch.

Configuring the Monitor display

There are many options that you can use to configure the Monitor display according to your preferences. For example, you can use the following options to configure the Monitor display:

- Arrange the watch windows.
- Change update intervals.
- Change background and grid line colors.

Each option is described here.

Note: All procedures to configure the Monitor display begin from the Launcher Monitor window.

To arrange watch windows

You can arrange watch windows to display in the Launcher Monitor window.

Select View>Tile.

- [Watches](#)
- [Adjusting colors](#)

Watches

There are two options for configuring watches:

- Changing the interval
- Choosing specific watches

To change the interval for watch updates

You can change the interval at which the watch windows in the Monitor are updated. Options include $\frac{1}{4}$ second, $\frac{1}{2}$ second, and 1 second.

1. Select Options>Update Interval.
2. Choose the number of seconds: $\frac{1}{4}$, $\frac{1}{2}$, or 1.

To select specific watches

You can select specific watches to view as well as the watch instance limit for the maximum number of watch instances.

Select Options>Snapshot Settings.
The Watch Settings window opens.

Adjusting colors

You can choose from nine different colors for the Monitor's background, grid lines, and maps. Additionally, you can select a different color for each type of map status. For example, maps in progress, successful maps, maps with warnings, and maps with errors. All options are available from the colors menu.

Vertical Grid

There are two options for configuring the vertical grid:

- Changing the spacing
- Changing the time interval

To change vertical grid spacing

You can change the vertical grid spacing by choosing the number of pixels per second. Choices include 10, 20, and 40 pixels.

1. Select Options > One Second Equals.
2. Choose the number of pixels: **10**, **20**, or **40**.

To change the vertical grid time interval

You can change the time interval between vertical grid lines. Options include $\frac{1}{2}$ second, 1 second, and 2 seconds.

1. Select Options > Vertical Grid.
2. Choose the number of seconds: **10**, **20**, or **40**.

Snapshots

From the Launcher Monitor, you can take snapshots of a watch running as well as configure how the snapshots are taken. Snapshots capture Launcher activity. The Snapshot Viewer enables you to select the type of snapshot to capture each time an error occurs, for any error or warning, or for all map instances. See ["Snapshot Viewer"](#) for more information about the Snapshot Viewer.

- [Snapshots on demand](#)
- [Snapshot settings](#)

Snapshots on demand

You can take a snapshot at any time during processing.

To capture a snapshot

1. Click the **Snapshot!** menu command.
2. Open the Snapshot Viewer (["Snapshot Viewer"](#)) to view detailed information about the snapshot.

Snapshot settings

The snapshot settings available in the Monitor enable you to configure how snapshots are taken. For example, you can select specific watches or set a maximum limit for instances. The documentation provides a description of all the options.

To access Snapshot settings from the Launcher Monitor

Select Options > Snapshot Settings.
The Snapshot Settings window opens.

Each setting is described in the following table.

Control	Description
---------	-------------

Instance Limit	Maximum number of total watch instances to include in a single snapshot. The maximum number of watch instances to be included in one snapshot is 1000. Click the arrow buttons to change the limit.
-----------------------	---

Snapshot	Select an option to specify the type of snapshot:
-----------------	---

On Demand Only	- Snapshots are only taken when you choose the Snapshot! menu command.
-----------------------	--

On Error	- A snapshot is taken automatically whenever a map error occurs.
-----------------	--

On Warning/Error	- A snapshot is taken automatically whenever a map error or warning occurs.
-------------------------	---

Continuous	- A continuous snapshot is taken, including all watch instances specified by Instance Limit .
-------------------	--

Include these watches

Select a check box next to each watch to include in a snapshot.

Snapshot Viewer

The Snapshot Viewer enables the analysis of snapshots taken of Launcher activity from the Launcher Monitor.

- [How are Snapshots created?](#)

How are Snapshots created?

A snapshot of Launcher activity is saved from the Launcher Monitor by clicking **Snapshot!** from the menu bar.

Use the Snapshot Viewer to view and analyze the snapshots taken. Each snapshot contains information that is used to display a chart of map instances over time.

When a snapshot is created, it is written to a file with this format:

MMDD<four-digit-number>.mss

where MMDD represents the two-digit month and two-digit day on which the snapshot was created. The four-digit number begins with one and is increments by one for each snapshot for the current day.

The Snapshot file (.mss) is created in the WebSphere® Transformation Extender installation directory by default.

To view a snapshot

This procedure assumes that you have already captured a snapshot from the Launcher Monitor.

1. From the Start->Programs menu, open the Snapshot Viewer under **WebSphere Transformation Extender n.n** (where **n.n** represents the version number).
2. Select **File->Open**.
3. Navigate to the .mss file, which is located in the WebSphere Transformation Extender installation directory, and open it.

The snapshot from the Launcher Monitor appears.

Map instances are color-coded, so it is easy to understand a map's status at a glance. The default colors are:

- **Green**-Maps that completed successfully.
- **Yellow**-Maps that encountered a warning condition during execution.
- **Red**-Maps that did not complete because of an error condition.

From the Colors menu, you can change colors for map instances, background, grid, and text associated with a map instance.

To see detailed information about the map instance

Right-click over a map instance and hold to see detailed information about the execution for that instance of the map.

Command line options

You can use the command line to control the Launcher and to configure all of the options that are available through the graphical Management Console and Launcher Administration tools. The command line supports automation (for example, by using a batch file or shell script) and unattended installation (for example, in a Hypervisor environment).

In addition to the Microsoft Windows **net pause** and **net continue** commands, the Launcher supports the following commands:

Table 1. Launcher commands for
Windows and UNIX systems

Windows	UNIX
launcher.bat	launcher.sh
launcheradmin.bat	launcheradmin.sh
mgmtconsole.bat	mgmtconsole.sh

On Microsoft Windows systems, the Launcher runs as a service. On UNIX and z/OS® systems, the Launcher runs as a daemon. The command line topics use the term *Launcher service* generically to refer to either environment.

- [**Syntax conventions**](#)
The command line syntax identifies keywords and variables, required and optional choices, and default values.
- [**Running the setup script**](#)
Run the **setup** script before you invoke any command. The **setup** script sets up the paths for the binary modules and libraries to load and run properly.
- [**Net pause and net continue commands**](#)
- [**Launcher command line syntax**](#)
You can use the command line to control the Launcher and get system status. You can also set trace and logging options as well as stop, start, pause, resume, and detect the status of a system.
- [**Launcher Administration command line syntax**](#)
The Launcher Administration commands configure the Launcher service and the launchers that are created by the Launcher service. You can use Launcher Administration commands to add and remove HTTP Listeners and to configure deployment directories, users and user access rights, listening ports, and Launcher service properties.
- [**Management Console command line syntax**](#)
Use the Management Console options to create the Launcher definitions and firewall and override configurations. Each launcher definition establishes a connection to one Launcher service.
- [**HTTP Listener command line syntax**](#)
You can use the **httplsnr** command to configure, start, and stop the Launcher HTTP Listener.

Syntax conventions

The command line syntax identifies keywords and variables, required and optional choices, and default values.

Syntax item

Meaning

Normal font

Keyword

italics

Variable
underline
 Default value
`[x | y]`
 Optional choice. You can choose either option or omit the parameter.
`{ x | y }`
 Required choice. You must specify one of the options.

Additional requirements:

- If a parameter contains blanks, enclose the parameter in quotation marks (" "). For example, specify:

```
"C:\IBM\WebSphere Transformation Extender
9.0.0\latest install"
```

- On UNIX and z/OS® systems, use quotation marks (" ") to enclose multiple parameters that are delineated by semicolons (;). For example, specify:

```
launcheradmin.sh -adduser "user:admin;login:admin;pwd:admin"
```

Examples

In the following example, the -action parameter is optional. If you specify the -action parameter, you must specify either the create keyword or the append keyword:

```
[-action {create | append}]
```

Running the setup script

Run the **setup** script before you invoke any command. The **setup** script sets up the paths for the binary modules and libraries to load and run properly.

From the command prompt, enter the following command:

```
. setup
```

Net pause and net continue commands

On Windows, the Launcher is controlled by the Launcher service. *Pausing* entails pausing all Launchers. *Resuming* entails resuming or continuing any paused Launchers. The **net pause** and **net continue** commands interact with the Launcher service to pause and resume the Launcher.

The Windows **net pause** and **net continue** commands are used in the following ways:

```
net pause {ServiceName | "Service Name"}
net continue {ServiceName | "Service Name"}
```

where *ServiceName* is the case-sensitive name of the service that is being controlled, such as **WebSphere® Transformation Extender Launcher**.

To use the Net command options, the service must be started, otherwise an error message is displayed at the command prompt: **The service has not been started**. The command line will be blocked until the service pauses or resumes.

Pause and **Resume** actions can also be initiated from the Windows Computer Management console. The service must be started; otherwise the **Pause** option will not be enabled. If the service is not in a paused state, the **Continue** option is not enabled.

The following table lists the Net command-line options. Note the following rules that need to be observed when specifying service names on the command line:

- The service name must be enclosed in double quotation marks if it contains spaces.
- Service names are case-sensitive.

Command	Description
<code>net pause "WebSphere Transformation Extender Launcher"</code>	Pauses the Launcher service that is running
<code>net continue "WebSphere Transformation Extender Launcher"</code>	Resumes the paused Launcher service

The return values for the Net commands are zero for success and non-zero for failure.

Launcher command line syntax

You can use the command line to control the Launcher and get system status. You can also set trace and logging options as well as stop, start, pause, resume, and detect the status of a system.

Use the **launcher.bat** command in a Microsoft Windows environment and the **launcher.sh** command in a UNIX environment.

In a Microsoft Windows environment, the Launcher runs as a service. You use Start > Control Panel > Administrative Tools > Services to stop, start, pause, and resume the Launcher.

Supported options in a Microsoft Windows environment:

```
launcher.bat
[-status launchername {systemname | -lsnr listener_name}]
[{-summary | -history | -statusinfo | -configuration | -all} [-xml]
 launchername systemname]
[{-startsystem | -stopsystem} launchername {systemname | -all}]
[{-pausesystem | -resumesystem} launchername {systemname | -all}]
[-settrace launchername systemname systemfilename componentname
 -trace {default | on | off} [-action {create | append}] [-tracefile tracefile_name] ]
[-setlogging launchername systemname -logtype {launcher | resmgr | commgr}
 -logflags {[to | tx],[do | dx],[wo | wx],[fo | fx],[io | ix],[eo | ex]}}
 [-list launchername [{-lsnr listener_name} | {systemname [systemfilename [componentname]]}]] [-trace] [-logging]]
```

Supported options in a UNIX environment:

```
launcher.sh
[-status launchername {systemname | -lsnr listener_name}]
[{-summary | -history | -statusinfo | -configuration | -all} [-xml] launchername systemname]
[-start [adminprop.xml]]
[-stop [listenerport [hostname]]]
[-pause [listenerport [timeout [hostname]]]]
[-resume [listenerport [timeout [hostname]]]]
[{-startsystem | -stopsystem} launchername {systemname | -all}]
[{-pausesystem | -resumesystem} launchername {systemname | -all}]
[-settrace launchername systemname systemfilename componentname
 -trace {default | on | off} [-action {create | append}] [-tracefile tracefile_name] ]
[-setlogging launchername systemname -logtype {launcher | resmgr | commgr}
 -logflags {[to | tx],[do | dx],[wo | wx],[fo | fx],[io | ix],[eo | ex]}}
 [-list launchername [{-lsnr listener_name} | {systemname [systemfilename [componentname]]}]] [-trace] [-logging]]
```

- [Status command](#)

The **launcher -status** command returns the state of the specified Launcher system or Launcher HTTP Listener. The status returns as a message to the console or as a return code that you can retrieve by using the **ECHO** command.

- [Snapshot commands](#)

- [Starting, stopping, pausing, and resuming the Launcher service](#)

On UNIX systems, you can use command line options to start, stop, pause, and resume the Launcher daemon.

- [Starting, stopping, pausing, and resuming systems](#)

You can use the command line to control a specific system or all systems.

- [Trace command](#)

Use the trace command to set the trace flags for a component that is running under the specified system or compound system on the specified Launcher.

- [Logging command](#)

Use the logging command to set the logging flags for the Launcher, the Resource Manager, or the Connection Manager.

- [List system information command](#)

Use this command to list information about Launcher systems and Launcher HTTP Listeners. System information includes system files, components within each system, trace settings for each component in a system, and log settings for the system. Listener information includes ports, certificates, logging, and audit enablement.

Related reference

- [Running the setup script](#)

Status command

The **launcher -status** command returns the state of the specified Launcher system or Launcher HTTP Listener. The status returns as a message to the console or as a return code that you can retrieve by using the **ECHO** command.

Syntax

```
{launcher.bat | launcher.sh}
[-status launchername {system_name | listener_name}]
```

system_name

Returns the status of the specified Launcher system. The *system_name* keyword is optional, but you must specify either a *system_name* or a *listener_name* for the specified Launcher.

The system status is one of the following:

Table 1. Launcher system return codes and status

Return code	Status
-------------	--------

Return code	Status
0	Stopped
1	Stopping
2	Pausing
3	Paused
4	Started
5	Starting
6	Not Responding
7	Unknown Error
101	The Launcher (with the specific settings) is not started.
102	The name of the Launcher supplied on the command line is not valid.
103	The user name, password, or both user name and password are not valid.
104	The connection between this utility and the Launcher is lost when trying to retrieve the status. For example, if another user stops the Launcher.
105	The command line supplied is invalid.
106	Launcher is not in a running state.
107	The name of the system (<i>systemname</i>) supplied on the command line is invalid, or it is blank and there is no compoundsystem present under the Launcher service.
108	The Launcher raised an exception.
	Unable to connect to the Launcher.

listener_name

Returns the status of the specified Launcher HTTP Listener, as well as the start time and running time (*up time*) of a running listener. The *listener_name* keyword is optional, but you must specify either a *system_name* or a *listener_name* for the specified Launcher.

The HTTP Listener status is one of the following:

Table 2. HTTP Listener return codes and status

Return code	Status
0	Stopped
1	Starting
2	Running
3	Not responding

Example

The following example returns the HTTP Listener status as a message to the console and retrieves the status return code.

```
C:\IBM\WebSphere Transformation Extender
9.0.0>launcher -status MyServer -lsnr LSNRA
Status of the listener "LSNRA" on the server "localhost" and port "5015" is "Listener Running"
Listener "LSNRA" Start Time is 16:24:11 and Up Time is 03:53
C:\IBM\WebSphere Transformation Extender
9.0.0>echo %ERRORLEVEL%
2
```

Snapshot commands

Snapshot options are available using the Windows or UNIX command line. You can use these commands for automation with batch files.

The Snapshot options from the command line facilitate the capturing of Launcher information by enabling you to:

- Request and view the information in XML or text format.
- Redirect and store the information in a text or XML file.
- [Using Snapshot commands](#)
- [File storage commands](#)
- [Display commands](#)
- [Return codes for system-based command options](#)

Using Snapshot commands

The same Snapshot command line options are available for both Microsoft Windows and UNIX platforms. For Windows, the associated file name is **launcher.bat**; for UNIX, it is **launcher.sh**. The following table lists the Snapshot command options.

Command

Description

-summary

This option retrieves summary information about:

- Memory and CPU Usage
- System Status
- Active Component Maps
- Active Listeners Up and Down
- Active Connections

- Start, Success, Failure, and Up Time
- Pending Initialization, Resource, Connection, and Total Maps
- History Successes, Failures, Total Maps, Connection Failures, Deadlocks Detected, and Function Failures

-history

This option retrieves history information about:

- Map Failures
- Adapter Connections
- Function Failures

-statusinfo

This option retrieves status information about:

- Active Components
- Pending Components
- Adapter Connections

-configuration

This option retrieves configuration information about:

- System
- Adapter Connections

-all

This option retrieves all Launcher information; or is the equivalent to invoking the **-summary**, **-statusinfo**, **-history**, and **-configuration** commands together.

It also can be combined with any of the **-startsystem**, **-stopsystem**, **-pausesystem**, and **-resumesystem** options so that all the systems can be acted upon at one time. This is equivalent to using the **Start All**, **Stop All**, **Pause All** and **Resume All** menu items in the Management Console.

-xml

This option enables you to retrieve and display Launcher information in XML format. The XML format follows the DTD definition of the snapshot.dtd file that is shipped with the Launcher. If you specify this option, the output is printed in XML format. If this option is not specified, the output is printed in a readable text format.

When using a Snapshot command, in addition to specifying either the **launcher.sh** (UNIX) or **launcher.bat** (Windows) file, you must specify the Launcher name that was configured in the Management Console.

Related reference

- [Return codes for system-based command options](#)
-

File storage commands

On Windows platforms, the following DOS redirection command can be used to store the summary information of the **CompoundSystem** (see ["Multiple Processes"](#) for additional information when using the multiple-processes feature) running under a Launcher named "Server1" in XML format:

```
launcher.bat -summary -xml "Server1" > MySnapshot.xml
```

On UNIX platforms, the following command line can be used to store the summary information of the **CompoundSystem** running under a Launcher named "Server1" in XML format:

```
launcher.sh -summary -xml "Server1" > "/usr/home1/
snapshot.xml"
```

Display commands

On Windows platforms, the following command can be used to display all information about the **CompoundSystem** (see ["Multiple Processes"](#) for additional information when using the multiple-processes feature) running under a Launcher named "Server1" in a readable text format:

```
launcher.bat -all "Server1"
```

On UNIX platforms, the following command line can be used to display all information about the **CompoundSystem** running under a Launcher named "Server1" in a readable text format:

```
launcher.sh -all "Server1"
```

Return codes for system-based command options

For all Snapshot command line options, including **-summary**, **-statusinfo**, **-history**, and **-configuration**, and system-controlling commands, including **-startsystem**, **-stopsystem**, **-pausesystem**, and **-resumesystem**, an error message is displayed if the operation is not successful.

If the operation is successful, a code will be returned by the batch file as follows:

- 0 for Snapshot command line options
- 1 for system-controlling commands

Code	Description
101	The specific Launcher is not started.
102	The name Launcher supplied on the command line is not valid.
103	The user name and password are not valid.
104	The connection between this utility and the Launcher is lost during the attempt to retrieve summary information. For example, this might happen if trying to find the summary information and another user stops the Launcher.
105	Command is invalid.
106	Launcher is not in a running state.
107	The name of the system (<code>systemname</code>) supplied on the command line is invalid, or it is blank and there is no compoundsystem present under the Launcher service.
108	The Launcher raised an exception.
109	Unable to connect to the Launcher.
110	The control code and the system state are not compatible. Note: This code is valid only for system-controlling commands.
111	The user does not have the proper user rights to control the system. Note: This code is valid only for system-controlling commands.

Starting, stopping, pausing, and resuming the Launcher service

On UNIX systems, you can use command line options to start, stop, pause, and resume the Launcher daemon.

```
launcher.sh
[-start [adminprofile]]
[-stop [listenerport [hostname]]]
[-pause | -resume [listenerport [timeout [hostname]]]]

-start [adminprofile.xml]
Starts the Launcher daemon with the properties that are configured in the adminprofile file. If the adminprofile file is not specified or fails to import, starts the Launcher daemon with the properties that are configured in the launcheradmin.bin properties file. If the launcheradmin.bin file does not exist, starts the Launcher daemon with the default properties.

In a Microsoft Windows environment, you specify the name of the properties file on the ADMINPROPFILE setting of the [LAUNCHER] section in the JavaServices.ini file. The properties file that is configured on the ADMINPROPFILE setting overrides the LauncherAdmin.bin file. If the LauncherAdmin.bin file does not exist, the Launcher daemon uses default settings on startup.

Start only one Launcher daemon per Launcher installation.

-stop [listenerport [hostname]]
Stops the Launcher daemon that is listening on the specified listener port and host system. If the listener port and host system are not specified, stops the Launcher daemon that is listening on the default listener port (port 5015).

The -stop command has a default timeout interval of 120 seconds. During the timeout interval, the Launcher daemon is blocked by the command line until the Launcher daemon stops.

-pause [listenerport [timeout [hostname]]]
Pauses the Launcher daemon that is running on the specified listener port and host name, if specified. Otherwise, pauses the Launcher service that is listening on the default listener port (port 5015).

-resume [listenerport [timeout [hostname]]]
Resumes the Launcher daemon that is paused on the specified listener port and host name, if specified. Otherwise, resumes the Launcher service that is listening on the default listener port (port 5015).

timeout
A value from 30 to 3600 seconds that specifies the time interval that can elapse without an initial response from the Launcher service before a failure is reported. During the time interval, the Launcher daemon is blocked by the command line unless the Launcher daemon pauses or resumes. When the timeout interval expires, the Launcher daemon returns to the command prompt.

The default timeout value is zero. A timeout value of zero indicates that the Launcher daemon is blocked by the command line for an infinite amount of time until the Launcher daemon pauses or resumes.
```

Based on the following command example, if the Launcher daemon pauses before 60 seconds, TRUE or SUCCESS is returned. Otherwise launcher.sh exits, returning FALSE.

```
. setup
launcher.sh -pause 3000 60
```

Related tasks

- [Starting and stopping the Launcher](#)
- [Controlling systems](#)

Starting, stopping, pausing, and resuming systems

You can use the command line to control a specific system or all systems.

```
{launcher.bat | launcher.sh}
[{-startsystem | -stopsystem} launchername {systemname | -all}]
[{-pausesystem | -resumesystem} launchername {systemname | -all}]
```

{-startsystem | -stopsystem} launchername {systemname | -all}

Starts or stops a specific system or all of the systems that are on the specified Launcher.

{-pausesystem | -resumesystem} launchername {systemname | -all}

Pauses or resumes a specific system or all of the systems that are on the specified Launcher.

Trace command

Use the trace command to set the trace flags for a component that is running under the specified system or compound system on the specified Launcher.

```
{launcher.bat | launcher.sh}
[-settrace launchername systemname systemfilename componentname
 -trace {default | on | off} [-action {create | append}] [-tracefile tracefile_name] ]
```

-settrace launchername

The name of the Launcher that is defined in the mgmtconsole.bin file. The *launchername* variable identifies the host name, port, user name, and password of a particular Launcher definition.

systemname

The name of the system or group of systems running under one Launcher process. The *systemname* is defined with the Launcher Administration tool.

systemfilename

The name of an individual system file (.msl) that is running under the specified system and Launcher.

componentname

The name of an individual map component in the system file that is running on the specified system and Launcher.

-trace

Specifies one the following trace options:

default

Use the settings that are configured on the adapter command line in the map. This is the default option.

on

Turn on adapter tracing for all adapters, including child RUN maps.

off

Turn off adapter tracing. This option overrides the option that is defined in the map.

-action

Specifies the action to take on the trace file:

create

Write all trace information to a new trace file.

append

Append all trace information to an existing file, or create a new trace file if none exists.

-tracefile tracefile_name

Specifies the name and path to a trace file.

Related reference

- [Syntax conventions](#)

Logging command

Use the logging command to set the logging flags for the Launcher, the Resource Manager, or the Connection Manager.

```
{launcher.bat | launcher.sh}
[-setlogging launchername systemname -logtype {launcher | resmgr | conmgr}
 -logoptions {[to | tx],[do | dx],[wo | wx],[fo | fx],[io | ix],[eo | ex]} ]
```

-setlogging launchername

The name of the Launcher that is defined in the mgmtconsole.bin file. The *launchername* variable identifies the host name, port, user name, and password of a particular Launcher definition.

systemname

The name of the system or group of systems running under one Launcher process. The *systemname* is defined with the Launcher Administration tools.

-logtype

Enables logging for one of the following resources:

launcher

The logging options apply to the Launcher.

resmgr
The logging options apply to the Resource Manager.

conmgr
The logging options apply to the Connection Manager.

-logoptions
Specifies the logging options to use. Multiple options must be delimited by commas.

to	Log trace information.
tx	Do not log trace information. This is the default.
do	Log debugging information.
dx	Do not log debugging information. This is the default.
fo	Log fatal error messages.
fx	Do not log fatal error messages. This is the default.
eo	Log error messages.
ex	Do not log error messages. This is the default.
io	Log informational messages.
ix	Do not log informational messages. This is the default.
wo	Log warning messages.
wx	Do not log warning messages. This is the default.

- [Syntax conventions](#)

List system information command

Use this command to list information about Launcher systems and Launcher HTTP Listeners. System information includes system files, components within each system, trace settings for each component in a system, and log settings for the system. Listener information includes ports, certificates, logging, and audit enablement.

```
{launcher.bat | launcher.sh}
[-list launchername [[-lsnr listener_name] | [systemname [systemfilename [componentname]]]] [-trace] [-logging]]
-list launchername
    Lists all the systems, the system files in each system, and the components in each system file. launchername is the Launcher that is defined in the mgmtconsole.bin file. The launchername variable identifies the host name, port, user name, and password of a particular Launcher definition.
-systemname
    Lists the system files in the specified system and the components in each of the system files. The systemname is the name of the system or group of systems that is running under one Launcher process. The systemname is defined with the Launcher Administration tools. The systemname is optional, and is mutually exclusive with the -lsnr option.
-systemfilename
    Lists the components in the specified system file. The systemfilename is the name of an individual system file (.msl) that is running under the specified system and Launcher.
-lsnr listener_name
    Lists the ports, certificates, logging level, and audit enablement of the specified HTTP listener. An HTTP Listener is defined with the Launcher Administration. The -lsnr listener_name is optional, and is mutually exclusive with the systemname option.
-trace
    Lists the trace settings for the specified component.
-logging
    Lists the logging settings for the Launcher, Resource Manager, and Connection Manager for the system, if specified. Otherwise, lists the logging settings for all systems. The systemfilename and componentname are not required.
```

- [Syntax conventions](#)

Launcher Administration command line syntax

The Launcher Administration commands configure the Launcher service and the launchers that are created by the Launcher service. You can use Launcher Administration commands to add and remove HTTP Listeners and to configure deployment directories, users and user access rights, listening ports, and Launcher service properties.

Use the Launcher **launcheradmin.bat** command in a Microsoft Windows environment and the **launcheradmin.sh** command in a UNIX environment.

On UNIX and z/OS® systems, use quotation marks (" ") to enclose multiple parameters that are delineated by semicolons (;). For example, specify **launcheradmin.sh -adduser "user:admin;login:admin;pwd:admin"**

To display the Launcher Administration graphical interface, invoke the command without any parameters. To display help for the command line options, invoke the command with the **-help** option.

```
{launcheradmin.bat | launcheradmin.sh}
[-help]
[-list [general | access | deploydirs | advanced | options | all]]
[-manual | -auto]
[-single | -separate]
[-lport listening_port]
[-prange startport:endport]
[-mrc resource_config_file]
[-ini ini_file_path]
[-status]
[-firewall {enable | disable}]
[-fsport server_port]
[-fcport client_port]
[-restart {enable | disable}]
[-retry retry_number]
[-rtimeout minutes]
[addlsnr name:listener_name[:mode:{enabled | disabled}][;httpport:port][;lnchport:port]
 [;httpcert:certificate][;lnchcert:certificate][;loglevel:{none | standard | verbose}]
 [;audit:{enabled | disabled}][
[-remlsnr name:listener_name]
[addprop property_name:property_value [:property_name:property_value; ...]]
[-delprop property_name[:property_name;... ] ]
[-deluser user:user_name;login:login_name;pwd:password[,access:{[gss|rss],[gpr|rpr],[gm|rm]}]
[-deluser user_name ]
[-addir | -raddir deployment_directory]
[-addir deployment_directory -asf system_file
 [-pd {[ini:ini_file];[rm:{local | global}];[mrc:resource_config_file]}}
 [-pf {[name:name];[desc:description];[ini:ini_file];[rm:{local | global}];[mrc:mrcfile]};[as:{yes | no}]]]
[-addir deployment_directory -dsf system_file[;system_file;...]]
[-addir deployment_directory -sys system_file {-af | -df} file1[,file2;...]
[-import properties_file]
[-export properties_file]
```

- [List the configured administration options](#)

The Launcher Administration **-list** command displays the options that are configured in the launcheradmin.bin file. You can display all configured options or a subset of the options. The subsets group the options according to the tabs where the options are configured in the graphical Launcher Administration interface.

- [General options](#)

The General options control how systems start and run, the ports and the configuration files that are used by the Launcher service, and the display of the Launcher service status. These options correspond to the options that you configure on the General tab of the graphical Launcher Administration interface.

- [Access options](#)

The Access options add, delete, or edit the permissions of Launcher users. These options correspond to the options that you configure on the Access tab of the graphical Launcher Administration interface.

- [Deployment directories options](#)

The deployment directories options add, edit, and remove directories from the list of deployment directories, add systems to the list of systems, and configure directory and file properties. These options correspond to the options that you configure on the Deployment Directories tab of the graphical Launcher Administration interface.

- [Advanced options](#)

The Advanced options specify system properties, such as java.rmi.server.hostname, that are to be added or removed from the list of properties that are initialized during Launcher service startup. These options correspond to the options that you configure on the Advanced tab of the graphical Launcher Administration interface.

- [HTTP Listener options](#)

Options control automatic restarts when the Launcher fails, and whether clients connect to the Launcher service through a firewall. You also add and remove HTTP Listeners by using Options. These options correspond to the options that you configure on the Options page of the graphical Launcher Administration interface.

- [HTTP Listener startup configuration](#)

An HTTP Listener routes HTTP requests from external clients to maps in the Launcher and returns a response to the external client. Use the Launcher Administration utility Options page and select Listeners to add, remove, and update HTTP Listeners.

- [Import and export properties options](#)

The **-import** option imports properties from an XML file and updates the launcheradmin.bin file. The **-export** option creates an XML properties file by exporting all of the launcheradmin.bin file properties.

List the configured administration options

The Launcher Administration **-list** command displays the options that are configured in the launcheradmin.bin file. You can display all configured options or a subset of the options. The subsets group the options according to the tabs where the options are configured in the graphical Launcher Administration interface.

```
{launcheradmin.bat | launcheradmin.sh}
[-list [general | access | deploydirs | advanced | options | all]]
```

-list

Lists the specified options that are configured in the launcheradmin.bin file. If you invoke **-list** without specifying any additional options, it is equivalent to specifying **-list all**.

```
general          Lists only the options that are configured on the General tab of the graphical Launcher Administration interface.  
access           Lists only the options that are configured on the Access tab of the graphical Launcher Administration interface.  
deploydirs       Lists only the options that are configured on the Deployment Directories tab of the graphical Launcher Administration interface.  
advanced         Lists only the options that are configured on the Advanced tab of the graphical Launcher Administration interface.  
options          Lists only the options that are configured on the Options of the graphical Launcher Administration interface.  
all              Lists all of the options that are configured on the all tabs of the graphical Launcher Administration interface.
```

General options

The General options control how systems start and run, the ports and the configuration files that are used by the Launcher service, and the display of the Launcher service status. These options correspond to the options that you configure on the General tab of the graphical Launcher Administration interface.

```
{launcheradmin.bat | launcheradmin.sh}  
[-manual | -auto]  
[-single | -separate]  
[-lport listening_port]  
[-prange startport:endport]  
[-mrc resource_config_file ]  
[-ini ini_file_path]  
[-status]  
  
-manual          Specifies that manual startup of systems is required.  
-auto            Specifies that systems and compound systems start automatically as part of the Launcher service startup.  
-single          Specifies that all systems and compound systems are to run under one Launcher process.  
-separate        Specifies that each system and compound system is to run in a separate process.  
-lport listening_port  
    Specifies a listening port on which the Launcher service listens for client connection requests from the Management Console and the Launcher Administration graphical and command line tools. When it listens for the Launcher Monitor, the Launcher service adds 1 to the value of the listening port that you specify. For example, the default listening port is 5015. The Launcher service adds 1 to the value and listens for the Launcher Monitor on port 5016.  
-prange startport:endport  
    Specifies the range of ports to be used by the launcher processes that are started by the Launcher service. Because the Status, Control and Monitor ports are included in this range, the minimum range is three ports.  
-mrc resource_config_file  
    Specifies the name of the resource configuration file that is used by the Launcher. The resource configuration file resolves the resource aliases that are used in maps.  
-ini ini_file_path  
    Specifies the full path to the Launcher initialization file. If the path contains spaces, enclose the path in quotation marks (""). By default, the initialization file is the config.yaml file in the installation directory.  
-status          Specifies the status of the Launcher service. The status is either Running or Stopped. When the Launcher service is stopped, any options that you set are saved in the launcheradmin.bin file and used the next time the Launcher service starts. When the Launcher service is running, the options that you set dynamically update the settings of the Launcher service. If the Launcher service is running and you attempt to set options that cannot be updated dynamically, the command line returns an error.
```

Access options

The Access options add, delete, or edit the permissions of Launcher users. These options correspond to the options that you configure on the Access tab of the graphical Launcher Administration interface.

```
{launcheradmin.bat | launcheradmin.sh}  
[-adduser user:user_name;login:login_name;pwd:password [:access:{[gss|rss],[gpr|rpr],[gm|rm]}]}  
[-deluser user_name]
```

On UNIX and z/OS® systems, use quotation marks (" ") to enclose multiple parameters that are delineated by semicolons (;).

-adduser user:*user_name*
 Adds the specified user. If the user already exists, updates the user configuration with the specified options.

login:*login_name*
 Specifies the login name for the user. This keyword is required to add a new user and optional to edit an existing user configuration.

pwd:*password*
 Specifies the password for the user. This keyword is required to add a new user and optional to edit an existing user configuration.

gss|rss
 Grants (gss) or revokes (rss) permission for the user to start and stop the Launcher. By default, permission is revoked.

gpr|rpr
 Grants (gpr) or revokes (rpr) permission for the user to pause and resume the Launcher. By default, permission is revoked.

gm|rm
 Grants (gm) or revokes (rm) permission for the user to monitor the Launcher. By default, permission is revoked.

-deluser *user_name*
 Deletes the specified user.

- [Syntax conventions](#)

Deployment directories options

The deployment directories options add, edit, and remove directories from the list of deployment directories, add systems to the list of systems, and configure directory and file properties. These options correspond to the options that you configure on the Deployment Directories tab of the graphical Launcher Administration interface.

```
{launcheradmin.bat | launcheradmin.sh}
[-addir | -rddir deployment_directory]
[-eddir deployment_directory -ASF system_file
 [-pd {[ini:ini_file];[rm:{local | global}];[mrc:resource_config_file]}}
 [-pf {[name:name];[desc:description];[ini:ini_file];[rm:{local | global}];
 [mrc:mrcfile];[as:{yes | no}]}}
 [-eddir deployment_directory -DSF system_file[;system_file;...]]
 [-eddir deployment_directory -SYS system_file {-af | -df } file1[;file2;...]
```

On UNIX and z/OS® systems, use quotation marks (" ") to enclose multiple parameters that are delineated by semicolons (;).

-addir *deployment_directory*
 Adds the specified directory to the list of deployment directories.

-rddir *deployment_directory*
 Removes the specified directory from the list of deployment directories.

-eddir *deployment_directory*
 Edits the specified deployment directory.

-ASF *system_file*
 Adds the specified system file to the list of system files that should be launched in a separate launcher process. The system file is part of the directory specified by the -eddir keyword.

-pd
 Configures the properties of the directory that is specified by the -eddir keyword. Separate each keyword:value pair with a semicolon (;).

ini:*ini_file*
 Specifies the path to the initialization file. By default, it is the initialization file that is specified in the General options by the **-ini ini_file_path** option.

rm:{local | global}
 Specifies whether the resource manager is local or global. By default, the resource manager is local.

mrc:*resource_config_file*
 Specifies the path to the resource configuration file. By default, the resource configuration file path is blank.

-pf
 Configures the properties of the specified system file. Separate each keyword:value pair with a semicolon (;).

name:*name*
 Specifies the name of the system file.

desc:*description*
 A brief description of the system file.

ini:*ini_file*
 Specifies the path to the initialization file. By default, it is the initialization file that is specified in the General options by the **-ini ini_file_path** option.

rm:{local | global}
 Specifies whether the resource manager is local or global. The default value is local.

mrc:*mrcfile*
 Specifies the path to the resource configuration file. By default, it is blank.

as:{yes | no}
 Specifies whether (yes) or not (no) the system is to start automatically. The default value is no.

-DSF *system_file*[;*system_file*;...]
 Specifies one or more system files to be deleted. Separate multiple system file names with a semicolon (;).

-SYS *system_file*
 Specifies the system file to which files are added or from which files are deleted. A system file can launch multiple .msl files.

```

-af file1[file2;...]
    Specifies the full path to one or more .msl files that are to be added to system file and launched as part of the launcher process.
-df file1[file2;...]
    Specifies the full path to one or more .msl files that are to be deleted from the system file.

```

- [Syntax conventions](#)

Advanced options

The Advanced options specify system properties, such as java.rmi.server.hostname, that are to be added or removed from the list of properties that are initialized during Launcher service startup. These options correspond to the options that you configure on the Advanced tab of the graphical Launcher Administration interface.

```
{launcheradmin.bat | launcheradmin.sh}
[-addprop property_name:property_value [property_name:property_value; ...]]
[-delprop property_name[;property_name;... ]]
```

On UNIX and z/OS® systems, use quotation marks (" ") to enclose multiple parameters that are delineated by semicolons (;).

```
-addprop property_name:property_value
    Specifies the name and the value of the property that is to be added. If the property exists, it is updated. Otherwise, the property is added.
-delprop property_name
    Specifies the name and the value of the property that is to be deleted. If the property does not exist, the command line returns an error.
```

HTTP Listener options

Options control automatic restarts when the Launcher fails, and whether clients connect to the Launcher service through a firewall. You also add and remove HTTP Listeners by using Options. These options correspond to the options that you configure on the Options page of the graphical Launcher Administration interface.

```
{launcheradmin.bat | launcheradmin.sh}
[-firewall {enable | disable}]
[-fsport server_port]
[-fcport client_port]
[-restart {enable | disable}]
[-rretry retry_attempts]
[-rrtimeout minutes]
[-addlsnr name:listener_name[;mode:{enabled | disabled}][;httpport:port][;lnchport:port]
[;httpcert:certificate][;lnchcert:certificate][;loglevel:{none | standard | verbose}]
[;audit:{enabled | disabled}]
[-remlsnr name:listener_name]

-firewall {enable | disable}
    Specifies whether to enable a firewall configuration. In a firewall environment, clients like the Management Console use a designated server port to connect to the Launcher service. The Launcher service opens up a listening port to establish the initial connection. All the client requests for service are exported to the server port and all services are provided through this port. By default, the firewall is disabled.
-fsport server_port
    Specifies the server-port value of the firewall-specific server port that is to be used by the Launcher service.
-fcport client_port
    Specifies the client-port value of the firewall-specific client port that is to be used by the Launcher service.
-restart {enable | disable}
    Enables or disables automatic restart when the Launcher fails. Restart is enabled by default.
    This option is valid only on distributed platforms. It is not supported on USS.
-rretry retry_attempts
    Specifies how many times the Launcher is to attempt to restart after a failure. The default value is two restart attempts. If the specified number of restart attempts has not occurred when the time specified by -rrtimeout elapses, the Launcher continues to retry until it reaches the specified number of attempts.
-rrtimeout minutes
    Specifies how long, in minutes, the Launcher is to attempt to restart after a failure. The default value is 10 minutes. There are five minutes between each restart attempt.
-addlsnr name:listener_name
    Specifies the name of the HTTP Listener to add or edit. If the specified listener does not exist, -addlsnr creates it and sets the specified properties. If the listener exists, -addlsnr edits the specified properties:
        mode:{enabled | disabled}
            Specifies whether the HTTP Listener starts when the Launcher starts. By default, the listener is disabled and does not start with the Launcher.
        httpport:port
            Specifies the port where the client posts an HTTP request. The default port number is 5017.
        lnchport:port
            Specifies the HTTP Listener port that connects to the Launcher to trigger a map. The default port number is 5018.
        httpcert:certificate
            Specifies the name in the key store of the certificate from the Certificate Signing Authority, used to for secure communication with clients.
```

```

Inchcert:certificate
    Specifies the name in the key store of the certificate that enables secure communication with maps. The key store is set in the config.yaml file in the
    installation directory.

loglevel:{none | standard | verbose}
    Specifies the trace setting for the HTTP Listener. By default, the listener is not traced (none).

audit:{enabled | disabled}
    Enables or disables auditing of HTTP Listener client requests and connections. Auditing is disabled by default.

-remlsnr name:listener_name
    Deletes the specified HTTP Listener.

```

HTTP Listener startup configuration

An HTTP Listener routes HTTP requests from external clients to maps in the Launcher and returns a response to the external client. Use the Launcher Administration utility Options page to add, remove, and update HTTP Listeners.

HTTP Listener settings

Name

A unique name of up to 25 characters to represent a listener.

Mode

When enabled, the listener starts automatically when the Launcher starts. By default, the listener is disabled.

HTTP port

The port that the listener uses to communicate with external clients. The listener monitors the HTTP port for incoming HTTP requests and responds to the external client through the HTTP port. Each listener must use a unique HTTP port. If you configure multiple listeners to use the same HTTP port, only one listener starts when the Launcher starts. The default HTTP port is 5017.

Launcher port

The port that the listener uses to communicate with the Launcher. Each listener must use a unique Launcher port. If you configure multiple listeners to use the same Launcher port, only one listener starts when the Launcher starts. The default Launcher port is 5018.

HTTP certificate

Specifies the server certificate used for SSL communication with external HTTP clients on the client port. If you omit it, SSL communication between the HTTP Listener and external HTTP clients is disabled.

Launcher certificate

Specifies the server certificate used for SSL communication with HTTP adapters on the Launcher port. If you omit it, SSL communication between the HTTP Listener and maps is disabled.

Log level

The trace setting for the HTTP Listener. The Launcher creates a unique trace file name by appending the current date, timestamp, and computer host name to the HTTP Listener name (for example, lsnr_a_socket07-06-02-11-14-PM_myhostname.log). Logs are created in the installation directory on Windows systems and in the \bin directory on UNIX systems.

None

Tracing is not enabled for the HTTP Listener. This is the default setting.

Standard

Logs the HTTP Listener activity. The log file name is *listenername_timestamp_hostname.log*.

Verbose

Logs the HTTP Listener activity and socket activity. The log file name is *listenername_socket_timestamp_hostname.log*.

Audit

Enables or disables an audit log of Transformation Extender map executions and each adapter connection and external client connection to the listener. The audit log is in XML format that can be queried with XSLT transformations. The audit log schema is LHL-Audit.xsd, installed in the Transformation Extender installation directory on Windows systems or the /bin directory on UNIX systems. Auditing is disabled by default. There is one audit log per listener.

Import and export properties options

The **-import** option imports properties from an XML file and updates the launcheradmin.bin file. The **-export** option creates an XML properties file by exporting all of the launcheradmin.bin file properties.

```
{launcheradmin.bat | launcheradmin.sh}
[-import properties_file]
[-export properties_file]
```

-import properties_file

Specifies an XML file that contains properties to be added to the launcheradmin.bin file. If the launcheradmin.bin file exists, the existing properties are updated and saved. If the launcheradmin.bin file does not exist, a new launcheradmin.bin file is created with the properties from the XML file.

If the Launcher service is running, it is updated with the information from the XML file. If the Launcher service is running and you attempt to set options that cannot be updated dynamically, the command line returns an error.

The following properties cannot be updated dynamically:

- Automatic startup
- Separate launcher processes
- Listening ports
- Port Range
- Remove user
- Advanced options
- Firewall options

-export *properties_file*

Creates an XML properties file that is compliant with the LauncherAdmin.xsd schema file. You can create multiple customized properties files to use in different environments.

Management Console command line syntax

Use the Management Console options to create the Launcher definitions and firewall and override configurations. Each launcher definition establishes a connection to one Launcher service.

Use the mgmtconsole.bat command in a Microsoft Windows environment and the mgmtconsole.sh command in a UNIX® environment.

To display the Management Console graphical interface, invoke the command without any parameters. To display help for the command line options, invoke the command with the -help option.

```
{mgmtconsole.bat | mgmtconsole.sh}
[-help]
[-list [launchers | options | all]]
[-add name:launcher_name;host:host_name;port:port;login:login_name;password:pwd;interval:refresh_interval]
[-delete launcher_name]
[-override name:launcher_name;oc:{enable | disable};host:host_name;sp:status_port;
 cp:control_port]
[-firewall fc:{enable | disable};fp:firewall_port]
[-import properties_file]
[-export properties_file]

-list [launchers | options | all]
    Displays the specified options that are configured in the mgmtconsole.bin file. If you invoke -list without any other options, it is equivalent to the -list all command.

-launchers
    Displays the following Launcher information that is configured in the mgmtconsole.bin file:
        • Launcher name
        • Host name
        • Port
        • Refresh interval
        • Login and password

-options
    Displays the Override Configuration and Firewall options that are configured in the mgmtconsole.bin file.

-all
    Displays all of the Launcher information that is configured in the mgmtconsole.bin file.

-add
    Adds the specified Launcher definition to the mgmtconsole.bin file. If the Launcher definition already exists, updates the definition.

        name:launcher_name
            Specifies the name of the Launcher service that is to be added.
        host:host_name
            Specifies the Launcher service host name or IP address that is to be added to the mgmtconsole.bin file. The IP address can be in either IPv4 format or IPv6 format.
        login:login_name
            Specifies the login name for the Launcher service to be added mgmtconsole.bin file. The login name is the name that the Management Console uses to connect to the Launcher service.
        port:port
            Specifies the port on which the Launcher service is to listen. The default port is 5015.
        refresh:refresh_interval
            Specifies the time interval, in seconds, that is used to refresh the system statistics that are displayed by the Management Console. The default refresh interval is five seconds.

-delete launcher_name
    Deletes the specified Launcher from the list of Launcher definitions in mgmtconsole.bin.

-override
    Overrides the Launcher service that is defined in the Management Console and enables a direct connection to the specified Launcher.

        name:launcher_name
            Specifies the name of the Launcher service that is to be overridden.
        oc:{enable | disable}
            Enables or disables the override configuration for the launcher definition.
        host:host_name
            Specifies the IP address or host name of the computer where the Launcher is running. The default host name is localhost.
        cp:control_port
```

-firewall fc:{enable | disable};fp:*firewall_port*
 Enables or disables a firewall configuration for the Management Console and specifies a client port to be used by a Management Console that is behind the firewall.
 -import *properties_file*
 Specifies an XML file that contains properties to be imported to the mgmtconsole.bin file. If the mgmtconsole.bin file exists, the existing properties are updated and saved. If the mgmtconsole.bin file does not exist, a new mgmtconsole.bin file is created with the properties from the XML file.
 -export *properties_file*
 Creates an XML properties file that is compliant with the MgmtConsole.xsd schema file. You can create multiple properties files to use in different environments.

HTTP Listener command line syntax

You can use the **httplsnr** command to configure, start, and stop the Launcher HTTP Listener.

```

httplsnr
[[-?]{config_file {-view | -stop} | {config_file {-edit | -start}
  [-clntport HTTP_port_number]
  [-lnchport Launcher_port_number]
  [-clntcert client_request_certificate]
  [-lnchcert HTTP_adapter_request_certificate]
  [-lpolicy {RR | FCFS | RND}]
  [-authclients {enable | disable}]
  [-adminuser username]
  [-adminpswd password]
  [-adduser username%path%password]
  [-deluser username%path]
  [-trace file_name | -traceoff]
  [-verbose file_name | -verboseoff]
  [-audit file_name | -auditoff]
  [-noprompt]})]

httplsnr
  When invoked without parameters, displays the list of httplsnr command options.

? 
  The httplsnr ? command displays the list of monitoring, auditing, and tracing commands that correspond to the HTTP Listener Status controls that are available from the Management Console or the http://Launcher_host_address:http_port/admin/status URL.

config_file
  The unique name of the configuration file used to start and stop an HTTP Listener.

-view
  Displays the settings in the specified configuration file.

-stop
  Stops the HTTP Listener specified by the configuration file.

-edit
  Sets or overrides the specified settings in the configuration file.

-start
  Starts the HTTP Listener specified by the configuration file. If the configuration file exists, the -start option saves or edits the options that are specified on the command line. If the configuration file does not exist, the -start option creates the file and saves the specified options in it.

-clntport
  Specifies the HTTP port number for communicating with the client, and saves it in the configuration file.

-lnchport
  Specifies the port number for communicating with the Launcher, and saves it in the configuration file.

-clntcert
  Specifies the server certificate used for SSL communication with HTTP clients on the client port. The -clntcert is optional. If you omit it, SSL communication with HTTP clients is disabled.

-lnchcert
  Specifies the server certificate used for SSL communication with HTTP adapters on the Launcher port. The -lnchcert is optional. If you omit it, SSL communication with HTTP clients is disabled.

-lpolicy {RR | FCFS | RND}
  Specifies how to load-balance HTTP requests among Launchers, and saves the load-balancing method in the configuration file. Load-balancing is in effect when there are multiple Launchers on one listener or multiple watches on the same Launcher.

  RR
    Round robin
  FCFS
    First come, first served
  RND
    Random

```

-authclients {enable | disable}
 Specifies whether browser requests should be authenticated, and saves it in the configuration file. By default, authentication is disabled.

-adminuser *username*
 Specifies the user ID to authenticate the connection to Launcher Administration, and saves it in the configuration file. The user ID is a maximum of 31 bytes.

-adminpswd *password*
 Specifies the password for the adminuser, and saves it in the configuration file. The password is a maximum of 31 bytes.

-adduser *username%path%password*
 Specifies the name, path, and password of a new Launcher user to add to the configuration file. The values are delimited by the percentage symbol (%).

username
 The ID that the Launcher uses to connect to the HTTP listener. The user name is a maximum of 31 alphabetic or numeric characters. A user name can have more than one path, and each *username%path* combination represents a unique Launcher user.

path
 The URI where the Launcher user account is to be created. The path is a maximum of 127 bytes.

password
 The password for the Launcher user ID. The password is a maximum of 31 alphabetic or numeric characters.

-deluser *username%path*
 Specifies the name and path of a Launcher user to remove from the configuration file. The values are delimited by the percentage symbol (%). The name and password are a maximum of 31 bytes.

-traceoff
 Specifies the HTTP Listener trace file name and enables tracing, or disables HTTP Listener tracing.

-verbose *file_name*
-verboseoff
 Specifies the HTTP Listener log file name and enables logging of HTTP Listener socket activity, or disables logging of HTTP Listener socket activity.

-audit *file_name*
-auditoff
 Specifies the HTTP Listener audit file name and enables auditing of HTTP client requests and connections, or disables auditing of HTTP client requests and connections.

-noprompt
 Runs the **httpsnr** command without returning any output to the console.

Multiple processes

The WebSphere® Transformation Extender Launcher has a multiple-processes feature.

This feature enables the Launcher to run multiple Launcher processes, each containing one or more systems (.msl files), within a single installation. It will run each system or group of systems in a separate Launcher process allowing you to add, remove and modify a Launcher process without affecting other running Launcher processes. Running the Launcher in separate Launcher processes also offers a more scalable and robust run-time environment. The WebSphere Transformation Extender Launcher can be configured to run using the **CompoundSystem** approach (all systems run in a single Launcher process), or to run each system (.msl file) or group of systems in multiple Launcher processes.

The documentation describes the different types of configurations available for running multiple processes within a single installation and how each configuration type affects system processing.

The WebSphere Transformation Extender Launcher multiple-processes feature is also available to use with the z/OS® operating system on IBM® z/Architecture® platforms.

Note: If you will be running systems specifically through the z/OS native administration interface (NAI), the WebSphere Transformation Extender Launcher multiple-processes feature allows you to run multiple Launcher processes, each containing one or more systems (.msl files), within a single installation of the Launcher as described in the "[z/OS Launcher](#)" documentation.

- [Activities summary](#)
- [Installation](#)
- [Using resource management](#)
- [Using Launcher Administration to run systems as separate processes](#)

The multiple-processes feature of the Launcher runs an .msl system file or group of .msl system files as separate Launcher processes. Use the Launcher Administration application to configure separate Launcher processes.

- [Managing the Launcher process](#)

Activities summary

To run multiple processes within a single installation:

- change resource management settings through the Resource Manager section of the initialization file depending on the way in which the Launcher will be running the Launcher processes
- change settings through the various windows within the Launcher Administration to configure the Launcher to use this feature
- manage the Launcher process by:
 - starting the Java™ Launcher
 - controlling the Launcher and viewing the status of the system either through the Management Console or by using command line utilities
 - viewing map execution information and taking snapshots of Launcher activity through the Launcher Monitor
 - analyzing the contents of debug trace and log files

Installation

In Windows environments, the Launcher installation setup program installs WebSphere® Transformation Extender Launcher as a service with **Manual** as the default value for **Startup Type** and **LocalSystem** as the default value for **Log On As**. An example of the service name that you might see is **TX n.n Launcher**.

See the [release notes](#) for more information about the installation.

Note: The Launcher run on UNIX and z/OS® does not run under a service.

Using resource management

The Resource Manager is a subsystem of the Launcher that controls those resources that do not have inherent resource management such as databases. File adapters are the most common adapters that require resource management. You can change resource management settings, which will affect how the Launcher will run.

There are two types of resource management:

- local - used within a single Launcher process.
- global - used across all of those Launcher processes that have been configured to use this type of resource management.
- [Global resource management](#)
- [Launcher systems run options](#)

Global resource management

Use global resource management, also referred to as central resource management, when running a system or group of systems in separate Launcher processes and the systems can share resources. The extra overhead of central resource management is minimal. The Resource Manager table requires an operating system-level lock rather than a process-level lock while accessing the Resource Manager. You should use central resource management if a system or group of systems running in separate Launcher processes start to have map errors that produce the error messages such as: source not available or failed to put data on output.

When running systems in multiple Launcher processes, central resource management can be turned on or off for a select Launcher process. Central resource management enables these different processes from the same installation to manage shared resources.

Launcher systems run options

The following list presents four data transformation scenarios and the various ways in which the Launcher can run a system or group of systems

- in a single Launcher process, as a Compound System
- in separate Launcher processes, each with localized resource management
- in separate Launcher processes, all using centralized resource management
- in separate Launcher processes, with a combination of centralized and local resource management

Using Launcher Administration to run systems as separate processes

The multiple-processes feature of the Launcher runs an **.msl** system file or group of **.msl** system files as separate Launcher processes. Use the Launcher Administration application to configure separate Launcher processes.

- [Benefits of using separate Launcher processes](#)
It is simpler to maintain and configure a system or group of systems that run with separate Launcher processes.
- [General tab](#)
- [Access tab - User Properties dialog](#)
- [Adding and removing processes and system files with the Deployment Directories tab](#)
Use the Launcher Adminstration application to add or remove a Launcher process or .msl system file when a system or group of systems is configured to run as separate processes. In the Deployment Directories tab, click Edit to work with the processes and .msl system files.

Related reference

- [Restrictions when modifying deployment directories and processes](#)
- [Benefits of using separate Launcher processes](#)
- [Selecting separate Launcher processes](#)

Benefits of using separate Launcher processes

It is simpler to maintain and configure a system or group of systems that run with separate Launcher processes.

- The run-time environment is more robust. Problems that occur in maps or adapter connections in one Launcher process do not cause problems in other Launcher processes.
- You can add and reconfigure Launcher processes without stopping other Launcher processes.
- You can use systems within systems for a single .msl Launcher system file for logical processes definitions.
- You can group systems to run in a separate Launcher process and start and stop them without having to shut down the Java™ Launcher.

General tab

The General tab of the Launcher Administration window has controls that you can set to enable the Launcher to use the multiple-processes feature.

The following list presents the controls, used with the multiple-process feature, along with their location in the Launcher Administration window:

- **Automatic startup**
Enabling **Automatic startup** gives you the ability to start up a Launcher process automatically. For information about using this option, see "[Configuring Launcher Processes to Start Automatically](#)".
- **Separate Launcher system processes**
Indicates that the Launcher will be run in different Launcher processes and that one or more system files can be configured for each process.
- **Initialization File:**
Identifies the initialization file, which contains configuration settings for WebSphere® Transformation Extender.
Default is *install_dir\config.yaml*.
- **Status:**
Displays the status of the Java™ Launcher.
- [Selecting separate Launcher processes](#)
- [Connection ports](#)

Selecting separate Launcher processes

When selecting Separate Launcher processes, configuration for different initialization files can be set for each Launcher process. Also, checking both **Automatic startup** and **Separate Launcher processes** adds the **Automatic Start** property in the Properties window for each process. The **Automatic Start** property has two options:

- **Yes**
 - Enables the specific Launcher process on which the **Yes** option is set to start up automatically.
- **No**
 - Prevents the specific Launcher process on which the **No** option is set from starting up automatically.

When the **Separate Launcher processes** checkbox is not checked, the Launcher runs all systems as a Compound System.

Related tasks

Related reference

- [Restrictions when modifying deployment directories and processes](#)
- [Using Launcher Administration to run systems as separate processes](#)
- [Benefits of using separate Launcher processes](#)

Connection ports

Three consecutive ports for each separate Launcher process are required. The Launcher automatically assigns them based on the first port entered in the port range.

For information about the listening ports, see "[Connection Ports](#)".

Access tab - User Properties dialog

Through the Access tab of the Launcher Administration window, you can invoke the User Properties window to add new or edit existing users and access permissions for the Management Console and the Launcher Monitor by clicking **Add** or **Edit**.

After clicking **Add** or **Edit**, the User Properties window will appear with default access permission set to **ALL Systems** under the **Systems** column heading. You can change the permissions for **Start/Stop**, **Pause/Resume** and **Monitor** to **Grant**.

To change the permissions in the User Properties window

1. Click on the permissions under one of the permission category columns (**Systems**, **Start/Stop**, **Pause/Resume**, and **Monitor**) to expand the drop-down menu.
2. Select the permission you want from the drop-down list.
3. To apply the changes, click **OK**.
4. You can repeat these steps for any of the permission categories you want to change.

Adding and removing processes and system files with the Deployment Directories tab

Use the Launcher Adminstration application to add or remove a Launcher process or .msl system file when a system or group of systems is configured to run as separate processes. In the Deployment Directories tab, click **Edit** to work with the processes and .msl system files.

In the Deployment Directories tab in the Launcher Administration application, select **Separate Launcher processes** to enable the **Edit** button. Click **Edit** to display the File List window.

Use the File List window to:

- add or remove individual Launcher processes.
 - [Adding a Launcher process](#)
 - [Removing a Launcher process](#)
- add or delete individual .msl system files for a specific Launcher process.
 - [Adding .msl system files to a Launcher process](#)
 - [Deleting .msl system files from a Launcher process](#)

Note: The Launcher process that is listed in the File List window under the Properties tab is treated as if it were the *main* .msl system file; it must exist before others can be added and it cannot be deleted until all additional systems are deleted.

Related reference

- [Selecting separate Launcher processes](#)
- [Restrictions when modifying deployment directories and processes](#)
- [Benefits of using separate Launcher processes](#)

Adding a Launcher process

1. Click **Add** in the view under the Properties tab.
The Select window appears.
2. Click on the .msl system files you want to deploy.
To select multiple files, click Ctrl and click on the files you want. Your selected files will be highlighted.
3. Click **OK**.
The Select window closes and the File List window reappears with the selected files listed.
4. Click **OK**.
The File List window closes and the window under the Deployment Directories tab in the Launcher Administration application reappears.

Removing a Launcher process

1. In the File List window, click the Launcher process that you want to remove.
2. Click **Remove** in the view under the Properties tab.
The Launcher process is removed from the list.

Before you can remove a Launcher process, you must first stop its execution.

Adding .msl system files to a Launcher process

1. In the File List window, click the Launcher process to which you want to add .msl system files.
2. Click **Add Files...** in the **Select additional files...** view under the **Files...** tab.
The Select window opens.
3. Click on the .msl system files you want to deploy in the specified Launcher process.
To select multiple files, click Ctrl and click on the files you want. Your selected files will be highlighted.

4. Click Select.

The Select window closes and the File List window reappears with the selected files listed in the main pane of the **Select additional files...** view.

Deleting .msl system files from a Launcher process

1. In the File List window, click the Launcher process from which you want to delete .msl system files.
2. Click in the main pane of the **Select additional files...** view on the specific .msl system file you want to delete.
3. Click Delete files... in the **Select additional files...** view under the Files... tab.

The .msl system file is removed from the list.

The .msl system file that appears in the File Name property, acting as a control file, defines the main Launcher process. As such, you cannot delete it as described in this procedure, which is only for the additional Launcher system files.

To delete the main Launcher .msl system file, you would have to remove the Launcher process entirely.

Configuring Launcher processes in the File List dialog

When using separate Launcher processes, configure each of them in the File List window. There are two sections of the File List window: the Property (Directory) section and the Property (File) section.

- [Property \(Directory\)](#)
 - [Property \(File\)](#)
-

Property (Directory)

The Property (Directory) enables you to override the default values and configure settings for those specific Launcher processes (.msl files). It allows you to propagate the default settings to those Launcher processes (.msl files) within that directory.

To propagate the Property (Directory) default settings

1. Select the property in the Property (Directory).
2. Right-click on the property.
A menu appears.
3. Select Propagate.
The default settings are copied to those Launcher processes (.msl files) within that directory.

Property (File)

The Property (File) enables you to configure the specific Launcher process to override the default settings.

The following table lists the Launcher process properties along with a description, and default and valid values.

Property (File)	Description
Name	Unique name that will be used for the Management Console and command line utilities to control the Launcher process individually.
Description	Description for the Launcher process.
File Name	Launcher system path and name.
Initialization File	Valid WebSphere® Transformation Extender initialization file. Default value is the global entry on the General tab of the Launcher Administration.
Resource Manager	Configuration value indicating whether to use global or local resource management. Valid values are Global and Local selected from pull-down menu. Default value is Local .
	Global indicates that resource management will allow multiple Launcher processes to share common resources properly.
Resource Configuration	Resource configuration file for this system. Default value is the entry on the General tab of the Launcher Administration.
Automatic Start	This property row appears when Automatic startup is enabled on the General tab of the Launcher Administration window. It allows you to start up this Launcher process automatically. Valid values are Yes and No , which are selected from a pull-down menu. Default value is No .

To apply your system configuration changes

Click OK.

The File List window closes and the window under the Deployment Directories tab in the Launcher Administration application reappears.

Configuring Launcher processes to start automatically

After you have configured the Launcher to run as multiple Launcher processes within a single installation, they are ready to be configured to start automatically. When **Separate Launcher processes** and **Automatic startup** are both selected on the General tab of the Launcher Administration, the **Automatic Start** property on the Properties window appears for each Launcher process under the Properties tab in the File List window.

To configure the Launcher processes to start automatically

1. Navigate to the File List window from the Deployment Directories tab in the Launcher Administration application.
2. In the File List window, click the configured Launcher process that you want to start up automatically.
3. Select Yes from the pull-down menu of the **Automatic Start** property.
Note: You can select Automatic startup if **Separate Launcher processes** is not selected. In this case, the **CompoundSystem** will automatically start when the Java™ Launcher starts.
4. Click OK.

The Launcher processes have been configured to start automatically. After they are started, while the Java Launcher is running, you can modify them through the Launcher Administration application by following the instructions.

Modifying systems while the Launcher is running

While the Java™ Launcher is running, you can make changes to Launcher system files (**.msl**) that are in separate Launcher processes in the Launcher Administration application. You can also add and remove Launcher processes.

Note: Before you can remove a Launcher process, you must first stop its execution.

After the Launcher processes are started, while the Java Launcher is running, the Launcher Administration application allows you to make the modifications but also has some functionality restrictions; some of the options are disabled and grayed out. They are presented in the following topics:

- [Changing file configurations](#)
- [Restrictions when modifying deployment directories and processes](#)
You can add deployment directories or Launcher processes while the Launcher service (or daemon) is running. You cannot remove a deployment directory while the Launcher service is running, and you must stop a Launcher process before you can remove the process.
- [Modifying administration user access](#)

Changing file configurations

While the Launcher service is running, you can change file configurations. The detailed procedures are described in the ["General Tab"](#) documentation.

- Cannot Change Startup, Execution and Connection Settings
 - Under the General tab, the Startup, Execution and Connection sections are disabled.
- Changing Initialization File Configuration Settings
 - You can make changes to the initialization file in the Configuration section.
 - The Apply button is enabled. When you click Apply, changes will take effect after the Java™ Launcher is restarted.
 - When the Java Launcher is started, you will see the **Running** status of the Launcher in the Launcher section of the window under the General tab.

Restrictions when modifying deployment directories and processes

You can add deployment directories or Launcher processes while the Launcher service (or daemon) is running. You cannot remove a deployment directory while the Launcher service is running, and you must stop a Launcher process before you can remove the process.

The detailed procedures are described in [Deployment Directories Tab](#).

- Cannot Remove Deployment Directories
 - Under the Deployment Directories tab, the Remove button is disabled and grayed out so you are unable to remove deployment directories while the Launcher service is running.
- Removing a Launcher Process
 - Under the Deployment Directories tab in the File List window that is invoked by clicking the Edit button, the Remove button is disabled and grayed out if the specific Launcher process is running, and enabled if the specific Launcher process has been stopped. (To remove a Launcher process, it must first be stopped.)
- Adding Deployment Directories
 - However you can still add new deployment directories under the Deployment Directories tab by clicking the Add button.
- Adding Launcher Processes
 - And you can still add new Launcher processes in the File List window by clicking the Add button. (The File List window is invoked by clicking the Edit button.)
 - Modification of a Launcher process that is currently running takes effect after the Launcher is restarted.

Related tasks

- [Adding and removing processes and system files with the Deployment Directories tab](#)

Related reference

- [Using Launcher Administration to run systems as separate processes](#)
 - [Selecting separate Launcher processes](#)
 - [Benefits of using separate Launcher processes](#)
-

Modifying administration user access

While the Java™ Launcher is running, you can modify administration user access. The detailed procedures are described in [Access Tab - User Properties window](#).

- Adding or Editing Administration User Access
 - Under the Access tab, you can add new or edit existing Administration users.
 - The **Edit** button settings will take effect after the Java Launcher is restarted.
 - Cannot Remove Administration User Access
 - Under the Access tab, the **Remove** button is disabled.
-

Configuring the initialization file

Whether using the single process **CompoundSystem** or separate Launcher processes comprising one or more **.msl** system files, you can configure the Launcher initialization file. You can rename it (the default name is **config.yaml**) as well as make modifications to its contents.

Some of the changes you can make to the initialization file include modifications to the following resource manager settings in the **[Resource Manager]** section:

Resource Management Settings

Description

CentralMgmt

Valid values are:

0, local resource management

1, global (centralized) resource management

Default is 0.

TableSize

Size in megabytes for the Resource Manager table.

Default is 10.

If the Launcher Administration is set to run systems in separate Launcher processes and the resource manager setting for a Launcher process is set to **Local**, the **CentralMgmt** entry in the initialization file has precedence over those other settings. Setting **CentralMgmt** to 1 will enable global (centralized) resource management. The default is 0 or local resource management.

The **TableSize** entry is used for both local and global resource management. It determines the initial size of the Resource Manager table before having to re-size it if required. Re-sizing requires all Launchers using the table to re-calculate the entries and might fail if memory cannot be obtained. The value is in megabytes, and the minimum value is 1. The default table size is 10 (10 megabytes).

The following table correlates the size of the Resource Manager table to the number of entries that the table can hold.

Resource Manager Table Size (in megabytes)	Total Entries	Unique Entries (138 bytes average size)
1	5461	4369
5	27306	21845
10	54613	43690
25	136533	109226

Note: There is, at most, one entry for each initialize pending map and one entry for each card for each resource pending map during Launcher processing, depending on the type of resource (file, database, ftp, and so on) and whether it needs WebSphere® Transformation Extender resource management.

When using global resource management, the initial Launcher process that creates the Resource Manager table determines the size for subsequent processes that use global resource management.

Managing the Launcher process

There are several activities you can do to manage the Launcher process. You can manage it by:

- starting the Java™ Launcher
- controlling the Launcher process and viewing the status either through the Management Console or by using command line utilities
- viewing map execution information and taking snapshots of Launcher process activity through the Launcher Monitor
- analyzing the contents of debug trace and log files
- [Starting the Launcher service or Launcher daemon](#)
- [Monitoring systems through the Management Console](#)
- [Shell script and batch file \(launcher.sh and launcher.bat\)](#)
- [Using the Launcher Monitor](#)
- [Debug trace and log files](#)

Starting the Launcher service or Launcher daemon

Start the Launcher daemon or Launcher service before you start the Launcher processes that run within the Management Console or use the **launcher.bat** (Windows systems) or **launcher.sh** (UNIX systems) commands.

Start only one Launcher daemon or Launcher service per Launcher installation.

Monitoring systems through the Management Console

After WebSphere® Transformation Extender has been installed and configured, and the Java™ Launcher started, the Management Console can be used to control and view the statistics about the Launcher processes (.msl system files) that are running.

You must log in to the Management Console and connect to the Java Launcher.

If **Separate Launcher processes** in the Launcher Administration was not checked, and the connection was successful, you will see the **CompoundSystem**.

The Management Console is connected to the Java Launcher, which is running all Launcher systems (.msl files) in a single Launcher process, or CompoundSystem, or in one or more separate Launcher process.

If **Separate Launcher processes** in the Launcher Administration was checked, and the connection was successful, you will see the unique names given to the individual Launcher processes (.msl files) from the File List window in the Launcher Administration. The Management Console is connected to the Java Launcher, which is running separate system Launcher processes for each Launcher system (.msl file) or group of systems.

In this configuration, you can control and monitor each of the different Launcher processes individually without affecting another.

Expand one of the Launcher system files to see the categories of information that you can view in the Management Console. They are **Status**, **History** and **Configuration**.

The **Summary** tab of the Management Console is an example of the statistical information for one of multiple Launcher processes.

Shell script and batch file (launcher.sh and launcher.bat)

The command line utilities that control the Launcher (**launcher.sh** on UNIX operating systems and **launcher.bat** on Windows operating systems) can be configured specifically for running systems in multiple Launcher processes.

When running systems in separate Launcher processes, you control each process with the **systemname** parameter, which is the unique name of the system file (.msl) as defined in the File List window when **Edit** is selected from the Deployment Directories tab in the Launcher Administration. Select -all for all configured Launcher processes.

- [UNIX shell script](#)
- [Windows batch file](#)

UNIX shell script

The following code shows the UNIX **launcher.sh** command usage:

```
Usage: launcher.sh [-start] [-stop [listenerport [hostname]]]
                  [-pause [listenerport [timeout [hostname]]]]
                  [-resume [listenerport [timeout [hostname]]]]
                  [-status launchername systemname]
                  [<[-summary] [-history] [-statusinfo] [-configuration]
                   [-all] [-xml]> Launchername systemname]
                  [-startsystem Launchername <systemname [-all]>]
                  [-stopsystem Launchername <systemname [-all]>]
                  [-pausesystem Launchername <systemname [-all]>]
                  [-resumesystem Launchername <systemname [-all]>]
```

Windows batch file

The following code shows the Windows **launcher.bat** command usage:

```
Usage: launcher.bat [-status Launchername systemname]
                  [<[-summary] [-history] [-statusinfo] [-configuration] [-all]
                   [-xml]> Launchername systemname]
                  [-startsystem Launchername <systemname [-all]>]
                  [-stopsystem Launchername <systemname [-all]>]
                  [-pausesystem Launchername <systemname [-all]>]
                  [-resumesystem Launchername <systemname [-all]>]
```

On Windows platforms, use the operating system's **NET** command to start, stop, pause and continue the Java™ Event Service through the command line.

On UNIX platforms, use the first four *Usage* commands in the **launcher.sh** shell script, start, stop, pause and resume.

Using the Launcher Monitor

When running the Launcher with the **Separate Launcher processes** checkbox in the General tab of the Launcher Administration enabled for multiple Launcher processes, each Launcher process (.msl file) that is configured will be displayed in the Select System window.

Because the Launcher Monitor can only observe one Launcher process at a time, multiple Launcher Monitor instances are required to monitor multiple processes.

Debug trace and log files

The Launcher debug trace and log files are located in the logs directory under the *install_dir*, which refers to the directory where your product is installed.

See [Trace and Log Files Naming Conventions](#) for the specific naming conventions.

z/OS Launcher

This documentation includes detailed information about how to enable the Launcher execution on z/OS® environments.

- [Overview](#)

With WebSphere® Transformation Extender for z/OS, you can run multiple maps or systems on a z/OS operating system on the IBM® z/Architecture® platforms.

- [Referenced terms](#)

Throughout the documentation, the following references are made:

- [Architecture](#)

- [Utilities and tools](#)

- [Native file system](#)

- [Local z/OS administration interfaces](#)

WebSphere Transformation Extender for z/OS includes a set of local administration interfaces that you will use to run the Launcher on the z/OS operating system running on z/Architecture platforms.

- [Multiple processes in the native administration interfaces](#)

- [Troubleshooting tip](#)

Overview

With WebSphere® Transformation Extender for z/OS®, you can run multiple maps or systems on a z/OS operating system on the IBM® z/Architecture® platforms.

Note: To use the z/OS Launcher, you will need to deploy systems. Although the focus of this documentation is to present the details of the z/OS Launcher, you will still need to reference other documentation for the details pertaining to deploying systems.

There are minimal differences between the z/OS implementation, and the Windows and UNIX implementation.

Among the differences are the methods available to administer the Launcher operations. They are:

- Native administration interfaces (ISPF Panel and Operator's Console)

◦ For native administration interfaces, reference the specific documentation.

- Existing user interfaces based on UNIX operating systems (Launcher Administration and Management Console)

◦ For administration user interfaces based on UNIX operating systems, you can reference processes presented in ["Getting Started"](#).

Note: The **DISPLAY** environment variable must be exported and an X Server must be available to host the user interface displays.

Note: Reference ["Starting the Launcher Monitor"](#) for details on how to start the Window Launcher Monitor:

Another difference between the implementations is the capability of the z/OS implementation to access the native file system.

Referenced terms

Throughout the documentation, the following references are made:

Term	References
WebSphere® Transformation Extender for z/OS®	
Includes Launcher	
Command Server	
Batch	
CICS® Execution Option	
CICS	

See the WebSphere Transformation Extender glossary for additional information about terminology used in this documentation.

Architecture

WebSphere® Transformation Extender for z/OS® runs in and uses both the z/OS UNIX System Services (z/OS UNIX) layer and the Hierarchical File System (HFS). It runs as a single process, multi-threaded server from within the z/OS UNIX layer of z/OS. It relies on TCP/IP sockets as the communications method under the TCP/IP communications protocol.

Utilities and tools

WebSphere® Transformation Extender for z/OS® includes JCL utilities and tools to transfer log, trace, and debug data from the HFS into the native file system. A z/OS UNIX System Services Command Server (z/OS UNIX Command Server) is provided as a tool to verify expected map operation prior to deployment in the Launcher.

Note: The z/OS UNIX Command Server is used for testing map behavior only. It is not a tool to be used for running maps in a production environment.

Note: When you are testing maps using the z/OS UNIX Command Server, if those maps were set up in the IFD with overrides, you need to use those override names directly in the maps.

- [JCL tools](#)

The following tools are available in the DTX.SDTXSAMP PDS to assist in transferring data from the HFS into the native file system.

- [z/OS UNIX System Services Command Server](#)

The z/OS UNIX System Services (z/OS UNIX) Command Server allows you to verify a map's behavior prior to deploying it in a system in the Integration Flow Designer.

JCL tools

The following tools are available in the DTX.SDTXSAMP PDS to assist in transferring data from the HFS into the native file system.

Member Name

Description

DTXDHFS

Defines, allocates, and mounts an HFS filesystem.

- Installation process defines a user ID, an HFS mount point, and 'HOME' directory.

DTXH2PDS

Copies the file from the HFS to a PDS or PDS/E member

DTXH2SF

Copies the file from the HFS to a sequential file

By default, all diagnostic information is stored in the HFS in the following locations:

Default Location

File Types in the HFS

\$DTX_HOME_DIR/config/config.yaml

Contains configuration information, including diagnostic definitions

\$DTX_HOME_DIR/dump

Contains diagnostic information when failures are generated by a Launcher execution

\$DTX_HOME_DIR/logs

The logs from each of the user interfaces

\$DTX_TMP_DIR

Contains data generated during execution of a map or system

z/OS UNIX System Services Command Server

The z/OS® UNIX System Services (z/OS UNIX) Command Server allows you to verify a map's behavior prior to deploying it in a system in the Integration Flow Designer.

It is the same as the UNIX Command Server with the additional functionality:

- [Access to native files \(PDS and PDS/E members and Sequential files\)](#).
- Ability to specify output file-creation options for native files using allocation parameters ([Allocation Parameters](#)).
- Ability to specify record terminators using the Record Terminators (/V) command option ([Record Terminators \(/V\)](#)).

Note: For more information and a comparison of the UNIX and Batch/CICS Command Servers, refer to the appropriate chapters in the *Command Server* documentation.

Note: Avoid running the z/OS UNIX Command Server and the Launcher at the same time if both servers are attempting to access the same resources.

Native file system

The native file system is used in processing the Launcher for z/OS®. The Launcher supports the various native file system file types ("[File Types](#)") in various contexts.

The subsequent documentation describes the native file system:

- "[File Types](#)"
- "[File Access](#)"
- "[File Triggering](#)"
- "[Map Names](#)"

- [File types](#)
 - [File access](#)
 - [Map names](#)
 - [Related data file locations](#)
 - [Map sources and targets](#)
 - [File triggering](#)
-

File types

The Launcher for z/OS® supports the following native file system file types:

- Sequential files
- PDS and PDS/E members
- Virtual Storage Method (VSAM) files
- Generation Dataset Group (GDG) Files

Note: For information on these file types, see the specific version of the IBM® z/OS C/C++ Programming Guide for your operating system release.

File access

There are different ways to access files in the native file system through specifications in map input/output.

- IFD specifications
 - ALLOC syntax
 - Map server location
 - Describe location of 'related' data files
 - [Allocation](#)
-

Allocation

Native file system files can be specified in the following locations:

- as input or outputs on maps in your systems.
 - as maps in your map server location setting.
-

Map names

The Launcher for z/OS® supports native file system conventions for specifying the location of compiled maps on the execution server.

- [Compiled map name specifications](#)
-

Compiled map name specifications

When specifying a native file system location for the compiled map, the Launcher for z/OS® supports native file system formats for the following file types:

- [Sequential files](#)
- [PDS and PDS/E members](#)
- [Virtual Storage Method \(VSAM\) files](#)
- [Generation Dataset Group \(GDG\) Files](#)

Note: For formatting information about these file types, see the specific version of the IBM® z/OS C/C++ Programming Guide for your operating system release.

Related data file locations

The location of data files for compiled maps is dependent on the option chosen at WebSphere® Transformation Extender for z/OS® map or system definition time.

The location of related data files (for example, log and trace files) for maps that are stored in the native file system is dependent on the options configured for those map in the Integration Flow Designer prior to deployment. The options are:

- DEFAULT ("DEFAULT")
 - CUSTOM ("CUSTOM")
 - UNIQUE ("UNIQUE")
-
- [DEFAULT](#)
 - [CUSTOM](#)
 - [UNIQUE](#)

DEFAULT

The following information presents the location of data files related to the compiled maps in the native file system when the **DEFAULT** option was specified in the map settings at map or system definition time:

Note: For files in the HFS, the default location is **\$DTX_TMP_DIR**.

Data File in Native File System

Default Location

Audit log
 \$DTX_TMP_DIR/MYUSERNAME.ANY/MAP.log
Input work file
 \$DTX_TMP_DIR/MYUSERNAME.ANY/MAP.Inn
Output work file
 \$DTX_TMP_DIR/MYUSERNAME.ANY/MAP.Onn
Trace file
 \$DTX_TMP_DIR/MYUSERNAME.ANY/MAP.mtr

CUSTOM

The following information presents the location of data files related to the compiled maps in the native file system when the **CUSTOM** option was specified in the map settings at map or system definition time:

Note: For files in the HFS, the location that was specified at map or system definition time is used.

Data File in Native File System

Default Location

Any file
 If the file is in the native file system, the map will fail.

Note: Do not use the **CUSTOM** setting for maps in the native file system.

UNIQUE

The following information presents the location of data files related to the compiled maps in the native file system when the **UNIQUE** option was specified in the map settings at map or system definition time.

Note: For files in the HFS, the default location is **\$DTX_TMP_DIR**.

Data File in Native File System

Default Location

Audit log
 \$DTX_TMP_DIR/MYUSERNAME.ANY/Mer_MAP_process-key_map-counter_hostname.log
Input work file
 \$DTX_TMP_DIR/MYUSERNAME.ANY/Mer_MAP_process-key_map-counter_hostname.Inn
Output work file
 \$DTX_TMP_DIR/MYUSERNAME.ANY/Mer_MAP_process-key_map-counter_hostname.Onn

Map sources and targets

For map source (["Map Sources"](#)) and targets (["Map Targets"](#)), the Launcher for z/OS® supports native file system formats for the following file types:

- [Sequential files](#)
- [PDS and PDS/E members](#)
- [Virtual Storage Method \(VSAM\) files](#)
- [Generation Dataset Group \(GDG\) Files](#)

Note: Many type definitions use [terminators](#) such as <CR><LF>. If data is created locally on the z/OS environment or transferred to the z/OS environment using a file transfer protocol (FTP), the terminators, which would indicate that there is no more data in the record, are not used to terminate the data. When the map processes that data, it would not know when to complete because it would not understand where the end of the data in the record occurs. Therefore, an override must be used to allow the map to complete as if the terminators were contained in the data stream. This override would indicate to the map where the end of each record occurs.

If the target of the FTP is z/OS UNIX System Services (z/OS UNIX), the FTP converts the <CR><LF> terminators (**ASCII** mode) in Windows files to <NL> (**EBCDIC**) on the z/OS environment.

If the target of the FTP is a file in the native file system, the <CR><LF> characters are removed; there is no record terminator at all.

Type trees are designed to indicate the record terminators. Make sure that the appropriate overrides are specified when running the maps on z/OS so that type validation works as expected. The override is used to place an end of record indicator in an otherwise unmarked record.

- [Record Terminators \(/V\)](#)

- [Allocation parameters](#)
- [Map sources](#)
- [Map targets](#)

Record Terminators (/V)

Use the Record Terminators execution command (/V) in source and target map settings to enable special handling of data with embedded record terminators in files with variable-length records, specifically with a record format of variable (V), variable block (VB), or variable block spanned (VBS).

`[/V[terminator_list...]]`

Option

Description

terminator_list

A comma-delimited string of bytes that can be expressed in hex format (for example: /VX5B,X6C,X7C) or character format (for example: /VS,,@). The default record terminator, if none, is indicated on the /V command as a single byte, hex15.

This string of terminator bytes should match the record terminator defined in the type tree that represents this data.

This command functions differently for data sources and targets. If specified for input data, the indicated (or default) record terminator string is appended to each record after it has been read. If specified for an output data set, the record terminator string is interpreted as marking the end of a record in the output.

For inputs, this command causes a string of one or more bytes to be appended to each record to ensure that the data maps properly when using the Launcher for z/OS®. For example, suppose you are mapping an input file on the PC that consists of lines of text terminated by carriage-return/line-feed (0D 0A) pairs. Even though you cannot see them in a text editor, these terminators are embedded in the data, they are defined in the type tree that is created to represent this data, and the map expects them to be there.

Now you need to run this same map using the Launcher for z/OS. However, when you upload the input file to a z/OS environment, the record terminators embedded in the data are removed during the transfer. Consequently, when the file is read in for mapping using the Launcher for z/OS, the record terminators must be reinstated or the data will not map correctly. The solution is to use the command [/VX0D,X0A] to append a hex 0D 0A string to the end of each record.

For outputs, this command specifies that the indicated (or default) byte or bytes are used to mark the ends of each record in the output. When this command is used, the map must embed record terminators in the output data. These terminators indicate the places where record boundaries are to occur in the final output. The record terminators are removed when the records are created in the output target or targets and do not appear in the resulting output.

Allocation parameters

Use allocation parameters to specify output file-creation options when native files are specified as targets and the targets do not exist. It is comparable to specifying output data set definitions on the DD statement in the JCL used if you were executing the Command Server for z/OS® Batch.

Allocation parameters are specified as an ALLOC statement in the **FilePath** setting in the Settings window as part of the file name.

When you use allocation parameters, the **BPXWDYN** service handles file allocation. It is used to define the new output and enables file allocation to be available to programs running outside of a TSO environment. Allocation parameters must be specified in the output card settings for the output file to be created successfully.

Note: See the *z/OS Using REXX and z/OS UNIX System Services* manual for more information about file allocation and the **BPXWDYN** service.

Example

The following example demonstrates how to define the same output data set using two different methods. One method is to use allocation parameters specified in an ALLOC statement and the other method is to use data set definitions specified in the DD statement in the JCL.

Allocation (ALLOC) Parameters

```
ALLOC DD(LABELS) DSN('MYUSERNAME.LABELS') RECFM(F,B) LRECL(80)
UNIT(SYSDA) TRACKS SPACE(5,2) NEW CATALOG DELETE
```

JCL DD Statement

```
//LABELS DD DSN=MYUSERNAME.LABELS,
//          DCB=(RECFM=FB,LRECL=80),
//          UNIT=SYSDA,
//          SPACE=(TRK,(5,2)),
//          DISP=(NEW,CATLG,DELETE)
```

Map sources

This is a description of the specifications you might need to use when native files are specified as sources in the Integration Flow Designer.

Input or inputs

- Record Terminators
 - Place the record terminators in the **FilePath** setting when specifying the map input in the Launcher Settings window.

- A set of brackets ([]) indicates to the z/OS® environment that the data contained inside the brackets are the file characteristics.
- Place the record terminators inside a set of [] in the map input **FilePath**.
- Input(s).#1 FileIn.>.GET.>.Source **FilePath**
Example: // 'MYUSERNAME.IN1' [/VX0D,X0A]

Map targets

This is a description of the specifications you might need to use when native files are specified as targets in the Integration Flow Designer.

Output or outputs

- Allocation Parameters and Record Terminators (if required)
 - Place allocation parameters and record terminators (if required) in the **FilePath** setting in the Settings window as part of the file name when specifying native files as targets.
 - A set of brackets ([]) is used to define allocation parameters and potential record terminators.
 - Place the allocation parameters and record terminators (if required) inside a set of [] in the map output **FilePath**.
 - Output(s).#1 FileOut.>.PUT.>.Target.>.FilePath

Example: [ALLOC DD(OUT1) DSN('MYUSERNAME.OUT1') TRACKS SPACE(5,1) NEW CATALOG RECFM(F,B) LRECL(80) /VX0D,X0A]

Note: Systems (.msl files) will not reside in the native file system; they will reside in the HFS.

File triggering

The Launcher can be set to trigger when files are updated or created on UNIX and Windows systems. Triggering on files in the native z/OS® file system is more complex than in the HFS. This is most evident when trying to do file-update triggering because the z/OS operating system, in general, does not maintain update information for files.

Triggering on native file creation or update supports the following native file system file types, depending on the triggering type:

- [Sequential files](#)
Example: // 'MYUSERID.DATA.INPUT1'
- [PDS and PDS/E members](#)
Example: // 'MYUSERID.DATA(INPUT1)'
- [File-creation triggering](#)
- [File-update triggering](#)
- [Wildcards in native file system names](#)
- [File pre-allocation](#)
- [Incomplete file creation or update](#)

File-creation triggering

File-creation triggering is allowed for any native file system or file system member. In file-creation triggering, when a specified file is created and there is a successful open-file attempt, the event is triggered.

File-update triggering

File-update triggering is more complex because, as mentioned previously, in general, the z/OS® operating system does not maintain information for files that could be used as a way of recognizing that the file changed. The z/OS Launcher will infer a change of a PDS or PDS/E member by recognizing the change in its location, TTR, or pointer.

File-update triggering is allowed for PDS or PDS/E members, but not sequential files. There is no straightforward way to check for sequential file updates.

The following process repeats until the specified event is triggered. The process awaits a specified file to be updated and when it recognizes that it has been updated, by a successful directory read attempt, it triggers execution of an event.

To trigger on an updated file:

1. Retrieve the current TTR information for the PDS or PDS/E member or members by reading the directory.
2. Save the retrieved information.
3. Repeat the loop until the process recognizes that the file has been updated.
 - Get the TTR information.
 - If the TTR information has changed, the event is triggered and the TTR is updated.
 - If the TTR information has not changed, the process repeats the loop to check for file updates.

Wildcards in native file system names

Wildcards are characters that are used to substitute unknown characters. Using wildcards for file creation or update triggers can be costly on z/OS® operating systems.

Note: When using wildcards, place them in a location of native file system names where you are certain that the search will be performed for a well-defined portion of the catalog. The search that is invoked acts like a TSO Data Set List Utility search. It is very powerful and searches through the entire portion of the catalog defined by the location of the wildcard. The larger the portion of the catalog that is searched, the longer the search takes to complete.

Examples of wildcard-triggering uses

The following examples present different ways you can specify and use wildcard-triggering. The bullet points highlight their characteristics, similarities and differences.

```
//'MYUSERID.DATA.INPUT(*)'
```

- The partitioned data set (PDS) being searched is a single data set.
- Any of its members can be a potential trigger.
- The system catalog does not have to be searched.
- There will be repeated reads on the data set to check for new or changed files.

```
 //'MYUSERID.DATA.INPUT*' or  
 //'MYUSERID.DATA.INPUT.*'
```

- The search is on all data sets that have the same specified pattern of nodes or qualifiers.
- Any data set that meets the criteria can be a potential trigger.
- The system catalog is searched.
- There will be repeated searches of the system catalog for new or changed files that match the specified pattern.

Note: In the z/OS operating system, the system catalog is a single resource used by all tasks running on the system. CPU and resource consumption could be very high.

File pre-allocation

Some jobs are designed to create or pre-allocate a file in advance of being populated with data. If the Launcher is set up to trigger on file creation, file pre-allocation might cause the map execution not to complete as expected. Considerations about whether or not to design your jobs with pre-allocated files might be necessary when setting up your Launcher processes.

Incomplete file creation or update

It is possible to trigger on file creation or update if only a portion of the file was created or updated. If the Launcher is set up to trigger on file creation or update, incomplete file creation or update might cause the map execution not to complete as expected.

A method of triggering on file creation or update when it has not completely been created or updated is to create a file with the following disposition parameter setting so that the file will not appear until it is cataloged at the end of the job:

```
DISP=(NEW,CATLG)
```

Local z/OS administration interfaces

WebSphere® Transformation Extender for z/OS® includes a set of local administration interfaces that you will use to run the Launcher on the z/OS operating system running on z/Architecture® platforms.

The two local administration interfaces are:

- [ISPF Panel Interface](#)
- [z/OS Operator Console Interface](#)
- [Overview](#)
- [ISPF panel interface](#)
- [z/OS operator console interface](#)

Overview

A benefit to using the local administration interfaces is that they provide the ability to connect to the user interfaces.

The only limitation of using the local administration interfaces is that you cannot start systems from the Management Console.

- [Activities summary](#)
- [Using the Launcher Management Tools](#)
- [Using the Management Console](#)

After the Management Console is started, you will perform the following activities to establish a connection to the Launcher process running on a z/OS environment.

- [Starting the Launcher Monitor](#)

The Windows Launcher Monitor can be used to monitor the Launcher.

- [Default port settings](#)
- [Environment settings](#)

To run WebSphere Transformation Extender for z/OS, a set of environment variables must be set.

Activities summary

Local administration interfaces perform the following activities:

- Read the system deployment directory.
- Build the command to start the Launcher, including a fully qualified path to the Launcher, list of systems, and command ports.
- Start the Launcher.
- The operator console interface invokes Write-To-Operator (WTO) calls, which communicate status for the operator console interface. WTO messages display the results from the Launcher process for each operation.
- The ISPF interface processes return codes and messages for display in the ISPF panel.

Note: WebSphere® Transformation Extender for z/OS® can be managed through the Management Console and monitored through the Windows Launcher Monitor, even though the administration is performed locally.

After WebSphere Transformation Extender for z/OS is started using one of the local administration interfaces, the Windows/UNIX Management Console can be used to manage the Launcher. The Management Console can be used to view statistical data and also control the compound system that is running from the process running. See [Multiple Processes](#) for additional information when using the multiple-processes feature.

For more details, see the following documentation:

- [Launcher Options](#)
- [Using the Launcher Management Tools](#)
 - [Using the Management Console](#)
 - [Starting the Launcher Monitor](#)

Using the Launcher Management Tools

When using the local administration interfaces to perform Launcher administration tasks, there are Management Console and Launcher Monitor configuration considerations.

Management and monitoring of the Launcher process is dependent on the service having been started. Since the Launcher service is not started when using the local administration interfaces, a different method of accessing the Management Console and Launcher Monitor must be performed.

Using the Management Console

After the Management Console is started, you will perform the following activities to establish a connection to the Launcher process running on a z/OS® environment.

The connection will enable you to use the Management Console to manage your systems running on the z/OS environment.

Note: Because the local administration interfaces are used to start systems, you cannot start systems from the Management Console. The Management Console performs all the other capabilities required to manage the Launcher process running your systems on a z/OS environment.

To configure the Launcher in the Windows and UNIX Management Console

1. Define a new Launcher.
2. In the Management Console, select Tools->Options.
The Options window opens.
3. From the Options list, select Launchers to connect to the remote Launcher.
The override configuration options appear.

Starting the Launcher Monitor

The Windows Launcher Monitor can be used to monitor the Launcher.

The following method can be used to start the Window Launcher Monitor:

- Issue the following command from the Windows command prompt:
 - `dtxmon -c:<computer_name> -p:<monitor_port_number>`
 - *computer_name* is the TCP/IP hostname of the system running the Launcher.
 - *monitor_port_number* is the second port in the 'port range'.
 - Default port is 7001.
- Note: The Launcher Monitor application saves the configuration information you entered in the user interface when you initially started the Launcher Monitor through the command line. It makes the configuration information available for subsequent starts that you can do through the Windows Start menu as follows: Select Start->Programs->Transformation Extender->Launcher->Launcher Monitor.

Default port settings

The local administration interface applications used to run the Launcher on the z/OS® operating system running on z/Architecture® platforms work collectively and must communicate by means of ports. Each application has default port settings. However, you can change them as needed.

The following list displays the default port settings for each application, and the interrelated structure of the applications.

- The Launcher relays monitoring information over port 7001 to the Monitor.
- The Launcher relays status information over port 7000 to the Management Console.
- The local administration interface sends control information (start, stop, pause, resume) to the Launcher process that is running over port 7002.

Environment settings

To run WebSphere® Transformation Extender for z/OS®, a set of environment variables must be set.

They are usually established by running a shell script from the UNIX command line. Since there is no UNIX command line being used in this case, an environment-variable file is used to configure the settings for the local administration interfaces.

File location

The sample environment variable file location resides in DTX.SDTXCNFG(DTXENVAR). It contains pre-specified default values that are included in the WebSphere Transformation Extender for z/OS installation.

Note: The location of the PDS and member name containing the environment variable file must be specified in the DTXENV DD statement of the JCL for starting the z/OS Operator Console command. A sample PROC is included in the installation-defined data set, DTX.SDTXSAMP(DTXPROC).

The location of the DTXENVAR must also be specified in a CLIST or REXX EXEC to start the ISPF interface. A sample REXX EXEC is included in the installation-defined data set, DTX.SDTXCLST(DTXCLIST).

DTXENVAR environment variable file

The contents of **DTXENVAR** include settings for the following variables:

Environment Variable

Description

_CEE_RUNOPTS

Language Environment® runtime options for the Launcher process.

This is an optional field that you can override. See the IBM® z/OS Language Environment Programming Reference, SA22-7562 for a description of the valid runtime options.

CENTRAL_MGMT

Configuration value indicating whether to use centralized (global) or local resource management.

Valid values are YES for centralized (global) resource management and NO for local.

Centralized (global) indicates that resource management will allow multiple processes to share common resources properly.

Default value is NO.

CONNECTION_RETRY_COUNT

The maximum number of times the z/OS native interface is allowed to attempt the TCP/IP connection to the Launcher control port before an error condition, if attempts are not successful, is raised.

Default value is 10.

Note: If the **CONNECTION_RETRY_COUNT** value is reached before the z/OS native interface can start or detect the Launcher, the "TX is not active..." message will appear.

DEBUG

Enable debug option. Valid values are YES to enable the debug option and NO to disable it.

Default value is NO.

INI_FILE

config.yaml file

Override the default location and name of the **config.yaml** file.

Uncomment the line by removing the # character in front of **INI_FILE** and replace <configuration directory>/<ini file> with a valid file location of the **.ini** file to be used.

LAUNCHER_NAME

Symbolic name assigned to the current Launcher. It uniquely identifies the Launcher instance and is also used to prefix the Launcher and debug logs when running the multiple-process Launcher.

The name is displayed in the ISPF DTXEVNT window.

Default value is Launcher-Name.

Note: Maximum length is 19 characters and the name should not contain any spaces.

DTX_CONTROL_PORT

TCP/IP port number used for control information when communicating with the Launcher process.

Default value is 7002.

DTX_HOME_DIR

Installation location for the Launcher)

Default value is /u/dtx/Launcher.

DTX_MONITOR_PORT

TCP/IP port number used for monitoring information when communicating with the Launcher process.
Default value is 7001.

DTX_STATUS_PORT

TCP/IP port number used for status information when communicating with the Launcher process.
Default value is 7000.

SYSTEM_FILE

Location of a single system (.MSL) to be used in a multiple-process Launcher configuration.

Uncomment the line by removing the # character in front of **SYSTEM_FILE**. Replace <deployment directory>/<system name>.msl with the valid file location of the system to be executed.

TIME_ZONE

Time zone used.

This is required only if the locale defined to z/OS UNIX System Services (z/OS UNIX) does not contain a valid **LC_TOD** category.

Default value is EST5EDT.

VIPA_HOSTNAME

The host name for the Virtual IP Address (VIPA) where the Launcher is running. This environment variable is required only when the ports used by the Launcher are defined as VIPA ports.

ISPF panel interface

The ISPF panel interface allows you to manage the Launcher as well as view Launcher information on the z/OS® operating system.

- [**Commands**](#)
The ISPF commands are available to control the execution of the ISPF administration interface.
- [**Menu options**](#)
To manage the Launcher through the ISPF panel interface, select the function by entering the associated menu option number at the **Option ==>** prompt in the **Launcher Administration Main Menu** panel as follows:
- [**Server information**](#)
The server information is contained in the **Launcher Information** area of the panel.
- [**Managing multiple Launchers**](#)

Commands

The ISPF commands are available to control the execution of the ISPF administration interface.

The following procedure uses the ISPF Command Shell screen to initiate the execution of the interface.

To start the ISPF administration interface

1. From ISPF, select Primary Option Menu > option 6 - Command.
 2. At the command prompt in the ISPF Command Shell screen, enter the EXEC 'DTX.SDTXCLST(DTXCLIST)'.
- The ISPF administration interface starts. The Administration Main Menu appears, listing the command options available to control the execution.

See the menu options ([Menu options](#)) for the available ISPF administration commands presented in the Launcher Administration Main Menu.

Menu options

To manage the Launcher through the ISPF panel interface, select the function by entering the associated menu option number at the **Option ==>** prompt in the **Launcher Administration Main Menu** panel as follows:

Menu Function Use	Menu Option	Option Description
Start the Launcher	1	Start the Launcher identified in the Launcher Information area of the panel. Status field must be Unknown.
Stop the Launcher	2	Stop the Launcher identified in the Launcher Information area of the panel. Status field must be Running or Paused.
Pause the Launcher	3	Pause the Launcher identified in the Launcher Information area of the panel. Status field must be Running.
Resume the Launcher	4	Resume the Launcher identified in the Launcher Information area of the panel. Status field must be Paused.
Refresh Launcher Status	5	Get the status of the Launcher identified in the Launcher Information area of the panel. This is allowed for any current state; Status field can contain any valid value.

Server information

The server information is contained in the **Launcher Information** area of the panel.

The following list describes the various fields that are used in the LauncherAdministration Main Menu panel to display information about the Launcher, the status of the Launcher, as well as the ports used.

Field	Description
Server	Name of the current Launcher (user-supplied name)
Status	Current status of the Launcher. Values are: <ul style="list-style-type: none">• Not Responding - not started.• Starting - in the process of starting• Started - has started• Stopping - in the process of stopping• Stopped - has stopped• Pausing - in the process of being paused• Paused - currently paused and not running deployed systems• Unknown - in an unknown state• Error - has detected an error and might or might not continue
Status Port	Port used to communicate the status of the Launcher. Also used by the Management Console interface.
Monitor Port	Port used to communicate monitoring information. Also used by the Windows Launcher Monitor interface.
Control Port	Port used to send commands (start, stop, pause, resume) to the Launcher. Also used by the Management Console interface.

The ISPF panel resides in DTX.SDTXPENU(DTXYEVNT). It must be invoked from a REXX EXEC or CLIST.

Managing multiple Launchers

Multiple Launchers are administered by starting multiple ISPF panels. They must be invoked through multiple CLIST or REXX EXECs and use different configuration files.

Note: You must create a separate environment variable file for each Launcher instance to be able to manage your systems.

z/OS operator console interface

The z/OS® Operator Console interface provides a standard interface that allows the z/OS system operator to control a server by using a cataloged procedure (PROC).

- [Commands](#)
The operator console interface commands are available to control the execution of the Operator Console administration interface.
- [Managing multiple Launchers](#)

Commands

The operator console interface commands are available to control the execution of the Operator Console administration interface.

The following procedure uses the start command to initiate the execution of the interface.

To start the Operator Console interface:

From the Operator Console, enter S DTXPROC.

The Operator Console administration interface has started.

The following table lists the available Operator Console administration commands.

Operator Console Command Use

Commands
Start S DTXPROC
Stop P DTXPROC
Pause F DTXPROC, APPL=PAUSE
Resume F DTXPROC, APPL=RESUME
Status F DTXPROC, APPL=Status

DTXPROC is a PROC that resides in DTX.SDTXSAMP.

Note: The DTXPROC PROC must first be copied to a system procedure library, such as SYS1.PROCLIB, before the procedure can be started from the Operator Console.

Managing multiple Launchers

The z/OS® Operator Console interface manages multiple Launchers in a similar manner as the ISPF panel interface. The only difference is that they are invoked through multiple PROCs, instead of multiple REXX EXECs or CLISTS.

Note: You must create a separate environment variable file for each Launcher instance so that you can manage your systems.

Multiple processes in the native administration interfaces

The WebSphere® Transformation Extender Launcher multiple-processes feature, as described in [Multiple Processes](#), is also available to use with the z/OS® operating system on IBM® z/Architecture® platforms. If you will be running systems specifically through the z/OS native administration interfaces (NAI), the WebSphere Transformation Extender Launcher multiple-processes feature allows you to run multiple Launcher processes (systems or .msl files) within a single installation of the Launcher as described in this documentation.

To enable the multiple-processes feature, global management is selected through resource management settings in the Resource Manager section of the NAI **DTXENVAR** environment variables file. This file is included in the WebSphere Transformation Extender Launcher installation. See [Using Resource Management](#) for background information about global resource management.

The NAI will optionally launch a single system for each Launcher installation instance or recognize a request for global resource management and launch multiple systems in a single instance depending on the way in which you instruct the Launcher, through the settings in the **DTXENVAR** environment variables file, to run the system or systems. Also, there are additional settings in the file that you can change to enable the Launcher to create debug and Launcher log files.

See [DTXENVAR Environment Variable File](#) for the settings that you can configure to enable the WebSphere Transformation Extender Launcher multiple-processes feature.

Troubleshooting tip

If you encounter a problem when running the Launcher for your z/OS® environment, run the maps through the z/OS UNIX System Services (z/OS UNIX) Command Server as a debugging test. The results from running maps through the z/OS UNIX Command Server should be the same as running maps through the Launcher for the z/OS environment. If the source, targets, and settings have changed, you can override them by using the appropriate command line options.

SNMP Agent

Hardware and software network resources that are to be managed and controlled by SNMP-enabled network management software must provide an interface that supports the Simple Network Management Protocol (SNMP). That interface is known as an SNMP Agent. The SNMP Agent allows you to manage the Launcher using SNMP and SNMP-enabled network management software such as HP OpenView, Tivoli® NetView®, and BMC Patrol.

For the purpose of this documentation, the generic term **SNMP manager** is used when referencing SNMP-enabled network management software.

With the SNMP Agent, you can monitor and control the status of the Launcher and associated map events. The following functionality is provided using the SNMP Agent:

- Configure thresholds
- Detect errors
- Monitor Launcher performance and help identify failure situations
- Start, stop, pause, or resume Launcher
- Notify SNMP manager of changes in the state of:
 - Connections
 - Listeners
 - Launcher
- [SNMP overview](#)
- [How an SNMP Agent works](#)
- [How It all fits together](#)
- [Configuration](#)
- [SNMP operations and thresholds](#)
- [DTX MIB](#)

SNMP overview

SNMP is composed of the following components:

Management Information Base (MIB)

The MIB is a database of object definitions. The definition specifies if an SNMP manager can monitor the object.

Simple Network Management Protocol (SNMP)

A network protocol used to manage TCP/IP networks. This protocol provides functions that allow you to access the data object whose definitions are located in the MIB.

- [What is MIB?](#)

What is MIB?

Hardware and software network resources that are controllable using an SNMP manager must provide a definition of the data objects that can be queried or updated. These definitions are located in a database known as the Management Information Base (MIB).

MIB data object definitions that are supported by the SNMP Agent are specified in the **dtx_sm1.mib** file. This file is located in the directory in which the SNMP Agent is installed.

- [MIB data objects](#)
- [MIB variables](#)

MIB data objects

The MIB has an inverted tree structure and each MIB data object is uniquely identified by its location in the MIB tree. Each object is given a unique numeric object identifier (OID) and a descriptive name. A MIB browser allows you to navigate through the MIB tree and to GET and SET MIB variables. All vendor-specific MIB data objects are located under the **iso.org.dod.internet.private.enterprise (1.3.6.1.4.1)** OID. For example, the MIB data object for IBM is located under the **iso.org.dod.internet.private.enterprise.ibm (1.3.6.1.4.1.4769)** OID.

See ["DTX MIB"](#) for the DTX MIB data object definitions.

MIB variables

MIB variables are located at the termination point of each branch in the MIB tree. These variables contain actual configuration, status, and statistical information for the Launcher and the map system it is running. MIB variables can be a single value or string, or even an array or table. Access permission for MIB variables is defined as read-only, read-write, write-only, or none.

How an SNMP Agent works

The SNMP Agent handles the SNMP network communication. When the agent receives a request from an SNMP manager, it checks the OID of the requested data object and if the OID is valid, the agent sends a response back to the SNMP manager. If the OID is not valid, the agent returns an error.

The SNMP Agent is the software component responsible for the Launcher object and responds to queries, carries out requests, and issues traps. A trap is a message sent by an SNMP Agent to the SNMP manager indicating that an event has occurred on the host running the network resource.

How It all fits together

The basic communication process among the key components, SNMP, SNMP manager, SNMP Agent, MIB, and the Launcher, is as follows:

- The SNMP manager issues a request to the SNMP Agent.
- The SNMP Agent SETS and GETS information from the MIB based on the request.
- SNMP Agent sends a reply to the SNMP manager and issues a trap.

When SNMP messages are passed between the SNMP Agent and the SNMP manager, they include the MIB OID, MIB value, what the variable is set to, and the community name of the agent.

Configuration

Before the SNMP Agent can be used in conjunction with third-party SNMP management tools to monitor the Launcher, the following steps must be performed:

To prepare the SNMP Agent to monitor and manage the Launcher status

1. Install and configure the SNMP Agent.
 2. Define user-based security or community permissions for the Launcher's MIB space.
 3. Import the MIB into the SNMP management software. For information about how to import a MIB, consult your vendor-specific documentation.
The Launcher does not require special command lines or other options to enable SNMP management support.
- [Installation](#)
 - [To change the SNMP Agent locale](#)
 - [Configuring the SNMP Agent](#)
 - [SNMP security](#)
 - [Starting the SNMP Agent](#)

Installation

See the release notes for the latest information.

To change the SNMP Agent locale

The SNMP Agent application must be closed before performing this task.

1. Open *install_dir/snmpadmin.bat* (*snmpadmin.sh*) in a text editor.
2. At the **REM set USRLANGUAGE=** line, remove the **REM** comment indicator. At the end of the line, enter a locale value.
Example for Japanese: **set USRLANGUAGE=ja**
3. At the next line, **REM set USRCOUNTRY=**, remove the **REM** comment indicator. At the end of the line, enter the corresponding country indicator if needed.
Example for Traditional Chinese:

```
set USRLANGUAGE=zh
set USRCOUNTRY=TW
```
4. At the line that begins with **REM call %JRE% -DINSTALLDIR="%DTXHOME%"**
-Duser.language=%USRLANGUAGE% ..., remove the **REM** comment indicator from the beginning of the line.
5. At the next line (**call %JRE% -DINSTALLDIR="%DTXHOME%"**
-Dsun.java2d.nodraw ...), add an **REM** comment indicator to the beginning of the line.
For Traditional Chinese, the modified text should look similar to the following:

```
set USRLANGUAGE=zh
set USRCOUNTRY=TW

call %JRE% -DINSTALLDIR="%DTXHOME%" -Duser.language=%USRLANGUAGE% ...
REM call %JRE% -DINSTALLDIR="%DTXHOME%" -Dsun.java2d.nodraw ...
```

6. Save and close the file.

See the *IBM Transformation Extender Introduction* documentation for additional information about locale settings.

Configuring the SNMP Agent

The SNMP Administration utility is used to configure the SNMP Agent. To launch the SNMP Administration utility, click Start > Programs > Transformation Extender > SNMP Agent Administration.

For UNIX platforms, the SNMP Agent Administration utility can be accessed from *install_dir/bin/snmpadmin.sh*. For Windows platforms, the SNMP Agent Administration utility can be accessed from *install_dir\SNMPAdmin.exe*.

- [SNMP administration utility](#)

SNMP administration utility

The SNMP Administration utility is composed of two tabs: **General** and **Startup Settings**.

- [General tab](#)
- [Startup Settings tab](#)

General tab

The following tasks can be performed from the General tab:

- Login and connect to the Launcher
- Configure SNMP Agent IP address and port number information
- Specify interval at which to check Launcher status

Launcher

The following information is used when connecting to the Launcher:

Login Name

This is the name of the Launch user. Launcher user profiles are set up in the Launcher Administration

Password

This is the password for the Launcher user. Launcher user profiles are set up in the Launcher Administration.

Port

This is the port number of the Launcher's listening port. The listening port for the Launcher is set up in the Launcher Administration.

See the Launcher documentation for more information about the Launcher.

Host

This name of the machine on which the Launcher is physically located.

SNMP Agent

The following information is used if multiple instances of the SNMP Agent are installed on the same machine.

On the Windows platform, the agent can be binded to one IP address on multiple ports. On UNIX platforms, the agent can be binded to multiple IP addresses on the same port or on multiple ports using virtual network interfaces.

SNMP IP Address

This is the Internet Protocol (IP) address of the SNMP Agent.

SNMP Port

This is the port number of the SNMP Agent.

SNMP Trap Port

This is the port number to receive trap notifications. The SNMP manager installed on the machine that is connected to that port will receive trap notifications. The default port number is **162**.

A trap community must be defined in the **dtx.acl** file that specifies which IP addresses or domains are to receive trap notifications. The port number that the specified IP address is binded to is specified in the **SNMP Trap Port** field.

System heartbeat

The following information is used to specify an interval for determining the system status of the Launcher:

System Status Polling Period (sec)

This is the interval, in seconds, at which the SNMP Agent will check the Launcher status.

Startup Settings tab

The following tasks can be performed from the Startup Settings tab:

- Specify thresholds that trigger map and connection pending state traps.
- Identify the Launcher and contact information for the human network manager.

Thresholds

The following information is used to set thresholds for map and connection pending states. These thresholds settings are implemented when the SNMP Agent first establishes a connection with the Launcher and are used to trigger a trap.

See "[Thresholds](#)" for more information on thresholds. See "[Traps](#)" for more information on traps.

Init Pending Count

This is the number of maps in initialization pending state that will trigger a trap.

IO Pending Count

This is the number of maps in input/output pending state will trigger a trap.

Connection Pending Count

This is the number of connections in pending state will trigger a trap.

Resource Pending Count

This is the number of maps in resource pending state will trigger a trap.

See the Launcher documentation for more information on map pending states.

MIB II

The following information is used to help you physically locate the machine hosting the Launcher and contact the person responsible:

sysName

This is the contact name for the person that is responsible for the Launcher in case of problems.

sysContact

This is the phone number for the person that is responsible for the Launcher in case of problems

sysLocation

This is the physical location and description of the Launcher.

Authentication Traps

This option enables the SNMP Agent to send a notification to the valid SNMP manager when the community name or context name and access rights of the SNMP manager sending the request does not match the community name and access rights defined in the **dtx.acl** file or the **dtx.uacl** file.

SNMP Agent tracing

The SNMP Agent Trace Level option appends tracing information to the log file that is generated when the SNMP Agent is started. The following options are available:

Option

Description

Disable

No tracing information is added to the log file.

Level 1

Exception error information is added to the log file.

Level 2

Trap and exception error information is added to the log file.

When you run the SNMP Agent on UNIX operating systems with tracing enabled, log information about the Launcher and associated map events is not only output to a file, but also output to the standard output console. To see how to disable the logging of the messages to the output console, see [Disabling the logging of messages to the output console](#).

For more information about the SNMP Agent log file, see ["SNMP Security"](#).

- [Disabling the logging of messages to the output console](#)

This procedure describes the steps to disable the logging of the messages about the Launcher and associated map events to the standard output console.

Disabling the logging of messages to the output console

This procedure describes the steps to disable the logging of the messages about the Launcher and associated map events to the standard output console.

Use this procedure when you are running the SNMP Agent on UNIX operating systems with tracing enabled, and you do not want the SNMP Agent to output the log information to the output console.

To disable the logging of messages to the output console, modify the `logging.properties` file in the following way:

1. Open the `logging.properties` file, which is located under the `java/lib` subdirectory of the path where IBM Transformation Extender is installed.
2. Set the following entry to `OFF` and then save the file:

```
java.util.logging.ConsoleHandler.level  
= OFF
```

When you run the SNMP Agent with the `java.util.logging.ConsoleHandler.level` set to `OFF`, the log information is no longer output to the console screen; it is only output to the log file.

SNMP security

With SNMP version 1 and version 2, SNMP security is controlled through communities that you configure in the `dtx.acl` file. With SNMP version 3, the SNMP user-based security model (USM) is controlled through users and contexts that you configure in the `dtx.uacl` file and the `dtx.security` file.

- [SNMP communities](#)
- [SNMP user-based security model](#)

SNMP version 3 (SNMPv3) supports a user-based security model (USM) that provides message-level security through authentication, privacy, and access control.

SNMP communities

In SNMP version 1 and version 2 (SNMPv1 and SNMPv2), administration groups are known as *communities*. SNMP communities consist of one agent and one or more SNMP managers. You can assign groups of hosts to SNMP communities for limited security checking of agents and management systems or for administrative purposes. Defining communities provides security by allowing only management systems and agents within the same community to communicate.

Communities are identified by community names that you assign. A host can belong to multiple communities at the same time, but an agent does not accept a request from a management system outside its list of acceptable community names. All `GET` and `SET` requests from an SNMP manager to an agent need to specify the community name of which the SNMP manager is a member so that the agent can perform access permission checking.

The `dtx.acl` file, located in the IBM Transformation Extender installation directory, identifies the SNMP communities to the SNMP Agent.

There is no relationship between community names and domain or workgroup names. Community names represent a shared password for groups of network hosts, and should be selected and changed as you would change any password. Deciding which hosts belong to the same community is generally determined by physical proximity.

- [Defining SNMP communities](#)

Defining SNMP communities

The `dtx.acl` file is used to define and maintain community definitions that specify the SNMP managers who can `GET` and `SET` MIB variables. A community definition contains the following:

Component	Description
Community Name	The name used to group SNMP hosts.
Permissions	MIB variable access rights which can be none, read-only, read-write, or write-only.
Host	The domain name or IP address of the physical machine. You can specify an IP address that is in IPv4 (for example, 1.2.3.4) or IPv6 (for example, a:b:c:d:0:1:2:3) format.

The `dtx.acl` file contains three default community definitions: Public, Private, and Trap. Public communities usually enable view-only access to MIB variable information. Typically, all hosts belong to Public, which is the standard name for a common community of all SNMP hosts. Private communities usually grant more permissions such as read-write or write-only. Trap communities identify the SNMP managers that are to receive trap notifications.

1. In a text editor, open the `install_dir\dtx.acl` file.

2. Add the following within the **acl** section and replace variables with actual values:

```
{  
    communities = community_name  
    access = MIB_variable_permissions  
    managers = localhost  
}
```

3. Save the file.

SNMP user-based security model

SNMP version 3 (SNMPv3) supports a user-based security model (USM) that provides message-level security through authentication, privacy, and access control.

- [Defining SNMPv3 users](#)
 - [Adding users to the security file](#)
-

Defining SNMPv3 users

The *install_dir\dtx.uacl* file defines the users, contexts, and security information that control access to the SNMP agent. Do not modify the file name. If you do, the SNMP Agent cannot validate the information when receiving SET and GET requests from the SNMP manager.

context-names

The comma-delimited list of context names. The *context* defines a scope within which an instance of a managed object type can be uniquely identified. For example, a context can be a physical or logical device. An MIB can include multiple contexts.

access

The access-level for retrieving or setting objects in the MIB:

```
read  
    The user can retrieve objects by using the SNMP Get operation  
read-write  
    The user can retrieve or set objects by using the SNMP Get and Set operations
```

security-level

The SNMP security level of requests to the SNMP Agent:

```
noAuthNoPriv  
    No authentication and no privacy  
authNoPriv  
    Authentication and no privacy  
authPriv  
    Authentication and privacy
```

users

The comma-delimited list of SNMPv3 users that are authorized to the SNMP Agent.

For more information, see the *Java™ Dynamic Management Kit* product documentation.

1. In a text editor, open the *install_dir\dtx.uacl* file.

2. Add the following within the **acl** section and replace variables with actual values:

```
{  
    context-names = context_name,context_name...  
    access = MIB_variable_permissions  
    security-level = security_level  
    users = user_name,user_name...  
}
```

3. Save the file.

Adding users to the security file

The *install_dir\dtx.security* file defines the local SNMP engine and the users that are authorized to the SNMP Agent.

localEngineID

A hexadecimal string identifying the local SNMP engine.

localEngineBoots

The number of times the local engine will boot. The SNMP Agent uses this value to evaluate the timeliness of SNMP requests.

userEntry

The SNMPv3 local engine ID, user name, and optional security information. Include a *userEntry* keyword for each user that is authorized to the SNMP Agent. The *userEntry* keyword can include the following variables:

localEngineID
A hexadecimal string identifying the local SNMP engine. This parameter is required.

user_name
An SNMPv3 user that is authorized to the SNMP Agent. SNMPv3 users are defined in the **dtx.uacl** file. This parameter is required.
security_name

A text string used to authenticate communication between the SNMP Agent and the SNMP manager. This parameter is optional.
authentication_algorithm

One of the following algorithms. This parameter is optional.

- usmHMACMD5AuthProtocol
- usmHMACSHAAuthProtocol
- usmNoAuthProtocol

authentication_key

A text password or hexadecimal key that conforms to the requirements of the authentication algorithm. This parameter is optional.

privacy_algorithm

One of the following. This parameter is optional. If omitted, the default value is usmNoPrivProtocol.

- usmDESPrivProtocol
- usmNoPrivProtocol

privacy_key

A text password or hexadecimal key. If you provide a hexadecimal key, it must be a localized key.

For more information about generating the engine ID and the optional userEntry parameters, see the *Java™ Dynamic Management Kit* product documentation.

1. In a text editor, open the **install_dir\dtx.security** file.
2. Add the following and replace variables with actual values:

```
{  
localEngineID = engine_ID  
localEngineBoots = number_of_boots  
userEntry = localEngineID,user_name,security_name,authentication_algorithm,  
authentication_key,privacy_algorithm,privacy_key  
}
```

3. Save the file.

Starting the SNMP Agent

The SNMP Agent is started as a service on Windows or as a daemon on UNIX.

SNMP operations and thresholds

SNMP operations include retrieving information (GET), modifying information (SET) and reporting an event (TRAP). These operations provide management access to MIB variables and agent status:

- **GET:** fetch value of one or more variables
- **SET:** set value of one or more variables
- **TRAP:** unsolicited event notification generic to all or vendor-specific

Any implementation supporting the SNMP operations must adhere to requirements as defined in RFC1157.

- [GET](#)
- [SET](#)
- [Traps](#)

GET

GET is a retrieval operation. The SNMP manager uses the MIB to issue requests across the network to the SNMP Agent running on the remote site. The agent then looks in its list of configured objects to find the requested object. The result is passed back to the SNMP manager from the SNMP Agent.

SET

SET is a modification operation used to set the value of one or more variables. When setting a value, the SNMP manager issues a SET request and forwards it to the SNMP Agent. The SET operation is used to configure and control the managed system.

When a SET request is issued to the SNMP Agent to change the state of a variable, the agent makes the change in the MIB and sends a GET response back to the SNMP manager with the updated state of the variable. Another indicator, error status, informs the SNMP manager if the change was successful.

For example, to start, stop, pause, or resume the Launcher, a SET request is issued by the SNMP Manager, the SNMP Agent modifies the MIB variable and then sends a GET response back to the SNMP Manager with the updated state of the variable. The request to change the state of the Launcher is not executed until this GET response is received.

The error status codes included in response to a SET request are listed below.

Error Code	Description
0	

```

SET was successful
2      SET specified nonexistent variable
3      SET specified invalid value or syntax
4      SNMP manager tried to modify read-only variable

```

Traps

Traps are event-reporting operations issued by the SNMP Agent. A trap is an unsolicited, device-initiated message or notification. The notification containing the OID is always sent from the Launcher.

Using the SNMP adapter, you can create and send custom-defined traps to an SNMP manager. See the SNMP Adapter documentation for more information.

The SNMP manager cannot set traps. It can only receive traps from the SNMP Agent. Traps are stored in the DTX MIB and users define which traps they want by means of the SNMP manager.

Traps can send notifications of warnings and errors. The following table lists the five types of traps that can be issued:

Trap	Description
Map failure	Signals when a map fails
State and Listener change	Signals a change in state of the Launcher or Listeners
Launcher/resource connection failure	Notifies the SNMP manager that a connection between the Launcher and the resource could not be established
Thresholds	Signals when a map or connection pending state threshold has been met
Custom	User-defined trap created and sent using the SNMP adapter

- [Defining SNMP traps](#)
- [Supported traps](#)
- [Thresholds](#)
- [Troubleshooting](#)

Defining SNMP traps

The **dtx.acl** file contains three default community definitions: Public, Private, and Trap. Trap communities identify the SNMP managers that are to receive trap notifications. You can define only one trap community in the **dtx.acl** file.

SNMPv3 does not use the community string to identify destinations. When creating an SNMPv3 trap group, use only the SNMP manager's IP address. For more information, see the *Java™ Dynamic Management Kit product* documentation.

1. In a text editor, open the **install_dir\dtx.acl** file.
2. Add the following within the **trap** section and replace variables with actual values:

```
{
trap-community = trap_community_name
hosts = localhost
}
```

3. Save the file.

Do not modify the **dtx.acl** file name. If you do, the SNMP Agent cannot validate community information when receiving **SET** and **GET** requests from the SNMP manager.

Supported traps

The following table lists all traps, and the variables for which information is included on in the notification message, that are supported by the SNMP Agent. These traps are defined in the **dtx_smi1.mib** file. This file is located in the directory in which the SNMP Agent is installed.

See ["DTX MIB"](#) for descriptions of the MIB object variables.

Trap	#	Trap Description	Variables Returned
dtxInitPendingThreshold	1	Notification of an initialization pending threshold that has been met	dtxMslFileName dtxSystemName dtxInitPendingCount
dtxResourcePendingThreshold	2	Notification of a resource pending threshold that has been met	dtxMslFileName dtxSystemName dtxResourcePendingCount

Trap	#	Trap Description	Variables Returned
dtxIoPendingThreshold	3	Notification of an I/O pending threshold that has been met	dtxMslFileName dtxSystemName dtxIoPendingCount
dtxConnectionPending Threshold	4	Notification of a connection pending threshold that has been met	dtxMslFileName dtxSystemName dtxConnectionPendingCount
dtxSystemStopped	5	Notification that the System has stopped	dtxMslFileName dtxSystemName dtxSystemStatus
dtxSystemStopping	6	Notification that the System is preparing to stop	dtxMslFileName dtxSystemName dtxSystemStatus
dtxSystemPausing	7	Notification that the System is preparing to pause	dtxMslFileName dtxSystemName dtxSystemStatus
dtxSystemPaused	8	Notification the system has entered a pause state	dtxMslFileName dtxSystemName dtxSystemStatus
dtxSystemStarted	9	Notification the system has started	dtxMslFileName dtxSystemName dtxSystemStatus
dtxSystemStarting	10	Notification the system is preparing to start	dtxMslFileName dtxSystemName dtxSystemStatus
dtxSystemNotResponding	11	Notification the system is not responding	dtxMslFileName dtxSystemName dtxSystemStatus
dtxSystemError	12	An unknown error has occurred within the system process	dtxMslFileName dtxSystemName dtxSystemStatus
dtxSystemModified	13	The system definition has been modified	dtxMslFileName dtxSystemName
dtxSystemNew	14	A new system has been added	dtxMslFileName dtxSystemName
dtxSystemDeleted	15	System has been deleted	dtxMslFileName dtxSystemName
dtxSystemResumed	16	Notification that the system has resumed	dtxMslFileName dtxSystemName
dtxEventMapFailed	17	Notification of a map failure	dtxMslFileName dtxSystemName dtxComponentName dtxMapFile dtxMapReturnCode dtxMapErrorMessage dtxFailingCardNumber dtxFailingCardDirection dtxFailingCardReturnCode
dtxEventConnectionFailed	18	Notification of a connection failure	dtxMslFileName dtxSystemName dtxAdapterAliasName dtxAdapterErrorCode dtxConnectionFailureCount
dtxEventListenersDown	19	Listener has lost a connection to the resource	dtxMslFileName dtxSystemName dtxComponentName dtxListenerCardNumber

Trap	#	Trap Description	Variables Returned
dtxEventListenersUp	20	Listener has reestablished the connection to the resource	dtxMslFileName dtxSystemName dtxComponentName dtxListenerCardNumber
dtxUserData	21	User-defined trap created and sent using the SNMP adapter	dtxMapFile dtxUserDataInt dtxUserDataTxt dtxUserDataBin

Thresholds

Thresholds are used to monitor the performance and to help identify situations that require attention. When a threshold limit has been met or exceeded, a notification message is sent to the SNMP manager. Notifications of warnings and errors are used by human managers to actively log and respond to situations when necessary.

The Launcher monitors counts for the following statistical information:

Threshold	Description
Initialization pending count	When the number of maps in init pending state have reached or exceeded the specified threshold
IO pending state	When the number of maps in IO pending state have reached or exceeded the specified threshold
Connect pending	When the number of connections in pending state have reached or exceeded the specified threshold
Resource pending state	When the number of maps in resource pending state have reached or exceeded the specified threshold

- [Setting threshold limits](#)
- [Threshold notification](#)

Setting threshold limits

Users can set limits for each count. The startup threshold values are configured in the SNMP Administration utility. When the SNMP Agent first establishes a connection with the Launcher, the agent sets the threshold limits. Limits can be changed dynamically using the SNMP manager. However, the modification is only a temporary override as the next time the SNMP Agent is restarted, the threshold values originally configured using the SNMP Administration utility will once again be used. To permanently change the values, use the SNMP Administration utility to make the modifications.

See "[SNMP Administration Utility](#)" for more information on setting threshold values.

Threshold notification

Once a threshold meets or reaches a limit, the Launcher sends a notification message to the SNMP Agent, who then issues a trap to the SNMP manager.

While the threshold count is still equal or above the limits, no more messages will be sent for that threshold until the count falls below the limit. A flag is reset at this time, and notifications are sent the next time the limit is reached.

Threshold notification method

The type of notification method used by the SNMP Agent is called single edge. Single edge notification occurs when a value exceeds the threshold limit and the *LowerBound* and *UpperBound* values, the upper or lower limit in a permitted range of values, are the same.

Troubleshooting

Every time the SNMP Agent is started, a log file is created containing information on major events such as Launcher connection status and map failure. This log file can be used as a troubleshooting aide for the Launcher and the map system it is running.

The log file, **SNMPagentlogdate-time.log**, is created in the **install_dir\logs** directory. For example, if the SNMP Agent is started at 4:35 pm on November 16, 2005, the **SNMPagentlog11-16-05-4-35-22-pm.log** file is created.

DTX MIB

This documentation provides information on the variables for the DTX MIB object. The variables in the Listener, Map, and Adapter properties are used in trap notifications. The Table objects contain variables that pertain to a map system component. The associated map system component is located in a System object.

The tables in this documentation also note which variables allow a GET or SET to be performed and which variables are included in trap notifications.

See "[MIB Data Objects](#)" for more information on the structure the DTX MIB.

- [Listener properties](#)
- [Map properties](#)
- [Adapter properties](#)
- [System objects](#)
- [Table objects](#)

Listener properties

The following table lists information on the variables for Listener properties:

Name and OID	Description	GET	SET	TRAP
dtxListenerCardNumber 1.3.6.1.4.1.4769.1.1.3.1	The number of the input card for which a listener is associated	✓		✓

Map properties

The following table lists information on the variables for Map properties:

Name and OID	Description	GET	SET	TRAP
dtxConnectionFailureCount 1.3.6.1.4.1.4769.1.1.3.1.9	Number of times that a connection to a resource has failed	✓		✓
dtxFailingCardReturnCode 1.3.6.1.4.1.4769.1.1.3.1.8	Return code from the failing card	✓		✓
dtxFailingCardDirection 1.3.6.1.4.1.4769.1.1.3.1.7	Whether the failing card is input or output	✓		✓
dtxFailingCardNumber 1.3.6.1.4.1.4769.1.1.3.1.6	The number of the failing card	✓		✓
dtxMapErrorMessage 1.3.6.1.4.1.4769.1.1.3.1.5	Error message associated with the map return code	✓		✓
dtxMapReturnCode 1.3.6.1.4.1.4769.1.1.3.1.4	Return code from the map execution. See the Map Designer documentation for a list of map return codes.	✓		✓
dtxMapFile 1.3.6.1.4.1.4769.1.1.3.1.3	The fully qualified path name of a map file	✓		✓
dtxComponentName 1.3.6.1.4.1.4769.1.1.3.1.2	The name of the map component	✓		✓
dtxWatchID 1.3.6.1.4.1.4769.1.1.3.1.1	Unique identifier assigned by the Launcher	✓		✓
dtxSysTable 1.3.6.1.4.1.4769.1.1.2.1.2	A list of system entries. The number of entries is specified as the value of dtxSysCount .	✓		✓

Adapter properties

The following table lists information on the variables for Adapter properties:

Name and OID	Description	GET	SET	TRAP
dtxAdapterErrorCode 1.3.6.1.4.1.4769.1.1.3.2.2	Return code from the adapter indicating the nature of the failure	✓		✓
dtxAdapterAliasName 1.3.6.1.4.1.4769.1.1.3.2.1	Adapter alias name identifying which resource has failed	✓		✓

System objects

The following table lists information on the variables for System objects:

Name and OID	Description	GET	SET	TRAP
dtxSysCount 1.3.6.1.4.1.4769.1.1.2.1.1	The number of systems in the table, regardless of the current state of the systems	✓		
dtxAdminAllSystemsStatus 1.3.6.1.4.1.4769.1.1.2.1.3	Describes the <i>intended</i> status of the system: 1 = Stop 2 = Start 3 = Pause 4 = Resume	✓	✓	

Table objects

The following table lists information on the variables for Table objects:

Name and OID	Description	GET	SET	TRAP
dtxSysTableEntry 1.3.6.1.4.1.4769.1.1.2.1.2.1	A system entry containing objects for a particular system	✓		✓
dtxMaxWatchCount 1.3.6.1.4.1.4769.1.1.2.1.2. 1.19	The maximum number of instances of any specific map	✓		
dtxMaxThreadCount 1.3.6.1.4.1.4769.1.1.2.1.2. 1.18	The maximum number of threads used to execute maps	✓		
dtxThreadUsage 1.3.6.1.4.1.4769.1.1.2.1.2. 1.17	Number of threads being used by the system	✓		
dtxCPUUsage 1.3.6.1.4.1.4769.1.1.2.1.2. 1.16	Percentage of CPU being used by the system	✓		
dtxMemoryUsage 1.3.6.1.4.1.4769.1.1.2.1.2. 1.15	The number of Mbytes being used by the system	✓		
dtxWatchCount 1.3.6.1.4.1.4769.1.1.2.1.2. 1.14	The number of events being monitored	✓		
dtxFailureTime 1.3.6.1.4.1.4769.1.1.2.1.2. 1.13	Sum of time, in seconds, used by failed map	✓		
dtxSuccessTime 1.3.6.1.4.1.4769.1.1.2.1.2. 1.12	Sum of time, in seconds, used by successful maps	✓		
dtxFailureCount 1.3.6.1.4.1.4769.1.1.2.1.2. 1.11	The number of maps that have failed as long as the Launcher has been running	✓		
dtxConnectionPendingMaps 1.3.6.1.4.1.4769.1.1.2.1.2. 1.10	The number of maps in a 'connection pending' state	✓		✓
dtxIOPendingMaps 1.3.6.1.4.1.4769.1.1.2.1.2. 1.9	The number of maps in an 'IO pending' state	✓		✓
dtxResourcePendingMaps 1.3.6.1.4.1.4769.1.1.2.1.2. 1.8	The number of maps in a 'resource pending' state	✓		✓
dtxInitPendingMaps 1.3.6.1.4.1.4769.1.1.2.1.2. 1.7	The number of maps in an 'initialization pending' state	✓		✓
dtxCurrentMapCount 1.3.6.1.4.1.4769.1.1.2.1.2. 1.6	The number of maps currently being executed	✓		
dtxTotalMaps 1.3.6.1.4.1.4769.1.1.2.1.2. 1.5	The number of maps that have been executed	✓		
dtxUpTime 1.3.6.1.4.1.4769.1.1.2.1.2. 1.4	The amount of time, in seconds, that the system has been running	✓		
dtxMslFileName 1.3.6.1.4.1.4769.1.1.2.1.2. 1.3	The name of the .msl file in which the system is defined	✓		✓

Name and OID	Description	GET	SET	TRAP
dtxConnectionPendingCount 1.3.6.1.4.1.4769.1.1.2.1.2. 1.24	Upper bound limit for connection pending maps	✓	✓	
dtxSystemName 1.3.6.1.4.1.4769.1.1.2.1.2. 1.2	The name of the system defined in the system definition	✓		✓
dtxIoPendingCount 1.3.6.1.4.1.4769.1.1.2.1.2. 1.23	Upper bound limit for I/O pending maps	✓	✓	
dtxSystemIndex 1.3.6.1.4.1.4769.1.1.2.1.2. 1.1	A unique value for each system. The value ranges between 1 and the value of the dtxSysCount .	✓		
dtxResourcePendingCount 1.3.6.1.4.1.4769.1.1.2.1.2. 1.22	Upper bound limit for resource pending maps	✓	✓	
dtxInitPendingCount 1.3.6.1.4.1.4769.1.1.2.1.2. 1.21	Upper bound limit for initialization pending maps	✓	✓	
dtxAdminSystemStatus 1.3.6.1.4.1.4769.1.1.2.1.2. 1.25	Describes the <i>intended</i> status of the Launcher: 1 = Stop 2 = Start 3 = Pause 4 = Resume	✓	✓	
dtxActSystemStatus 1.3.6.1.4.1.4769.1.1.2.1.2. 1.26	Describes the <i>actual</i> status of the Launcher: 1 = Stopped 2 = Started 3 = Paused 4 = Resumed 5 = Stopping 6 = Starting 7 = Pausing 8 = Not Responding 9 = Error	✓		
dtxAdminDebugSystemStat us 1.3.6.1.4.1.4769.1.1.2.1.2. 1.27	Describes the <i>intended</i> trace status: 1 = Off 2 = On	✓	✓	
dtxActDebugSystemStatus 1.3.6.1.4.1.4769.1.1.2.1.2. 1.28	Describes the <i>actual</i> trace status: 1 = Off 2 = On	✓		

Resource Adapters

A comprehensive collection of communication, database, messaging, and utility adapters are available for IBM Transformation Extender, as well as adapters for third-party applications and web services. Use Custom installation to install the adapters.

[Resource Adapters overview](#)

Resource adapters overview

IBM Transformation Extender resource adapters are used to retrieve and route data. They provide access to databases, files, messaging systems, enterprise applications and other data sources and targets. You can use adapters with the Command Server, Launcher, Software Development Kit, or with a map in a map rule.

Each adapter includes a set of adapter commands that can be used to customize its operation. Use the adapter commands to specify different queues and queue managers, specific messages by message ID, specific sets of messages with the same message ID, message descriptors in your data, and more.

Resource adapters answer the questions "Where should the data come from?" and "Where should the data go?"

Source and target data may be in a file, from a specific application, in a database, from a message queue, from an archive file, or from other sources. The client components of the Design Server, Integration Flow Designer, map designer, schema designer, and Database Interface Designer are integral to using the resource adapters.

Each input of data and each output of data requires content definition settings. These card settings are specific to input and output cards, although some settings are common to both cards.

Importers

The Importer Wizard uses a series of maps to convert metadata into a schema script file (.mts). The Type Tree Maker then processes this schema script and generates a schema that contains all the supported types that are defined in the imported metadata.

Many of the schemas that are generated by the Importer Wizard can be immediately used for map development. However, depending on the contents of the interface-specific metadata file, it might be necessary to modify the generated schema using the schema designer.

For information about importers corresponding to adapters that you have installed, see the specific resource adapter documentation.

System requirements

See the system requirements for operating system and hardware requirements. See the release notes and the adapter documentation for adapter-specific configuration requirements.

It is assumed that a Command Server has already been installed on the computer where the utility adapters are to be installed for run-time purposes.

General rules for adapter commands

Following is a list of the general rules that apply when specifying adapter commands:

- Each command must begin with a hyphen.
- Command characters can be uppercase, lowercase, or mixed-case.
- Command strings are parsed in left-to-right order.
- The order of commands is not important.
- Command files can contain multiple lines. Line breaks can be used in place of the required space that must exist between commands. The line breaks are converted to spaces before processing.
- Space characters:
 - Spaces preceding the first command are ignored.
 - At least one space between commands is required
(for example: **-KEEP -TRACE**).
 - A space is required preceding a variable value
(for example: **-TRACE+S full_pathname**).
- The value of the **Command** setting (adapter-specific commands) in input and output cards and in a **GET** or **PUT** function within a map rule may not exceed 2000 bytes. The expansion of the resource value is included in this limitation.

For platform-specific information about using specific adapter commands with execution commands, refer to the following:

- [For Windows Sources and Targets on the Command Line](#)
- [For UNIX Sources and Targets on the Command Line](#)

Command syntax summaries

A syntax summary is a comprehensive list of the adapter-specific commands organized for use with data sources and data targets. Syntax notation, as applied to all command documentation, indicates required and optional commands, as well as options available for each command.

Required commands appear at the beginning of the list. Optional commands appear in brackets []. Command dependencies are also noted when commands appear on the same line.

The following is a portion of the syntax summary for the IBM® MQSeries® messaging adapter command available for use with data sources:

```
-QMN queue_manager_name  
-QN queue_name
```

This example illustrates that both the Queue Manager Name adapter command (**-QM**N****) and the Queue Name adapter command (**-QN**) are required for data sources. In this example, you may use the Queue Manager Name adapter command (**-QM**N****) to specify the name of the queue manager on which the queue (specified by the **-QN** command) exists.

The following is an additional example of the syntax notation used by the IBM MQSeries messaging adapter:

```
-QMN queue_manager_name  
-QN queue_name  
[-MID message_ID| -HMID hex_message_ID]
```

This example illustrates the use of brackets to indicate optional message ID adapter commands. The brackets [] indicate that both of the message ID commands are optional. The pipe | indicates that you may choose one of these commands, but not both.

In this example, you may use the Message ID adapter command (**-MID**) to specify a particular message ID for a data source. Or you may choose to use the Hex Message ID adapter command (**-HMID**) to specify message identifiers using hexadecimal pair notation.

* The File and Sink adapters do not require any adapter commands for their operation. The File adapter uses only the full pathname and filename for a parameter.

Adapter command aliases

Specify the adapter commands using an execution command string on the command line. You can also create a command file that contains adapter commands dictating the desired execution settings.

Use the appropriate Input Source Override and Output Target Override execution commands with the adapter alias.

Refer to the specific adapter documentation for detailed information for each alias command.

Configuring Java-based adapters

Jar files included with the software and installed in the **install_home** directory are normally added to the CLASSPATH environment variable automatically as in the case of the Command Server and the Launcher. You must modify the CLASSPATH environment variable for all Java-based adapters that rely on external .jar files in order to execute properly.

You can do this directly, or by adding the .jar files to the **config.yaml** file. You must use a full path in the **config.yaml** file. To do so, add entries to the /runtime/External Jar Files dictionary section. Refer to the *Launcher documentation* for more information on the **config.yaml** file.

For example:

```
[External Jar Files]  
jar1=c:\J2EE\lib\j2ee.jar  
jar2=c:\mypath\myjar.jar
```

Note: For Windows, use either a forward slash "/" or two back-slashes "\\\" for the directory delimiter in config.yaml.

- [UNIX only](#)
- [API usage](#)

UNIX only

For all Java™ components the directories containing the Java Virtual Machine (JVM) libraries need to be in the library path environment variable. Typically, this is already defined in the environment, however if it is not, then it must be manually added to the library path environment variable. The following environment variables exist for:

UNIX Platform

Environment Variable

AIX®

LIBPATH

Solaris

LD_LIBRARY_PATH

HP-UX

SHLIB_PATH

Linux®

LD_LIBRARY_PATH

API usage

When a map is started using the Java™ API, where the main process starts with the java command, all necessary .jar files from the **install_home** directory and external .jar files related to the adapter must be added to the CLASSPATH environment variable manually.

Encoding and decoding data

There are a number of adapters which only manipulate data (for example, SOAP), while others provide transport (for example, HTTP). Chaining these adapters together provides greatly enhanced functionality.

Using the **-ENCODE** and **-DECODE** commands in combination with the **-TRANSPORT** command allows you to effectively combine the encoding/decoding capabilities of one adapter with the getting or sending of data of another adapter.

- [Supported adapters](#)
- [Limitations](#)
- [Encoding](#)
- [Decoding](#)
- [Transporting](#)

Supported adapters

Almost any adapter can be used as a transport adapter, although it must be used in its supported contexts. The only adapter that cannot be a transport adapter is the File adapter because it is the only adapter that is not started from the Resource Manager.

The following adapter can be used as an encoding or decoding adapter:

- SOAP

Limitations

The following limitations exist:

- There can be only ONE transport adapter in a card. Since the transport generally represents the end point or start point in a process, it does not make sense to permit more than one transport adapter.
- Encode/decode adapters can be nested. However, the total length of the command line cannot exceed 2000 bytes.

Encoding

Data can be encoded using a specified adapter. The encoding adapter is called before the transport adapter in an output card, **PUT** or **GET** where request data is passed as the third parameter.

The following characteristics exist for the **-ENCODE** command:

- The **-ENCODE** command is used within the command line of a transport adapter, or another encoding adapter.
- The **-ENCODE** command cannot be used in an input card.

For example:

```
-ENCODE 'encoding_adapter (command_line)'
```

The **-ENCODE** command is not required if the **-TRANSPORT** command is used. Encoding is implied by using **-TRANSPORT** in an output card, **PUT** or **GET** where request data is passed as the third parameter.

See "[Encode/Decode Scenarios](#)" for more information.

Decoding

You can also decode the data using a specified adapter. The decoding adapter is called after the transport adapter in an input card or **GET**.

The following characteristics exist for the **-DECODE** command:

- The **-DECODE** command is used within the command line of a transport adapter, or another decoding adapter.
- The **-DECODE** command cannot be used in an output card or a **PUT** function.

For example:

```
-DECODE 'decoding_adapter (command_line)'
```

The **-DECODE** command is not required if the **-TRANSPORT** command is used. Decoding is implied by using **-TRANSPORT** in an input card, or **GET** function.

See "[Encode/Decode Scenarios](#)" for more information.

Transporting

After specifying either an encode or decode command, data can be transported using a specified adapter. The transport adapter is called:

- Before the decoding adapter in an input card or **GET**
- After the encoding adapter in an output card or **PUT**
- Between the encoding and decoding adapters in a **GET** where request data is passed as the third parameter.

The **-TRANSPORT** command is used in the command line of an encoding or decoding adapter. If used from a **GET**, the *transport_adapter* must support request-reply and the adapter that is used with the first parameter of the **GET** must support both encode and decode functions.

For example:

```
-TRANSPORT 'transport_adapter (command_line)'
```

When reversing the chained adapters and using the **-ENCODE** or **-DECODE** commands rather than the **-TRANSPORT** command the **-TRANSPORT** command the behavior is unaltered.

For example, the following **PUT** function calls are functionally equivalent.

```
=PUT(" email ", "-TO fred@hotrods.com -ENCODE ' SOAP (-T)'", Message)
=PUT(" SOAP ", "-T -TRANSPORT ' email (-TO fred@hotrods.com)'",
Message)
```

See [Transport Encode/Decode Examples](#) for more information.

Encode/decode scenarios

The following scenarios apply when using the encode/decode commands in an input card, output card, or in a **GET** function.

- [Input card or GET](#)
- [Output card or PUT](#)
- [GET function](#)

Input card or GET

In an input card or **GET**, where the **-DECODE** command is specified, data is:

- received by the transport adapter,
- decoded by the decoding adapter.

Output card or PUT

In an output card or **PUT** function, where the **-ENCODE** command is specified, data is:

- sent by the transport adapter,
- encoded by the encoding adapter.

GET function

In a **GET** function performing a request/reply using the optional third parameter, the following activities occur:

- Encoding by the encoding adapter
- Sending by the transport adapter
- Receiving by the transport adapter
- Decoding by the decoding adapter

Transport encode/decode examples

The following examples show how the transport adapter encodes or decodes the data when used in an input card, an output card, or in a **GET** function.

- [SOAP Input card](#)
- [SOAP Output card](#)
- [SOAP request/reply in a GET function](#)

SOAP Input card

SOAP
Command
-ENV -TRANSPORT 'HTTP (-URL <http://www.mysite.com>)'
Meaning
The HTTP adapter is called for the transport, then the data is passed to the SOAP adapter to decode.

SOAP Output card

Adapter
SOAP
Command
-ENV -TRANSPORT 'HTTP (-URL <http://www.mysite.com>)'
Meaning
The SOAP adapter is called to encode the data, then the data is passed to the HTTP adapter to transport.

SOAP request/reply in a GET function

Function Call
GET ("SOAP", "-ENV -TRANSPORT 'HTTP (-URL <http://www.mysite.com>, Request)'
Meaning
The SOAP adapter is called to encode the data. The data is then passed to the HTTP adapter to send the request and pick up the response. The SOAP adapter is called again to decode the response.

Using resource adapters

Resource adapters can be specified:

- As a resource in the map designer
 - In map rules and component rules when using the functions **RUN**, **GET**, or **PUT**
 - From the execution settings in the Integration Flow Designer
 - On the command line for a Command Server or Integration Platform Programming Interface
- A wide range of execution commands are available with the Command Server or Software Development Kit. For a complete list of the available options, refer to the Execution Commands documentation.

See the map designer documentation for information on source and target settings in input and output cards.

Using an adapter in the map designer

Use the **Source** setting on an input card or the **Target** setting on an output card to specify an adapter, for example, HTTP, or database, representing any of the database adapters. The adapter-specific commands are entered in the **Command** setting on the card. The adapter-specific commands define how to connect to the data source or target and how to retrieve or route the data.

Using the map designer, select an adapter for a source to retrieve files or data, or a target to transfer files or data.

Maps define how to generate data objects of a certain type. A map contains input and output cards that transform data content from source formats to target formats.

- The **Command** setting on the input card of a map identifies the source of the input data and specifies the use of a resource adapter for input data.
- The **Command** setting on the output card specifies the use of a resource adapter for output data.

On an input card, a **Source** setting of **File** defines the input source as a file and the Source FilePath setting is used to define the **Name** and **Path** of the input file.

If the input data is coming from a database, the **GET Source** Command setting might include commands specifying the database name, user ID, and password.

See the following example to learn how to specify the FTP adapter as a data source in the map designer.

- [Specifying the FTP adapter in the map designer](#)

Specifying the FTP adapter in the map designer

The FTP value for the **Source** setting in this input card identifies the FTP adapter as the source of the input data.

To specify the FTP adapter:

1. In the input card for a map, set **Source** to **FTP**.
2. For the **Command** setting, enter the required FTP URL adapter command (-**URL**), the name of the file to transfer, and other FTP adapter commands as needed.
3. Click OK.

The Source Command value for the FTP input card above is:

```
-TS -URL FTP://sales@host/c:/forms/myfile.txt
```

When this map is run, a file named **myfile.txt** is retrieved from a remote host named **sales**. The Summary Trace adapter command **-TS** specifies that the adapter will create a summary trace file to report adapter activity information during the FTP process.

Using an adapter in a map or component rule

Specify adapter commands using the **GET**, **PUT**, **RUN**, **DBLOOKUP** or **DBQUERY** functions when defining map rules in the map designer or in component rules in the schema designer. The **DBLOOKUP** and **DBQUERY** functions are used for databases only. You must specify the resource adapter with an execution command and a resource adapter alias. For information about adapter aliases, see [Adapter Command Aliases](#).

Use adapter commands in functions and in component rules in the schema designer and map rules in the map designer.

- [Examples of database adapter commands](#)

Examples of database adapter commands

- The following example shows a map rule using a **DBQUERY** function with database adapter commands to specify particular adapter settings.

```
DBQUERY ("SELECT PART_NAME from PARTS where PART_NUMBER =1",
        "-DBTYPE ORACLE -CONNECT MyDatabase -USER janes")
```

This example uses the **-DBTYPE ORACLE** adapter command to specify the database adapter type as Oracle and **-CONNECT MyDatabase** to designate MyDatabase as the Oracle connect string. The **-USER janes** adapter command identifies janes as the user ID.

For information about using the **DBLOOKUP** and **DBQUERY** functions, refer to the Database Interface Designer documentation.

- Use adapter commands with either the Input Source Override - Database execution command (**-ID**) or the Output Source Override - Database execution command (**-OD**) in a **RUN** function to override particular settings. The following example shows using a **RUN** function to specify adapter commands without using an **.mdq** file:

```
RUN ("somemap.mmc" ,
      "-od1 '-dbtype oracle -connect remotedb -user " +
      "userid:profile -password " + password:profile +
      " -table purchordr'")
```

In this example, a map named **somemap.mmc** is being run. The output of this map will be inserted in the PurchOrdr table in an Oracle database defined by the RemoteDB connect string. The logon, user ID, and password settings are retrieved from an input card named Profile.

For information about using the **RUN**, **GET** and **PUT** functions, refer to the Functions and Expressions documentation.

Using an adapter in the Integration Flow Designer

In the Integration Flow Designer, while accessing the Launcher or Command Server execution settings for a map, you can use the adapter as a source to retrieve files or as a target to transfer files.

The **Execution Mode** of the system component determines the execution settings modified to use a resource adapter.

If the **Execution Mode** setting is Launcher, edit the **Launcher Settings** for that system component.

If the **Execution Mode** setting is Command Server, edit the **Command Server Settings**.

For documentation purposes, these settings are referred to as execution settings regardless of the execution mode selected.

You can use the adapter as a source to retrieve files or as a target to transfer files.

For example, to override database-specific adapter settings in an input card or to use the adapter for a source, access the execution settings for a map. From the **GET > Source** list in the execution settings of the map, select Database. In the **GET > Source > Command** setting, specify the adapter commands.

An example of a database-specific adapter command is as follows:

```
-M c:\MDQfiles\Orders.mdq -DN Parts -TE+
```

where **-M** and **-DN** are used to specify usage of a database/query file named **Orders.mdq** and a database named **Parts**. The **-TE+** command causes database trace information containing only errors occurring during map execution to be produced and appended to the existing trace file.

- [Specifying the TIBCO RV adapter in the Integration Flow Designer](#)

Specifying the TIBCO RV adapter in the Integration Flow Designer

The following example illustrates the use of the **TIBCO RV** adapter in the Integration Flow Designer.

To specify the TIBCO RV adapter:

1. Open a system in the Integration Flow Designer.

2. Open the Launcher settings for a map component.
3. Go to the Input(s) #1 in1 > GET-> Source setting.
4. For the **Source** setting, select TIBCO RV from the drop-down list.
5. In the **Command** field, enter a TIBCO RV adapter command. For example, enter:

```
-SBN rvcm.test.in -CONFIRM -T -CMN input_CM -LFN rvcmcfmin.lgr
-LSN 100
```

This example input card retrieves incoming messages with the subject name defined as **rvcm.test.in** using the Subject Name adapter command (-SBN rvcm.test.in). The -CONFIRM adapter command requests that the messaging adapter send an explicit confirmation to the sender that the message was received after successful completion of the map. The Trace adapter command (-T) dictates that a trace file be created to report adapter activity information, recording the events that occur while the adapter is retrieving this data.

The adapter returns messages with the certified session named **input_CM** using the required Certified Session Name adapter command (-CMN input_CM). The ledger file named **rvcmcfmin.lgr** is specified as the ledger file to log the TIBCO Rendezvous PRO certified delivery for this particular certified session using the Ledger File Name adapter command (-LFN rvcmcfmin.lgr). The adapter waits 100 seconds for a message receipt, as specified using the Listen adapter command (-LSN 100).

On the command line

In addition to using a command string on the command line, you can also use adapter commands in command files, batch files, shell scripts, or with the z/OS Platform API.

Use adapter-specific execution commands to:

- Override particular settings for an existing source, such as a user ID and password for database adapters.
- Override an existing source or target, using file, application, message or another entity.

Specify the preferred adapter commands using an execution command string on the command line, or, create a command file that contains adapter commands dictating the execution settings.

For information on adapter-specific input and output execution command overrides, see the Execution Commands documentation.

- [Database-specific adapter commands on the command line](#)
- [For Windows sources and targets on the command line](#)
- [For UNIX sources and targets on the command line](#)

Database-specific adapter commands on the command line

For a database-specific adapter, an existing data source which is a file, can be overridden and specified to be a database using the Input Source Override - Database execution command (-ID). Or, you can override an existing data target that is a table in one database with a table in a different database using the Output Source Override - Database execution command (-OD). For information about all of the options to use within these database execution commands, refer to the Execution Commands documentation.

The values specified using the Input Source Override - Database execution command (-ID) and the Output Source Override - Database execution command (-OD) can be used to designate a query or table to be used as the data source or target, or to override one or more of the adapter commands of an existing database definition as follows:

- using an **.mdq** file
Specify the name of an .mdq file and the name of a particular database that will override the appropriate adapter settings. In this usage, the .mdq file must be available at map execution time. The values in the .mdq file will override all values defined in the map.
- not using an **.mdq** file
Use a command string that includes all of the database adapter commands necessary to specify the desired settings for a map. An **.mdq** file is not used.
- [Command line examples](#)

Command line examples

The following examples show various ways to use the database-specific adapter commands on the command line.

The following examples for data sources and targets are for Oracle database adapters using UNIX-specific syntax. For the Windows platform, adapter commands are enclosed in single quotation marks. Specify adapter commands using an **.mdq** file as follows:

```
dtx parts -ID1 "'-MDQ crib1.mdq -DBNAME Inventory
-QUERY 003A'"
```

This example shows a data source override. The data for input card 1 for the parts map will come from the Inventory database using the query named 003A, all of which are defined in the **crib1.mdq** database/query file.

- Override individual adapter commands as follows:

```
dtx XlatLgcy -ID3 "'-STMT SELECT CustID, Name,
Addr FROM Cust_Table'"
```

This example shows how a SELECT statement may be specified on the command line. Note that the SQL statement consists of all of the input following **-STMT** until the next adapter command or until the single quotation mark ending the adapter command is reached. In this example, the remaining database information from the values compiled into the map file XlatLgcy is used (for example, the **.mdq** file, database, user ID, and other non-overridden values).

- Specify and override the settings in an **.mdq** file:

```
dtx CvtApps -OD6 "'-MDQ /test/new.mdq -DBNAME Purchases -USER  
John -PASSWORD sds34u -TABLE NewerTable -UPDATE'"
```

This example shows that the target for output card 6 in a map named CvtApps. This map is first overridden by the database definition Purchases in **/test/new.mdq** by using the Database/Query File adapter command (**-MDQ**) and the Database Name adapter command (**-DBNAME**). The **new.mdq** database/query file is first read to override the data target that is compiled into the CvtApps map. Subsequently, the User ID adapter command (**-USER**), the Password adapter command (**-PASSWORD**), the Table Name adapter command (**-TABLE**), and the Update adapter command (**-UPDATE**) override those settings obtained from the **.mdq** file.

- Override both a data source and a target adapter command:

```
dtx XferMsgs -ID1 "'-MDQ /share/prod.mdq -DBNAME LgcyProd  
-QUERY xToday'" -OD1 "'-DBTYPE ORACLE -CONNECT ProdDB  
-USER shaz -PASSWORD shaz01 -TABLE ActiveMsgs -UPDATE'"
```

This example shows both an input and an output being overridden. For the data source (**-ID1**), the **.mdq** file (**/share/prod.mdq**), database name (**LgcyProd**), and query (**xToday**) are specified. For the data target (**-OD1**), an Oracle database (**ProdDB**) is designated by the connect string. Subsequent adapter commands specify the user ID (**shaz**), password (**shaz01**), and table (**ActiveMsgs**) to be updated.

For Windows sources and targets on the command line

When using execution commands on Windows platforms, the specified adapter commands must begin with a single quote and end with a single quote. Separate each command with a space within the single quotes.

For example:

```
-IMMQS1 'command1 command2'
```

For UNIX sources and targets on the command line

When using execution commands, while running in a shell environment on UNIX platforms, the specified adapter commands must begin with a double quote, followed by a single quote and end with a single quote, followed by a double quote. Separate each command with a space within the single quotes.

For example:

```
-IAMQS1 "'command1 command2'"
```

Functions

For detailed information about using the **GET**, **PUT** and all other functions, refer to the Functions and Expressions documentation.

- [Using the GET function](#)
- [Using the PUT function](#)
- [Using the RUN function](#)

Using the GET function

The **GET** function returns messages from the adapter as a single text item.

The following example shows a map rule using a **GET** function with messaging adapter commands to specify particular adapter settings:

```
GET ("MQS", "-QM globalque -QN top1")
```

This **GET** example retrieves messages from the MQSeries® server messaging adapter as a single text item. The Queue Manager Name adapter command (**-QM** **globalque**) specifies a queue manager named **globalque**. The Queue Name adapter command (**-QN** **top1**) specifies the **top1** queue.

For more adapter-specific usage information, refer to adapter-specific documentation.

Using the PUT function

The **PUT** function sends messages to the adapter as output and returns a single text item that is always "none".

For all adapters, the scope of the **PUT** function is burst. The executable map controls the transaction behavior, commit or roll back, regardless of nested **RUN** functions.

The following example shows a map rule using a **PUT** function with messaging adapter commands to specify particular adapter settings:

```
PUT ("MQSC", "-QMN myque -QN best", TEXT(messageobject))
```

This PUT example places **TEXT (messageobject)** on the MQSeries® client messaging adapter and returns a single text item of NONE. The Queue Manager Name adapter command (**-QMN myque**) specifies the myque queue manager. The Queue Name adapter command (**-QN best**) specifies the best queue.

For more adapter-specific usage information, refer to each adapter-specific documentation.

Using the RUN function

In a **RUN** function, use adapter commands with the appropriate Input Source Override execution command or the Output Source Override execution command to override particular settings.

The following example shows using a **RUN** function to specify adapter commands without using a database/query file (.mdq):

```
RUN ("somemap.mmc",
    "--od1 '-dbtype oracle -connect remotedb -user " +
    "userid:profile + -password" + password:profile +
    "-table purchordr'")
```

In this example, a map named **somemap.mmc** is being executed. The output of this map is to be inserted in the PurchOrdr table in an Oracle database defined by the **RemoteDB** connect string. The logon, user ID, and password settings are retrieved from an input card named **Profile**.

For more information about using the **RUN** function, refer to the Functions and Expressions documentation.

For more adapter-specific usage information, refer to adapter-specific documentation.

Using wildcards

In most cases, the use of wildcards is supported when using resource adapter commands. Refer to the specific adapter documentation to see if wildcards are supported.

If resource adapter commands with wildcards are used with event triggers on input, events are coordinated to ensure that wildcards are matched. A wildcard value returned from an event trigger is used in other non-input event input cards or output cards, substituting any wildcard value that may exist in any of their properties.

For example:

Card	Adapter	Command
Input card 1 (event):	MQSeries®	MID = *
Input card 2 (not-event):	MQSeries	MID = 123*456
Output card 1:	File	Filename = OUT*.TXT

If a message is received from input card 1 with a message ID of **XYZ**, then:

- input card 2 is called with the MID property set to **123XYZ456**.
- the file created from output card 1 is named **OUTXYZ.TXT**.

Scope settings and FetchUnit interpretation

The following table shows the Scope settings and FetchUnit interpretation available by adapter type. The Scope settings are:

M	Map
B	Burst
C	Card

Table 1. Scope settings and FetchUnit interpretation by adapter type

Source Adapter	Source > Scope Settings	Target > Scope Settings	Aggregates	Divides	FetchUnit Interpretation
Application	M, B, C	M, B, C	No	No	Logical
Archive (Tar, Zip)	M, B, C	M, B, C	Yes	Yes	File in archive
Batch File	M, B, C	M, B, C	No	No	Logical
COM Automation	M, B, C	M, B, C	No	Yes	Logical
Connect:Direct®	M, C	M, C	No	No	Logical
Database	M, C	M, B, C	No	Yes	Row
E-mail	M, B, C	M, B, C	Yes	Yes	Message
File	M	M, C	No	No	Logical
FTP	M, B, C	M, B, C	Yes	Yes	File
GZIP	M, B, C	M, B, C	Yes	Yes	File in archive

Source Adapter	Source > Scope Settings	Target > Scope Settings	Aggregates	Divides	FetchUnit Interpretation
HTTP	M, C	M, C	No	No	Logical
MLLP	M, B, C	M, B, C	Yes	Yes	Message
MQSeries® (client & server)	M, B, C	M, B, C	Yes	Yes	Message
MSMQ	M, B, C	M, B, C	Yes	Yes	Message
Oracle AQ	M, B, C	M, B, C	Yes	Yes	Message
R/3 (ALE, BAPI, BDC)	M, C	M, B, C	No	No	Logical
Shell Script	M, B, C	M, B, C	No	No	Logical
Socket	M, B, C	M, B, C	Yes	Yes	Message
TIBCO Rendezvous	M, B, C	M, B, C	Yes	Yes	Message

Using global transaction management

Certain database and messaging adapters support triggering and global transaction management. Triggering and global transaction management allows monitoring of transactions that can include operations on two or more different data sources. For more information, refer to the Global Transaction Management documentation.

File Adapter

The File adapter is a listener for the Launcher that supports file triggering. The `GET` and `PUT` commands are internal for this adapter.

The only parameter available for the file adapter is the filename specified in the **FilePath** card setting. The settings for this adapter are:

- `GET Source.>.FilePath` for the input card
 - `PUT Target.>.FilePath` for the output card
- The File adapter does not require any adapter commands for its operation. It uses only the full path and filename for a parameter.

The File adapter is internal to the Command Server, Launcher, and z/OS Platform API. However, listener functionality for the Launcher is an external adapter.

Text File Importer

The Text Importer Wizard allows users to select text fragments and create composition of schema groups and items and edit some of the properties. The schemas that are generated by the Text Importer Wizard can be used immediately for map development. However, depending on the contents, it may be necessary to modify the generated schema by using the schema designer. You cannot import a schema while a schema with the same name is open in the schema designer.

- [Supported character sets](#)

Supported character sets

The Text File Importer supports all of the character sets that are supported by the schema editor.

- [Western character sets, international and non-international versions](#)
- [Japanese character sets \(international version\)](#)

Western character sets, international and non-international versions

- ASCII
- EBCDIC
- UTF - 8
- UNICODE Little Endian
- UNICODE Big Endian

Japanese character sets (international version)

- SJIS
- EUC
- UNICODE Big Endian
- UNICODE Little Endian
- UTF - 8

Sink adapter

The Sink adapter is used as a temporary data destination for an output map card which then discards the mapped data.

This capability is useful when a temporary destination is needed to accept output data as part of the map execution without writing the output to a stationary destination.

- [Using the Sink adapter](#)

Using the Sink adapter

The Sink adapter does not require any adapter commands for its operation. In addition, the Sink adapter does not access a persistent source or destination, therefore, a rollback and retry capability is not provided.

For example, use a Sink adapter instead of a file as the destination for temporary output. The advantages of using the Sink adapter include:

- faster map performance due to less file I/O
- reduced file resource conflicts when running multiple instances of the map
- reduced disk space usage

This adapter can be used with the Command Server, Launcher, Software Development Kit, or in a map rule.

For example, using the map designer, select Sink for the **Target** setting in an output card dialog box. The Sink adapter does not require any additional card settings or adapter commands.

You can use the Output Target Override execution command (-OA) with the Sink adapter alias. For example, to override the output card with the Sink adapter so that the data is discarded, the command string would be:

```
-OASINK1 .
```

The Sink adapter command line, for example, -OASINK1 ., must be followed by any dummy argument, for example, a period (.) or an asterisk (*) in order for the adapter to parse the information correctly.

Application adapter

The application adapter and the APP alias is provided only for backwards compatibility for pre-6.0 application adapters.

Source and target card settings

Each input of data and each output of data require content definition settings. These settings are specific to input and output cards, although some settings are common to both cards. For detailed information about source and target settings, see the map designer documentation.

- [Source settings](#)
- [Target settings](#)

Source settings

The Source settings identify the source of the input data. The data may be in a file, from a specific application, in a database, from a message queue, or from other possible sources. Defining the adapter source specifies where to go to get the data and specifics for the data to get.

The significance of the various source settings is specific to the adapter being used to get the input data.

Target settings

The Target settings identify the target for the data produced by the map. The data may be written to a file, inserted into or updated in a table in a database or copied into an e-mail message. The adapter target is the destination of the output data after it is built by the map.

The significance of the various target settings is specific to the adapter being used to send the output data.

Communication adapters overview

Communication adapters provide connectivity to other data sources or targets using industry standards or by using protocols for moving data, for example, the FTP or HTTP adapters.

This group of adapters also provides access to customer applications, either data objects, for example, the Java™ Class adapter, or transactions such as the CICS® adapter. Each adapter includes a set of commands to customize its operation.

VAN access through the FTP adapter

VANs provide services beyond normal transmission, such as protocol conversion or message storing and forwarding, and are often used to transport Electronic Data Interchange (EDI) data.

Many VANs support access through FTPs.

For example, you can access the GXS VAN with the FTP adapter and send and receive secure data using a customized map. This is convenient for the following reasons:

- No special hardware is required
- Internet usability
- Secure transfer of data using FTPs

The *install_dir\examples\adapters\ftp\gxs* directory contains an example of how to gain VAN access through the FTP adapter.

- [Specifying the FTP adapter for GXS VAN access](#)
- [GXS VAN command syntax](#)

Specifying the FTP adapter for GXS VAN access

The following steps explain how to specify the **FTP** adapter while using the GXS VAN and sending example data to an EDI mailbox.

Note that this is only an example and the maps and schemas trees that are provided in the examples folder are example data developed for testing purposes. You must substitute your actual data when using this procedure.

In this example scenario, we will be sending a test file from a map to a test mailbox and then retrieving the file for viewing.

1. Using the map designer, open the **gxscert.mms** file.
2. Verify that you have the **gxs1to1.edi** file located in the *install_dir\examples\adapters\ftp\gxs* directory.
3. Open the **gxs_transmit #1 Output Card**.
4. Edit the **PUT > Target > Command** by changing the **<LUSERID:LPASSWORD>** to the **<LUSERID:LPASSWORD>** needed to access your EDI mailbox.
For example, change: **<LUSERID:LPASSWORD>** to **AAA22406:A3KPP3HB** as the respective User ID and Password.

You must enter a colon (:) between the User ID and Password.

5. Build and run the **gxs_transmit map**.
6. Open the **gxs_retrieve #1 Input Card**.
7. Edit the **GET > Source > Command** by changing the **<LUSERID:LPASSWORD>** to the **<LUSERID:LPASSWORD>** needed to access your EDI mailbox.
For example, change: **<LUSERID:LPASSWORD>** to **AAA22406:A3KPP3HB** as the respective User ID and Password. As previously noted, there must be a colon (:) between the User ID and Password.

We use the same User ID and Password that we used in the transmit (Output card) because the file has been sent to the same location.

8. Build and run the **gxs_retrieve map**.
9. View the results. Your EDI data should be in the **gxs_receive.out** file, which you can view using any text editor.

GXS VAN command syntax

The following command is used in the **gxs_transmit #1 Output card** example for accessing the GXS VAN through the FTP adapter. Although this is only an example, the command structure is the same for when you use the adapter in your work environment.

```
-TV -implicit -URL FTPS://  
AAA22406:A3KPP3HB@sftp.beta.am.gxsics.com:6366/send/  
sendfile;type=A
```

Messaging adapters overview

Messaging-specific adapters are a collection of middleware drivers used to provide a way to specify data sources and targets for maps. Each adapter includes a set of commands used to customize its operation.

The use and operation of a specific messaging adapter is documented separately under its own name.

- [Message flow](#)
- [Adapter transactions](#)
- [Messages as a data source](#)
- [Messages as a data target](#)

Message flow

Maps control the flow of messages between messaging applications in the following ways:

- One-to-one
Messages can flow from a single data source message to a single data target message using a map.
 - One-to-many
Messages can flow from a single data source message to many data target messages using a map.
 - Many-to-one
Messages can flow from many data source messages to a single data target message using a map.
 - Many-to-many
Messages can flow from many data source messages to many data target messages using a map.
- Additionally, message flow can be sequenced between applications and used to integrate non-messaging environments.

Adapter transactions

Map definitions provide settings to control the scope of messaging adapter transactions. It is important to understand how connections to messaging systems are controlled and how this relates to transactional scope.

- [Transactional control](#)
- [Connection management](#)

Transactional control

Use the **Scope** setting for a source or target in a map to determine transaction commitment. The **Scope** setting can be one of the following:

- Map
- Burst
- Card

Connection management

Connection management results in fewer connections being made to the messaging system which may improve performance. Existing connections are reused whenever possible. Two situations exist where connection sharing occurs:

- between cards and maps within a map
- between multiple maps running serially within the Launcher

In the situation in which connection sharing occurs between cards and maps within a map, the connection is described as "active" as long as at least one card or rule is accessing a database and has yet to be committed or rolled back (that is, there is an active transaction). When all cards or rules complete the database access, connection is "inactive", but still open.

Messages as a data source

The two data source processing modes are: integral mode and burst mode.

For each input card in the map, the mode is set to either **Burst** or **Integral** in the map designer Input Card dialog box using the **SourceRule > FetchAs** setting.

Within a map, some input cards may be in burst mode while others are in integral mode, indicating that these cards are executed only once.

- [Example of data processing modes](#)

Example of data processing modes

In addition to the burst mode on a per card basis, the map itself may be set to operate iteratively, thereby invoking multiple source card bursts in a single map invocation. For example, if the Quantity adapter command (**-QTY**) is specified with a setting of 50 on the input card **GET > Source > Command** and the **FetchUnit** value is 5, the map processes the input and output cards until 50 data source objects (messages) are retrieved. The map executes 10 (50÷5) times, with each input card returning five messages concatenated together.

Messages as a data target

When any messaging adapter is specified as the data target, the messaging adapter formulates and sends a single message.

Database adapters overview

This section discusses database-specific adapter information. The use and operation of these adapters is covered in each database-specific adapter's documentation.

Using the Database Interface Designer with the database adapters, data stored in a database under the control of a Relational Database Management System (RDBMS) can be easily identified, defined, and accessed as the source or target for a map.

The Database Interface Designer is used to:

- Specify the databases to use for a source or target.
- Define query statements.
- Automatically generate schemas for queries or tables.

After defining the specifications for accessing each database in the Database Interface Designer, define your map in the map designer where, in map cards, you can specify a query or stored procedure as an input source or a table or a stored procedure as an output target.

The Database Interface Designer is installed as part of the Design Server, along with all of the Windows-based database adapters. These Windows-based adapters provide connectivity to databases residing on your local PC and on other platforms so that you can automatically create schemas for those queries and tables. The adapters installed as part of your Design Server provide a test environment for maps that access the database.

Non-Windows database adapters do not require the Database Interface Designer if you plan to only use **mtsmaker** without a database or query (.mdq) file to generate each schema. For information about using **mtsmaker**, refer to [Generating Type Trees Using mtsmaker](#).

- [Supported database adapters](#)
- [Restrictions and limitations](#)
- [Using database-specific adapters](#)
- [List of commands](#)
- [Generating schemas using mtsmaker](#)

Supported database adapters

- DB2 (z/OS)
- DB2 (z/OS ODBC)
- DB2 (Windows/UNIX)
- Informix
- Microsoft SQL Server
- ODBC
- OLE DB
- Oracle
- Sybase SQL Server

Restrictions and limitations

The Database Interface Designer and database adapters offer options and functions for accessing and manipulating data contained within a database. However, there are some restrictions and limitations for the following functions when using certain adapters:

- **Database triggers:** Using a data source as an input event trigger for the Launcher.
- **Bind facility:** Using bind values in database functions.
- **Stored procedures:** Using stored procedures to access adapter commands and return values from stored functions.

The following table indicates the functions that are not supported by a specific adapter. The Oracle adapters support all functions.

Database-specific Adapter	Triggers	Bind Facility	Stored Procedures
DB2® (z/OS®)	NO	NO	NO
DB2 (z/OS ODBC)	NO		
DB2 (Windows/UNIX)	NO		
Informix®	NO		
Microsoft SQL Server		NO	
ODBC	NO		
OLE DB	NO	NO	
Sybase SQL Server	NO	NO	

Using database-specific adapters

Database-specific adapter commands can be used in any of the following ways:

- When specifying adapter settings for sources and targets.
- With functions in map and component rules.
- On the command line using execution commands to override source or target settings.

See [General Rules for Adapter Commands](#) and [Using Resource Adapters](#) for more information.

- [Adapter usage in functions](#)
- [Adapters in Input Data and Output Data Settings](#)

Adapter usage in functions

The set of adapter commands specified in functions must begin with one double quotation mark and end with one double quotation mark. Each adapter command is separated by one space. For example:

```
DBLOOKUP ("SELECT * FROM PARTS", "command1 command2...")
```

Adapters in Input Data and Output Data Settings

Use the map designer or Integration Flow Designer to specify a database adapter either as a source or as a target by selecting Database as the value for the GET...Source or PUT...Target setting, respectively. In addition to the common adapter settings such as **Scope**, **Retry**, and so forth, you can enter any of the database adapter commands for the **GET > Source > Command** or **PUT > Target > Command** settings.

List of commands

The following table lists each database-specific adapter command and whether the command can be used for a source or target, or in a **DBLOOKUP**, **DBQUERY**, **GET**, or **PUT** function. Usage is indicated with ✓. For a **RUN** function, any adapter command can be used as indicated for a source or target.

Name	Adapter Command Syntax	Source	Target	DBLOOKUP DBQUERY	GET	PUT
Audit (-A or -AUDIT)	-AUDIT[G][+] [full_path]	✓	✓	✓	✓	✓

Audit (-A or -AUDIT)

Use the Audit adapter command (-AUDIT) to create a file that records the adapter activity for each specified input and output card. This adapter command can be specified for individual input and output cards on a card-by-card basis, or, optionally, as a global audit that encompasses all database activity for the entire map. This command can be used for a source or target, or in a **DBLOOKUP**, **DBQUERY**, **GET**, or **PUT** function. The default usage is to produce a file named **audit.dbl** in the directory in which the map is located. Optionally, you can append the audit information to an existing file or specify a name or full pathname for the file. For more information, refer to the Database Interface Designer documentation.

-AUDIT [G] [+] [*full_pathname*]

Value	Description
G	Activate a global audit for the entire map by specifying this command for the first database card that will have database activity. This records all database activity for all sources, targets, and functions for all defined cards.
+	Append audit information to an existing file.
<i>full_path</i>	Specify the name of the audit file that can include the directory pathname.

Bad Data (-BD or -BADDATA)

Use the Bad Data adapter command (-BADDATA) for a target or in a **PUT** function so that if any inserts, updates, or procedure calls fail to execute, the data that could not be processed is written to a file you specify, and processing continues. The map completes successfully and the following adapter warning code and message are recorded in the execution section of the audit log:

1 One or more records could not be processed
-BADDATA[+] [*full_path*]

Value	Description
+	Append the information to the specified bad data file. This allows multiple cards or multiple iterations of the same map to be able to write to the same file.
<i>full_path</i>	Specify the name for the bad data file or the full pathname to specify the directory. By default, the directory is where the map is located. However, you must specify the file name.

If the **PUT > Target > Transaction > Warnings** setting is set to Fail in an output card, the data that could not be processed is still written to the specified file. However, the map fails.

Connect String (-C or -CONNECT)

Use the Connect String adapter command (-CONNECT) to specify the Oracle host connect string. This command can be used for a source or target, or in a **DBLOOKUP**, **DBQUERY**, **GET**, or **PUT** function. If an SQL*Net host connection string is specified, the connection is established through SQL*Net. If none is specified, a direct connection is established to the database identified by the **ORACLE_SID** environment setting.

-CONNECT *connect_string*

Commit by Card (-CC or -CCARD)

Use the Commit by Card adapter command (-CCARD) to commit or roll back the transaction when the card has been processed. This command can be used for a source or target, or in a **DBLOOKUP**, **DBQUERY**, **GET**, or **PUT** function. When used for a source or within **DBLOOKUP**, **DBQUERY**, or **GET** functions, the behavior is identical to the

Commit by Statement adapter command (-CSTMT) because there is only a single statement or action to be executed.

Note that even if there are multiple **DBLOOKUP**, **DBQUERY**, **GET** and **PUT** map functions in a single output card, each of them will be committed immediately upon execution and not after the card completes, even if they had the -CCARD adapter command specified.

If specified for a database output card, a commit or rollback, based upon the **OnFailure** setting of a card, is made after the completion of the execution of the output card in which multiple **INSERT**, **UPDATE**, or stored procedure statements may have been made.

For a source, this adapter command can be used when the input is a query that executes a stored procedure to perform inserts, updates, or deletes.

-CCARD

Using this command is equivalent to selecting Card as the **PUT > Target > Transaction > Scope** value. If you specify the Commit by Card adapter command (-CCARD), it overrides the value in the **Scope** card setting.

Commit by Statement (-CS or -CSTMT)

Use the Commit by Statement adapter command (-CSTMT) to commit or roll back the transaction after the execution of every statement, or, optionally, after a specified number of statements. A statement is one of the following:

- An **INSERT** or **UPDATE** statement as generated in an output card or **PUT** function.
- The execution of a stored procedure.
- The statement specified in a **DBLOOKUP**, **DBQUERY**, or **GET** function.

In an example for a target, if an output card is a database table for which the Update adapter command (-UPDATE) has also been specified, the Commit by Statement adapter command (-CSTMT) would cause each row to be committed as it is inserted or updated into the database.

For a source, the Commit by Statement adapter command (-CSTMT) can be used when the input is a query that executes a stored procedure performing inserts, updates, or deletes.

-CSTMT [*number*]

Value

Description

number

Specify the number of statements to be executed before committing the data.

The Commit by Statement adapter command (-CS) is an extra call to the database and may degrade performance. However, this command may be beneficial in situations in which the number of statements is large because the database server writes all such updates to its rollback segment, which increases continually with each call.

Commit by Card (-CCARD) and Commit by Statement (-CSTMT) are mutually exclusive. Also, if -CSTMT is specified, it overrides the value in the **PUT > Target > Transaction > Scope** card setting that was compiled into the map.

Delete (-D or -DELETE)

Use the Delete adapter command (-DELETE) to delete all rows in the output table before processing the output data. Use this command for a target or in a **PUT** function.

-DELETE

Database Name (-DN or -DBNAME)

Use the Database Name adapter command (-DBNAME) to specify the name of a database defined in the **.mdq** file that is specified using the Database/Query File adapter command (-MDQ). The Database Name adapter command can be used for a source or target, or in a **DBLOOKUP**, **DBQUERY**, **GET**, or **PUT** function.

-DBNAME *database_name*

The *database_name* you supply is case-sensitive. Also, if -DBNAME is specified, it overrides the value in the **GET > Source > DatabaseQueryFile > Database** card setting.

Database Adapter Type (-DT or -DBTYPE)

Use the Database Adapter Type adapter command (-DBTYPE) to specify the database adapter type you are using. This command can be used for a source or target, or in a **DBLOOKUP**, **DBQUERY**, **GET**, or **PUT** function.

-DBTYPE {ODBC|ORACLE|SQLSVR|SYBASE|DB2|DB2MVS|OLEDB|IFMX}

The adapter type must be specified if the original card is not a database and no database is specified using the Database/Query File adapter command (-MDQ) and the Database Name adapter command (-DBNAME).

Value

Description

ODBC	ODBC database adapter
ORACLE	Oracle database adapter
SQLSVR	Microsoft SQL Server database
SYBASE	Sybase SQL Server database
DB2®	DB2 database on a Windows or UNIX platform
DB2MVS	DB2 database on an z/OS® (formerly MVS™) platform
OLEDB	OLE DB database adapter
IFMX	Informix® database adapter

Data Source (-DS or -SOURCE)

Use the Data Source adapter command (-SOURCE) to specify the name of the ODBC, Microsoft SQL Server, Sybase SQL Server, DB2®, or Informix® data source. This command can be used for a source or target, or in a **DBLOOKUP**, **DBQUERY**, **GET**, or **PUT** function.

-SOURCE datasource|server\\database

Value

Description

datasource	Specify the ODBC, DB2 (Windows/UNIX), or Informix data source.
server\\database	Specify the Microsoft SQL Server or Sybase SQL Server data source.

File (-F or -FILE)

Use the File adapter command (-FILE) for database sources, or in a **GET** function to write the retrieved data to a temporary file that is read by either the Command Server or Launcher. This is useful when the amount of data retrieved by the adapter is large, possibly resulting in high memory consumption. By default, that is, without this command, data is passed between the adapter and the database server in memory. The default specification for this adapter command is for the temporary file to be created in the same directory as the map. The temporary file is then deleted after the map completes.

-FILE [directory]

Value

Description

directory	Specify the directory in which the temporary file should be created.
-----------	--

It is recommended that you specify a value for the StreamMaxMemLimit Resource Manager setting in the **config.yaml (/runtime/stream/MaxMemLimit)** file to limit the memory consumption of the process you are running, instead of using the File database adapter command (-F or -FILE).

If you are currently running processes that are using the File database adapter command (-F or -FILE) and are retrieving data without resulting in high memory consumption, you can continue to use this command.

Do not use the File database adapter command (-F or -FILE) when you are running maps in burst mode. Instead, use the StreamMaxMemLimit Resource Manager setting in the **config.yaml** file to limit memory usage.

Global Transaction Management (-GTX)

Use the Global Transaction adapter command (-GTX) to indicate that the operations on a card, whether input or output, should be processed within a global transaction.

This command is available only for Oracle, Oracle AQ, and Microsoft SQL Server database adapters.

-GTX

For more information about global transaction management, refer to the Global Transaction Management documentation.

Database/Query File (-M or -MDQ)

Use the Database/Query File adapter command (-MDQ) to specify the name of the **.mdq** file that contains the database definition for the database to be used, as specified with the **-DBNAME** adapter command. This Database/Query File adapter command can be used for a source or target, or in a **DBLOOKUP**, **DBQUERY**, **GET**, or **PUT** function.

-MDQ *mdq_file_name*

When this adapter command is used, the **.mdq** file must be available at map execution time. Also, if the **.mdq** file is not in the same directory as the compiled map file, the full pathname is required.

If the Database/Query File adapter command (**-MDQ**) is specified, it overrides the value in the **GET > Source > DatabaseQueryFile > File** setting.

Password (-PW or -PASSWORD)

Use the Password adapter command (**-PASSWORD**) to specify the password that authenticates the user logon. This command can be used for a source or target, or in a **DBLOOKUP**, **DBQUERY**, **GET**, or **PUT** function.

-PASSWORD *password*

If you specify the parameter as `$ (env_var)` where `env_var` represents the name of an environment variable, the actual value of the password is retrieved from this environment variable.

Stored Procedure Name (-PR or -PROC)

Use the Stored Procedure Name adapter command (**-PROC**) to specify the name of a stored procedure to be executed in an output of a map. Use this command either for a target or in a **PUT** function. If the Stored Procedure Name adapter command (**-PROC**) is specified, it overrides the value in the **DatabaseQueryFile > Table** output card setting.

-PROC *procedure_name*

Query (-Q or -QUERY)

Use the Query adapter command setting (**-QUERY**) for a source to specify the name of a query in an **.mdq** file as specified using the Database/Query File adapter command (**-MDQ**) and the database defined by the Database Name adapter command (**-DBNAME**).

-QUERY *query_name*

The name of the query (`query_name`) you supply is case-sensitive. Also, if the Query adapter command (**-QUERY**) is specified, it overrides the value in the **DatabaseQueryFile > Query** input card setting.

Row Count (-RC or -ROWCNT)

For ODBC, Oracle, DB2® for Windows, and DB2 for UNIX adapters only.

Use the Row Count adapter command (**-ROWCNT**) to specify the number of rows to be retrieved in one fetch from the database by the database adapter. This command can be used for a source or in a **DBLOOKUP**, **DBQUERY**, or **GET** function.

This adapter command specifies the number of rows that the adapter should retrieve from the database. It should not be confused with the **FetchAs > FetchUnit** card setting that specifies the number of rows the adapter will pass to the Command Server. For more information about the **FetchUnit** card setting, refer to the Database Interface Designer documentation.

The time to fetch is optimized in accordance with the increase in the number of rows to be retrieved. Therefore, a significant performance improvement may be gained by retrieving as many rows as possible in a single fetch. The number of rows to be retrieved is limited by the memory requirement, because the return buffer must be large enough to hold the rows that are retrieved.

-ROWCNT *row_count*

Without using this command, the default number of rows to be retrieved per fetch is:

- for ODBC, one row
- for DB2, one row
- For Oracle, a 64K buffer is allocated. Then, a calculation is performed to determine the number of rows that can be held in the buffer.

SQL statement (-S or -STMT)

Use the SQL Statement adapter command (**-STMT**) either for a source or in a **GET** function to specify an SQL statement or a call to a stored procedure using either the database-independent or native call syntax to be executed. This execution will provide the input data to a map.

-STMT *SQL_statement*

The "database-independent" syntax for invoking a stored procedure requires the query statement to commence with a "call" command. Following the "call" command, you must specify the input, output and return parameters. Use parentheses to enclose the input and output parameters, separating consecutive parameters with a comma. To indicate a return or an output parameter, use a "?" mark. If you do not need the return value, simply omit it, and if you want to disregard an output parameter, replace it with an 'X'.

Input parameters can be specified as they are or enclosed within single quotation marks, especially when the input contains spaces. If the input data itself includes a single quote, escape it by doubling it. For example:

```
-STMT "call sp_input_param ('I''m escaping a single quote in this input value.')
```

In cases where both input and output parameters are necessary, place the output parameter's "?" mark first, and delimit it from the input parameter using a forward slash character, '/'.

For example, consider the following statement that invokes a stored procedure with an input and output parameter. The first parameter is for input only, while the second one is for both input and output:

```
-STMT "call sp_params (param1,?/param2)"
```

If the above stored procedure includes a return value, it will be ignored unless you precede the stored procedure name with "?=". For example:

```
"call ?=sp_params (...)"
```

Table Name (-TB or -TABLE)

Use the Table Name adapter command (-TABLE) to specify the table to which or in which the map will insert or update data, respectively. Use this command either for a target or in a PUT function. If the Table Name adapter command is specified, it overrides the value in the **DatabaseQueryFile > Table** output card setting.

```
-TABLE table_name
```

Trace (-T or -TRACE)

Use the Trace adapter command (-TRACE) to produce a database trace file. The recorded Trace information details the database adapter activity. This command can be used either for a source or target, or in a DBLOOKUP, DBQUERY, GET, or PUT function.

To produce a trace, you must specify the Trace adapter command (-TRACE) or Trace Error adapter command (-TRACEERR). A database trace is not produced if only map trace is enabled, as was true in previous versions of the database adapters.

The default is for a database trace file to be produced in the directory in which the map is located, using the full name of the map file and a .dbl extension (**map_name.dbl**). Optionally, you can append the trace information to an existing database trace file, specify a file name, or specify the full pathname for the file.

```
-TRACE[+] [full_path]
```

Value**Description**

+

Append trace information to an existing trace file.

full_path

Create a trace file with the specified name in the specified directory. By default, the directory is where the map is located and the file name is **map_name.dbl**.

Trace Error (-TE or -TRACEERR)

Use the Trace Error adapter command (-TRACEERR) to produce a database trace file containing only the database errors that occurred during map execution. This command can be used either for a source or target, or in a DBLOOKUP, DBQUERY, GET, or PUT function.

When this adapter command is specified, a database trace file is produced in the directory in which the map is located, using the full name of the map file and a .dbl extension. Optionally, you can append the trace information to an existing trace file, specify a file name, or specify the full pathname for the database trace file.

The Trace Error adapter command (-TRACEERR) and the Trace adapter command (-TRACE) are mutually exclusive.

```
-TRACEERR[+] [full_path]
```

Value**Description**

+

Append trace information to an existing trace file. Do not put a space between -TRACEERR and the plus [+] sign.

full_path

Create a trace file with the specified name in the specified directory. By default, the directory is where the map is located and the file name is **map_name.dbl**.

Trigger (-TR or -TRIG)

This command is available only for the Oracle and Microsoft SQL Server database adapters.

Use the Trigger adapter command (-TRIG) for a source to specify the trigger string for a trigger specification. For more information about specifying database triggers, refer to the Database Interface Designer documentation.

The Trigger adapter command (-TRIG) can be used as a trigger specification for a query that has no defined trigger in the Database Interface Designer. It can also be used to override conditions that are already defined in a trigger specification associated with a query.

The pipe character (|) is used to represent OR and the ampersand character (&) is used to represent AND. The combination of characters &| represents an AND/OR statement. The value inserted as the `when_clause` must be a valid SQL syntax with `table.column_name` enclosed in square brackets.

```
-TRIG {[R] [I tablename1 [{&|} tablename2]...]
[D tablename1 [{&|} tablename2]...
[U tablename1 [{&|} tablename2]...]
[W when_clause [[table.column_name]]]...}
```

Value

Description
R
This indicates that row-based triggering is being used as opposed to table-based.
I tablename1 [{& } tablename2]...
The insertion of rows into the specified table(s) serves as an input event trigger to the map using this query as a source.
D tablename1 [{& } tablename2]...
The deletion of rows from the specified table(s) serves as an input event trigger to the map using this query as a source.
U tablename1 [{& } tablename2]...
Updating values in the specified column(s) serves as an input event trigger to the map using this query as a source.
W when_clause [[table.column_name]]]
This is an expression that will be evaluated when the other events have occurred. If this expression evaluates to TRUE, the conditions of the trigger specification are met and the map is launched. If the expression is not TRUE, the state is restored as it was prior to any events occurring.
This expression may contain any SQL expressions that are valid for the target database. If database columns are referenced, the column name must be qualified with the table name and enclosed in square brackets.

The following is an example of specifying trigger events and conditions using the adapter:

```
-TR I ACCT_INFO | TRANSACTIONS D ACCT_INFO U ACCT_INFO
W [TRANSACTION.TRANS_TYPE]='PY'
```

This example causes the following to occur:

- Launch the map that uses this query as a data source when one of the following conditions is met:
 - there is insertion into the ACCT_INFO TRANSACTIONS tables
 - there is a deletion from the ACCT_INFO table
 - ACCT_INFO is updated,

but only when a row exists in TRANSACTION with the column TRANS_TYPE set to 'PY'.

You cannot combine both | and & in an event class (*Insert into, Delete from, or Update of*) if more than two tables or columns are being combined. For example, the following command is invalid:

```
-TR I TABLE1 & TABLE2 | TABLE3
```

Update (-UP or -UPDATE)

Use the Update adapter command (-UPDATE) to enable update mode. Update mode causes update operations to be performed for tables or views based upon the defined update keys and key columns to update. For information about defining updating keys and key columns to be updated, refer to the Database Interface Designer documentation.

If enabled, the default is to update each row, if possible, and upon failure, to insert the data. Optionally, you can specify to insert a row or update each row, if possible, and upon failure, to not insert the data. This command can be used either for a target or in a **PUT** function.

If used in a **PUT** function, you must define your update keys and columns to update in an **.mdq** file. Then specify this **.mdq** file in the **PUT** function using the Database/Query File adapter command (-MDQ), together with the Database Name adapter command (-DBNAME), the Table Name adapter command (-TABLE), and the Update adapter command (-UPDATE). The **.mdq** file must be available at runtime.

```
-UPDATE [OFF|ONLY]
```

Value

Description
OFF
Insert a row. Insertions are allowed regardless of success or failure.
ONLY
Update each row, if possible. Upon failure, do not insert the data.

User ID (-US or -USER)

Use the User ID adapter command (-USER) to specify the user ID for connection to the database. This command can be used either for a source or target, or in a **DBLOOKUP**, **DBQUERY**, **GET**, or **PUT** function.

If you specify the parameter as `$ (env_var)` where `env_var` represents the name of an environment variable, the actual value of the password is retrieved from this environment variable.

```
-USER username
```

Variable (-V or -VAR)

Use the Variable adapter command (-VAR) for a source at runtime to pass a value for a variable defined in the SQL SELECT statement. It can also be used in a **DBLOOKUP**, **DBQUERY**, or **GET** function.

```
-VAR name=value
```

Generating schemas using mtmaker

This documentation discusses using the **mtmaker** application to generate schemas.

- [Overview](#)
- [Generating a schema script](#)
- [General parameter rules](#)
- [List of parameters](#)

Overview

The **mtmaker** application helps generate schemas for a query, table, view, or stored procedure when you do not have connectivity between the Database Interface Designer and your non-Windows database.

Use **mtmaker** to produce schema script files (.mts) on your non-Windows database host system that you will subsequently transfer to your development PC in binary mode.

On your development PC, run the Type Tree Maker using the transferred schema script file as input. The Type Tree Maker generates the schema for you.

Generating a schema script

When using **mtmaker**, schema scripts can be created in either of two modes:

- by using a database/query file (.mdq)
- by not using an .mdq file

Control how you want the tree script file to be generated by specifying **mtmaker** parameters.

- [Using mtmaker with a database/query file](#)
- [Using mtmaker without a database/query file](#)

Using mtmaker with a database/query file

You can use a database/query file (.mdq) that was created using the Database Interface Designer and transfer it, in binary mode, to the system hosting your database. The **.mdq** file is then used as a source of information about a particular query, database, or stored procedure.

To generate a tree script file (.mts) for a database query, specify the following **mtmaker** parameters. For specific information about each **mtmaker** parameter, refer to the [List of Parameters](#).

```
mtmaker -M mdq_file  
-Q query_name [-B database_name]  
-F mtt_file_name  
-O mts_file_name  
[-X {F|O|T|FOT}]
```

To generate a tree script file (.mts) for a table, view, or stored procedure, specify the following **mtmaker** parameters:

```
mtmaker -M mdq_file  
-B database_name  
-T table_name|-G stored_procedure_name  
-F mtt_file_name  
-O mts_file_name  
[-X {F|O|T|FOT}]
```

- [Using mtmaker with an .mdq File](#)

Using mtmaker with an .mdq File

The following is an example of how to use **mtmaker** with a database/query file to generate a schema script file for a table:

```
mtmaker -m mdqfile.mdq -b mybase -t mytable -f tree.mtt  
-o mtsfile.mts -x f
```

Using mtmaker without a database/query file

Schemas can be generated without using database/query files. However, you must specify all of the necessary information so that **mtmaker** can generate the tree scripts for queries, tables, views, or stored procedures.

To generate a schema script file (.mts) for a query, specify the following **mtmaker** parameters:

```
mtmaker -S "sql_select_statement"  
-Z database_adapter_type  
[-U user_id]  
[-P password]  
[-D {datasource|connect_string|server\\database}]  
-O mts_file_name  
-F mtt_file_name  
-N type_name  
[-X [F][O][T]]
```

To generate a schema script file for a table, view, or stored procedure, specify the following **mtmaker** parameters:

```
mtmaker -T table_name|-G stored_procedure_name  
-Z database_adapter_type  
[-U user_id]  
[-P password]  
[-D {datasource|connect_string|server\\database}]  
-O mts_file_name  
-F mtt_file_name  
[-X [F][O][T]]
```

- [Using mtmaker without an .mdq File](#)

Using mtmaker without an .mdq File

The following is an example of how to generate a schema script for a query without using a database/query file and specifying an Oracle connect string with the Data Source parameter (-D).

The -D parameter can also be used to specify a data source for ODBC, Sybase SQL Server, or DB2®, as appropriate.

```
mtmaker -s "select * from AddressList" -u yourid -p password  
-z oracle -d "oracle connect string" -o addlist.mts  
-f maillist.mtt -n adddata
```

As part of the SQL Statement parameter (-s) format, the SELECT statement must be enclosed in a double quotation mark.

General parameter rules

To properly enter **mtmaker** parameters, you must observe the correct syntax, as well as follow these general rules:

- Each parameter must begin with a hyphen, for example, -X.
- All parameters can be either upper or lower case, but cannot be mixed case.
- A space is required between the parameter and its value. Refer to the following example:

```
-z oracle
```

- The order of parameters is unimportant.
- If you do not specify all required parameters, **mtmaker** prompts for any missing information. The displayed parameter prompts depend upon the mode in which you are operating, whether using a database/query file or not.

List of parameters

The following table lists the **mtmaker** parameters that can be used for generating schemas, the parameter syntax, and if each one can be used (✓) with or without a database or query file. To access the list of **mtmaker** parameters and the syntax for each parameter, enter **mtmaker** parameters -H or ? on the command line.

Parameter Name	Parameter Syntax	With .mdq	Without .mdq
Database Name (-B)	-B database_name	✓	
Data Source (-D)	<ul style="list-style-type: none"> -D datasource -D connect_string -D server\database 		✓ ✓ ✓
ODBC and DB2®			
Oracle			
Sybase SQL Server			
Type Tree File (-F)	-F mtt_file_name	✓	✓
Stored Procedure Name (-G)	-G stored_procedure_name	✓	✓
Database/Query File (-M)	-M mdq_file	✓	
Category Type (-N)	-N type_name		✓
Tree Script File (-O)	-O mts_file_name	✓	✓
Password (-P)	-P password		✓
Query Name (-Q)	-Q query_name	✓	
SQL Statement (-S)	-S "sql_statement"		✓
Table Name (-T)	-T table_name	✓	✓

Variable Name (-V)	-V name=value	✓	✓
Format (-X) *	-X [F][O][T]	✓	✓
Database Adapter Type (-Z)	-Z database_adapter_type		✓

*

The **O** option of the Format parameter (-x) can be used only with the Oracle adapter.

- [Database Name \(-B\)](#)
- [Data Source \(-D\)](#)
- [Schema File \(-F\)](#)
- [Stored Procedure Name \(-G\)](#)
- [Database/Query File \(-M\)](#)
- [Category Type \(-N\)](#)
- [Schema Script File \(-O\)](#)
- [Password \(-P\)](#)
- [Query Name \(-Q\)](#)
- [SQL statement \(-S\)](#)
- [Table Name \(-T\)](#)
- [User ID \(-U\)](#)
- [Variable Name \(-V\)](#)
- [Format \(-X\)](#)
- [Database Adapter Type \(-Z\)](#)

Database Name (-B)

Specify the name of the database as defined in the **.mdq** file.

-B database_name

Data Source (-D)

Specify the name of the ODBC, DB2®, Oracle, or Sybase SQL Server data source.

-D {datasource|connect_string|server\\database}

Option

Description

datasource

Specify the ODBC or DB2 data source.

connect_string

Specify the Oracle host connect string.

server\\database

Specify the Sybase SQL Server data source.

Schema File (-F)

Specify the name of the schema (.mtt) file to be generated by the Type Tree Maker. Enter the file name in the Windows file system format. For example, if a full path name is specified, use the backslash directory separator (\).

-F mtt_file_name

Stored Procedure Name (-G)

Specify the name of the stored procedure for which you want to generate the schema script (.mts).

`-G stored_procedure_name`

Database/Query File (-M)

Specify the name of the database/query file created using the Database Interface Designer. This **.mdq** file contains the definition of either the database, specified by the **-B** parameter, or the query, specified by the **-Q** parameter.

`-M mdq_file`

Category Type (-N)

Specify the name of the category type from which the types defining the table or query will stem.

`-N type_name`

Schema Script File (-O)

Specify the name of the tree script file (.mts) to be generated by **mtsmaker** and used by the Type Tree Maker to create the schema.

`-O mts_file_name`

Password (-P)

Specify the password used to connect to the data source. This parameter is required if it is necessary for your database security environment. Otherwise, it is optional.

`-P password`

Query Name (-Q)

Specify the name of the query in the **.mdq** file for which you want to generate the schema script (.mts).

`-Q query_name`

SQL statement (-S)

Specify an SQL statement or a call to a stored procedure using either the database-independent or native call syntax that is passed to the database management system to determine the content and format of the database output. This statement should be the same as the statement you are using to generate input for your map. However, you may exclude SQL WHERE clauses because they do not affect the format of the result. The SQL statement must be enclosed in double quotation marks.

`-S "sql_statement"`

Table Name (-T)

Specify the name of the table, or the view that can be updated, for which you want to generate the schema script file (.mts).

`-T table_name`

User ID (-U)

Specify the user ID to use to connect to the data source. This parameter may be required based upon your database security.

-U user_id

Variable Name (-V)

Specify this parameter whenever needing variable name substitution in an SQL query that is contained in an MDQ file. The equal sign (=) must be included to properly associate the substituted value with the variable name.

-V name=value

whereby:

name is the name of the variable in the SQL query.

value is the value that should be substituted.

For example:

If using the following query from an .mdq file, select * from BigTable where Identifier=#ID# then specify the following option on the mtsmaker command line:

-V ID=2

In this way, the query to be executed would be as follows:

```
select * from BigTable where Identifier=2
```

Note that variable name values are read by default from the .mdq file, unless overridden on the command line.

See the Database Interface Designer documentation for more information regarding the definition of variables in SQL statements.

Format (-X)

Specify a format for the schema to be generated. Do not use the default, which is delimited.

-X [F] [O] [T]

Option

Description

F

Generate a fixed row format schema.

O

(Oracle only) Generate a 1.4.x format schema.

T

Generate a schema with dates represented as text items. If this option is not specified, the default is to represent dates as date items.

Database Adapter Type (-Z)

Specify the database adapter type to connect to.

-Z {ODBC|ORACLE|SQLSVR|OLEDB|SYBASE|DB2|DB2MVS|IFMX}

Option

Description

ODBC

ODBC database adapter

ORACLE

Oracle database adapter

SQLSVR

Microsoft SQL Server database

OLEDB

OLE DB database adapter

SYBASE

Sybase SQL Server database adapter

DB2*

DB2 (Windows/UNIX) database adapter

DB2MVS

DB2 (z/OS®) database adapter

IFMX

Informix® database adapter

Return codes and error messages

Adapter return codes and messages provide information on the adapter operations, adapter command syntax errors, and reasons for unsuccessful transactions. See the associated adapter documentation for specific error message information.

- [General adapter messages](#)
- [Database-specific adapter messages](#)

General adapter messages

The following is a list of all the codes and messages that are common among all resource adapters. Return codes with positive numbers are warning codes that indicate a successful operation. Return codes with negative numbers are error codes that indicate a failed operation.

See [Database-specific Adapter Messages](#) for information on database-specific return codes and error messages.

Return Code	Message
-1	Unknown error code
-2	Exception occurred
-3	Function failed
-4	Invalid property specified
-5	Property type mismatch
-6	Property not set
-7	Invalid index
-8	Null argument
-9	Invalid argument
-10	Failed to allocate memory
-11	No properties defined for the object
-12	Invalid type specified
-13	Connection failed
-14	File open failed
-15	File write failed
-16	File read failed
-17	File position function failed
-18	Invalid object specified
-19	Null object specified
-20	Illegal function call
-21	Unexpected end-of-file
-22	Only one top level element allowed
-23	Not a top level element
-24	3rd party function failed
-25	Attempt was made to resize non-resizable memory
-26	Running map failed
-27	Loading map failed
-28	Item requested does not exist
-29	Failed to load library

```

-30      Invalid seek performed
-31      Buffer too small - data truncated
-600     Internal error
         Message indicates nature of problem.

```

Database-specific adapter messages

After database adapter activity completes, messages display indicating the results. These messages may also be recorded in the appropriate files as specified, which may include audit logs, trace files, and execution summary. These codes and messages can be returned for the following database adapters:

- DB2® (z/OS® ODBC)
- DB2 (z/OS)
- DB2 (Windows/UNIX)
- Informix®
- Microsoft SQL Server
- ODBC
- OLE DB
- Oracle
- SQL/MP
- SQL/MX
- Sybase SQL Server

The following is a listing of all the codes and messages that can be returned as a result of using the database adapters for sources or targets.

You can also troubleshoot database-specific adapters by using the adapter Trace (-T or -TRACE) or the Trace Error (-TE or -TRACEERR) command.

Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Return Code	Message
0	Success
12	Database -b argument is required with arguments mdqfile -m and query -q
1001	One or more records could not be processed
1002	No data found
-1001	Memory allocation error
-1002	Failed to allocate ODBC environment
-1003	Failed to allocate ODBC statement
-1004	Failed to allocate ODBC connection
-1005	Failed to connect to the database
-1006	Failed to prepare the SQL statement
-1007	Failed to obtain definition of column
-1008	Failed to bind parameters to the SQL statement
-1009	Failed to execute the SQL statement
-1010	Failed to open a cursor
-1011	Failed to insert a row into the database
-1012	Failed to read file
-1013	Failed to open file
-1014	The input buffer was of incorrect form
-1015	Failed to write to file
-1016	Database type is unknown
-1017	Failed to parse SQL statement
-1018	Failed to define host variables

-1019 Failed to logoff the database
-1020 Failed to close the cursor
-1021 Failed to bind parameters to the SQL statement
-1022 Failed to fetch a long data value
-1023 Failed to perform a file seek
-1024 Failed to create file
-1025 The specified query could not be found
-1026 The specified database could not be found
-1027 Failed to load DLL
-1028 Failed to get address of function
-1029 Failed to fetch a row of data
-1030 Failed to get data from the database
-1031 Failed to get data from the database
-1032 No rows were updated
-1033 The number of rows affected was undeterminable
-1034 The supplied statement was syntactically invalid
-1035 Failed to create an execution thread
-1036 Failed to get extended error text
-1037 Table is not accessible
-1038 Failed to disconnect from the database
-1039 Failed to free the database connection
-1040 Failed to free the environment
-1041 MDQ file is invalid
-1042 Failed to close file
-1043 No database connection could be found
-1044 No database type was specified with -DBTYPE
-1045 Failed to find column attributes
-1046 Failed to get the number of result columns
-1047 Failed to get large data
-1048 Failed to cleanup the database connection
-1049 Databases are not supported
-1050 Failed to load DLL
-1051 Failed to get address of function
-1052 Failed to commit or rollback the transaction
-1053 Failed to free the statement
-1054 Insufficient data was provided
-1055 Failed to bind parameters to the SQL statement
-1056 Failed to define large data value
-1057 Failed to put large data value
-1058 Failed to commit the transaction

-1059 Failed to rollback the transaction
-1060 The update statement was invalid
-1061 No type could be found to match column name
-1062 No suitable presentation could be found for a column
-1063 No suitable presentation could be found for a column
-1064 No suitable presentation could be found for a column
-1065 Internal error
-1066 No more rows were returned
-1067 No trigger was defined for the input
-1068 Data was unexpectedly terminated
-1069 Required command line options missing
-1070 The database command line was invalid
-1071 Could not find environment variable
-1072 Failed to attach to database
-1073 Failed to convert datatype to native database type
-1074 Failed to get list of SQL servers
-1075 Failed to get list of databases
-1076 Failed to initialize stored procedure
-1077 Failed to set parameter to stored procedure
-1078 Failed to execute stored procedure
-1079 Failed to get column information
-1080 Failed to declare host variables
-1081 Command line token could not be found
-1082 Failed to create an event
-1083 The command line is too long
-1084 The function/procedure has no return value
-1085 A variable length binary column is not permitted
-1086 Error occurred writing to a LOB column
-1087 Error occurred reading from a LOB column
-1088 Connection to Open Server failed
-1089 Poll to Open Server failed
-1090 The map contains outdated DB parameters. Rebuild the map
-1091 An output date was of an incorrect format
-1092 Internal error occurred
-1093 Burst complete
-1094 Type already exists and override was not specified
-1095 No Row or ProcedureCall group can be found
-1096 Failed to format output from an object type
-1097 Failed to create an object
-1098 An object is not permitted in fixed schema

-1099 Failed to convert database parameters from ASCII to EBCDIC
-1100 One or more columns/parameters are of an unsupported datatype
-1101 Failed to configure run-time environment.
-1102 Failed to Allocate context structure, unknown reason or not enough memory
-1103 A trigger could not be defined for a watch event
-1104 Unique table columns are required for row-based watch events
-1105 Procedure is not accessible
-1106 The configured transaction manager is not supported
-1107 System error occurred while waiting for a watch event
-1108 Triggering is not supported for this adapter.
-1109 User terminated database access
-1110 The trace file name is too long, or the running directory is too deep
The database trace file name and/or the directory name in which the failed map is located, may be longer than 128 characters.
Ensure the file and directory name are shorter than 128 characters.
-1302 A trigger event could not be registered
-2002 Insufficient data passed to output card

Apache ActiveMQ Adapter

This document provides an overview of the Apache ActiveMQ message-broker service and the Apache ActiveMQ adapter.

Overview

With the ActiveMQ Adapter, users can access any of the queues of the Active MQ Adapter to send and receive messages. Users can also create a new queue altogether for sending and receiving messages.

Introduction

Apache ActiveMQ picks up messages from a message queue—breaks-up a message in a way that the message does not give away much information of the sender-application to the application that picks up the message. After breaking up, it places the message to the queue to be picked up by any application. The Apache ActiveMQ can then collect the response from the recipient-application, break down the response in a way that reveals the least information about the recipient-application—and, then place the transformed response to the message queue. In doing so, it effectively implements decoupling of the two communicating applications by minimizing the mutual awareness that these two applications should have of one another to be able to exchange messages. Apache ActiveMQ is an open source message broker and an asynchronous messaging system, written in Java with Java Message Service (JMS) client.

The ActiveMQ adapter establishes a connection to the ActiveMQ server from an application, through which users of the application can access any of the queues of the ActiveMQ server to send and receive messages. With this adapter, users can send the following three types of messages to a queue: Text, Byte, and Blob. Messages are received one at a time in the order of their insertion.

- **[Authentication connections](#)**
The ActiveMQ adapter supports username and password-based authentication to establish the connections to the ActiveMQ broker. The username and password credentials need to be specified in the Username and Password properties in the connection definition for the adapter.
 - **[Adapter properties and commands](#)**
This section lists the properties supported by the adapter and Java Message Service(JMS) headers.
 - **[Examples](#)**
-

Authentication connections

The ActiveMQ adapter supports username and password-based authentication to establish the connections to the ActiveMQ broker. The username and password credentials need to be specified in the Username and Password properties in the connection definition for the adapter.

In addition to the authentication of the user based on the username and password credentials, the adapter supports certificate-based authentication with the ActiveMQ broker.

- The adapter can be configured to request the ActiveMQ broker to provide a certificate that the adapter validates using the truststore information specified in the **Truststore Location** and **Truststore Password** properties.
- The adapter can be configured to present its certificate using the keystore information specified in the Keystore Location, Keystore Password, and Key Password properties when the broker is configured to request clients to provide their certificate when connecting to it. The Key Password is applicable when the private key in

the keystore is protected by a password different from the keystore password.

Adapter properties and commands

This section lists the properties supported by the adapter and Java Message Service(JMS) headers.

This section lists the properties supported by the adapter.

URL

Specifies the URL or the broker URL that allows to run a configured broker using a single URL for all the configuration (Example of default broker URL: `tcp://localhost:61616`). This is a mandatory property. It is required at the time of setting the connection.

The corresponding adapter command is **-URL**.

Login Username

Specifies the username to use for authentication when connecting to the message broker. The corresponding adapter command is **-U username** (or **-USERNAME username**).

Login Password

Specifies the password value to use for authentication when connecting to the message broker. The corresponding adapter command is **-P password** (or **-PASSWORD password**).

Truststore File

Specifies the path to the truststore in PKCS#12 or JKS format that the adapter uses to validate the broker certificate when SSL/TLS is enabled. The truststore must contain the chain of certificates up to the CA certificate that is used to sign the broker certificate. The corresponding adapter command is **-TSL path** (or **-TRUSTSTORELOCATION path**).

Truststore Password

Specifies the password for the adapter to use to access the specified truststore when SSL/TLS is enabled. The corresponding adapter command is **-TSP password** (or **-TRUSTSTOREPASSWORD password**).

Truststore Type

Specifies the type of truststore (PKCS#12 or JKS). The corresponding adapter command is **-TST type** (or **-TRUSTSTORETYPE type**).

Keystore File

Specifies the path to the keystore in PKCS#12 or JKS format that the adapter uses to retrieve the private key and certificate with the public key. Which is required, if the broker is configured to request clients to provide a certificate for SSL/TLS connections. The corresponding adapter command is **-KSL path** (or **-KEYSTORELOCATION path**).

Keystore Password

Specifies the password for the adapter to access the specified keystore when SSL/TLS is enabled. The corresponding adapter command is **-KSP password** (or **-KEYSTOREPASSWORD password**).

Key Password

Specifies the password for the adapter to access the private key in the specified keystore when SSL/ TLS is enabled. The password is required, if the private key is secured with a password different from the keystore password. The corresponding adapter command is **-KP password** (or **-KEYPASSWORD password**).

Keystore Type

Specifies the type of Keystore (PKCS#12, JKS, or JVM). The corresponding adapter command is **-KST type** (or **-KEYSTORETYPE type**).

Read Mode

Specifies whether to keep or delete the messages in ActiveMQ queue after a successful read operation. The corresponding adapter command is **-RM keep/delete** (or **-READMODE keep/delete**).

Note: The default is `keep`, so it is not necessary to specify **-READMODE keep**.

Queue Name

Specifies the queue name to and from which messages are to be sent and received. This is mandatory parameter. Queue name property can be passed to adapter input or output cards using **-Q** (or **-QUEUE**) command.

Create Queue

This is a boolean flag. It is used at the time of sending a message to the ActiveMQ. If this flag is set to true and the particular queue is not present, it will create the queue. If this flag is set to false and the queue is not present, user will get invalid queue name exception. If the value is not mentioned for this flag, then by default the value is false. The corresponding adapter command is **-CQ** (or **-CREATEQUEUE**).

Validate Queue

Specifies whether to validate queue before reading or sending message. The corresponding adapter command is **-V** (or **-VALIDATE**).

Message Type

Specifies the type of message being sent to the ActiveMQ adapter. The currently supported message types are: Text, Blob, Byte. Examples of Blob file are a large image file, and a PDF file among others. An 'invalid message type' exception will occur, if a user tries to set a message type other than the supported ones. Though this is an

optional parameter, it is recommended to set a message type at the time of creating an output card. Message type property can be passed to adapter output cards using -**MT** (or **-MSGTYPE**) command.

Delay Time

Specifies the time duration after the lapse of which, the adapter will look out for the next message. A timeout of zero never expires, and the call blocks indefinitely. The timeout value is specified in milliseconds. This property is optional but recommended to set when receiving message from ActiveMQ (used in input card) with a minimum value (1) to avoid getting stuck in case no message is present in the queue. The Delay-time property can be passed to adapter input using -**DT** (or **-DELAYTIME**) command.

Logging

Specifies the level of logging to use for the log (trace) file produced by the adapter. The default is Off. The value Information means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

The corresponding adapter command is:

-T [E|V] [+|] [file_path]

-T -> Log adapter informational messages.

-TE -> Log only adapter errors.

-TV -> Use verbose (debug) logging. The log file records all activity that occurs while the adapter is producing or consuming messages.

+ -> Appends the trace information to the existing log file. Omit this argument to create a new log file.

file_path -> The full path to the adapter trace log. If you omit this keyword, the adapter creates the m4activeMQ.trc log file in the map directory

Append Log

Specifies the flag that indicates the action to be taken when the specified log file already exists. When set to true, the log messages are appended to the file. When set to false: the file is truncated, and the messages are written to the empty file. The default value is true.

Log File Name

This is the name of the log file, where the log messages are written. If not specified, the default log file name m4activeMQ.trc is used, and the file is stored to the directory in which the executed compiled map resides.

Java Message Service(JMS) headers

Enables users to include standard Java Message Service(JMS) headers and user-defined properties in the messages produced to the ActiveMQ broker and retrieve them from messages consumed from the broker.

Messages in link, which include header information, are always represented as JSON documents.

The version of the header is stored in the version JSON element, while the actual payload of the ActiveMQ messages are stored in the payload JSON element. Binary payloads are stored using hex digit pairs or base64 encoding.

The JMS headers are represented by JSON elements with elements that match the JMS headers, except they are in lowercase and use an underscore as a word separator.

The JMS properties are represented by JSON elements that start with an underscore ("_") character.

JSON Template

The following JSON template captures the version element, and all supported JMS headers, two user-defined message properties (title and size), and the payload element. This element can be used as the starting point to create JSON schemas for use in ActiveMQ adapter cards and nodes.

```
{
  "version": 1,
  "destination": "",
  "reply_to": "",
  "type": "",
  "delivery_mode": 0,
  "priority": 0,
  "message_id": "",
  "timestamp": 0,
  "correlation_id": "",
  "expiration": 0,
  "redelivered": false,
  "_title": "",
  "_size": 0,
  "payload": ""
}
```

Table 1. JMS header properties and command

Adapter property	Command	Source	Target
Message Header	-HDR version	✓	✓
Message Header Elements	-MHE list	✓	
Message Payload Encoding	-MPE encoding	✓	✓
Destination	-DES name		✓
Reply To	-RTO name		✓
Type	-TYP type		✓
Delivery Mode	-DM mode		✓
Priority	-PRI priority		✓
Message Id	-MID id		✓

Adapter property	Command	Source	Target
Timestamp	-TMS time		✓
Correlation Id	-CID id		✓
Expiration	-EXP duration		✓
Redelivered	-RED		✓

Message Header

Specifies the version of the JSON document used to represent ActiveMQ messages. The default value None means that the entire data passed to and from the adapter represents the message payload. No header information is present, and the message is not represented as a JSON header document. The value Version 1 indicates the JSON document version 1 is used. The corresponding adapter command is **-HDR version** (or **-HEADER version**).

Message Header Elements

Specifies a comma-separated list of elements to include in the JSON document representation of the consumed messages. Any whitespace characters in the list are NOT ignored and are considered part of the element names. The order of elements in the provided list will match the order of elements in the generated JSON document. Note that the version and payload elements must be explicitly included in the list for the message payload to be included in the JSON document. The corresponding adapter command is **-MHE list** (or **-MESSAGEHEADERELEMENTS list**)

Message Payload Encoding

Specifies the encoding of the payload element value in the JSON message representation. The corresponding adapter command is **-MPE encoding** (or **-MESSAGEPAYLOADENCODING encoding**).

The supported values are:

Text: The value is a string representation of the message payload. It assumes that the actual message payload is already in text format, encoded in the current system locale character set. The corresponding adapter command value is **text**.

JSON: The value is in JSON format. This can be an atomic JSON value, a JSON object, or a JSON array. It assumes that the actual message payload is already in JSON format, encoded in the current system locale character set. The corresponding adapter command value is **json**.

Hex Pairs: The value is a string consisting of consecutive hex-digit pairs, where each pair corresponds to a single byte from the message payload. The corresponding adapter command value is **hex_pairs**.

Base64: The value is a string that represents base64 encoded message payload's binary content. The corresponding adapter command value is **base64**.

Destination

Specifies the name of the destination queue to set for the messages produced. It corresponds to the JMSDestination standard JMS header. The value can also be set on a per-message basis using the destination element in the JSON message document. The corresponding adapter command is **-DES name** (or **-DESTINATION name**).

Reply To

Specifies the name of the response queue to set for the produced messages. It corresponds to the JMSReplyTo standard JMS header. The value can also be set on a per-message basis using the reply_to element in the JSON message document. The corresponding adapter command is **-RTO name** (or **-REPLYTO name**).

Type

Specifies the user-defined message type to set for the produced messages. It corresponds to the JMSType standard JMS header. The value can also be set on a per-message basis using the type element in the JSON message document. The corresponding adapter command is **-TYP type** (or **-TYPE type**).

Delivery Mode

Specifies the mode of delivery to set for the produced messages. It corresponds to the JMSDeliveryMode standard JMS header. The value can also be set on a per-message basis using the delivery_mode element in the JSON message document. The following values are supported:

Non Persistent: For instructing the broker that it is not required to store messages in transit to stable storage. The corresponding adapter command value is 1.

Persistent: For instructing the broker to store messages in transit in to stable storage. It is the default value, and the corresponding adapter command value is 2.

The corresponding adapter command is **-DM mode** (or **-DELIVERYMODE mode**).

Priority

Specifies the priority value to set for the produced messages. It corresponds to the JMSPriority standard JMS header. The value can also be set on a per-message basis using the priority element in the JSON message document. The corresponding adapter command is **-PRI priority** (or **-PRIORITY priority**).

Message Id

This property specifies the message identifier value to set for the messages that are produced. It corresponds to the JMSMessageID standard JMS header. The value can also be set on a per-message basis using the message_id element in the JSON message document. The corresponding adapter command is **-MID id** (or **-MESSAGEID id**).

Timestamp

This property specifies the timestamp value to set for the messages that are produced. It corresponds to the JMSTimestamp standard JMS header. The value can also be set on a per-message basis using the timestamp element in the JSON message document. The corresponding adapter command is **-TMS time** (or **-TIMESTAMP time**).

Correlation Id

This property specifies the correlation identifier value to set for the messages produced. It corresponds to the JMSCorrelationID standard JMS header. The value can also be set on a per-message basis using the correlation_id element in the JSON message document. The corresponding adapter command is **-CID id** (or **-CORRELATIONID id**).

Expiration

This property specifies the message expiration duration in milliseconds to set for the messages produced. It corresponds to the JMSExpiration standard JMS header. The value can also be set on a per-message basis using the expiration element in the JSON message document. The corresponding adapter command is **-EXP duration** (or **-EXPIRATION duration**).

EXPIRATION *duration*).

Redelivered

Specifies that the message is being resent. It corresponds to the JMSRedelivered standard JMS header. The value can also be set on a per-message basis using the delivery_mode element in the JSON message document. The corresponding adapter command is **-RED** (or **-REDELIVERED**).

Examples

Examples of GET map function

In the following example, assume that the adapter being used in a GET function is defined as follows:

This will pick the first message in the queue and transform according to the adapter mentioned in the output card.

```
GET("ACTIVEMQ", "-URL tcp://localhost:61616 -Q TEST_QUEUE -DT 5 -TV C:\temp\m4activemq.log")
```

Now, assume the GET map function was defined as follows (the specified queue name is not present):

```
GET("ACTIVEMQ", "-URL tcp://localhost:61616 -Q MISSING_QUEUE -DT 5 -TV C:\temp\m4activemq.log")
```

In this case, the adapter throws error: Queue MISSING_QUEUE doesn't exist, as it cannot find the queue name specified.

Examples of PUT map function

In the following example, assume that the adapter being used in a PUT function is defined as follows:

If the queue is not present, it will create the queue and put the message; if the queue is present, it will simply put the message into the queue TEST_QUEUE. Here, the message type is byte.

```
PUT("ACTIVEMQ", "-URL tcp://localhost:61616 -Q TEST_QUEUE -CQ -MT byte -TV C:\temp\m4activemq.log", in_data_type)
```

Now, assume that the message type is not mentioned.

```
PUT("ACTIVEMQ", "-URL tcp://localhost:61616 -Q TEST_QUEUE -CQ -TV C:\temp\m4activemq.log", in_data_type)
```

In this case, it will throw the following error: Message type must be blob/byte/Text.

Now, assume that the adapter is used in a PUT function, but the queue name mentioned is not present.

```
PUT("ACTIVEMQ", "-URL tcp://localhost:61616 -Q TEST_QUEUE -MT byte -TV C:\temp\m4activemq.log", in_data_type)
```

It will throw the following error message: Queue TEST_QUEUE does not exist. By default, the create queue flag is false. It needs to be set to true explicitly, if the queue is not present and the user wants to create the queue.

Apache HDFS Adapter

The Apache HDFS Adapter allows the IBM Transformation Extender to access the HDFS file system in Apache Hadoop environments.

Input cards and GET functions in the IBM Transformation Extender can be configured to read files from HDFS. Similarly, output cards and PUT functions can be configured to write data to HDFS files. Also, IBM Transformation Extender Launcher watches can be defined to detect creation of a new or modified file in HDFS, and to trigger the map to read and process that file.

- **[System requirements](#)**
See the release notes for the HDFS Adapter requirements.
- **[HDFS Adapter commands overview](#)**
The HDFS Adapter can be used to read and write files in HDFS. The adapter uses WebHDFS API to access HDFS. This is a REST API and uses HTTP protocol.
- **[HDFS Adapter commands](#)**
The Hadoop cluster must be configured to enable WebHDFS access. The WebHDFS server and port to which the adapter connects, the file to read or write, and various options for tuning these operations are specified by the adapter commands described in this documentation.
- **[HDFS Adapter transaction settings](#)**
This documentation describes how transaction settings in input and output HDFS cards affect the operation of the adapter.

System requirements

See the release notes for the HDFS Adapter requirements.

HDFS Adapter commands overview

The HDFS Adapter can be used to read and write files in HDFS. The adapter uses WebHDFS API to access HDFS. This is a REST API and uses HTTP protocol.

Note: The following is a high level overview of the HDFS Adapter commands. See [HDFS Adapter commands](#) for a detailed description of the adapter commands.

- **-S, -H and -P** commands - These commands specify the protocol scheme, the host, and the port to which to connect, respectively. The **-S** command is optional, and it defaults to *http*, which is the only supported value. Both the **-H** and the **-P** commands are required (no default).
- **-U** command - Specifies the name of the user known to HDFS.
- **-F** command - Specifies the path to the file in HDFS to read or write.
- **-CS** - command - Specifies the size (in bytes) of chunks of data the adapter reads from or writes to the file at a time.
- **-SCM** command -Enables special mode in a read or write operation where the entire file is read from or written to in a single chunk.
- **-IWM** command - Enables another special mode of write operation where the data is written to the target file immediately as it becomes available, instead of being buffered and written when the buffered chunks reach the specified size.
- **-BLS** command - Specifies the block size to use for the target file.
- **-BUS** command - Specifies the buffer size (in bytes) to use at the transport layer.
- **-OW** command - Used to allow overwriting the target file, if the file exists.
- **-CSRFH** command -Used to specify the header to set when Cross-Site Request Forgery prevention is enabled in HDFS.
- **-XATTR** command - Used to set extended attributes on the target file, or to specify extended attributes criteria for processing files in the Launcher.
- **-PER** command - Specifies the permissions to set on the target file.
- **-REP** command - Specifies the replication factor for the target file.
- **-TSL, -TSP, -KSL, -KSP, -AS, -AC and -VH** commands - Used to configure SSL.
- **-KM, -LCFL, -KCFL, -KAU, -KAP and -KCN** adapter commands - Used to configure Kerberos.
- **-BAU** and **-BAP** adapter commands - Used for basic HTTP authentication.
- **-T** command - This command, and its variants, is used to manage adapter tracing.

HDFS Adapter commands

The Hadoop cluster must be configured to enable WebHDFS access. The WebHDFS server and port to which the adapter connects, the file to read or write, and various options for tuning these operations are specified by the adapter commands described in this documentation.

Adapter commands summary list

Table 1. Adapter commands summary list

Short name	Long name	Description
-S	-SCHEME	Scheme
-H	-HOST	Host
-P	-PORT	Port
-U	-USER	User
-F	-FILE	File
-CS	-CHUNKSIZE	Chunk size
-SCM	-SINGLECHUNKMODE	Single chunk mode
-IWM	-IMMEDIATEWRITEMODE	Immediate write mode
-OW	-OVERWRITE	Overwrite
-PER	-PERMISSION	Permission flags
-REP	-REPLICATION	Replication factor
-CSRFH	-CSRFH	Cross-Site Request Forgery prevention header
-XATTR	-XATTR	Extended input and output attributes
-TSL	-TRUSTSTORELOCATION	Truststore full path
-TSP	-TRUSTSTOREPASSWORD	Truststore password
-KSL	-KEYSTORELOCATION	Keystore full path
-KSP	-KEYSTOREPASSWORD	Keystore password
-KP	-KEYPASSWORD	Key password
-AS	-AUTHSERVER	Authenticate server
-AC	-AUTHCLIENT	Authenticate client
-VH	-VERIFYHOSTNAME	Verify hostname
-KM	-KERBEROSMODE	Kerberos mode authentication
-LCFL	-LOGINCONFIGFILELOCATION	Login configuration file location
-KCFL	-KERBEROSCONFIGFILELOCATION	Kerberos configuration file location
-KAU	-KERBEROSAUTHUSER	Kerberos authentication user
-KAP	-KERBEROSAUTHPASSWORD	Kerberos authentication password
-KCN	-KERBEROSCONFIGNAME	Kerberos configuration namem
-BAU	-BASICAUTHUSER	Basic authentication user
-BAP	-BASICAUTHPASSWORD	Basic authentication password
-T	-TRACE	Adapter log full path - info level log
-T+	-TRACE+	Adapter log full path - append to log file
-TV	-TRACEVERBOSE	Adapter log full path - verbose level log
-TV+	-TRACEVERBOSE+	Adapter log full path - verbose level log - append to log file
-TE	-TRACEERROR	Adapter log full path - error log only
-TE+	-TRACEERROR+	Adapter log full path - error log only - append to log file

- **Protocol scheme -S (-SCHEME)**

Use the **-S** scheme command to determine the protocol scheme to use.

- **WebHDFS host name -H (-HOST)**

Use the **-H** hostname command to identify the WebHDFS host name.

- **[WebHDFS port number -P \(-PORT\)](#)**
Use the **-P** *port* command to identify the WebHDFS port number.
- **[Username -U \(-USER\)](#)**
Use the **-U** *user* command to identify the username, for simple username based authorization
- **[Path prefix -PP \(-PATHPREFIX\)](#)**
Use the **-PP** *prefix* command to identify the path prefix in the URL.
- **[Filename -F \(-FILE\)](#)**
The **-F** *filename* command indicates the path of the file to read from, or write to.
- **[Chunk size -CS \(-CHUNKSIZE\)](#)**
Use the **-CS** *size* command to indicate the chunk size in bytes.
- **[Single chunk mode -SCM \(-SINGLECHUNKMODE\)](#)**
Use the **-SCM** command to instruct the adapter to read data from the HDFS file and write data to the HDFS file in a single chunk.
- **[Immediate write mode -IWM \(-IMMEDIATEWRITEMODE\)](#)**
Use the **-IWM** command to instruct the adapter to write data to the target HDFS file as soon as it becomes available from the engine without buffering it for later write.
- **[Block size -BLS \(-BLOCKSIZE\)](#)**
Use the **-BLS** *size* command to set the block size, in bytes, to use for the target file when the adapter creates a new file.
- **[Buffer size -BUS \(-BUFFERSIZE\)](#)**
Use the **-BUS** *size* command to set the buffer size, in bytes, to use at the HTTP transport layer.
- **[Overwrite -OW \(-OVERWRITE\)](#)**
Use the **-OW** command to set target file overwrite.
- **[Permission flags -PER \(-PERMISSION\)](#)**
Use the **-PER** *flags* command to set permission flags on the target file created by the adapter.
- **[Replication factor -REP \(-REPLICATION\)](#)**
Use the **-REP** *factor* command to set the replication factor to specify for the target file created by the adapter.
- **[Cross-Site Request Forgery Prevention Header -CSRFH \(-CSRFH\)](#)**
Use the **-CSRFH** [*header[:value]*] command to specify the header in each HTTP request to comply with Cross-Site Request Forgery prevention when enabled in the HDFS.
- **[Extended attributes -XATTR \(-XATTR\)](#)**
Use the **-XATTR** *name=value[,name=value]** command to specify extended input and output attributes.
- **[Truststore file full path -TSL \(-TRUSTSTORELOCATION\)](#)**
The **-TSL** *path* command indicates the Truststore file full path for SSL handshake.
- **[Truststore password -TSP \(-TRUSTSTOREPASSWORD\)](#)**
The **-TSP** *password* command indicates the Truststore password.
- **[Keystore file path -KSL \(-KEYSTORELOCATION\)](#)**
Use the **-KSL** *path* command to specify the Keystore file full path.
- **[Keystore password -KSP \(-KEYSTOREPASSWORD\)](#)**
Use the **-KSP** *password* to specify the Keystore password.
- **[Key password -KP \(-KEYPASSWORD\)](#)**
Use the **-KP** *password* command to specify the Key password.
- **[Authenticate server -AS \(-AUTHSERVER\)](#)**
Use the **-AS** command to authenticate to the server.
- **[Authenticate client -AC \(-AUTHCLIENT\)](#)**
Use the **-AC** command for client certificate validation.
- **[Verify host name -VH \(-VERIFYHOSTNAME\)](#)**
Use the **-VH** command to instruct the adapter to verify the hostname value in the server certificate presented by the WebHDFS server during the SSL handshake.
- **[Kerberos mode -KM \(-KERBEROSMODE\)](#)**
Use the **-KM** command to perform Kerberos authentication and to perform WebHDFS operations as the authenticated user.
- **[Login configuration file location -LCFL \(-LOGINCONFIGFILELOCATION\)](#)**
Use the **-LCFL** *path* command to identify the login configuration file location.
- **[Kerberos configuration file location -KCFL \(-KERBEROSCONFIGFILELOCATION\)](#)**
Use the **-KCFL** command to specify the location of the Kerberos configuration file.
- **[Kerberos authentication user -KAU \(-KERBEROSAUTHUSER\)](#)**
Use the **-KAU** *username* command when the login configuration file is configured to prompt the user for username and password, as opposed to using ticket cache or keytab file.
- **[Kerberos authentication password -KAP \(-KERBEROSAUTHPASSWORD\)](#)**
Use the **-KAP** *password* command to authenticate the Kerberos authentication password.
- **[Kerberos configuration file -KCN \(-KERBEROSCONFIGNAME\)](#)**
Use the **-KCN** *name* command to specify the name of the configuration section in the login configuration file.
- **[Basic authentication user -BAU \(-BASICAUTHUSER\)](#)**
Use the **-BAU** *username* command when HTTP basic authentication is required on the connection.
- **[Basic authentication password -BAP \(-BASICAUTHPASSWORD\)](#)**
Use the **-BAP** *password* command when HTTP basic authentication is required on the connection.
- **[Adapter log file full path -T, -T+, -TV, -TV+, -TE, -TE+](#)**
Use the **-T**, **-T+**, **-TV**, **-TV+**, **-TE**, and **-TE+** commands to specify the adapter log file full path.

Protocol scheme -S (-SCHEME)

Use the **-S** *scheme* command to determine the protocol scheme to use.

The two supported schemes are *http* and *https*. Default is *http*.

WebHDFS host name -H (-HOST)

Use the **-H** *hostname* command to identify the WebHDFS host name.

This is the name of the HDFS Name Node server.

WebHDFS port number -P (-PORT)

Use the **-P** *port* command to identify the WebHDFS port number.

This is the port on which Name Node listens for WebHDFS HTTP requests. This port is typically 5870 or 50070, depending upon Hadoop distributions.

Username -U (-USER)

Use the **-U** *user* command to identify the username, for simple username based authorization

Path prefix -PP (-PATHPREFIX)

Use the **-PP** *prefix* command to identify the path prefix in the URL.

This is the part of the URL located between the *scheme://hostname:port/* part and the HDFS file path part. Default: *webhdfs/v1*

Filename -F (-FILE)

The **-F** *filename* command indicates the path of the file to read from, or write to.

In case of the Launcher, the path specified on the input card on which a source event watch is defined. The path consists of the directory path and glob pattern file name, for example: */user/user1*.txt*

Chunk size -CS (-CHUNKSIZE)

Use the **-CS** *size* command to indicate the chunk size in bytes.

The HDFS Adapter reads data from the HDFS file and writes data to the HDFS file in chunks of this size. Read and write for each chunk is a separate WebHDFS REST call. The value must be greater than zero. The maximum supported value is 2147483647. Default size: 65536

Single chunk mode -SCM (-SINGLECHUNKMODE)

Use the **-SCM** command to instruct the adapter to read data from the HDFS file and write data to the HDFS file in a single chunk.

Setting this property results in the adapter ignoring the value specified in the **-CS** command.

Immediate write mode -IWM (-IMMEDIATEWRITEMODE)

Use the **-IWM** command to instruct the adapter to write data to the target HDFS file as soon as it becomes available from the engine without buffering it for later write.

When the target card is configured to run in burst mode, the adapter immediately writes all available data in each burst to the target HDFS file.

This command is for Output operations only.

Block size -BLS (-BLOCKSIZE)

Use the **-BLS** *size* command to set the block size, in bytes, to use for the target file when the adapter creates a new file.

The value must be greater than 0 (zero). The maximum value supported by the adapter is 9223372036854775807. See your Hadoop distribution documentation for information about supported values in your HDFS environment.

This command is for Output operations only.

Buffer size -BUS (-BUFFERSIZE)

Use the **-BUS size** command to set the buffer size, in bytes, to use at the HTTP transport layer.

If this value is not specified, the default buffer size as defined in the HDFS is used. Contrast this to **-CS** which is the size of chunks of data the adapter uses to read or write to HDFS. The value must be greater than 0 (zero). The maximum supported value is 2147483647.

Overwrite -OW (-OVERWRITE)

Use the **-OW** command to set target file overwrite.

When the Overwrite command is set, the adapter overwrites the target file if **OnSuccess** card option is set to **Create**, or to **CreateOnContent**, and the file the adapter is about to create already exists. If the command is not specified, the adapter does not overwrite the target file but reports an error instead. This command is for Output operations only.

Permission flags -PER (-PERMISSION)

Use the **-PER flags** command to set permission flags on the target file created by the adapter.

The flag value is an octal (base 8) integer between 0 and 1777, inclusive. If the command is not specified, the target file is created with the default permissions flags configured in HDFS, typically 644.

This command is for Output operations only.

Replication factor -REP (-REPLICATION)

Use the **-REP factor** command to set the replication factor to specify for the target file created by the adapter.

The value must be greater than 0 (zero). The maximum value supported by the adapter is 32767, however, consult your Hadoop distribution documentation for information about supported values in your HDFS environment.

This command is for Output operations only.

Cross-Site Request Forgery Prevention Header -CSRFH (-CSRFH)

Use the **-CSRFH [header[:value]]** command to specify the header in each HTTP request to comply with Cross-Site Request Forgery prevention when enabled in the HDFS.

If the *header* argument is omitted, the X-XSRF-HEADER header is set to empty string value. If *header* is provided, but *value* is not the specified, the header is set to the empty string value. If both *header* and *value* are provided, the specified header is set to the specified value. The adapter sets the header in each HTTP request that it makes to WebHDFS server. See the HDFS documentation for more information about Cross-Site Request Forgery prevention.

Extended attributes -XATTR (-XATTR)

Use the **-XATTR name=value[,name=value]*** command to specify extended input and output attributes.

When used on the output, the adapter sets the specified extended attributes on the target file. If any of the attributes are already defined on the target file, they are overwritten with the specified new value.

When used on the input, it is only applicable in the Launcher when it is set on the input card on which source event watch is defined. In this case, the adapter inspects the watch file before it is reported as an event. This is to ensure that it has the specified extended attributes set to the specified values. Only those files that meet this criteria are reported.

For more information about extended attributes in HDFS see the HDFS documentation.

Truststore file full path -TSL (-TRUSTSTORELOCATION)

The **-TSL path** command indicates the Truststore file full path for SSL handshake.

Applicable only when the **-SCHEME** adapter command is set to *https* and the **-AS** adapter command is specified.

Default path:

JAVA_HOME/lib/security/cacerts

Truststore password -TSP (-TRUSTSTOREPASSWORD)

The **-TSP** password command indicates the Truststore password.

Applicable only when the **-SCHEME** adapter command is set to *https* and the **-AS** adapter command is specified.

Default password: *changeit*

Keystore file path -KSL (-KEYSTORELOCATION)

Use the **-KSL** *path* command to specify the Keystore file full path.

Applicable only when the **-SCHEME** adapter command is set to *https* and the **-AC** adapter command is specified.

Default path:

JAVA_HOME/lib/security/cacerts

Keystore password -KSP (-KEYSTOREPASSWORD)

Use the **-KSP** *password* to specify the Keystore password.

Applicable only when the **-SCHEME** adapter command is set to *https* and the **-AC** adapter command is specified.

Default password: *changeit*

Key password -KP (-KEYPASSWORD)

Use the **-KP** *password* command to specify the Key password.

Applicable only when the **-SCHEME** adapter command is set to *https*, the **-AC** adapter command is specified, and the key password differs from the keystore password.

Default password: *changeit*

Authenticate server -AS (-AUTHSERVER)

Use the **-AS** command to authenticate to the server.

The Authenticate Server command is applicable only when the **-SCHEME** adapter command is set to *https*. This command notifies the adapter that client server certificate validation will take place during the SSL handshake.

Authenticate client -AC (-AUTHCLIENT)

Use the **-AC** command for client certificate validation.

The Authentication Client command is applicable only when the **-SCHEME** adapter command is set to *https*. The command notifies the adapter that client certificate validation will take place during SSL handshake.

Verify host name -VH (-VERIFYHOSTNAME)

Use the **-VH** command to instruct the adapter to verify the hostname value in the server certificate presented by the WebHDFS server during the SSL handshake.

Applicable only when the **-S** command is set to *https* and the **-AS** command is specified.

Kerberos mode -KM (-KERBEROSMODE)

Use the **-KM** command to perform Kerberos authentication and to perform WebHDFS operations as the authenticated user.

Login configuration file location -LCFL (-LOGINCONFIFILELOCATION)

Use the **-LCFL** *path* command to identify the login configuration file location.

Applicable when the **-KM** adapter command is set. Specifies the location of the JAAS login configuration file which specifies the Kerberos security module and parameters to use for authentication for testing and debugging purposes. The preferred way for specifying the location of this file is by providing the `Djava.security.auth.login.config=file_path` JVM parameters for the Java process in which the adapter runs. When the adapter command is used, the adapter sets the `java.security.auth.login.config` system property each time it initializes a connection client to HDFS, and it applies to the entire JVM process. This is important in cases with multiple threads or multiple adapters running in the JVM. The operation of these adapters might be affected by the value of this system property. Each time this system property is set, it becomes the active value for all threads and adapters that run the JVM.

Kerberos configuration file location -KCFL (-KERBEROSCONFIGFILELOCATION)

Use the **-KCFL** command to specify the location of the Kerberos configuration file.

Applicable when the **-KP** adapter command is set. Use this adapter command only for testing and debugging. The preferred way for specifying the location of this file is by providing the `-Djava.security.krb5.conf=file_path` JVM parameter for the Java process in which the adapter runs. When the adapter command is used, the adapter sets the `java.security.krb5.conf` system property each time it initializes the connection client to HDFS and it applies to the entire JVM process. This is important for cases with multiple threads or multiple adapters running in the JVM. In such cases, operation might be affected by the value of this system property. Each time this system property is set, it becomes the active value for all threads and adapters running in the JVM. The name of this file is typically, `krb5.conf`.

Kerberos authentication user -KAU (-KERBEROSAUTHUSER)

Use the **-KAU** *username* command when the login configuration file is configured to prompt the user for username and password, as opposed to using ticket cache or keytab file.

Kerberos authentication password -KAP (-KERBEROSAUTHPASSWORD)

Use the **-KAP** *password* command to authenticate the Kerberos authentication password.

Used when the login configuration file is configured to prompt the user for username and password as opposed to using ticket cache or keytab file.

Kerberos configuration file -KCN (-KERBEROSCONFIGNAME)

Use the **-KCN** *name* command to specify the name of the configuration section in the login configuration file.

The Kerberos client authentication section is typically named *Client*.

Basic authentication user -BAU (-BASICAUTHUSER)

Use the **-BAU** *username* command when HTTP basic authentication is required on the connection.

This might be the case, for example, when connecting to the HDFS through a proxy server as opposed to connecting directly.

Basic authentication password -BAP (-BASICAUTHPASSWORD)

Use the **-BAP** *password* command when HTTP basic authentication is required on the connection.

This might be the case, for example, when connecting to the HDFS through a proxy server as opposed to connecting directly.

Adapter log file full path -T, -T+, -TV, -TV+, -TE, -TE+

Use the **-T**, **T+**, **-TV**, **-TV+**, **-TE**, and **-TE+** commands to specify the adapter log file full path.

-T *path*(-TRACE)
-T+ *path*(-TRACE+)
-TV *path*(-TRACEVERBOSE)
-TE *path*(-TRACEERROR)
-TE+ *path*(-TRACEERROR+)

Adapter log file full path. **-T** is for info level log **-TV** is for verbose (debug) level log and **-TE** is for logging errors only. If **+** is included, it means to append to the log file if it exists. If it does not exist a new file is created. The path argument can be omitted, in which case the default trace file name, **m4hdfs.mtr**, is used and the file is created in the executable directory of the map.

HDFS Adapter transaction settings

This documentation describes how transaction settings in input and output HDFS cards affect the operation of the adapter.

The only supported transaction scope for input and output cards is Map. This means that the specified transaction action takes place only once per card, per map, prior to completing the map.

OnSuccess and **OnFailure** actions for HDFS input and output cards are described as follows:

OnSuccess actions for input cards

The **OnSuccess** actions for HDFS input cards are **Delete**, **Keep**, and **KeepOnContent**.

- **Delete** - Delete the source file.
- **Keep** - Keep the source file.
- **KeepOnContent** - Keep the source file if it is not empty. If it is empty, delete the file.

OnFailure actions for input cards

The only supported **OnFailure** action for HDFS input cards is **Commit**. The **Commit** action completes the write operation by flushing any data still staged in the adapter but not yet written to the target file.

OnSuccess actions for output cards

The **OnSuccess** actions for HDFS output cards are **Create**, **CreateOnContent**, **!Create**, and **Append**.

- **Create** - Create the target file if target file does not exist. If the target file with the same name already exists, overwrite the file if the -OW adapter command is included, otherwise report an error.
- **CreateOnContent** - Same description as **Create**, except the file is not created if there is no data to be written to it.
- **!Create** - Do not create the target file, even if the target file does not exist. The data provided to the adapter is not sent to HDFS, but is silently ignored. If the target file exists, it is left intact.
- **Append** - Append data to the target file, if it already exists. If the target file does not exist, the file is created, and data is written to the file.

OnFailure actions for output cards

The **OnFailure** actions for HDFS output cards are **Commit**, and **Rollback**.

- **Commit** - Preserves all data that was written to the file prior to the failure.
- **Rollback** - Delete the target file if the target file was created by the adapter in the current map. Otherwise, preserve the target file including any data that was written to it in the current map.

Apache Kafka Adapter

With the Apache Kafka adapter, Transformation Extender maps can connect to a Kafka cluster to consume and produce messages. You also can configure Transformation Extender Launcher watches to detect the arrival of new messages on Kafka topics and trigger maps to process those messages.

See the release notes for the Kafka adapter requirements.

- [Authenticating Connection](#)
- [Adapter properties and commands](#)
This section lists the properties supported by the adapter.
- [Adapter commands for consumers and producers](#)
Kafka adapter commands for consumers and producers are valid for input data sources and output data targets. See the related Kafka configurations for both consumers and producers in the Apache Kafka documentation for additional details.
- [Adapter commands for producers](#)
Kafka adapter commands for producers are valid for output target data. For additional details, see the producer configuration information in the [Apache Kafka documentation](#).
- [Adapter commands for consumers](#)
Kafka adapter commands for consumers are valid for input data sources. For additional details, see the consumer configuration information in the [Apache Kafka documentation](#).

Authenticating Connection

Apache Kafka adapter as a source

As a source (in consumer), the adapter can receive Avro messages from Kafka in form of Avro **GenericRecord** objects and convert them to JSON strings.

Apache Kafka adapter as a target

As a target (in producer) the adapter can convert JSON strings to Avro **GenericRecord** objects based on the Avro schema provided by the user.

Adapter properties and commands

This section lists the properties supported by the adapter.

In maps:

- Use adapter commands on input cards and GET functions to configure the adapter to consume messages from Kafka topics.
- Use adapter commands on output cards and PUT functions to configure the adapter to publish messages to Kafka topics.

Many Kafka adapter commands are based on Apache Kafka consumer or producer configurations. Those adapter command descriptions include the name of the related Apache Kafka configuration. See the [Apache Kafka documentation](#) for details.

Apache Kafka adapter command aliases

Use KAFKA as the adapter command alias on input and output cards and in GET and PUT rules. For example:

Input source override execution command	-IAKAFKA card_num
Output target override execution command	-OAKAFKA card_num

Headers for data payloads

You can specify the optional **-HDR** command to prepend one of the following header versions to the messages. The numbers in brackets denote the number of bytes:

- [4] is 32-bit int
- [8] is 64-bit int

Version

Header structure

1

```
[4]           Total header size (excluding this field): 2*4 + size(key)
[4]
[4]key        Key size followed by the key value
```

2

```
[4]           Total header size (excluding this field): 4*4 + 2*8 + size(key) + size(topic)
[4]
[4]key        Key size followed by the key value
[4]topic      Topic size followed by the topic
[4]
[4]           Partition number
[4]
[8]           Offset
[8]           Timestamp
```

3

```
[4]           Total header size (excluding this field): 4*4 + 2*8 + size(key) + size(topic) + sum(2*4 + size(hkey_i) +
size(hvalue_i))
[4]
[4]key        Header Version: 3
[4]key        Key size followed by the key value
[4]topic      Topic size followed by the topic
[4]
[4]           Partition number
[4]
[8]           Offset
[8]           Timestamp
[4]
The size of the Kafka headers section (excluding this field), followed by an array of Kafka header key,
value pairs in the following format:
[4]hkey      Kafka header key size followed by Kafka header key
[4]hvalue    Kafka header value size followed by Kafka header value
```

The message header is always followed by the payload size and payload content:

```
[4]payload    Payload size followed by payload content
```

Adapter commands for consumers and producers

Kafka adapter commands for consumers and producers are valid for input data sources and output data targets. See the related Kafka configurations for both consumers and producers in the Apache Kafka documentation for additional details.

Server Hostname

Identifies one or more servers in a Kafka cluster that the adapter is to establish an initial connection with. After the initial connection, the adapter discovers and uses the full set of servers. If the connection to the first server fails, the adapter attempts to connect to each subsequent server in the list until it succeeds.

Related Kafka configurations: bootstrap.servers

The corresponding adapter command is **-SRV hostname:port [,hostname:port[,hostname:port, ...]]** (or **-SERVER hostname:port [,hostname:port[,hostname:port, ...]]**).

Topic Name

The target topic to publish to, or one or more source topics to consume from. Separate multiple topic names with spaces. This command is required unless producers identify the topic for each message separately using message header version 2 or later. See "Headers for data payloads" and the **-HDR** command.

topicname

Publish the target message to a partition of the topic selected by the Kafka cluster.

topicname:partition

Publish the target message to the specified partition of the topic.

To consume messages, specify one or more source topics to consume from, using any combination of the following:

topicname

Consume all source messages from the topic.

topicname:partition

Consume all source messages from the specified partition of the topic.

topicname:*

Consume source messages from all partitions of the topic.

topicname:partition-offset

Consume the source message at the specified offset of the specified partition of the topic.

- If the offset does not exist in the specified partition, the adapter consumes messages based on the policy specified by the [-AOR](#) command.
- If the -AOR command is not specified, the adapter consumes the message from the most recent offset position.

Client ID

A logical application name to identify the source of requests in Kafka server logs. The default value is a null string. The corresponding adapter command is -CID clientID (or - CLIENTID ClientID)

Related Kafka configurations: client.id

Header

The version of the header that precedes the message payload size and message payload data. See "Headers for data payloads" for details about the header versions. This is an optional property. The corresponding adapter command is -HDR {1 | 2 | 3} (or -HDR {1 | 2 | 3})

Security Protocol

Specifies the security protocol. Default is Plain Text. The corresponding adapter command is -SP {PLAINTEXT | SSL | SASL_PLAINTEXT| SASL_SSL} (or -SECURITYPROTOCOL {PLAINTEXT | SSL | SASL_PLAINTEXT| SASL_SSL}).

- PLAINTEXT: Use a plain connection.
- SSL: Use an SSL connection for host authentication and data encryption. With SSL connections, you must also provide the path (-TSL command) and password (-TSP command) of the truststore.
- SASL_PLAINTEXT: Use a Simple Authentication Security Layer (SASL) mechanism for authentication over a plain connection.
- SASL_SSL: Use a SASL mechanism for authentication over an SSL connection.

See the security section in the Apache Kafka documentation for more details.

Login Configuration File Location

Specifies the location of the Java Authentication and Authorization Service (JAAS) login configuration file, which contains information about the security model and parameters to use for authentication. The corresponding adapter command is -LCFL file_path (or -LOGINCONFIGFILELOCATION file_path). This command is valid when the -SP command is set to sasl_plaintext or sasl_ssl.

Use the -LCFL command only for testing and debugging. This command sets the java.security.auth.login.config system property each time it connects to Kafka, and the property applies to the entire JVM process and all threads and adapters that run in it.

In a production environment, specify the location of the login configuration file with the Java Virtual Machine (JVM) Djava.security.auth.login.config=file_path parameter for the Java process in which the adapter runs.

Kerberos Configuration File Location

Specifies the location of the Kerberos configuration file, which contains information about the security model and parameters to use for authentication. The corresponding adapter command is -KCFL file_path (or -KERBEROSCONFIGFILELOCATION file_path).

This command is valid when the -SP command is set to sasl_plaintext or sasl_ssl and the -SM command is set to gssapi. The file is typically named krb5.conf.

Use the -KCFL command only for testing and debugging. This command sets the java.security.krb5.conf system property each time it connects to Kafka, and the property applies to the entire JVM process and all threads and adapters that run in it.

In a production environment, specify the location of the Kerberos configuration file with the Java Virtual Machine (JVM) Djava.security.krb5.conf=file_path parameter for the Java process in which the adapter runs.

Truststore Location File Path

Specifies the full path to the truststore. The corresponding adapter command is **-TSL** *file_path* (or **-TRUSTSTORELOCATION** *file_path*). This command is valid only when the **-SP** command is set to **ssl** or **sasl_ssl**.

Truststore Password

Specifies the truststore password.

The corresponding adapter command is **-TSP** *password* (or **-TRUSTSTOREPASSWORD** *password*). This command is valid only when the **-SP** command is set to **ssl** or **sasl_ssl**.

Keystore Location File Path

Specifies the full path to the keystore. The corresponding adapter command is **-KSL** *file_path* (or **-KEYSTORELOCATION** *file_path*). This command is valid only when the **-SP** command is set to **ssl** or **sasl_ssl**.

Keystore Password

Specifies the key password. The corresponding adapter command is **-KP** *password* or **(-KEYPASSWORD** *password***)**.

Logical Message Mode

Specifies logical message mode, in which the adapter processes multiple physical Kafka messages as a single record (*a logical message*). In this mode, the message payload of each physical message within the logical message is preceded with the 4-byte size of the payload, regardless of whether the **-HDR** command is specified. The corresponding adapter command is **-LMM** **(-LOGICALMESSAGEMODE)**.

Add Profile Filename

Specifies the name of a file that contains additional Kafka producer or consumer configurations in Java™ properties format. The values specified in the file override those specified on the adapter command. The corresponding adapter command is **-APF** *filename* (or **-ADDPROPFILE** *filename*).

Add Profile

Specifies one or more Kafka producer or consumer configurations. Each *key=value* pair is separated by spaces. The values specified on the **-AP** command override the values specified on the adapter command and the configurations in the file specified by the **-APF** command. The corresponding adapter command is **-AP** *key=value [key=value [key=value]]* (or **-ADDPROP** *key=value [key=value [key=value]]*).

Logging

This property specifies the level of logging to use for the log (trace) file produced by the adapter.

The corresponding adapter command is:

-T [E|V] [+] *[file_path]*

-TRACE or **-T** -> Log adapter informational messages.

-TRACEERROR or **-TE** -> Log only adapter errors.

-TRACEVERBOSE or **-TV** -> Use verbose (debug) logging. The log file records all activity that occurs while the adapter is producing or consuming messages.

+ -> Appends the trace information to the existing log file. Omit this argument to create a new log file.

file_path -> The full path to the adapter trace log. If you omit this keyword, the adapter creates the m4jdbc.mtr log file in the map directory.

Key Handling Mode

Specifies the mode for handling message keys. The corresponding adapter command is **-KHM** {*bytes* | *string* | *object_string* | *avro_json*} (or **-KEYHANDLINGMODE** {*bytes* | *string* | *object_string* | *avro_json*}).

The supported modes are:

- *bytes*: The adapter assumes message keys to be represented as Java byte array instances and it passes message key bytes through without any modification. This applies to both the consumer and producer scenarios. This is the default mode.
- *string*: In consumer, the adapter assumes message keys to be provided as Java String instances and converts them to bytes using the current system encoding. In producer, the adapter converts bytes to Java String instances using the current system encoding.
- *object_string*: In consumer, the adapter assumes message keys to be provided as Java Object instances, calls **toString()** method on them to obtain their string representation and converts them to bytes using the current system encoding. In producer, this mode behaves the same as string mode.
- *avro_json*: In consumer, the adapter assumes message keys to be provided as Java Avro **GenericRecord** objects, calls **toString()** method on them to obtain their JSON string representation and converts them to bytes using current system encoding. In producer, the adapter converts bytes to Java String instances, and assumes that they are formatted as JSON documents. It then converts them to Avro **GenericRecord** instances based on the Avro schema specified with **-KASF** adapter command.

For all modes other than bytes mode, the adapter must be configured to use an appropriate deserializer (consumer case) or serializer (producer case) that can perform the respected key data deserialization and serialization. The adapter commands **-AP** and **-APF** can be used to specify the deserializer or serializer to use.

For example, for string mode, in case of consumer, the value **key.deserializer=org.apache.kafka.common.serialization.StringDeserializer** can be included in the **-AP** command to specify a deserializer that will deserialize consumed message key bytes to String format before providing them to the adapter. Similarly, in case of producer,

the value key.serializer=org.apache.kafka.common.serialization.StringSerializer can be included in the -AP command to specify a serializer that will receive message keys in String format from the adapter before serializing them as key bytes in the produced messages.

When the specified serializer or deserializer implementation resides in an external JAR that is not part of the standard Kafka client included with the adapter, the JAR and its dependencies need to be saved in the class path for the adapter. This can be done for example by adding them to extra or libs/extra sub-directory of the product home directory.

See the security section in the Apache Kafka documentation for more details.

Value Handling Mode

Specifies the mode for handling message values (payloads). The corresponding adapter command is -VHM {bytes | string | object_string | avro_json} (or -VALUEHANDLINGMODE {bytes | string | object_string | avro_json}).

The supported modes are:

- bytes: The adapter assumes message values to be represented as Java byte array instances and it passes message value bytes through without any modification. This applies to both the consumer and producer scenarios. This is the default mode.
- string: In consumer, the adapter assumes message values to be provided as Java String instances and converts them to bytes using the current system encoding. In producer, the adapter converts bytes to Java String instances using the current system encoding.
- object_string: In consumer, the adapter assumes message values to be provided as Java Object instances, calls **toString()** method on them to obtain their string representation and converts them to bytes using the current system encoding. In producer, this mode behaves the same as string mode.
- avro_json: In consumer, the adapter assumes message values to be provided as Java Avro **GenericRecord** objects, calls **toString()** method on them to obtain their JSON string representation and converts them to bytes using current system encoding. In producer, the adapter converts bytes to Java String instances, and assumes that they are formatted as JSON documents. It then converts them to Avro **GenericRecord** instances based on the Avro schema specified with -VASF adapter command.

For all modes other than bytes mode, the adapter must be configured to use an appropriate deserializer (consumer case) or serializer (producer case) that can perform the respected value data deserialization and serialization. The adapter commands -AP and -APF can be used to specify the deserializer or serializer to use.

For example, for string mode, in case of consumer, the value value.deserializer=org.apache.kafka.common.serialization.StringDeserializer can be included in the -AP command to specify a deserializer that will deserialize consumed message value bytes to String format before providing them to the adapter. Similarly, in case of producer, the value value.serializer=org.apache.kafka.common.serialization.StringSerializer can be included in the -AP command to specify a serializer that will receive message values in String format from the adapter before serializing them as value bytes in the produced messages.

When the specified serializer or deserializer implementation resides in an external JAR that is not part of the standard Kafka client included with the adapter, the JAR and its dependencies need to be saved in the class path for the adapter. This can be done for example by adding them to extra or libs/extra sub-directory of the product home directory.

See the security section in the Apache Kafka documentation for more details.

Adapter commands for producers

Kafka adapter commands for producers are valid for output target data. For additional details, see the producer configuration information in the [Apache Kafka documentation](#).

Acknowledgments Level

Specifies the level of acknowledgment required for message delivery to be considered successful. The corresponding adapter command is -ACK *level* (or -ACKNOWLEDGEMENTS *level*). The default acknowledgment level is 1.

0: No acknowledgment required. At this acknowledgment level, the -RET command is applicable.

1: Acknowledgment is required from the leader broker only.

-1

All: Acknowledgment is required from the leader broker and all replica brokers.

Related Kafka producer configuration: acks

Buffer Memory

Specifies the maximum amount of memory, in bytes, that the producer uses to buffer records that are queued to be sent to the server. The default buffer size is 33,554,432. The corresponding adapter command is -BM *bytes* (-BUFFERMEMORY *bytes*).

Related Kafka producer configuration: buffer.memory

Batch Size

The default size, in bytes, of a group of records being sent to the same partition in a single request. When a batch of records reaches this size, the producer sends the batch (regardless of the -LM setting). Records that exceed this size are sent immediately. The corresponding adapter command is -BS *bytes* (or -BATCHSIZE *bytes*).

A single publish operation sends multiple record batches: one batch for each partition on the server that the producer has data for.

The default batch size is 16384.

Related Kafka producer configuration: batch.size

Linger Milliseconds

Specifies the amount of time, in milliseconds, that the producer waits for additional records to arrive in order to batch the records. The default is 0 ms, meaning no delay. The corresponding adapter command is -LM *ms* (or -LINGERMILLISECONDS *ms*).

Related Kafka producer configuration: linger.ms

Compression Type

Specifies the compression type for full batches of data generated by the producer. The default is none. The corresponding adapter command is -CT {none | gzip | snappy | lz4} (or -COMPRESSIONTYPE {none | gzip | snappy | lz4}).

Related Kafka producer configuration: compression.type

Retries Count

Specifies the number of times the producer attempts to resend a message, in case the broker reports a transient error. The range of retries is 0 - 2147483647. The default is 0 retries. The corresponding adapter command is -RET *count* (or -RETRIES *count*).

Related Kafka producer configuration: retries

Enables Idempotence

Enables idempotence. Idempotent delivery ensures that messages are delivered exactly once to a particular topic partition during the lifetime of a single producer. The corresponding adapter command is -EI (or -ENABLEIDEMPOTENCE). When you specify this command:

- The retry count (-RET command) must be greater than zero.
- The acknowledgment level (-ACK command) must be -1 or all.

Otherwise, a configuration exception occurs.

Related Kafka producer configuration: enable.idempotence

Transactional ID

Enables transactional delivery. Together with idempotence (-EI command), allows producers to send data to multiple partitions so that either all messages are successfully delivered, or none of them are.

The corresponding adapter command is -TID *transactionalID* (or -TRANSACTIONALID *transactionalID*).

Related Kafka producer configuration: transactional.id

Key Avro Schema File file_path

Specifies location of the JSON file that represents Avro schema to use when converting message keys from JSON string representation to Avro **GenericRecord** instances when producing messages and -KHM avro_json command is specified. If the specified location is a relative file path, it is treated as the path relative to the directory in which the map is deployed. The corresponding adapter command is -KASF *file_path* (-KEYAVROSCHEMAFILE *file_path*).

Value Avro Schema File file_path

Specifies location of the JSON file that represents Avro schema to use when converting message values (payloads) from JSON string representation to Avro **GenericRecord** instances when producing messages and -VHM avro_json command is specified. If the specified location is a relative file path, it is treated as the path relative to the directory in which the map is deployed. The corresponding adapter command is -VASF *file_path* (-VALUEAVROSCHEMAFILE *file_path*).

JSON Avro Decoder Class Name

Specifies the Java class to use for converting JSON to Avro representation. This command is optional and if not specified the default class org.apache.avro.io.JsonDecoder is used. When specified, the provided value must be a fully qualified name of the Java class that implements a public constructor which takes two arguments: org.apache.avro.Schema which represents the Avro schema to use for the conversion and java.io.InputStream which represents the stream from which to read JSON content. The jar file that implements this class must be included in the classpath in use for the adapter.

The corresponding adapter command is -JADCN *name* (or -JSONAVRODECODERCLASSNAME *name*).

Adapter commands for consumers

Kafka adapter commands for consumers are valid for input data sources. For additional details, see the consumer configuration information in the [Apache Kafka documentation](#).

Group ID

Specifies the unique string that identifies the consumer group that a consumer belongs to. This property enables Kafka group management, which is used when the -TP command specifies only topic names without topic partitions. The default is a null string. The corresponding adapter command is -GID *groupID* (or -GROUPID *groupID*).

Related Kafka consumer configuration: group.id

Offset Commit Strategy

Specifies the policy that the adapter uses to commit an offset when it consumes a message. The corresponding adapter command is -OCS (or -OFFSETCOMMITSTRATEGY).

The policy is one of the following:

- Manual: The Kafka adapter commits the offset when it commits the transaction, as defined by the Transaction Scope setting on the input card of the map. This is the default.
- Auto: The Kafka cluster periodically commits the offset.
- Never: Neither the Kafka cluster nor the Kafka adapter commits the offset.

Offset Commit Retry Count

Specifies the number of times to ignore offset commit failures and proceed consuming messages. The corresponding adapter command is -OCRC (-OFFSETCOMMITTRYCOUNT).

When the offset commit operation fails and the specified count is not reached, the adapter increments the internal counter of failed commits and proceeds to consume messages as if the commit was successful. If the error topic was specified and the value for this command is different from 0, the adapter sends the error message with the topic, partition, and offset information of the failed commit operation to the error topic. The adapter retries to commit the pending offsets again the next time it is scheduled to perform the commit operation. The default value for this command is 0, which instructs the adapter to treat offset commit failures as fatal severity errors and not attempt retries. The special value S is supported and is used to specify unlimited number of retries.

Skip Duplicates

Instructs the adapter to keep track of all messages that it consumed in the current process, and to ignore messages that it has previously consumed. The corresponding adapter command is -SD (-SKIPDUPPLICATES).

q

If the error topic is configured, the adapter sends error messages indicating detected duplicate messages (their topic, partition and offset) to the error topic.

-OFFSETCOMMITTRYCONSTRAINT value [value] -OCC value [value]

Specifies constraints the adapter must meet when committing pending offsets. One of the following two values can be specified, or both can be specified, separated by a space:

apo: Stands for Assigned Partitions Only and means that the adapter consumer should commit only those pending offsets that belong to the partitions currently assigned to it. The offsets that belong to a partition that the consumer owned at some earlier point but that has subsequently been assigned to another consumer are skipped.

ssc: Stands for Skip Stale Commits and means that the adapter should not commit pending offsets on a partition that are older than the currently committed offsets on the same partition, for the same consumer group. Such old offsets are considered stale and are possible if the consumer loses a partition due to partition rebalancing, and another consumer in the same consumer group is assigned the partition and consumes and commits offsets past the last offset consumer by the original consumer. If the original consumer later regains ownership of the partition, the offsets that it still considers pending for that partition will be stale. If this constraint is specified and the consumer detects stale offsets, it does not commit them and it discards (forgets) them.

-LOGERRORMESSAGES (-LEM)

Specifies that Kafka error messages published to the error topic should also be written to the adapter trace file.

Error Message Format Version

Specifies the format of messages sent to the error topic. The corresponding adapter command is -EMFV version (or -ERRORMESSAGEFORMATVERSION version).

The supported values are:

- 1: The default version, each message is in format t:p:o where t, p and o are the topic, partition and offset of the consumed message for which the processing failed and for which the error record is produced to the error topic
- 2: Each message is in JSON format: {"topic": "t", "partition": "p", "offset": "o", "code": "c"} where t, p and o are the topic, partition and offset values of the consumed message for which the processing failed, and c is the error code indicating the reason for the failure, and is one of the following:
 - DUPLICATE: Indicates the message was skipped because it was already consumed earlier for the same consumer group in the current process, and -SKIPDUPPLICATES (-SD) adapter command was specified COMMIT_FAILED - indicates the message was processed successfully, but the offset commit operation for it failed ROLLBACK - indicates that an error was reported while processing the specified message, for example when performing database write operation in one of the map outputs in the same transaction scope in which the message was consumed.

Fetch Minimum Bytes

Specifies the minimum amount of data, in bytes, that must accumulate before the server returns the data to the consumer. The default data size is one byte, which means the server responds to a data request as soon as any data is available to return. The corresponding adapter command is -FMIB size (or -FETCHMINBYTES size).

Related Kafka consumer configuration: `fetch.min.bytes`

Fetch Maximum Bytes

Specifies the maximum amount of data, in bytes, that the server should return for a fetch request. The corresponding adapter command is -FMAB size (or -FETCHMAXBYTES size).

Related Kafka consumer configuration: `fetch.max.bytes`

Auto Offset Reset

The offset position to automatically use when no previous offset exists. The corresponding adapter command is -AOR (-AUTOOFFSETRESET).

The offset is one of the following:

- Latest: Starts consuming new messages from the most recent offset. This is the default.
- Earliest: Starts consuming from the oldest available record by automatically resetting the offset to the earliest offset.
- None: Reports an error.

Related Kafka consumer configuration: auto.offset.reset

Synchronized

Specifies that the Launcher listener thread is to operate synchronously. The listener waits to notify a map of an event (a message added to a topic) until the map acknowledges that it processed the previous event. The corresponding adapter command is -SYNC (or -SYNCHRONIZED).

If the map fails, the listener does not report subsequent events unless the -ETP command is specified. With the -ETP command, when the Launcher listener records the failed event on the error topic, the listener is unblocked and proceeds to report new events.

Error Topic

Specifies the name of the error topic where messages that result in an error are recorded. The corresponding adapter command is -ETP *topic* (or -ERRORTOPIC *topic*).

- The Command Server records the error at the time of transaction rollback. In a map, the input card Transaction_Scope setting controls when a transaction failure is processed by the adapter.
- The Launcher records the error when the listener thread is blocked because it's waiting for the status of the event processing, as specified by the -SYNC command.

After recording the error, the listener resumes processing new events.

Isolation Level

Controls the visibility of messages that are part of a transaction. The corresponding adapter command is -IL (or -ISOLATIONLEVEL).

- read_committed: Only messages from transactions that are committed (and messages that were not part of a transaction) are visible to consumers.
- read_uncommitted: All messages are visible to consumers, even if they were part of an aborted transaction. This is the default.

Related Kafka consumer configuration: isolation.level

Quantity

Specifies the number of messages to consume, or S to consume all available messages. The corresponding adapter command is -QTY (or -QUANTITY).

The default value is 1. If you specify a value other than 1, you must set the FetchAs input card setting to Burst and the FetchUnit input card setting to 1 in the map.

Listen

Specifies the wait time for messages. The corresponding adapter command is -LSN (-LISTEN)

- Seconds: The number of seconds that the consumer waits for messages to arrive.
- S: Wait for an unlimited time for messages to arrive. This is the default.
- 0: Consume all available messages and do not wait for new messages to arrive.

Logical Message Count

Specifies the logical message count. Specifies the number of Kafka messages to concatenate and return as a single logical message from the adapter. By default, the adapter returns each Kafka message as a separate logical message. To concatenate all available messages, specify 0. The corresponding adapter command is -LMC *count* (or -LOGICALMESSAGECOUNT *count*).

This command is valid only in logical message mode (-LMM command). Logical message mode is not valid in a Launcher scenario.

Logical Message Bytes

Logical message buffer-size limit, in bytes. The adapter buffers messages until it exceeds this limit, then returns all buffered messages as a single logical message. The corresponding adapter command is -LMS *bytes* (or -LOGICALMESSAGESIZE *bytes*)

This command is valid only in logical message mode (-LMM command). Logical message mode is not valid in a Launcher scenario.

Deserialize Failure Mode

Specifies deserialize failure mode. It determines the action to take when a deserializer registered with the adapter throws exception while deserializing Kafka messages before providing them to the consumer in the adapter. The corresponding adapter command is -DFM {fail | warn | ignore} (or -DESERIALIZEFAILUREMODE {fail | warn | ignore}).

The mode is one of the following:

- fail: The original deserialization exception is re-thrown. This is the default mode.
- warn: The deserialization error is logged (presuming trace command is provided) but the value is serialized as zero-length byte array.

- ignore: Same as warn, except the error is not logged.

Empty Key Substitution value

Specifies literal string value the adapter will present to the map as the key of the message when it is retrieved from topic as null or empty array value. The corresponding adapter command is -EKS value (or -EMPTYKEYSUBSTITUTION value).

This includes null values obtained for messages which failed deserialization in the deserialized registered with the consumer, when -DFM warn or -DFM ignore command was specified. For example, if processing Avro messages from a topic with keys in JSON format, and some of them are invalid keys that do not comply with the Avro schema associated with them, then the combination of commands -DFM ignore -EKS {} will result in adapter ignoring deserialization errors, and returning nulls as the message keys. Subsequently it will replace those nulls with {} string literals prior to returning them from the consumer.

Empty Value Substitution value

Specifies literal string value the adapter will present to the map as the value of the message when it is retrieved from topic as null or empty array value. The corresponding adapter command is -EVS value (or -EMPTYVALUESUBSTITUTION value).

This include null values obtained for messages which failed deserialization in the deserialized registered with the consumer, when -DFM warn or -DFM ignore command was specified. For example, if processing Avro messages from a topic as JSON messages, and some of them are invalid messages that do not comply with the Avro schema associated with them, then the combination of commands -DFM ignore -EVS {} will result in adapter ignoring deserialization errors, and returning nulls as the message values. Subsequently it will replace those nulls with {} string literals prior to returning them from the consumer.

Avro JSON Conversion Mode

Specifies the mode for converting Avro records to JSON representation. The default mode is Simple (case-insensitive) and results in producing the default simple JSON. The other mode is Strict (case-insensitive) and results in producing JSON in compliance with the Avro schema. Avro schema must be specified when using Strict mode. When this command is omitted, the default value is Simple. In most cases, the two modes will produce equivalent JSON representation, but in some cases, such as when the Avro schema contains elements of union types, the JSON produced in Strict mode will be more verbose. That will make it less convenient for processing, but it will allow converting it back to Avro in compliance with the same Avro schema.

The corresponding adapter command is -AJCM mode (or -AVROJSONCONVERSIONMODE mode).

Avro JSON Encoder Class Name

Specifies the Java class to use for converting Avro to JSON representation. This command is optional and if not specified the default class org.apache.avro.io.JsonEncoder from the Apache Avro library is used internally by the adapter. When specified, the provided value must be a fully-qualified name of the Java class that implements a public constructor which takes two arguments: org.apache.avro.Schema which represents the Avro schema to use for the conversion, and java.io.OutputStream which represents the stream to which to write JSON content. The jar file that implements this class must be included in the classpath in use for the adapter.

The corresponding adapter command is -AJECN name (or -AVROJSONENCODERCLASSNAME name).

Amazon S3 Adapter

With the Amazon S3 or Amazon Simple Storage Service adapter, a user can access S3 buckets to fetch the stored data and send new data to S3 buckets for storing.

- [Introduction](#)
This document provides an overview and the functional specifications of the Amazon S3 Adapter.
- [Adapter Properties and Commands](#)
This chapter provides a detailed description of the adapter.
- [Examples](#)

Introduction

This document provides an overview and the functional specifications of the Amazon S3 Adapter.

An S3 bucket is a public cloud object-storage offering. In Amazon S3, data is stored as an object, which is the fundamental storage unit. An object is comprised of data and the descriptive metadata of the data. These objects are organized into buckets. Like file folders contain files, these buckets store objects. A single object can be up to 5 terabytes in size. The S3 buckets are located at various geographic regions as served by Amazon Web Services (AWS).

The function of an Amazon S3 adapter is to fetch objects or data from S3 buckets and send data to S3 buckets for storing as objects. The S3 adapter needs to be first authenticated by an AWS access key and secret key (based on bucket permission) for gaining access to an S3 bucket. The AWS denotes every geographic region by a region-code. This code needs to be in the exact format to that of AWS's when specifying a region in the adapter properties.

The Amazon S3 adapter does not support the predefined-schema-import option. An AWS Identity and Access Management (IAM) user can be created in AWS for accessing the S3 services. This user represents a person or application that will interact with AWS. It is not the same as the AWS account root user. For more information, refer: https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users.html.

Amazon S3 adapter as a source

Amazon S3 adapter as a source:

- Reads a Blob
- Reads and deletes a Blob

Amazon S3 adapter as a target

- Creates an Object
- Overrides an Object

Troubleshooting large cloud object storage files

When you download large multi-megabyte files from Cloud Object Storage, the complete file is not downloaded. The S3 adapter saves only a portion of the designated file instead of the complete file. The following error message occurs during map processing:

Warning: Not all bytes were read from the S3ObjectInputStream, aborting HTTP connection. This is likely an error and may result in sub-optimal behavior. Request only the bytes you need via a ranged GET or drain the input stream after use.

The error message indicates that the S3 adapter closes the connection prematurely without fully downloading the file content.

Adapter Properties and Commands

This chapter provides a detailed description of the adapter.

Access Key

Specifies the key of AWS user for the connection. This access key is used to sign programmatic requests to AWS API calls through the adapter. The corresponding adapter command is **-AK** (or **-ACCESSKEY**).

Secret Key

Specifies the key of AWS user for the connection. Like the username and password, both the access key ID and secret access key are mandatory to authenticate S3 object for a Get or Put request. The corresponding adapter command is **-SK** (or **-SECRETKEY**).

Region Name

Specifies the name to connect to an AWS region for the IAM user account. The corresponding adapter command is **-R** (or **-REGION**).

Bucket Name

Specifies the name in which an S3 object would reside. During the action configuration, S3 Adapter provides options to select bucket name among available buckets. The corresponding adapter command is **-B** (or **-BUCKET**).

Folder Name

Specifies the folder name where S3 object may reside inside a bucket. This property is optional because an object may directly reside inside a bucket or under folder. When the folder property is not specified, adapter takes the direct path of the bucket to access the object. Otherwise, the folder name is prefixed to the key name. The corresponding adapter command is **-F** (or **-FOLDER**).

Object Name

Specifies the name of the S3 object to be accessed. A key can reside directly in a bucket or a folder inside the bucket. The corresponding adapter command is **-K** (or **-KEY**).

Content Type

Specifies the field that indicates the media type of the entity-body sent to Amazon S3. If the type is not set, adapter takes the default type, which is a standard MIME-type that describes the format of the content. For more information, go to https://www.w3.org/Protocols/rfc1341/4_Content-Type.html.

Type: String

Default: binary/octet-stream

Valid Values: MIME types

Constraints: None

The corresponding adapter command is **-CT** (or **-CONTENTTYPE**).

Content Language

Sets the Content-Language HTTP header, which specifies the natural language(s) of the intended audience for the enclosed entity. If no language is set, S3 adapter takes the default value 'en'. The corresponding adapter command is **-CL** (or **-CONTENTLANG**).

Encryption

Specifies the server-side encryption algorithm while encrypting the object using the AWS-managed keys. When the property is not specified, data uploaded to S3 remains unencrypted. The corresponding adapter command is **-E** (or **-ENCRYPTION**).

Valid Values: AES256, KMS.

AES256: 256 bit – Advanced Encryption Standard is a data or file encryption technique. The result of the process is downloadable in a text file. AES performs all its computations on bytes rather than bits. Hence, AES treats the 256 bits of a plaintext block as 16 bytes. It uses 14 rounds for 256-bit keys. For more information, see <https://docs.aws.amazon.com/AmazonS3/latest/dev/UsingServerSideEncryption.html>.

KMS: It represents the AWS Key Management Service (AWS KMS). The master keys that the user creates in AWS KMS are used to encrypt or decrypt the object uploaded to S3. For more information on KMS encryption technique, see <https://docs.aws.amazon.com/kms/latest/developerguide/concepts.html>.

Logging

Specifies the level of logging to use the log (trace) file produced by the adapter. The default is Off. The value Information means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

Logging can be specified using command:

-T [E|V] [+][file_path]

-T Log adapter informational messages.

-TE Log only adapter errors during map execution.

-TV Use verbose (debug) logging. The log file records all activity that occurs while the adapter is producing or consuming messages.

+ Appends the trace information to the existing log file. Omit this keyword to create a new log file.

file_path The full path to the adapter trace log. If you omit this keyword, the adapter creates the m4azblob.mtr log file in the map directory.

Append Log

Specifies the flag that indicates the action to take when the specified log file already exists. When set to true, the log messages are appended to the file. When set to false, the file is truncated, and the messages are written to the empty file. The default value is true.

Read Mode

Specifies the mode of operation for reading from the specified bucket. The supported values are:

- List: Return a list of keys of the objects detected in the bucket, separated by a linefeed character
- Keep: Return the contents of the object with the specified key and preserve the object in the bucket after reading it
- Delete: Return the contents of the object with the specified key and delete the object in the bucket after reading it

The default value is Keep.

The corresponding adapter command is -RM list|keep|delete (or -READMODE list|keep|delete). The command values are case-insensitive.

Key Prefix

Specifies the prefix to use for filtering objects from the specified bucket when the Read Mode property is set to value List. Only the objects with keys that begin with the specified prefix are included in the returned list. By default, no filtering is applied, and all the objects are returned in the list.

The corresponding adapter command is -KP prefix (or -KEYPREFIX prefix) where prefix is the key prefix value to use for the filtering.

For example, presume the bucket contains objects with the following keys:

key1

keyX

mykey1

mykeyX

test.txt

If -RM list -KP mykey commands are specified, the adapter will return the following list:

mykey1

mykeyX

Key Delimiter

Specifies the delimiter to use for filtering objects from the specified bucket when the Read Mode property is set to value List. Only the objects with keys that do not contain the specified delimiter will be included in the returned list. By default, no filtering is applied, and all the objects are returned.

The corresponding adapter command is -KD delimiter (or -KEYDELIMITER delimiter) where delimiter is the key delimiter value to use for the filtering.

For example, presume the bucket contains objects with the following keys:

dir1/obj1

dir1/obj2

dir1/subdirA/obj1

key1

key2

keyX

mykey1

mykeyX

test.txt

If **-RM list -KD** / commands are specified, the adapter will return the following list:

key1

key2

keyX

mykey1

mykeyX

test.txt

If **-RM list -KP /dir1/ -KD** / commands are specified, the adapter will take the specified key prefix **dir1/** into account as well, and will return the following list:

dir1/obj1

dir1/obj2

Endpoint

Specifies the endpoint to connect and access the S3 or S3 compatible buckets by the Amazon S3 adapter. If not specified, Amazon S3 adapter connects to the Amazon S3 Service endpoint based on the region specified.

To access an S3 compatible bucket hosted by an object storage service other than the default Amazon S3 service, Endpoint option must be specified. Region option is optional. The corresponding adapter command is **-EP** (or **-ENDPOINT**).

Log File Path

Specifies the location of the log file to which the log messages are written. If not specified, the default log file name m4s3.trc is used, and the file is stored to the directory in which the executed compiled map resides.

Convert Data

Specifies to convert data to parsed form. if enabled, support for converting CSV, Avro, Excel, Parquet and JSON documents into sets of data records in the CSV format. This means that the data produced by the converters can be loaded directly into relational databases.

Data Format

Specifies the data format. This is a mandatory property. Select one of the following as per the data format type. This property field is applicable when Convert Data property toggle is enabled.

- CSV
- Excel
- Avro
- Parquet
- JSON

Header

If enabled, specifies whether the CSV data contains a header row.

Quote

Specifies the quote character. Default value is ".

Delimiter

Specifies the field delimiter character. Default value is ,.

Escape

Specifies the escape character.

Separator

Specifies the row separator characters. Default value is \r\n.

Character Set

Specifies the character set of the data. Default value is UTF-8.

Limit

Specifies the maximum number of records to return.

Sample Size

Specifies the number of records to analyze when determining the data structure. Default value is 100.

Worksheet Index

Specifies the index of the worksheet. The index of the first worksheet is 1 (default).

Select Source Tables

Select which arrays of objects in the AVRO data you wish to map to tables in the target.

Find Array

If enabled, specifies that the output will iterate on the first array found in the JSON document.

Array Path

Specifies the path of the JSON array within the document. Omit if the document is an array. For example, "/resources".

Examples

GET example

GET example without **-FOLDER/-F** command:

```
GET("S3", " -AK AKSOMEACCESSKEY -SK SkSomeSecretKey/dBLo -R US_EAST_1 -B bucket-for-test -K persons.csv", inputdata)
```

As the **-FOLDER/-F** command is not present, the adapter looks for the S3 object directly under the mentioned bucket.

GET example with **-FOLDER/-F** command:

```
GET("S3", " -AK AKSOMEACCESSKEY -SK SkSomeSecretKey/dBLo -R US_EAST_1 -B bucket-for-test -F testfolder -K persons.csv", inputdata)
```

In this case, the adapter prepends the folder name to the key name passed, and the object is accessed from the folder residing under the specified bucket.

PUT example

PUT example without **-ENCRYPTION** command:

```
PUT("S3", " -AK AKSOMEACCESSKEY -SK SkSomeSecretKey/dBLo -R US_EAST_1 -B bucket-for-test -K persons.csv ", inputdata)
```

As **-ENCRYPTION** command is not present, the object uploaded to Amazon S3 is stored in its raw format.

PUT example with **-ENCRYPTION** command:

```
PUT("S3", " -AK AKSOMEACCESSKEY -SK SkSomeSecretKey/dBLo -R US_EAST_1 -B bucket-for-test -K persons.csv -ENCRYPTION KMS ", inputdata)
```

In this case, the adapter validates the algorithm passed to it and uses the same to set object metadata, which stores the data using the opted encryption technique to Amazon S3.

Amazon SQS Adapter

With the Amazon SQS or Amazon Simple Queue Service adapter, a user can access Amazon Simple Queue Services. The adapter connects to the fully managed Amazon Simple Queue Service system, using AWS keys. The SQS adapter can send and fetch messages to and from the queues to which a user has access.

Overview

This document provides an overview and the functional specifications of the Amazon SQS Adapter. The Amazon Simple Queue Service (SQS) is a distributed message-queueing service supporting programmatic sending of messages via web service applications. This message-queueing service is entirely manageable and scalable and can dissociate microservices, distributed systems, and server-less applications. The function of an Amazon SQS adapter is to access queues located at various Amazon Web Services-served geographic regions to fetch messages from standard queues and also store messages in standard queues in Amazon SQS.

IAM users can access SQS messages if they have the correct AWS access key and secret key, and also the queue-access permission. The SQS Adapter supports the sending and fetching of message attributes along with the message texts. SQS adapter supports standard queues having at-least-once delivery. For more information, see <https://aws.amazon.com/sqs/>.

The Amazon SQS adapter does not support the predefined-schema-import option. An AWS Identity and Access Management (IAM) user can be created in AWS for accessing the SQS services. This user represents a person or application that will interact with AWS. It is not the same as the AWS account root user. For more information, see https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users.html.

Authenticating connections

The Amazon SQS adapter uses AWS SDK programmatically, to verify the user identity in programmatic calls, the user needs to provide AWS access keys. Typically, access keys are either temporary (short-term) credentials or long-term credentials, such as those for IAM users or the root user of an AWS account. In many cases, there are alternatives to long-term keys to consider.

Amazon SQS adapter as a source

Amazon SQS adapter as a source supports:

- Read message from the queue.
- Read message from the queue and delete after reading.

Amazon SQS adapter as a target

Amazon SQS adapter as a target supports:

- Send message to the existing queue.
- Send message to the queue and create the queue, if does not exist.

Adapter properties and commands

This section provides the details of the adapter properties to be set to define connections and actions and import schemas in the new web UI of IBM Sterling Transformation Extender.

Access key

Specifies the access key of AWS user for the connection. This is a mandatory property. The access key is used to sign programmatic requests to AWS API calls through the adapter. The corresponding adapter command is -AK *access_key* (or -ACCESSKEY *access_key*).

Secret key

Specifies the secret key of AWS user for the connection. For the username and password, both the access key ID and secret access key are mandatory to authenticate SQS queue GET or PUT request. The corresponding adapter command is -SK *secret_key* (or -SECRETKEY *secret_key*).

Region name

Specifies the region name to connect to an AWS region for the IAM user account. This is a mandatory property. The corresponding adapter command is -R *region_name* (or -REGION *region_name*).

Queue

Specifies the SQS queue name to or from which messages need to be accessed. This is a mandatory property. During action configuration, SQS adapter provides options to select queue name among available queues in the provided region. The corresponding adapter command is -Q *queue_name* (or -QUEUE *queue_name*).

Create queue

If specified, this property indicates the SQS adapter to create a queue with the name passed in the 'queue_name' property in case it does not exist. This property is optional. When the CreateQueue property is not specified, adapter checks if the queue exists; if not, it throws an error. The corresponding adapter command is -CQ (or -CREATEQUEUE).

Attribute

Specifies if the SQS message should be accessed along with the corresponding message attributes. When the attributes flag is set to true in output card, the passed data should be in predefined JSON format, else data should be in a plain text message.

```
{"message": "text message", "attributes": [{"name": "attribute_name", "type": "String", "value": "attribute_value"}]}
```

When the attributes property is present in input card, SQS adapters get the data in the above JSON format; otherwise, the text message is fetched from SQS queue. If it is omitted, attributes are not used. The corresponding adapter command is -A (Or -ATTRIBUTES). For more information on Amazon SQS message attributes, see <https://docs.aws.amazon.com/AWSSimpleQueueService/latest/SQSDeveloperGuide/sqs-message-attributes.html>.

Timeout

Specifies the time duration (in seconds) to wait for before retrieving the message from the queue. The timeout property of SQS adapter is applicable and utilized only in IBM Sterling Transformation Extender deployments. The SQS adapter would listen to the queue for specified seconds. The corresponding adapter command is -LSN *name*.

Limit

Specifies the total number of messages to consume. Minimum value should be 1. The value S means all available messages. If no limit is specified, adapter fetches only one message at a time from the queue. The limit property is applicable and utilized only in IBM Sterling Transformation Extender deployments. The corresponding adapter command is -QTY *limit*.

Logging

Specifies the level of logging to use for the log (trace) file produced by the adapter. The default is Off. The value Information means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

The corresponding adapter command is:

```
-T [E|V] [+|] [file_path]
```

- T** -> Log adapter informational messages.
- TE** -> Log only adapter errors.
- TV** -> Use verbose (debug) logging. The log file records all activity that occurs while the adapter is producing or consuming messages.
- +** -> Appends the trace information to the existing log file. Omit this argument to create a new log file.
- file_name** -> Specifies the location of the log file to which to write log messages. If not specified, the adapter creates the m4sq.sqs.log file in the map directory.

Append log

Flag indicating what to do if the specified log file already exists. When set to true, the log messages are appended to the file. When set to false, the file is truncated, and the messages are written to the empty file. The default value is true.

Log file name

Specifies the location of the log file to which to write log messages. If not specified, the default log file name m4sq.sqs.log is used, and the file is stored to the directory in which the executed compiled map resides.

Examples

Examples of the GET map function

In the following example, assume that the adapter being used in a GET function is defined as follows:

- `GET("SQS", " -AK AKSOMEACCESSKEY -SK SkSomeSecretKey/dbLo -R US_EAST_1 -Q queue-for-test A", inputdata)`

Since the **-A/-ATTRIBUTES** command is not present, the adapter only text message from the queue.

- Assume the GET map function defined as follows:

```
GET("SQS", " -AK AKSOMEACCESSKEY -SK SkSomeSecretKey/dbLo -R US_EAST_1 -Q queue-for-test -A", inputdata)
```

- In this case the adapter retrieves message attributes along with the text message and the output data defined as follows:

```
{"messages": "It's get example", "attributes": [{"name": "attribute1", "type": "String", "value": "attribute example"}]}
```

Examples of the PUT map function

In the following example, assume that the adapter being used in a PUT function defined as follows:

- Example of create queue property use in PUT map function:

```
PUT("SQS", " -AK AKSOMEACCESSKEY -SK SkSomeSecretKey/dbLo -R US_EAST_1 -Q queue-for-test", inputdata)
```

In this case if the 'queue-for-test' does not exist in specified region, the adapter will show error, since the **-CQ/-CREATEQUEUE** is not present.

- Assume the PUT map function defined as follows:

```
PUT("SQS", " -AK AKSOMEACCESSKEY -SK SkSomeSecretKey/dbLo -R US_EAST_1 -Q queue-for-test -CQ", inputdata)
```

In this case the adapter creates the queue and send message to the newly created queue.

- Example of attribute property use in PUT map function:

```
PUT("SQS", " -AK AKSOMEACCESSKEY -SK SkSomeSecretKey/dbLo -R US_EAST_1 -Q queue-for-test", inputdata)
```

Since the **-A/-ATTRIBUTES** command is not present, input data is treated as message body to be sent over SQS queue

- Assume the PUT map function defined as follows:

```
PUT("SQS", " -AK AKSOMEACCESSKEY -SK SkSomeSecretKey/dbLo -R US_EAST_1 -Q queue-for-test -A", inputdata)
```

- In this case the adapter assumes the input data is passed in required JSON format; input data defined as follows:

```
{
  "message": "It's put example",
  "attributes": [
    {"name": "attribute1", "type": "String", "value": "attribute example"}
  ]
}
```

Amazon SNS Adapter

With the Amazon SNS adapter, a user can access the Amazon Simple Notification Services. This adapter connects to the Simple Notification Services (SNS) topics, using AWS keys. The adapter can fetch and send notifications from and to those AWS SNS topics, to which the user has subscribed.

This document provides an overview and the functional specifications of the Amazon SNS Adapter. The Amazon Simple Notification Service is a notification service provider that can deliver messages in mass, predominantly to mobile users. The Amazon SNS allows for creating topics. A topic is a logical communication-channel to launch mass delivery of a particular category of message. A topic supports high-throughput, push-based, and many-to-many messaging. The function of an SNS Adapter is to access the SNS topics the user has subscribed to for sending and fetching notifications to and from those topics. The SNS topics reside in various geographic regions as served by the Amazon Web Services (AWS). The AWS denotes every geographic region by a specific region code. The same code must be used—in the exact format—in the adapter properties for specifying any region. For more information on AWS SNS, refer <https://aws.amazon.com/sns/>.

The Amazon SNS adapter uses the PUT functionality to push notifications to a specified topic as a target in an output card. An SNS adapter cannot be used as a source in an input card. The notifications can be only in text format. The Amazon SNS adapter does not support the predefined-schema-import option.

An AWS Identity and Access Management (IAM) user can be created in AWS for accessing the SNS services. This user represents a person or application that will interact with AWS. It is not the same as the AWS account root user. For more information, refer: https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users.html

Adapter properties and commands

This section provides an overview of the adapter properties for defining connections and actions and importing schemas in the new web UI in HIP. The following table lists all the properties, their scope, whether they are required or not, and the adapter commands they map to for use in the compiled maps and map executions. "DI" scope means the property is dynamically enumerated - the adapter is invoked during action configuration to provide the set of allowed values for that property. A detailed description of the properties is provided after the table.

Table 1. SNS Adapter properties

Adapter property	Scope	Required	Corresponding adapter command must be used directly in GET and PUT functions
	<ul style="list-style-type: none">• CO: Connection• DI: Discovery• IC: Input card• OC: Output card• G: GET function• P: Put function		
accessKey= access_key	CO	Yes	-AK access_key
secretKey= secret_key	CO	Yes	-SK secret_key
region= region_name	CO	Yes	-R region_name
topicArn= topic_arn	DI/OC/P	Yes	-TARN topic_arn
create Topic= create_topic	OC/P	No	-CT
logging=info errors verbose off	OC/P	No	-T[E V]?[+]? [file_name]
append_log=true false	IC/OC/G/P	No	-T[E V]?[+]? [file_name]
log_file_name=file_name	OC/P	No	-T[E V]?[+]? [file_name]

accessKey= access_key

This property specifies the access key of AWS user for the connection. The access key is used to sign programmatic requests to AWS API calls through the adapter. The access key can be used with **-ACCESSKEY** or **-AK** command.

secretKey= secret_key

This property specifies the secret key of AWS user for the connection. Like the user name and password, both the access key ID and secret access key are mandatory to authenticate SNS topic PUT requests. The secret key can be passed to the adapter with **-SECRETKEY** or **-SK** command.

region= region_name

The adapter uses the region name to connect to an AWS region for the IAM user account. A region can be passed to the adapter using **-REGION** or **-R** command.

topicArn= topic_arn

Topic Amazon Resource Name (ARN) format is used to identify any topic in AWS. This property specifies the topic ARN where notifications are stored. During action configuration, the SNS Adapter provides options to select topic ARN among available topics in that region. Also, the topic_arn property can be passed to adapter input or output cards using the **-TOPICARN** or **-TARN** commands.

For creating SNS topic, refer the link: <https://docs.aws.amazon.com/gettingstarted/latest/deploy/creating-an-sns-topic.html>.

createTopic= create_topic

If this property is specified, the SNS adapter is indicated to create a topic with the name passed in the 'topic_arn' property, if it doesn't already exist. This property is optional. When the create_topic property is not specified, adapter checks if the topic already exists; if not it throws error. Create topic option can be passed to adapter input or output cards using **-CREATETOPIC** or **-CT** commands.

logging=info|errors|verbose|off

This property specifies the level of logging to be used for the log (trace) file produced by the adapter. The default is off. The value info means log informational and error messages, the value error means log error messages only, and the value verbose means log debug and trace level messages along with the informational and error messages.

append_log=true|false

This property flags to indicate the action to be taken when the specified log file already exists. When set to true, the log messages are appended to the file. When set to false: the file is truncated, and the messages are written to the empty file. The default value is true.

log_file_name=file_name

This is the name of the log file, where the log messages are to be written. If not specified, the default log file name m4s3.trc is used, and the file is stored to the directory in which the executed compiled map resides.

Examples

Examples of PUT map function (GET not supported in SNS Adapter)

In the following example, assume that the adapter is used in a PUT function defined as follows:

```
PUT("SNS", "-AK AKSOMEACCESSKEY -SK SkSomeSecretKey/dBLo -R US_WEST_2 -TARN arn:aws:sns:us-west-2:123456789012:gsg-signup-notifications",  
inputdata) In this case if the topic 'gsg-signup-notifications' doesn't exist in specified region, adapter will throw error since -CREATETOPIC/-CT is not present.
```

Now, assume the PUT map function was defined as follows:

```
PUT("SNS", "-AK AKSOMEACCESSKEY -SK SkSomeSecretKey/dBLo -R US_WEST_2 -TARN arn:aws:sns:us-west-2:123456789012:gsg-signup-notifications -  
CT",inputdata)
```

In this case, the adapter creates the topic ARN, and then pushes notification to the newly created topic.

Azure Service Bus Adapter

The Azure Service Bus adapter supports accessing queue on the Microsoft Azure Service Bus, a fully managed message broker service on the Microsoft Azure cloud.

- [Introduction](#)
- [Defining Connections](#)
- [Adapter Properties](#)
This section lists the properties supported by the adapter.
- [Examples](#)

Introduction

The Azure Service Bus adapter is used to send and receive messages from the Azure Service Bus queues. The messages can be JSON, XML, CSV messages, or of any other format, which must be captured in the schema specified when defining the adapter inputs and outputs.

Defining Connections

The adapter provides the Endpoint property for defining the connection string for the queue entity to access. The full URL for the entity endpoint can be specified, or a partial endpoint can be specified indicating for example only the namespace of the queue with additional attributes for the connection string, such as shared access key and queue name. Refer to the Endpoint property description for more information.

- [Azure Service Bus adapter as a source](#)
When the adapter is used as a source in a map, it receives messages from the specified queue. To act as a data source in a map, the adapter can be utilized as an input card in the map or it can be specified in the GET map function. The number of messages to retrieve and the maximum time to wait for new message to arrive can be specified. When either of the conditions is met, the adapter stops receiving and reporting new messages.
- [Azure Service Bus adapter as a target](#)

Azure Service Bus adapter as a source

When the adapter is used as a source in a map, it receives messages from the specified queue. To act as a data source in a map, the adapter can be utilized as an input card in the map or it can be specified in the GET map function. The number of messages to retrieve and the maximum time to wait for new message to arrive can be specified. When either of the conditions is met, the adapter stops receiving and reporting new messages.

The adapter supports two modes for receiving messages:

- Browse: To browse messages without deleting them.
- Peek Lock: To lock the messages and delete them from the queue at the successful completion of the transaction.
- Receive and Delete: To delete the messages immediately from the queue at the time of their retrieval. The adapter supports the use of message sessions for receiving the messages from the session-aware queues.

Azure Service Bus adapter as a target

When the adapter is used as a target, it sends messages to the specified queue. To act as a data target in a map, the adapter can be utilized as an output card in the map or it can be specified in the PUT map function. The adapter supports setting content type on the messages. It also supports setting the message session for sending the messages to the session-aware queues.

Adapter Properties

This section lists the properties supported by the adapter.

- [**Endpoint**](#)
Specifies the connection string URL of the endpoint for the adapter to access.
 - [**Shared Access Key Name**](#)
Specifies the name of the shared access key to use for the authentication, for example **RootManageSharedAccessKey**.
 - [**Shared Access Key**](#)
Specifies the value of the key to use for the authentication.
 - [**Queue Name**](#)
Specifies the name of the queue entity to access. When a value is specified for this property, the **;EntityPath=value** segment is automatically appended to the Endpoint property value when constructing connection string for the queue endpoint.
 - [**Content Type**](#)
Specifies the content type for the messages sent to the queue.
 - [**Session Identifier**](#)
When used in a source mode, it specifies the identifier of the message session to use for the receiving messages from a session-aware queue. When used in target mode, it specifies the message session identifier to set on the messages sent to the session-aware queue.
 - [**Receive Mode**](#)
Specifies the mode to use for receiving messages.
 - [**Message Limit**](#)
Specifies the maximum number of messages to receive from the queue.
 - [**Message Timeout**](#)
Specifies the time in seconds to wait for a new message to arrive after receiving the last message.
 - [**Logging**](#)
Specifies the level of logging to use for the log (trace) file produced by the adapter.
 - [**Append Log**](#)
 - [**Log File Path**](#)
-

Endpoint

Specifies the connection string URL of the endpoint for the adapter to access.

The value is in format `sb://namespace_name/;key=value;key=value...` where `namespace_name` is the fully qualified name of the namespace containing the queues to access. The `sb://namespace_name/` portion is required and the `key=value` pairs are optional. The specified connection string URL may be a partial connection string URL for the endpoint to access. For example, when a value is provided for the Queue adapter property, the **;EntityPath=value** segment is automatically appended to the specified Endpoint property when constructing the full connection string of the queue entity endpoint. The corresponding adapter command for this property is **-E url**.

Shared Access Key Name

Specifies the name of the shared access key to use for the authentication, for example **RootManageSharedAccessKey**.

When a **value** is specified for this property, the **;SharedAccessKeyName=value** segment is automatically appended to the specified Endpoint property value. When a value is not provided, the Endpoint property is assumed to contain all the necessary authentication details. The corresponding adapter command for this property is **-SAKN name**.

Shared Access Key

Specifies the value of the key to use for the authentication.

When a **value** is specified for this property, the **;SharedAccessKey=value** segment is automatically appended to the specified Endpoint property value. When a value is not provided, the value provided in the Endpoint property is assumed to contain all the necessary authentication details. The corresponding adapter command for this property is **-SAK key**.

Queue Name

Specifies the name of the queue entity to access. When a value is specified for this property, the **;EntityPath=value** segment is automatically appended to the Endpoint property value when constructing connection string for the queue endpoint.

If the value is not provided, the queue name is assumed to be included in the Endpoint property. The corresponding adapter command for this property is **-QN queue**.

Content Type

Specifies the content type for the messages sent to the queue.

When provided, the value must be in the Content-Type header format as defined in the RFC 2045 specification. The corresponding adapter command is **-CT type**.

Session Identifier

When used in a source mode, it specifies the identifier of the message session to use for the receiving messages from a session-aware queue. When used in target mode, it specifies the message session identifier to set on the messages sent to the session-aware queue.

Refer to the Azure Service Bus documentation for more information about the message sessions. The corresponding adapter command is **-SID id**.

Receive Mode

Specifies the mode to use for receiving messages.

There are three modes:

- Browse: The adapter only browses the message on the queue without deleting it.
- Peek Lock: The adapter does not delete the message from the queue immediately upon reading it. Instead, a lock is created for the message which the adapter completes at end of the transaction, as defined by the transaction scope for the adapter. The completion of the lock in turn results in deleting the message from the queue.
- Receive and Delete: The message is deleted immediately from the queue at the time it is received.

The corresponding adapter command for this property is **-RM**, where mode is one of browse, peek_lock or receive_and_delete (case-insensitive). The default value is browse.

Message Limit

Specifies the maximum number of messages to receive from the queue.

The default value is 1. The special value S is used to indicate no limit (all available messages). The corresponding adapter command is **-QTY limit**.

Message Timeout

Specifies the time in seconds to wait for a new message to arrive after receiving the last message.

The timeout countdown is restarted after each successfully retrieved message. The default value is S, which is a special value to indicate no timeout (indefinite waiting). Another special value is 0 which is used to indicate no waiting, that means once all currently available messages are received, the adapter does not wait for any more messages to arrive. The corresponding adapter command is **-LSN timeout**.

Logging

Specifies the level of logging to use for the log (trace) file produced by the adapter.

The default is Off. The value Information means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

The corresponding adapter command for informational level logging is **-T** or **-TRACE path**, where *path* is the optional log file path.

For error level logging, the **-TE** (or **-TRACEERROR**) command should be used instead of **-T**. For verbose level logging, the **-TV** (or **-TRACEVERBOSE**) command is used.

For the append mode, the + character should be added to the command name. For example, to append log messages to the **/tmp/logfile.log** file in verbose mode, the respective adapter command would be: **-TV+ /tmp/logfile.log**

Append Log

The flag indicates what to do if the specified log file already exists. When enabled, the log messages are appended to the file. When disabled, the file is truncated, and the messages are written to the empty file. The property is disabled by default.

Log File Path

Specifies the location of the log file to which to write log messages. This is the location of the log file to which to write log messages. If not specified, the default log file name m4azsb.mtr is used, and the file is stored to the directory in which the executed compiled map resides.

Examples

GET examples

```
GET("AZSB", "-E sb://namespace_name.servicebus.windows.net/ -SAKN RootManageSharedAccessKey -SAK key_value -Q queue_name -RM peek_lock -T /tmp/logfile.log")
```

PUT example

```
PUT("AZSB", "-E sb://namespace_name.servicebus.windows.net/ -SAKN RootManageSharedAccessKey -SAK key_value -Q queue_name -CT application/json -TV+ /tmp/logfile.log")
```

Azure SQL Adapter

Microsoft Azure SQL adapter provides support for performing read, write and discovery operations on Microsoft Azure SQL Database.

- [Introduction](#)
Microsoft Azure SQL Database is a general-purpose relational database, running as a managed service on the Microsoft Azure cloud computing platform
 - [Azure SQL Adapter commands](#)
This chapter provides a detailed description of the adapter.
-

Introduction

Microsoft Azure SQL Database is a general-purpose relational database, running as a managed service on the Microsoft Azure cloud computing platform

Authenticating connections

The adapter supports username/password based authentication method.

Microsoft Azure SQL adapter as a source

Microsoft Azure SQL adapter as a source supports:

- Fetching data from tables and views.
- Executing stored procedures and consuming results.
- Executing query statements and fetching results.

Microsoft Azure SQL adapter as a target

Microsoft Azure SQL adapter as a target supports:

- Inserting and updating rows in tables.
- Executing parameterized stored procedures.
- Executing parameterized query statements.
- Executing custom data manipulation language (DML) statements.

Azure SQL Adapter commands

This chapter provides a detailed description of the adapter.

- [Server Name](#)
- [Port](#)
- [Database](#)
- [User](#)
- [Password](#)
- [Encrypt](#)
- [Trust Server Certificate](#)
- [Hostname in Certificate](#)
- [Login Timeout](#)
- [Autocommit](#)
- [Table](#)
- [Query](#)
- [Procedure](#)
- [DML](#)
- [Schema](#)
- [Logging](#)
- [Append Log](#)
- [Log File Path](#)
- [Pre SQL](#)
- [Post SQL](#)

- [Write Mode](#)
 - [-QTY and -LSN adapter commands](#)
 - [-ARRAYSIZE adapter command](#)
 - [Examples](#)
-

Server Name

Specifies the address of the server to connect to. This is a mandatory property. The corresponding adapter command is -SN (or -SERVERNAME).

For example:

```
-SN azureserver.database.windows.net
```

Port

Specifies the port on which the server is listening for requests. The default is 1433. This is a mandatory property. The corresponding adapter command is -PORT.

Database

Specifies the name of the database instance on the server. This is a mandatory property. The corresponding adapter command is -DB (or -DATABASE).

For example:

```
-DB azuredb
```

User

Specifies the username for the connection. The corresponding adapter command is -USR (or -USER).

Password

Specifies the password for the connection. The corresponding adapter command is -PWD (or -PASSWORD).

Encrypt

Enforce the use of Secure Sockets Layer (SSL) on the connection. Default is true. This is an advanced property. The corresponding adapter command is -ENC (or -ENCRYPT).

Trust Server Certificate

Enables automatic trust in the SSL certificate presented by the database service. Default is false. This is an advanced property. The corresponding adapter command is -TSE (or -TRUSTSERVCERT).

Hostname in Certificate

Specifies the name of the host expected in the SSL certificate presented by the database service. This is an advanced property. The corresponding adapter command is -HNC (or - HOSTNAMECERT).

Login Timeout

Specifies the number of seconds to wait before timing out when establishing connection. The default is 30 seconds. The corresponding adapter command is -LT (or -LOGINTIMEOUT).

Autocommit

Instructs the adapter how to configure the driver in respect to automatic commit of SQL statements performed by the driver. Default is false. When set to true, the adapter explicitly requests the driver to enable and perform auto-commit, and when set to false the adapter explicitly requests the driver to disable and not perform auto-commit.

The corresponding adapter command is -AC (or -AUTOCOMMIT).

Table

Specifies the name of the table or view to access. The corresponding adapter command is -TBL (-TABLE).

Query

Specifies the text of the query statement to execute when fetching data. When GET map function is used with the adapter, the query statement text may contain query bind parameters (as '?' characters), and the values for the parameters are provided as the third argument of the GET function, with '|' character used as the value separator. The corresponding adapter command is -QRY (-QUERY).

Procedure

Specifies the name of the stored procedure to execute. When GET map function is used with the adapter, the stored procedure can have input and input/output parameters, and the values for those parameters are provided as the third argument of the GET function, with '|' character used as the value separator. The corresponding adapter command is -PROC (-PROCEDURE).

DML

Custom DML statement to use for writing rows to the database. When specified, the schema, table and write mode properties are ignored. The number of bind parameters in the statement must match the number of fields in the records pushed to the adapter. The corresponding adapter command is -DML.

Schema

Specifies the name of the database schema. It is case-sensitive. The adapter will automatically surround it with the quoted identifiers, so the specified value must not be quoted manually by the user. The corresponding adapter command is -SCH (-SCHEMA).

Logging

This property specifies the level of logging to use for the log (trace) file produced by the adapter. The default is Off. The value Information means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

Append Log

Flag indicating what to do if the specified log file already exists. When set to true, the log messages are appended to the file. When set to false, the file is truncated, and the messages are written to the empty file. The default value is true.

Log File Path

Specifies the location of the log file to which to write log messages. If not specified, the default log file name m4azsql.mtr is used, and the file is stored to the directory in which the executed compiled map resides.

Pre SQL

Specifies one or more SQL statements to execute after connecting to the database and prior to fetching any rows from the database or writing any rows to the database. The statements are committed by the adapter after the last one is executed, or automatically if autocommit is specified or the statements are non-transactional (e.g. DDL statements). Bind parameters are not supported – the statements must be static statements. The adapter assumes that individual statements are separated by a semicolon. Each semicolon and backslash character that is integral part of a statement needs to be escaped by a backslash character. The corresponding adapter command is -PRESQL.

Post SQL

The **T**SPECIES one or more SQL statement to execute after fetching or writing all rows and prior to disconnecting from the database. The statements are committed by the adapter after the last one is executed, or automatically if autocommit is specified or the statements are non-transactional (e.g. DDL statements). Bind parameters are not supported – the statements must be static statements. The adapter assumes that individual statements are separated by a semicolon. Each semicolon and backslash character that is integral part of a statement needs to be escaped by a backslash character. The corresponding adapter command is -POSTSQL.

Write Mode

Specifies the mode of operation to use in PUT map function and output card when the table property is specified. The default value is insert. The meaning of the values is as follows:

- Insert – Each input row is inserted to the target table.
- Update – Each input row is used to update the corresponding row in the target table.

The corresponding adapter command is -RM (or -WRITEMODE).

-QTY and -LSN adapter commands

The -QTY adapter command is used when fetching data from the database and it specifies the maximum number of rows to fetch from the database. The default value is **1**, and the values **S** means all available rows. The -QTY command must always be accompanied by the -LSN 0 command. The -QTY and -LSN commands are managed automatically when the adapter is utilized in input card in the Design Server web UI. But when the adapter command line is specified directly, the -QTY and -LSN commands must be included in it manually.

When using an API to create or overwrite an input Azure SQL card:

- When Fetch As is set to Integral mode, set the Fetch Unit to 1 and specify the following commands so that adapter reads and returns all available rows at one time:
 - -QTY 1
 - -LSN 0
 - -ARRAYSIZE 0
- When Fetch As is set to Burst mode, set the Fetch Unit to 1 and specify the following commands so that adapter reads and returns one row per burst:
 - -QTY S
 - -LSN 0

-ARRAYSIZE adapter command

Specifies the number of table rows the adapter concatenates and returns as a single logical record. When concatenating the rows, the adapter uses linefeed character as the row terminator and the pipe character as the field delimiter. The special value 0 means that all available rows should be concatenated and returned as a single logical record. The -ARRAYSIZE adapter command is managed automatically when the adapter is used in input card in the Design Server web UI

Examples

GET function example for fetching data from a table

```
GET("AZSQL", "-SN servername -DB databasename -PORT portname -USR username -PWD password -SCH schemaname -TBL tablename -QTY 1 -LSN 0 -AS 0")
```

PUT function example for inserting data into a table

```
PUT("AZSQL", "-SN servername -DB databasename -PORT portname -USR username -PWD password -SCH schemaname -TBL tablename -WM insert")
```

Azure Blob Storage Adapter

The Azure Blob Storage adapter provides support to perform read and write operations on the blobs in the block storage managed by the Azure Blob Storage cloud service.

- [Introduction](#)

The Azure Blob Storage adapter enables data integration with the Azure Blob Storage service, through its ability to retrieve data from blobs, and store new data to blobs managed by this service. For more information about the Azure Blob Storage service, refer to the Azure Blob Storage documentation.

- [Adapter Properties and Commands](#)

This section lists the properties supported by the adapter.

- [Examples](#)

Introduction

The Azure Blob Storage adapter enables data integration with the Azure Blob Storage service, through its ability to retrieve data from blobs, and store new data to blobs managed by this service. For more information about the Azure Blob Storage service, refer to the Azure Blob Storage documentation.

Azure Blob Storage adapter as a source

The Azure Blob Storage adapter as a source can be used to read blob data, with the option to delete the blob or to preserve it after reading the data from it.

Azure Blob Storage adapter as a target

The Azure Blob Storage adapter as a target can be used to perform the following operations;

- Create a container
- Create a new blob and store data in it
- Overwrite an existing blob with the provided data
- Append data to an existing blob

Adapter Properties and Commands

This section lists the properties supported by the adapter.

- [Account Name](#)
- [Access Key](#)
- [Endpoint Suffix](#)
- [Endpoints Protocol](#)
- [Container Name](#)
- [Write Mode](#)
- [Block Size](#)
Specifies the size, in kilobytes, of blocks when writing the blob.
- [Read Mode](#)
- [Overwrite Blob](#)
- [Blob Name](#)
- [Logging](#)
- [Log File Path](#)
- [Convert Data](#)
- [Data Format](#)
- [Header](#)
- [Quote](#)
- [Delimiter](#)
- [Escape](#)
- [Separator](#)
- [Character Set](#)
- [Limit](#)
- [Sample Size](#)
- [Worksheet Index](#)
- [Select Source Tables](#)
- [Find Array](#)
- [Array Path](#)

Account Name

Specifies a storage account name on Azure Blob Storage. This is a mandatory property. The corresponding adapter command is -AN *accountName* (or -ACCOUNTNAME *accountName*).

Access Key

Specifies access key to connect to Azure Blob Storage account. The corresponding adapter command is -AK *accessKey* (or -ACCESSKEY *accessKey*).

Endpoint Suffix

Specifies the endpoint suffix to use for establishing the connection. The default value is core.windows.net. The corresponding adapter command is -ES *suffix* (or -ENDPOINTSUFFIX *suffix*).

Endpoints Protocol

Specifies a protocol that is used to make a connection. It has two possible values: HTTP and HTTPS. The corresponding adapter command is -EP *protocol* (or -ENDPOINTSPROTOCOL *protocol*) where *protocol* is one of http or https.

Container Name

Specifies the name of the container for the blobs on which the actions need to be performed. The name must be specified as a lowercase value. The corresponding adapter command is -CN *containerName* (or -CONTAINERNAME *containerName*).

Write Mode

Specifies the mode to use for the blob write operation. The default value is Block Blob. The two supported modes are:

- Block Blob: : To perform write operation on the blob of Block type
- Append Blob: : To perform write operations on the blob of Append type

The corresponding adapter command is -WM *mode* (or -WRITEMODE *mode*) where *mode* is one of block_blob or append_blob.

Block Size

Specifies the size, in kilobytes, of blocks when writing the blob.

The default value is 4096. The corresponding adapter command is -BS *blockSize* (or -BLOCKSIZE *blockSize*)

Read Mode

Specifies whether to delete or keep the blob after reading it. Default is Keep. There are two values:

- Keep: To keep a Blob.
- Delete: To delete a Blob.

The corresponding adapter command is -RM *mode* or (-READMODE *mode*), where *mode* is one of Keep or Delete.

Overwrite Blob

Specifies whether to overwrite a new Block Blob over the existing Block Blob available in the container. Default is true. If this property is set to false, the adapter gives notification to user to overwrite the Blob. The corresponding adapter command is -O (or -OVERWRITE).

Blob Name

Specifies the name of Blob. The corresponding adapter command is -B *blobName* (or -BLOBNAME *blobName*).

Logging

This property specifies the level of logging to use for the log (trace) file produced by the adapter.

The default is Off. The value Information means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

Logging can be specified using command:

-T [E|V] [+][file_path]

-T -> Log adapter informational messages.

-TE -> Log only adapter errors.

-TV -> Use verbose (debug) logging. The log file records all activity that occurs while the adapter is producing or consuming messages.

+ -> Appends the trace information to the existing log file. Omit this keyword to create a new log file.

file_path -> The full path to the adapter trace log. If you omit this keyword, the adapter creates the m4azblob.mtr log file in the map directory.

Log File Path

Specifies the location of the log file to which to write log messages. If not specified, the default log file name m4azblob.mtr is used, and the file is stored to the directory in which the executed compiled map resides

Convert Data

Specifies to convert data to parsed form. If enabled, support for converting CSV, Avro, Excel, Parquet and JSON documents into sets of data records in the CSV format. This means that the data produced by the converters can be loaded directly into relational databases.

Data Format

Specifies the data format. This is a mandatory property. Select one of the following as per the data format type. This property field is applicable when Convert Data property toggle is enabled.

- CSV
 - Excel
 - Avro
 - Parquet
 - JSON
-

Header

If enabled, specifies whether the CSV data contains a header row.

Quote

Specifies the quote character. Default value is ".

Delimiter

Specifies the field delimiter character. Default value is ,.

Escape

Specifies the escape character.

Separator

Specifies the row separator characters. Default value is \r\n.

Character Set

Specifies the character set of the data. Default value is UTF-8.

Limit

Specifies the maximum number of records to return.

Sample Size

Specifies the number of records to analyze when determining the data structure. Default value is 100.

Worksheet Index

Specifies the index of the worksheet. The index of the first worksheet is 1 (default).

Select Source Tables

Select which arrays of objects in the AVRO data you wish to map to tables in the target.

Find Array

If enabled, specifies that the output will iterate on the first array found in the JSON document.

Array Path

Specifies the path of the JSON array within the document. Omit if the document is an array. For example, "/resources".

Examples

GET example

```
GET("AZBLOB", "-AN accountName -AK accessKey -ES core.windows.net -EP https -CN containerName -RM keep -B blobName")
```

PUT example

```
PUT("AZBLOB", "-AN accountName -AK accessKey -ES core.windows.net -EP https -CN containerName -WM block_blob -O -B blobName -BS 4096")
```

B2B Advanced Communications Storage Adapter

The B2B Advanced Communications Storage adapter gives IBM® Transformation Extender the ability to read and write payloads that were stored in the IBM Sterling B2B Integrator storage subsystem.

Overview

Table 1. B2B Advanced Communications Storage adapter overview. The following table provides an overview of the B2B Advanced Communications Storage adapter:

Characteristic	Definition
Adapter Name	B2B Advanced Communications Storage Adapter specifics are as follows: <pre><M4Adapter name="IBM B2B Storage" alias="BSTR" id="_home_markdown_jenkins_workspace_Transform_in_SSVSD8_11.0.1_com.ibm.websphere.dtx.adapb2bstorage.doc_b2b_storage_adapter_194" type="app" class="com.ibm.itx/dtx/m4storage"/></pre>
Description	This adapter integrates IBM Transformation Extender with IBM B2B Advanced Communications. This adapter enables communication between the two products and allows IBM Transformation Extender to get data from and put information to B2B Advanced Communications storage.

Characteristic	Definition
Business usage	<p>IBM Transformation Extender uses this adapter to retrieve data from B2B Advanced Communications storage and persist data to B2B Advanced Communications storage.</p> <p>Inbound The inbound integration steps are as follows:</p> <ol style="list-style-type: none"> 1. B2B Advanced Communications sends a business document object to IBM MQ. 2. The IBM Transformation Extender reads the business document object from IBM MQ using the IBM MQ adapter. 3. The IBM Transformation Extender map uses a B2B Advanced Communications schema on the input card to read and parse the business document object. 4. The IBM Transformation Extender map reads the B2B Advanced Communications storage of the input document (if the data is not sent inline) <p>Outbound The outbound integration steps are as follows:</p> <ol style="list-style-type: none"> 1. IBM Transformation Extender adds the message to B2B Advanced Communications storage. 2. The IBM Transformation Extender map creates a business document object. 3. The IBM Transformation Extender map writes the message to IBM MQ.
Preconfigured?	<p>No. The storage-required .jar files and business document object schemas are installed with IBM Transformation Extender. However, you must perform the following steps before using the adapter:</p> <ol style="list-style-type: none"> 1. Create a folder called com/ibm/itx/dtx/m4storage under the tx_install_dir/Jars folder. 2. Copy the following .jar files under the com/ibm/itx/dtx/m4storage folder: <ul style="list-style-type: none"> • m4storage.jar • ibm-b2b-meg-core-apiint-common*.jar • ibm-b2b-meg-core-apiint-common-api*.jar • ibm-b2b-meg-core-components-utils*.jar • ibm-b2b-meg-core-storage-core*.jar • ibm-b2b-meg-core-storage-fs*.jar • ibm-b2b-meg-core-storage-service*.jar 3. Create a Schemas folder under the com/ibm/itx/dtx/m4storage folder. 4. Copy the business document object related schemas into the new Schemas folder: <ul style="list-style-type: none"> • BaseMessages.xsd • BaseTypeDefinitions.xsd • BusinessDocument.xsd • ExchangeVisibilityEvent.xsd • NotificationMessage.xsd 5. Add the following two properties to the tx_install_dir/config.yaml file: <pre style="background-color: #f0f0f0; padding: 5px;">runtime: B2B STORAGE: BASE_FILE_PATH: location_of_root_storage DATA_DOMAIN: data_domain_for_B2B_Advanced_Communications_storage</pre>
Requires third-party files?	No. All required components are shipped with the product.
Platform availability	<ul style="list-style-type: none"> • Windows • Linux®
Related services	None
Application requirements	This adapter requires that you install B2B Advanced Communications version 1.0.0.5 or higher. If you do not install the full B2B Advanced Communications product, at a minimum you must deploy the Proof of Concept installation. Additionally, you must install IBM Transformation Extender V9.0.0.1 or later.
Initiates business processes?	No
Invocation	This adapter can be invoked through the command line.
Business process context considerations	None
Returned status values	None
Restrictions	<ul style="list-style-type: none"> • Data ID, which is provided when data is written to B2B Advanced Communications storage, is required for inbound process flows to read the data from storage. • PUT is not supported for this function.
Persistence level	None
Testing considerations	<p>There are two levels of testing, depending on whether you installed the B2B Advanced Communications Proof of Concept installation or the full version of the product:</p> <ol style="list-style-type: none"> 1. Install B2B Advanced Communications (Proof of Concept) version 1.0.0.5 or higher and perform storage adapter testing. 2. Install B2B Advanced Communications (production) version 1.0.0.5 or higher and test the Launcher with the MQ adapter.

Command line options

Use the following command line options with this adapter:

-BUCKET (-B)

- The name of the bucket.
- ID (-ID)
This is the unique identifier for the message or business document object.
- NOW (-NOW)
Indicates that the adapter is writing data to B2B Advanced Communications storage.
- SERVICE (-S)
This is the name of the adapter.
- ADDDOC (-A)
Adds a business document object to B2B Advanced Communications storage.

Implementing the B2B Advanced Communications Storage adapter

To implement this adapter, follow this procedure:

1. From the command line, go to *B2B_Advanced_Communications_install_dir/members/bin*
2. Invoke `execute member start all`
3. Invoke `execute storage -provision`

Inbound parameters passed from business process to adapter

Field	Description
Action	<p>The inbound storage action.</p> <ul style="list-style-type: none"> • GET - get payload from storage as primary document <p>For example:</p> <pre>=VALID(GET("BSTR", "-B 1st_provisioned -S 1st_provisioned_var01 -ID " + Output2), LASTERRMSG())</pre>
DataId	The unique identifier for the business document object to be retrieved from B2B Advanced Communications storage.

Outbound parameters passed from adapter to business process schema

Field	Description
Action	<p>The outbound storage action.</p> <ul style="list-style-type: none"> • GET - write payload from message to B2B Advanced Communications storage <p>For example:</p> <pre>=VALID(GET("BSTR", "-B 1st_provisioned -S 1st_provisioned_var01 -NOW -ADDDOC", "THIS IS A TEST"), LASTERRMSG())</pre>
DataId	The unique identifier for the business document object to be added to B2B Advanced Communications storage. This value is provided by the adapter.
PrimaryDocument	The business document object. This value is returned by the GET action from B2B Advanced Communications storage.

Batch File and Shell Script adapters overview

The Batch File adapter processes a (Windows) batch file as the data source of an input map card or the data target of an output map card. The Shell Script adapter processes a (UNIX) shell script as the data source of an input map card or the data target of an output map card.

You can achieve seamless data flow between applications regardless of format by combining the use of batch files or shell scripts to control where data is transferred.

Use the adapters with the Command Server, Launcher, Software Development Kit, or in a rule within a map.

- [System requirements](#)
- [Command aliases](#)
- [Commands for the Batch File and Shell Script adapters](#)
- [Syntax summary for Batch File and Shell Script adapters](#)
- [Return codes and error messages](#)

System requirements

See the IBM Transformation Extender [system requirements](#) for details. It is assumed that a Command Server has already been installed on the computer where the adapter is to be installed for runtime purposes.

Command aliases

Adapter commands can be specified by using a command string on the command line or by creating a command file that contains adapter commands. The execution command syntax is:

```
-IA[alias] card_num
-OA[alias] card_num
```

where `-IA` is the Input Source Override execution command and `-OA` is the Output Target Override execution command, `alias` is the adapter alias, and `card_num` is the number of the input or output card. The following table shows each adapter alias and its execution commands.

Adapter	Alias	As Input	As Output
Batch File	BAT	<code>-IABATcard_num</code>	<code>-OABATcard_num</code>
Shell Script	SHL	<code>-IASHLcard_num</code>	<code>-OASHLcard_num</code>

Commands for the Batch File and Shell Script adapters

The following table lists valid commands for the Batch File and Shell Script adapters, the command syntax, and whether the command is supported (✓) for use with data sources, data targets, or both.

Command	Syntax	Source	Target
Audit (-A or -AUDIT)	<code>-AUDIT[+][S] [full_path]</code>	✓	✓
Command Line Interpreter (-CL or -CLI)	<code>-CLI[! cmd_line_interpreter]</code>	✓	✓
Command File (-C or -CMD)	<code>-CMD batch_file_or_shell_script</code>	✓	✓
Transfer File (-F or -FILE)	<code>-FILE [transfer_file]</code>	✓	✓
Inline Output (-I or -INLINE)	<code>-INLINE</code>		✓
Poll Process (-P or -POLL)	<code>-POLL count:interval</code>	✓	✓
Show Mode (-S or -SHOW) (Batch file adapter only)	<code>-SHOW {HIDE MIN MAX NRM api_mode}</code>	✓	✓
Standard Input (-< or -STDIN)	<code>-STDIN "data"</code>	✓	✓
Trace (-T or -TRACE)	<code>-T[E][+][S V] [full_path]</code>	✓	✓

- [Audit \(-A or -AUDIT\)](#)
- [Command line interpreter \(-CL or -CLI\)](#)
- [Batch files in Windows environments](#)
- [Shell scripts in UNIX environments](#)
- [Command file \(-C or -CMD\)](#)
- [Transfer file \(-F or -FILE\)](#)
- [Inline output \(-I or -INLINE\)](#)
- [Poll process \(-P or -POLL\)](#)
- [Show mode \(-S or -SHOW\)](#)
- [Standard input \(-< or -STDIN\)](#)
- [Trace \(-T or -TRACE\)](#)

Audit (-A or -AUDIT)

Use the Audit adapter command (`-A` or `-AUDIT`) to produce an audit log file in the map directory. Audit information includes the command line, process id, adapter return code, number of bytes read/written, elapsed time of the command execution, number of retries and standard input, output or error messages as appropriate, if pipes are used.

`-AUDIT[+][S] [full_path]`

Option

Description
<code>+</code>
Append audit information to the existing audit log file. If an audit log file does not exist, one is created.
<code>S</code>
Record only summary information in the audit log file.

`full_path`

Create audit file with the specified name in the specified directory. By default, the directory is where the map is located and the file name is **m4batch.log** or **m4shell.log** (as applicable).

Command line interpreter (-CL or -CLI)

Use the Command Line Interpreter adapter command (`-CL` or `-CLI`) to specify the command line interpreter used to execute the batch file or shell script.

`-CLI[!|cmd_line_interpreter]`

Option

Description
<code>!</code>
Use no command line interpreter.

`cmd_line_interpreter`

Specify a command line interpreter.

Batch files in Windows environments

In Windows environments, use the Command Line Interpreter adapter command (`-CLI`) as follows. If `-CLI` is not specified, no command line interpreter is assumed.

Entering this

Specifies this command line interpreter

```
-CLI  
    cmd/c  
-CLI!  
    none  
-CLI command  
    command
```

Note: The result of not specifying the Command Line Interpreter adapter command (`-CL`) is the same as specifying the default of `-CLI!` which assumes no command line interpreter.

Shell scripts in UNIX environments

In UNIX environments, use the Command Line Interpreter adapter command (`-cli`) as follows. If `-cli` is not specified, a command line interpreter of `/bin/sh -c` is assumed.

Entering this

Specifies this command line interpreter

```
-cli  
    /bin/sh -c  
-cli!  
    none  
-cli command  
    command
```

Note: The result of not specifying the Command Line Interpreter adapter command (`-cl`) is the same as specifying the default of `-cli`, which assumes a command line interpreter of `/bin/sh -c`.

Command file (-C or -CMD)

Use the Command File adapter command (`-C` or `-CMD`) to specify a batch file or shell script file to run. This command and the file name are required to execute a batch file or shell script.

```
-CMD batch_file_or_shell_script
```

Option

Description

batch_file_or_shell_script
Specify the batch file or shell script file to run.

Transfer file (-F or -FILE)

By default, data is written through pipes (standard input for a source, standard output for a target). You can use the Transfer File adapter command (`-F` or `-FILE`) to specify a temporary holding file where the adapter can place its output data or obtain its input data. If a file name is not specified, the adapter will automatically generate a file name, which is passed as part of the command line to the batch file or shell script.

For example, `doit.bat` is called as `doit.bat transferfile.tmp`. If the process has not finished within the timeout period as specified with the Poll Process adapter command (`-POLI`), the file is not deleted.

For an input, on process completion, the content of the transfer file is used for the source data for the specified input card.

```
-FILE [transfer_file]
```

Option

Description

transfer_file
Specify the name of the transfer file.
For an input, the file name can include wildcards. If wildcards are used, the contents of the multiple files are concatenated (without delimiters) to become the data for the input card.
For an output, wildcards cannot be used.

Inline output (-I or -INLINE)

By default, data is written through pipes (standard input for a target). You can use the Inline Output adapter command (`-I` or `-INLINE`) to specify the data from an output card to be passed as part of the command line to the batch file or shell script.

```
-INLINE
```

Poll process (-P or -POLL)

Use the Poll Process adapter command (-P or -POLL) to specify the number of times and frequency at which the adapter polls for process completion.

-POLL count:interval

Option

Description

count

The number of times to check for process completion.

interval

The number of seconds to wait between each poll.

If the number of specified polling attempts is exhausted and the process has not yet completed, the adapter will exit with the message Command Still Executing. This is a warning for a target, but an error for a source.

Show mode (-S or -SHOW)

Use the Show Mode adapter command (-S or -SHOW) to specify the mode for displaying the command window. Use this command only with the Batch File adapters. If the Show Mode adapter command (-S or -SHOW) is not specified, the default show mode is HIDE.

-SHOW {HIDE|MIN|MAX|NRM|api_mode}

Option

Description

HIDE

The command window is hidden.

MIN

The command window is minimized.

MAX

The command window is maximized.

NRM

The command window is normal.

api_mode

Specify an integer value corresponding to the flags desired, as documented for the ShowWindow API in the Windows API for values.

Standard input (-< or -STDIN)

Use the Standard Input adapter command (-< or -STDIN) when passing the specified data through pipes as standard input (that is, when -file is omitted) during batch file or shell script processing. This is useful when keyboard response is required during the process.

-STDIN "data"

For example, if a batch file or shell script procedure requires a yes keyboard response three times during the process, specify:

-STDIN "yes yes yes"

Trace (-T or -TRACE)

Use the Trace adapter command (-T or -TRACE) to produce a diagnostics file that contains detailed information about Batch File and Shell Script adapters activity.

The default filename is **m4batch.mtr**, **m4shell.mtr**, or **map_name.mtr**, depending on the option(s) you select. The trace file is created in the map directory unless otherwise specified.

-T[E][+][S|V] [full_path]

Option

Description

E

Produce a trace file containing only the adapter errors that occurred during map execution. The adapter trace file is produced by default in the map directory, using the full name of the map file with an .mtr filename extension (map_name.mtr).

+

Append trace information to the existing trace file.

S

Summary mode. Record only minimal information in the log file. This is the default value.

V

Verbose mode. Record in the log file all activity occurring while the adapter is retrieving data. If not specified, summary mode is assumed.

full_path

Creates a trace file with the specified name in the specified directory.

Note: You can override the adapter command line trace options dynamically using the Management Console. Refer to *Dynamic Adapter Tracing* in the *Launcher Reference Guide* for detailed information.

Note: Because summary mode is the default, using -TRACES provides the same output as -TRACE.

Syntax summary for Batch File and Shell Script adapters

- [Data sources](#)
- [Data targets](#)

Data sources

Use the following data source command syntax for the Batch File and Shell Script adapters:

```
-CMD batch_file_or_shell_script
[-AUDIT[+] [S] [full_path]
[-CLI[!|cmd_line_interpreter]]
[-FILE [transfer_file]]|[-STDIN data]
[-POLL count:interval]
[-SHOW {HIDE|MIN|MAX|NRM|api_mode}]
[-T[E] [+][S|V] [full_path]]
```

Data targets

Use the following data target command syntax for the Batch File and Shell Script adapters:

```
-CMD batch_file_or_shell_script
[-AUDIT[+] [S] [full_path]
[-CLI[!|cmd_line_interpreter]]
[-FILE [transfer_file]]|[-INLINE]
[-POLL count:interval]
[-SHOW {HIDE|MIN|MAX|NRM|api_mode}]
[-T[E] [+][S|V] [full_path]]
```

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages may also be recorded as specified in the audit logs, trace files, execution summary files, and so on.

The following is a listing of all the codes and messages that can be returned as a result of using the Batch File and Shell Script adapters for sources or targets.

Note: Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Return Code	Message
0	OK
-1	Insufficient memory to continue
-1	Library Initialization Failed
-2	Invalid Entry Point (AIX® adapters only)
-3BATCH	Could not load adapter
-3	Error Sending Data
-4	Error Receiving Data
-5	BATCH: Insufficient memory to continue
1	No data provided. Create on content specified: command not executed.
7	Command Still Executing (Applies to adapter target)
-1	Incorrect Arguments
-2	Error Writing Output Files
-2	Error Reading Input Data
-5	Insufficient Memory to Continue
-6	Error Executing Command (Return Code XX) XX is return code from command
-7	Command Still Executing (Applies to adapter source)

CICS Adapter overview

The Customer Information Control System (CICS) adapter allows you to retrieve CICS screen data without the difficulties associated with 3270 "screen scraping." Using the CICS adapter with schemas generated from BMS maps you can easily send data to and retrieve data from CICS transactions.

For more information about CICS transactions see [CICS Transaction Server for OS/390® Version 1.3 External Interfaces Guide \(SC33-1944\)](#).

- [System requirements](#)
- [Command alias](#)
- [CICS Adapter commands](#)
- [Syntax summary](#)
- [Using the CICS adapter](#)

System requirements

The minimum system requirements and operating system requirements for the CICS adapter are detailed in the release notes. It is assumed that a IBM Transformation Extender has already been installed on the computer where the adapter is to be installed for runtime purposes.

In addition, the following requirements are necessary to use the CICS adapter:

- A correctly installed and configured CICS TCP/IP system
- IBM® supplied (TCP/IP Port) Listener
- IBM supplied 3270 Bridge transaction

Command alias

Adapter commands can be specified by using a command string on the command line or creating a command file that contains adapter commands. The execution command syntax is:

```
-IM[alias] card_num
-OM[alias] card_num
```

where **-IM** is the Input Source Override execution command and **-OM** is the Output Target Override execution command, *alias* is the adapter alias, and *card_num* is the number of the input or output card. The following table shows the adapter alias and its execution command.

Adapter	Alias	As Input	As Output
CICS	CICS	-IMCICS <i>card_num</i>	-OMCICS <i>card_num</i>

CICS Adapter commands

The following table lists valid commands for the CICS Adapter, the command syntax, and whether the command is supported (✓) for use with data sources, targets, or both.

Command	Syntax	Source	Target
Bridge Facility Like (-BFL)	-BFL <i>terminal_id</i>	✓	✓
Bridge Keep Time (-BKT)	-BKT <i>time</i>	✓	✓
Driver Transaction Name (-DT)	-DT <i>tran_name</i>	✓	✓
Host (-HOST)	-HOST <i>host_name</i>	✓	✓
Password (-PW)	-PW <i>password</i>	✓	✓
Port (-PORT)	-PORT <i>port_number</i>	✓	✓
Service (-SERVICE)	-SERVICE <i>service</i>	✓	✓
Timeout (-TIMEOUT)	-TIMEOUT <i>milliseconds</i>	✓	✓
Trace (-T)	-T [E][+][filename]	✓	✓
Transaction Name (-TRAN)	-TRAN <i>tran_name</i>	✓	✓
User ID (-UID)	-UID <i>user_id</i>	✓	✓

- [Bridge Facility Like \(-BFL\)](#)
- [Bridge Keep Time \(-BKT\)](#)
- [Driver Transaction Name \(-DT\)](#)
- [Host \(-HOST\)](#)
- [Password \(-PW\)](#)
- [Port \(-PORT\)](#)
- [Service \(-SERVICE\)](#)
- [Timeout \(-TIMEOUT\)](#)
- [Trace \(-T\)](#)

- [Transaction Name \(-TRAN\)](#)
- [User ID \(-UID\)](#)

Bridge Facility Like (-BFL)

Use the Bridge Facility Like adapter command (`-BFL`) to specify the four character name of the terminal type. This terminal type is defined by the `FACILITYLIKE` parameter of the **PROFILE** associated with the transaction.

This is an optional command.

`-BFL terminal_id`

For example:

`-BFL cujo`

Where `cujo` is the four character name of the terminal type.

Bridge Keep Time (-BKT)

Use the Bridge Keep Time adapter command (`-BKT`) to specify the time, in milliseconds, for the CICS server to keep information (CICS COMMAREA) for the next transaction in the pseudo conversation.

This is an optional command. The default value is set by your CICS system programmer.

`-BKT time`

For example:

`-BKT 60`

Where `60` is the specified time in milliseconds.

Driver Transaction Name (-DT)

Use the Driver Transaction Name adapter command (`-DT`) to specify the name of the supplied driver transaction. If not provided this will default to MDRV, the default name of the driver transaction.

Check with your CICS system programmer to verify the name of the driver transaction.

Action

Meaning
`transaction_name`

Name of the supplied driver transaction.

Host (-HOST)

Use the Host adapter command (`-HOST` or `-H`) to specify the name of the system or `localhost` to which you want to connect.

This is a required command unless you are running on a native CICS platform. Do not use the `-HOST` command if you are using the CICS adapter within a CICS region.

`-HOST host_name`

For example:

`-HOST Your.CICS.system`

Where `host_name` is the name of the z/OS® system that hosts the CICS to which you want to connect.

Password (-PW)

Use the User Password adapter command (`-PW`) to specify the password associated with the user ID. The password is not displayed in the adapter trace file.

This is a required command.

`-PW password`

Where `password` is the password of the local user specified in the `-UID` adapter command, or the default user, if `-UID` is not specified.

Port (-PORT)

Use the Port adapter command (-PORT or -P) to specify the port number on which the CICS Listener listens. This is customer defined.

This is a required command if -HOST is specified. Do not use the -PORT command if you are using the CICS adapter from within a CICS region.

This command is mutually exclusive with the Service (-SERVICE) command. Either Port or Service must be specified.

-PORT *port_number*

For example:

-PORT 4321

Where 4321 is the port number where the CICS listener listens. Consult your CICS systems programmer for the port number.

Service (-SERVICE)

Use the Service adapter command (-SERVICE or -s) to specify the service name that maps to a port. See the Port (-PORT) command for more information.

This is a required command if -HOST is specified.

This command is mutually exclusive with the Port (-PORT) command. Either Port or Service must be specified.

-SERVICE *service*

For example:

-SERVICE cicslsnr

Where *cicslsnr* is the service name that maps to the specified port.

Timeout (-TIMEOUT)

Use the Timeout adapter command (-TIMEOUT) to specify the time limit for lookup operations in milliseconds. If not specified the timeout is infinite.

-TIMEOUT *milliseconds*

Option

Description

milliseconds

The time limit in milliseconds.

For example, to specify **10,000** milliseconds as the time limit for lookup operations.

-TIMEOUT 10000

Trace (-T)

Use the Trace adapter command (-T) to produce a diagnostics file. This file contains detailed information about adapter activity. By default, the **m4cics.mtr** trace file is created in the directory where the map is located.

This command also determines the trace option that is provided to the server side. The server side transaction and 3270 bridge exit will trace to SYSPRINT.

You can override the adapter command line trace options dynamically using the Management Console. See *Dynamic Adapter Tracing* in the *Launcher* documentation for information.

-T[E][+] [filename]

Option

Description

E

Produce a trace file containing only the adapter errors that occurred during map execution.

+

Appends trace information to the existing trace file.

filename

Creates a trace file with the specified name in the specified directory.

Transaction Name (-TRAN)

Use the Transaction Name adapter command (-TRAN) to specify the customer defined transaction name, configured to use 3270 bridge.

This is a required command.

-TRAN *tran_name*

Where *tran_name* is the customer defined application identifier.

User ID (-UID)

Use the User ID adapter command (-UID) to specify the User ID for connection and transaction authorization.

This command is required.

```
-UID user_id
```

Where *user_id* is the ID for CICS sign on.

Syntax summary

- [Data sources](#)
- [Data targets](#)
- [Example 1](#)
- [Example 2](#)

Data sources

The following is the command syntax of the CICS adapter commands used for data sources:

```
-DT tran_name
-HOST host_name
-PORT port_number|-SERVICE service
-TIMEOUT milliseconds
[-BFL terminal_id]
[-BKT time]
[-PW password]
[-T[E] [+][filename]]
[-TRAN tran_name]
[-UID user_id]
```

Data targets

The following is the command syntax of the CICS adapter commands used for data targets:

```
-DT tran_name
-HOST host_name
-PORT port_number|-SERVICE service
-TIMEOUT milliseconds
[-BFL terminal_id]
[-BKT time]
[-PW password]
[-T[E] [+][filename]]
[-TRAN tran_name]
[-UID user_id]
```

Example 1

For the PUT>Target setting in an output card, select CICS. In the PUT>Target>Command field, enter:

```
-HOST myhost -SERVICE cicslsnr -TIMEOUT 20000 -UID user -PW
pass -TRAN ABCD
```

This Target output command will:

- connect to **host myhost using service cicslsnr**
- change the socket **timeout** to 20 seconds
- use the **userid user and the password pass**
- run **transaction ABCD** passing the data mapped to the output card. The response from the transaction will be discarded, but its success status will be returned from the adapter

Example 2

In a **GET** map function call enter:

```
=GET("CICS",
"-T+ myfile.mtr
-HOST myhost -PORT 3020
-TIMEOUT 30000 -UID user -PW pass
-TRAN DINQ ", PACKAGE( MyPackage ))
```

This **GET** map function call will:

- Enable a trace file called **myfile.mtr** in append mode.
- Connect to **host myhost using port 3020**.
- Change the socket **timeout** to **30 seconds**.
- Use the **userid user** and the **password pass**.
- Run **transaction DINQ** using data supplied in **PACKAGE MyPackage**.

Using the CICS adapter

Use the CICS adapter to send and receive CICS transaction data.

- [Adapter capabilities](#)
- [Adapter limitations](#)
- [Defining a bridge transaction for use with the CICS adapter](#)

Adapter capabilities

The capabilities of the adapter include:

- Communication between the client and the CICS based server software is synchronous.
- The client map sends data to the CICS server, and waits for the reply. The CICS server software receives data, sends a reply, and quits.
- Pseudo conversational and non-conversational transactions are supported.

Adapter limitations

The following limitations exist in the adapter:

- The adapter assumes only one map instance per connection.
- CICS conversational transactions are not supported.

Defining a bridge transaction for use with the CICS adapter

- The details of defining a 3270 bridge transaction are covered in the [CICS Transaction Server for OS/390® Version 1.3 External Interfaces Guide \(SC33-1944\)](#).
- Examples for defining the bridge transaction can be found in the CICS adapter examples **readme.txt**.

Cipher Adapter

The Cipher adapter encrypts and decrypts data by using the Advanced Encryption Standard (AES) established by the U.S. National Institute of Standards and Technology (NIST). A single cryptographic key enciphers (encrypts) and deciphers data. The cryptographic key is stored in a master key file (MKF) in an AES-based encrypted format. As long as the MKF is not compromised or lost, the enciphered data is cryptographically secure.

Encrypted data is preceded by a unique header that identifies the specific master key used for encryption, similar to the following example:

[TX id=13104 iv=7804721d4eb50b8de9185960a587ee45 m=a h=15B333C7]

In the header example:

id=	Encryption master key ID
iv=	GSKit cipher initialization vector (IV)
m=a	ASCII or binary encryption mode
h=	Internal checksum

To decrypt the data, the specified MKF must contain the master key ID that's specified in the header of the encrypted data. The encryption mode can be ASCII or binary. Decryption automatically uses the mode that's appropriate for the encrypted data.

In Transformation Extender, encrypted files are interchangeable between Windows and UNIX operating systems. For example, you can encipher a file on a Windows system and run a map on a UNIX system to decipher it.

Because z/OS® systems use a different encryption format, you cannot decipher file on a z/OS system that you encrypted on a Windows or UNIX system.

- [IBM GSKit requirements](#)

The encryption capabilities of the Cipher adapter require IBM Global Security Kit (GSKit). By default, Transformation Extender installs GSKit locally. A locally installed GSKit enables Transformation Extender to run a specific version of GSKit that is automatically used by Transformation Extender executable programs. Products that Transformation Extender integrates with might use their own local version of GSKit. When you run Transformation Extender with other products that are configured to use GSKit, you can configure the environment to use the latest or most appropriate version.

- [Cipher adapter commands](#)

Cipher adapter commands are valid for input data sources and output data targets.

IBM GSKit requirements

The encryption capabilities of the Cipher adapter require IBM Global Security Kit (GSKit). By default, Transformation Extender installs GSKit locally. A locally installed GSKit enables Transformation Extender to run a specific version of GSKit that is automatically used by Transformation Extender executable programs. Products that Transformation Extender integrates with might use their own local version of GSKit. When you run Transformation Extender with other products that are configured to use GSKit, you can configure the environment to use the latest or most appropriate version.

To use the Cipher adapter in an API or RMI environment, ensure that the library and executable path of your platform points to the local GSKit drivers by running the dtxcommon.bat file (on Windows) or the setup script (on UNIX) before you run a map. In an Integrated Server environment, you must manually adjust the paths to point to the GSKit drivers.

To prevent Transformation Extender from using its locally installed version of GSKit, rename the *tx_install_dir\GSKit* directory to any other name. At runtime, Transformation Extender automatically detects the missing GSKit directory and searches the platform-specific environment path for the GSKit modules.

When you have a globally installed version of GSKit on the same system due to the requirements of another product, renaming the *tx_install_dir\GSKit* directory ensures that the Transformation Extender local GSKit is bypassed. The global version is managed by the GSKit installation program, and makes the security modules available on a system-wide basis.

To determine the version of the local GSKit that Transformation Extender installed:

1. From the command line, run the Transformation Extender dtxcommon.bat file or the setup script.
2. Run the **gsk8ver_64** command.

Cipher adapter commands

Cipher adapter commands are valid for input data sources and output data targets.

Cipher adapter command aliases

Use CIPHER as the adapter command alias on input and output cards and in GET and PUT rules. For example:

Input source override execution command	-IACIPHER <i>card_num</i>
Output target override execution command	-OACIPHER <i>card_num</i>

Cipher adapter commands

-MKF *filename*

Specifies the name of the master key file (MKF) in which to locate an existing master key or store a new master key. When the MKF contains multiple existing master keys, TX uses the last key in the MKF by default. Use the **-ID** option to select a different key.

This keyword is optional. If you omit it, the adapter automatically creates a new cryptographic key in the *tx_install_dir\itx.mkf* file on Windows systems or the *tx_install_dir\configs\itx.mkf* file on UNIX systems.

-ID *key_ID*

Specifies the ID of the cryptographic key to use to decipher encrypted data. This keyword is optional. If you omit it, the adapter uses the last key in the MKF.

-BIN

Specifies binary encryption. This keyword is optional. If you omit it, the adapter uses ASCII encryption.

-ACTION { ENCRYPT | DECRYPT }

Specifies whether to encrypt or decrypt the data. This keyword is optional on **GET** and **PUT** rules. If you omit it, TX encrypts or decrypts the data based on whether the specified file has an encryption header.

-FILE *filename*

Specifies the name of the file to read from or write to. This keyword is required on input cards and output cards.

-T [E | V] [+] *[file_path]*

The adapter trace level and full path to the adapter trace log.

-T

Log adapter informational messages.

-TE

Log only adapter errors during map execution.

-TV

Use verbose (debug) logging. The log file records all activity that occurs while the adapter is enciphering or deciphering data.

+

Appends the trace information to the existing log file. Omit this keyword to create a new log file.

file_path

The full path to the adapter trace log. If you omit this keyword, the adapter creates the m4cipher.mtr log file in the map directory.

Examples

This command enciphers data stored in Mydata text item.

```
= Valid(GET("CIPHER", "-MKF bulk_key_multiple.mkf -ACTION encipher -T", Mydata), FAIL("Err Msg: " + LASTERRORMSG() + " Err Code: " + LASTERRORCODE()))
```

This command deciphers data stored in Myencrypteddata text item.

```
= Valid(GET("CIPHER", "-MKF bulk_key.mkf -ACTION decipher -T", Myencrypteddata), FAIL("Err Msg: " + LASTERRORMSG() + " Err Code: " + LASTERRORCODE()))
```

On a map input card with CIPHER as the input source, the following Source... Command deciphers data in EncryptedInput.txt input file.

```
-FILE EncryptedInput.txt -ACTION decipher -MKF bulk_key.mkf -T
```

COM Adapter overview

You can use the Component Object Model (COM) Automation adapter to create a custom solution, integration, or service and access that solution from within IBM Transformation Extender.

The COM Automation adapter is targeted to those who would consider using the Software Development Kit (SDK) but would rather create the solution in a more natural and object-based model. Unlike the SDK, using the COM Automation adapter allows you to create your solution in any language that supports COM Automation (for example, C, C++, VB, Java™, COBOL and so on), and then provides method-based access to that solution.

- [System requirements](#)
- [COM Adapter command alias](#)
- [COM Adapter commands](#)
- [Syntax summary](#)
- [Using the adapter](#)
- [Troubleshooting](#)
- [Type Library Importer](#)

System requirements

See the IBM Transformation Extender system requirements for the minimum system requirements and operating system requirements for the COM Automation adapter. It is assumed that a Command Server has already been installed on the computer where the adapter is to be installed for runtime purposes.

COM Adapter command alias

Adapter commands can be specified by using a command string on the command line or creating a command file that contains adapter commands. The execution command syntax is:

```
-IA[alias]card_num  
-OA[alias]card_num
```

where **-IA** is the Input Source-Override execution command and **-OA** is the Output Target-Override execution command, *alias* is the adapter alias, and *card_num* is the number of the input or output card. The following table shows the adapter alias and its execution command.

Adapter	Alias	As Input	As Output
COM Automation	COM	-IACOM <i>card_num</i>	-OACOM <i>card_num</i>

COM Adapter commands

The following table lists valid commands for the COM Automation adapter, the command syntax, and whether the command is supported (✓) for use with data sources, targets, or both.

Command	Syntax	Source	Target
Input Card Configuration File (-CFG)	-CFG <i>full_path</i>	✓	
Prequel (-PRE)	-PRE [<i>dispid:vartype:data</i>]	✓	✓
Post (-POST)	-POST [<i>dispid:vartype:data</i>]	✓	✓
Program ID (-PROGID)	-PROGID <i>progid</i>	✓	✓
Set Property (-PROP)	-PROP [<i>dispid:vartype:data</i>]	✓	✓
Trace (-T)	-T[E][+] [<i>full_path</i>]	✓	✓

- [Input card configuration file \(-CFG\)](#)
- [Prequel \(-PRE\) command for COM](#)
- [Post \(-POST\) command for COM](#)
- [Program ID \(-PROGID\) command for COM](#)
- [Set Property \(-PROP\) command for COM](#)
- [Trace \(-T\) command for COM](#)

Input card configuration file (-CFG)

Use the Input Card Configuration File adapter command (-CFG) to allow using the COM Automation adapter on an input card using a pre-prepared metadata file.

```
-CFG full_path
```

Option	Description
--------	-------------

full_path

Specifies the full path and the location of the configuration file for a pre-prepared metadata file (usually created on another output card).
The configuration file can be generated by using the **PACKAGE** function on an imported type tree.

Prequel (-PRE) command for COM

Use the Prequel adapter command (-PRE) to specify if you want one or more methods to be executed before the methods in the type tree.

-PRE [dispid:vartype:data]

Option

Description

[]	The brackets surrounding the parameter are required.
:	Required separator.
dispid	Specify a valid dispatch ID (DISPID) property.
vartype	Specify a valid data type. See Supported Data Types for more information.
data	Data type as represented by the text. A string is a sequence of characters; an integer is a sequence of digits, and so on.

For example, to specify a dispatch ID of 3, a data type of BSTR, and text data:

-PRE [3:VT_BSTR:data]

Note: If any properties exist on the command line, the properties are set before executing any other call on the component. If an error is received setting any of the properties, the process is aborted with errors.

See [Determining the Dispatch ID for a Method/Property](#) for information on how to determine the dispatch ID for a property.

Post (-POST) command for COM

Use the Post adapter command (-POST) to specify execution of one or more methods after the methods in the type tree are executed.

-POST [dispid:vartype:data]

Option

Description

[]	The brackets surrounding the parameter are required.
:	Required separator.
dispid	Specify a valid dispatch ID (DISPID) property.
vartype	Specify a valid data type. See Supported Data Types for more information.
data	Data type as represented by the text. A string is a sequence of characters; an integer is a sequence of digits, and so on.

For example, to specify a dispatch ID of 3, a data type of BSTR, and text data:

-POST [3:VT_BSTR:data]

Note: If any properties exist on the command line, the properties are set before executing any other call on the component. If an error is received setting any of the properties, the process is aborted with errors.

See [Determining the Dispatch ID for a Method/Property](#) for information on how to determine the dispatch ID for a property.

Program ID (-PROGID) command for COM

Use the Program ID adapter command (-PROGID) to override the Class ID (CLSID) and specify a different component.

-PROGID progid

Option

Description

progid	The program ID of the component to use overrides the CLSID and specifies a different component.
--------	---

For example, to override the program ID Nxf.Nxf.1:

-PROGID Nxf.Nxf.1

As part of the type tree importer process, the Class ID (CLSID) of the component to use is stored in the type tree. This CLSID is then passed to the COM Automation adapter at run time to specify the component to use.

An example of where this option could be used would be in the case where you have a number of different components all implementing the same interface and you want to be able to select which component to use at map run time.

The different components might access different files or systems or might do something altogether different; it does not matter to the adapter, provided that the interface has the same Dispatch IDs (DISPIDs), method names, parameters, and so on.

Note: The Program ID (-PROGID) specified must be a compatible component with the same interface.

Set Property (-PROP) command for COM

Use the Set Property adapter command (-PROP) to set specific properties on the component at run time.

-PROP [dispid:vartype:data]

Option

Description

[]

The brackets surrounding the parameter are required.

:

Required separator.

dispid

Specify a valid dispatch ID (DISPID) property.

vartype

Specify a valid data type. See[Supported Data Types](#) for more information.

data

Data type as represented by the text. A string is a sequence of characters; an integer is a sequence of digits, and so on.

For example, to specify a dispatch ID of 3, a data type of BSTR, and text data:

-PROP [3:VT_BSTR:data]

Note: If any properties exist on the command line, the properties are set before executing any other call on the component. If an error is received setting any of the properties, the process is aborted with errors.

See [Determining the Dispatch ID for a Method/Property](#) for information on how to determine the dispatch ID for a property.

Trace (-T) command for COM

Use the Trace adapter command (-T) to produce a diagnostics file. This file contains detailed information about adapter activity. By default, the m4com.mtr trace file is created in the directory where the map is located.

-T[E][+] [full_path]

Option

Description

E

Produce a trace file containing only the adapter errors that occurred during map execution.

+

Append trace information to the existing trace file.

full_path

Creates a trace file with the specified name in the specified directory.

Note: Trace (-T) and Trace Error (-TE) adapter commands are mutually exclusive.

Syntax summary

- [COM adapter data sources](#)
- [COM adapter data targets](#)
- [Determining the Dispatch ID for a Method/Property](#)

COM adapter data sources

```
[-CFG full_path]
[-POST [dispid:vartype:data]]
[-PRE [dispid:vartype:data]]
[-PROGID progid]
[-PROP [dispid:vartype:data]]
[-T[E][+] [full_path]]
```

COM adapter data targets

```
[-POST [dispid:vartype:data]]
[-PRE [dispid:vartype:data]]
[-PROGID progid]
[-PROP [dispid:vartype:data]]
[-T[E] [+]] [full_path]
```

Determining the dispatch ID for a method or property

A number of the command line options for the COM Automation adapter require a dispatch ID (DISPID) for a parameter.

You can determine the DISPID for a method or property by:

- Viewing the IDL file
 - Running the OleView.exe Utility
 - [Viewing the IDL file](#)
 - [Running the oleview utility](#)
-

Viewing the IDL file

A simple way to determine the DISPID for a method or parameter is to view the IDL file.

The following is an excerpt from the IDL file for the included sample component, NxfSrv. The DISPID corresponds to the identification number in the square brackets above the method or property.

Note: There are no properties shown here.

```
interface INxf : IDispatch{
[id(1), helpstring("Open the File")]
HRESULT OpenFile([in, string] BSTR File);
[id(2), helpstring("Close current file (called automatically when object
is destroyed)")]
HRESULT CloseFile();
[id(3), helpstring("Retrieve data associated with Key")]
HRESULT GetEntry([in, string] BSTR Key, [out, retval] BSTR* Data);
[id(4), helpstring("Add a new entry named Key")]
HRESULT AddEntry([in, string] BSTR Key, [in, string] BSTR Data);
[id(5), helpstring("Retrieve count of entries")]
HRESULT GetEntryCount([out, retval] long* Count);
[id(6), helpstring("Get name of entry (Key) by integer index")]
HRESULT GetEntryName([in] long Entry, [out, retval] BSTR* Name);
[id(7), helpstring("Delete entry associated with Key")]
HRESULT DeleteEntry([in, string] BSTR Key);
[id(8), helpstring("Call after numerous adds and deletes")]
HRESULT PackFile([in, string] BSTR File);
[id(9), helpstring("Get entry identified by Key from File")]
HRESULT GetFileEntry([in, string] BSTR File, [in, string] BSTR Key, [in,
out] VARIANT* Data);
};
```

Running the oleview utility

A second alternative for determining the DISPID for a method or parameter is to use the oleview.exe utility. This utility is available from Microsoft as a free download. It is also included with Visual Studio.

To determine DISPID for a method:

1. Start the oleview.exe application.
2. From the **File** menu, select **View typelib**.
3. Choose the type library file.

Note: Select the same type library file that was specified in the Type Library Importer.

Using the adapter

Use the COM Automation adapter to encapsulate your technology in a more object-oriented way and use your objects in a natural way.

The COM Automation adapter adheres to the semantics of the automation interface, IDispatch. This allows the user to provide a custom, in-house solution or service for nearly any integration requirement and then access that service from within IBM Transformation Extender (in other words, the adapter can then be thought of as a conduit to this component).

At **design time**, the user:

- Runs the importer selecting the component to use in a map.
- Selects one or more methods to execute on that component.

At **map runtime**, the adapter:

- Creates an instance of the specified component. The user specifies which component to use when running the importer.
 - Calls the method(s) that the user specified in the importer.
 - Frees the component.
 - [COM Automation advantages](#)
 - [Adapter capabilities](#)
 - [Supported data types](#)
 - [Object persistence](#)
 - [DCOM server considerations](#)
 - [Standard COM Automation terms](#)
-

COM Automation advantages

Implementing the desired service(s) as a COM Automation component has a number of advantages:

- Location transparency - The component can reside anywhere on the network.
 - Language - The user can use any programming language that supports COM Automation (VB, C/C++, Java™, and so on).
 - Runtime selection of services - Simple, well-known tools can specify which component to use (for service upgrades, load balancing, and so on). The map itself need not change.
 - Data types - COM Automation supports a set of well-known data types. See [Supported Data Types](#) for more information.
 - Simple method-based mapping.
-

Adapter capabilities

The following capabilities exist for the COM Automation adapter:

- A card (or **GET** or **PUT** rule) represents all or part of an IDL.
 - Objects created in one card can be used as parameters to methods in subsequent calls. These objects must be created by invoking an operation that returns an object.
 - Reference labels identify objects. Objects that are returned from method calls are assigned a label by the adapter. This label is of the form **Ref.nn**, where **nn** is a number which uniquely identifies the object.
 - The return values of any of the methods can be returned from a **GET** call. The IDL importer provides a mechanism allowing the user to select which methods the return values should be provided for. These return values can be primitive types (for example, **int**), strings, arrays, or local or remote objects. In the case of remote objects, the reference label is returned so that the object can be used in a subsequent call.
 - The adapter provides **GET** and **PUT** methods, which are invoked by the Resource Manager when the adapter is being invoked as an output.
-

Supported data types

COM Automation supports a well-known set of data types such as structures and arrays. The COM Automation adapter supports SAFEARRAY array types. Structures are supported in the preferred form and secondary form.

Other types such as record sets and multidimensional arrays are not supported.

Data Type	Example	Length
VT_I2	32767	Number of characters that make up the number
VT_I4	7729976	Number of characters that make up the number
VT_R4	8822.333	Number of characters that make up the number including decimal point
VT_R8	8822.7776	Number of characters that make up the number including decimal point
VT_DATE	MM/DD/CCYY	10 always
VT_BSTR	A string	Number of characters in the string
VT_ERROR	0x80000001	10 always (must be hex)
VT_BOOL	0, 00, -1	1 or 2 always (2 chars needed for ` -1`)
VT_UI1	X	1 always
VT_VOID	(empty)	0 always
VT_INT	7729976	Number of characters that make up the number
VT_UINT	7729976	Number of characters that make up the number
VT_U12	7729976	Number of characters that make up the number
VT_U14	7729976	Number of characters that make up the number
VT_CARRAY	Not available	Number of elements in an array
VT_USERDEFINED	Ref.123	12 characters maximum

Note: Each of the numerals could include a leading negative (-) sign. All parameter types are variable length.

Object persistence

Object persistence provides the functionality of keeping all object instances in the object pool. This in turn allows multiple cards to access methods of all objects in this pool. This same behavior currently exists in the Java™ Class adapter.

See "[COM Automation Objects](#)" for more information.

DCOM server considerations

Distributed Component Object Model (DCOM) is an extension of the Component Object Model (COM) to support objects distributed across a network.

The DCOM component is created internally using a location context of **CLSCTX_ALL** to permit location transparency. This component can use the location context whether it is an in-process server (a DLL) or local/remote server (an executable). This also permits the use of a DCOM component over a network.

In the case of a DCOM server, the actual component used is determined by the configuration settings made in the Windows NT DCOMCNFG utility.

Standard COM Automation terms

The following table lists standard COM Automation terms and their definitions.

Term	Definition
DISPID	Dispatch ID - Number of characters that make up the number.
ProgID	Program ID - A text string used to identify the component. For example, Nxf.Nxf.1.
CLSID	Class ID - A numeric identifier used to specify a COM component. The class ID's are usually shown within curly braces. For example, {682553C1-20A8-11D2-8711-00A024299A30}.
IDL	Interface Definition Language - A standard syntax for defining objects and interfaces.
CoClass	A creatable object defined in the IDL file. The main interface to the properties and methods exposed by the object.

Troubleshooting

For information about error codes and messages returned by the adapters, see the Return Codes and Error Messages section in the Resource Adapters documentation.

If the COM Automation object returns an exception, which is indicated by the DISP_E_EXCEPTION return code, the exception is handled properly and the values of the EXCEPINFO structure are logged if trace has been enabled.

- [Error code propagation](#)

Error code propagation

There is no dedicated list of adapter specific return codes. Rather, the HRESULT return code from the component is returned.

These codes can be especially useful at map run time if components specify their own particular error codes and you use the **LASTERRORCODE** function to control future map execution based on your return codes.

The error (or warning) code is also sent back to the map as part of the status message in hexadecimal format (for example, **M4COM_DispatchInvoke failed: 0x80020004**). One error code that the adapter itself can return is **E_FAIL**. This indicates an adapter initialization error.

Type Library Importer

The Type Library Importer is accessible through the Importer Wizard. The Importer Wizard is an applet that is run from the Type Designer by selecting Import from the Tree menu.

The Importer Wizard uses a series of maps to convert metadata into a type tree script file (.mts). The Type Tree Maker then processes this type tree script and generates a type tree that contains all the supported types that are defined in the imported metadata.

Many of the type trees that are generated by the Importer Wizard can be immediately used for map development. However, depending on the contents of the interface-specific metadata file, it might be necessary for the generated type tree to be modified using the Type Designer.

Note: You cannot simultaneously have a type tree open in the Type Designer while importing a schema with the same name.

- [Using the Type Library Importer](#)
- [Structures](#)
- [Arrays](#)
- [COM Automation objects](#)

Using the Type Library Importer

The Type Library Importer reads the format of COM Automation Components and Methods to automatically generate type trees for use with the COM Automation Adapter.

To run the Type Library Importer

1. Open the Type Designer application.
2. Select Import a type tree in the Startup window and click Next. Or select Import from the Tree menu at anytime while the Type Designer is running. The Importer Wizard dialog box appears.
3. Select Type Library. Click Next.
The Importer Wizard-Type Library dialog box appears.
4. Select an object from the list or click Browse and select a type library. Click Next.
Note: There will be a number of components that show up in the list that are not compatible with the adapter.
5. Select the desired component and click Next.
6. Select one or more methods from the list and click Next.
Depending on the component and how it is going to be used, you might need to reorder the methods. You can arrange the methods by using a drag-and-drop technique.
7. Enter the destination type tree name in the **File Name** field or click Browse and select a type tree (.mtt) file. Click Next.
Note: If the destination file already exists, it will be overwritten.
8. Click Finish.
9. When prompted, click Yes to open the generated type tree(s). Click No to close the Importer Wizard and return to the Type Designer application.

Structures

Structures are supported in the preferred form as well as the secondary form...

For example:

Preferred Form

```
typedef struct tagTestStruct {  
long lCount;  
float fPortion;  
} TestStruct;  
HRESULT SetWhatever([in] const TestStruct *pX);
```

Secondary Form

```
struct TestStruct {  
long lCount;  
float fPortion;  
}  
HRESULT SetWhatever([in] const struct TestStruct *pX);
```

Structures are presented as an object in the type tree. Access to member fields is only possible through the references to the object pool.

In the map rules, these reference values are indicated by a **Ref.** initiator and the reference number (*nn*) which follows the initiator. The COM Automation adapter uses that initiator to recognize the reference to the object pool and provides functionality for accessing the member fields using that reference.

The following text clarifies structure usage:

- Nested structures (where one of the fields in a structure is in another structure) are supported, and those values are passed as a reference through the **ref** item.
- The use of arrays as fields in the structure is permitted.

For example:

```
typedef struct {  
long lLength;  
float fSum;  
} SimpleStructA;  
typedef struct {  
int iPencils;  
int iPapers;  
} SimpleStructB;  
typedef struct {  
int iAge;  
SimpleStructA simpleStructA;
```

Arrays

Arrays are ordered lists of values that are all of the same type. These values are known as the array's elements. The elements of an array can be any simple type or range type. The SAFEARRAY array type is supported for the COM Automation adapter.

- [SAFEARRAY Arrays](#)

SAFEARRAY Arrays

SAFEARRAY arrays can contain any of the supported simple data types. This type of array is a common way to support arrays in (oleautomation) interfaces.

The number of elements is not known at compile time, however it is known at run time, so they are represented as a group of variable size(s) in the type tree.

In the adapter call of **Invoke** method, an array size is determined according to those attributes.

For example:

```
HRESULT SumOfInts( [in] SAFEARRAY(long) intsToSum, [out] long* sum );
```

COM Automation objects

Apart from scalar types (structures and arrays) the only other objects that can be used as parameters of the interface methods, are the pointers to other interfaces.

This is the only way to access code running in different address spaces because the pointers to C++ classes or pointers to functions are off limits to remote method calls.

The pointers to these objects are stored in the global object pool, and are accessed through the references to them.

The Type Library Importer creates a single item in the type tree for each object used as an `input/output/inout` parameter, and that item contains a reference to the object pool for a given object. That reference is used on the COM Automation adapter side to access the object methods and members, using the global object pool.

Connect:Direct Adapter

The Connect:Direct® adapter integrates IBM® Transformation Extender with IBM Sterling Connect:Direct file transfer.

- [System requirements](#)
- [Configuration requirements](#)
- [Connect:Direct adapter command overview](#)

This table summarizes the adapter commands, syntax, and whether you can use the command with data sources, data targets, or both. You can specify the commands on the adapter command line or through the adapter properties.

System requirements

See the IBM® Transformation Extender [system requirements](#) and the [release notes](#) for Connect:Direct® adapter requirements.

Configuration requirements

To use the Connect:Direct® adapter, you must configure a Sterling Connect:Direct network map (netmap) with a primary node (PNODE) and secondary node (SNODE), and configure users for each node. Verify that you can transfer a file between the Sterling Connect:Direct nodes before you attempt to use the Connect:Direct adapter.

To use the Launcher service on a Microsoft Windows system, run the service as the PNODE user rather than as the local system account.

On Linux® and UNIX systems:

- Set NDMAPICFG environment variable:

```
export NDMAPICFG=/CD_install_dir/ndm/cfg/cliapi/ndmapi.cfg
```

where `CD_install_dir` is the Sterling Connect:Direct installation directory.

- The Sterling Connect:Direct configuration determines whether you must use the Linux or UNIX login credentials instead of the **-PUSER**, **-PPASS**, **-SUSER**, and **-SPASS** commands.

Connect:Direct adapter command overview

This table summarizes the adapter commands, syntax, and whether you can use the command with data sources, data targets, or both. You can specify the commands on the adapter command line or through the adapter properties.

The commands are not case-sensitive, but the command values are case-sensitive. Choices are separated by the OR symbol | . Optional parameters are enclosed in brackets []. The topics that follow provide the command syntax in railroad track format.

Table 1. Connect:Direct adapter command summary

Command	Syntax	Use with Data Source	Use with Data Target
Primary node	{-PNODE -PN} {host_name IP_addr}	Yes	Yes
Primary node user	{-PUSER -PU} user_name	Yes	Yes
Primary node password	{-PPASS -PP} password	Yes	Yes
Secondary node	{-SNODE -SN} {host_name IP_addr}	Yes	Yes
Secondary node user	{-SUSER -SU} user_name	Yes	Yes
Secondary node password	{-SPASS -SP} password	Yes	Yes

Command	Syntax	Use with Data Source	Use with Data Target
File name to GET or PUT	{-FILENAME -F} {filename absolute_path}	Yes	Yes
Connect:Direct® process name	{-PROCNAME -P} process_name	Yes	Yes
File disposition (how to open the file)	{-DISPOSITION -D} {RPL MOD NEW}	Yes	Yes
Binary transfer	{-BINARY -B} {YES NO}	Yes	Yes
Checkpoint to restart interrupted transmissions	{-CKPT -C} size	Yes	Yes
Wait interval	{-WAIT -WI} seconds	Yes	Yes
Directory restriction	{-DIRRESTRICT -DR} directory	Yes	Yes
Create trace file	{-TRACE -T} {file_name}	Yes	Yes
Append trace file	{-TRACE+ -T+} {file_name}	Yes	Yes
Trace adapter errors	{-TRACEERR -TE} {file_name}	Yes	Yes
Append adapter errors	{-TRACEERR+ -TE+} {file_name}	Yes	Yes
Use translation table	{-XLATE -X} {YES NO}	Yes	Yes

- **Command aliases**

Use the **CD** adapter alias to use the Connect:Direct adapter on input and output cards and in GET and PUT map rules.

- **Primary Node (-PNODE) command**

The **-PNODE** command identifies the primary node in a Sterling Connect:Direct connection. The primary node is the server that initiates the connection. A primary node can both send and receive data.

- **Primary node user (-PUSER) command**

The **-PUSER** command identifies the user ID that is configured for the primary node.

- **Primary node password (-PPASS) command**

The **-PPASS** command specifies the password for the primary node.

- **Secondary node (-SNODE) command**

The **-SNODE** command identifies the secondary node in a Sterling Connect:Direct connection. The secondary node is the server that receives the connection. A secondary node can both send and receive data.

- **Secondary node user (-SUSER) command**

The **-SUSER** command identifies the user ID that is configured in Sterling Connect:Direct for the secondary node.

- **Secondary node password (-SPASS) command**

The **-SPASS** command specifies the password for the secondary node.

- **File name (-FILENAME) command**

Specifies the name of the file to **GET** from or **PUT** to the server. This command is required.

- **Process name (-PROCNAME) command**

The **-PROCNAME** command specifies the name of the process for Sterling Connect:Direct to run when the adapter calls Sterling Connect:Direct.

- **File disposition (-DISPOSITION) command**

The **-DISPOSITION** command specifies how to open or write to a file.

- **Binary transfer (-BINARY) command**

The **-BINARY** command specifies whether files are transferred in binary or text mode.

- **Restart checkpoint (-CKPT) command**

The **-CKPT** command specifies the byte interval for checkpoint support, which restarts interrupted transmissions at the last valid checkpoint point and reduces the time to retransmit the file.

- **Wait interval (-WAIT) command**

The **-WAIT** command specifies the number of seconds that Sterling Connect:Direct is to wait for a Sterling Connect:Direct **SUBMIT** process to finish. In addition, the IBM Transformation Extender Connect:Direct listener uses the wait interval as the polling time for the Launcher.

- **Directory restriction (-DIRRESTRICT) command**

The **-DIRRESTRICT** adapter command is required when you configure the Sterling Connect:Direct property to restrict file uploads or downloads to a specified directory.

- **Create trace file (-TRACE) command**

The **-TRACE** command produces a diagnostics file that contains detailed information about adapter activity. The trace file is overwritten each time the trace runs.

- **Append trace file (-TRACE+) command**

The **-TRACE+** appends detailed diagnostic information about adapter activity to an existing trace file.

- **Trace adapter errors (-TRACEERR) command**

The **-TRACEERR** command produces a trace file that contains only the adapter errors that occurred during map execution.

- **Append adapter errors (-TRACEERR+) command**

The **-TRACEERR+** command appends only the adapter errors that occurred during map execution to an existing trace file.

- **Use translation table (-XLATE) command**

The **-XLATE** command specifies whether to use the default Sterling Connect:Direct translation table.

Command aliases

Use the **CD** adapter alias to use the Connect:Direct® adapter on input and output cards and in GET and PUT map rules.

Specify adapter commands by using a command string on the command line or by creating a command file that contains adapter commands. The execution command syntax is:

```
-IA[alias]card_num
-OA[alias]card_num
```

where:

-IA

The Input Source Override execution command

-OA

The Output Target Override execution command

alias

The adapter alias **CD**

card_num
The number of the map card

To override an input card 1:

-IACD1 'adapter_commands'

To override an output card 1:

-OACD1 'adapter_commands'

Primary Node (-PNODE) command

The **-PNODE** command identifies the primary node in a Sterling Connect:Direct® connection. The primary node is the server that initiates the connection. A primary node can both send and receive data.

This command is optional. If you omit this command, the default node is the primary node that is configured in Sterling Connect:Direct.

-PNODE command syntax

host_name
Specifies the host name of the primary node.

IP_addr
Specifies the IP address of the primary node. You can specify an IP address when netmap checking is set to No for the Sterling Connect:Direct PNODE system.

Primary node user (-PUSER) command

The **-PUSER** command identifies the user ID that is configured for the primary node.

Depending on how Sterling Connect:Direct® is configured, this command might be required.

-PUSER command syntax

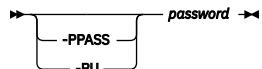

user_ID
The user ID that is configured in Sterling Connect:Direct for the primary node.

Primary node password (-PPASS) command

The **-PPASS** command specifies the password for the primary node.

This command is optional. Depending on how Sterling Connect:Direct® is configured, you might be required to use the Linux® or UNIX login credentials for the Sterling Connect:Direct connection instead of the **-PPASS** command.

-PPASS command syntax

password
See your Sterling Connect:Direct documentation for password requirements.

Secondary node (-SNODE) command

The **-SNODE** command identifies the secondary node in a Sterling Connect:Direct® connection. The secondary node is the server that receives the connection. A secondary node can both send and receive data.

This command is required.

-SNODE command syntax

host_name
Specifies the host name of the secondary node. You can specify an IP address when netmap checking is set to No for the Sterling Connect:Direct SNODE system.

IP_addr
Specifies the IP address of the secondary node.

Secondary node user (-SUSER) command

The **-SUSER** command identifies the user ID that is configured in Sterling Connect:Direct® for the secondary node.

Depending on how Sterling Connect:Direct is configured, this command might be required.

-SUSER command syntax

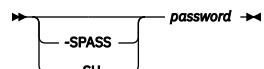

user_ID
The user ID that is configured in Sterling Connect:Direct for the secondary node.

Secondary node password (-SPASS) command

The **-SPASS** command specifies the password for the secondary node.

This command is optional. Depending on how Sterling Connect:Direct® is configured, you might be required to use the Linux® or UNIX login credentials for the Sterling Connect:Direct connection instead of the **-PPASS** command.

-SPASS command syntax

password
See your Sterling Connect:Direct documentation for password requirements.

File name (-FILENAME) command

Specifies the name of the file to **GET** from or **PUT** to the server. This command is required.

-FILENAME command syntax

file_name
Specifies a simple file name to **GET** from or **PUT** to a Sterling Connect:Direct® server. Use the file name only when Sterling Connect:Direct is configured with a directory restriction. Otherwise, use the absolute path to the file.
absolute_path
Specifies the absolute path to a file to **GET** from or **PUT** to a Sterling Connect:Direct server. Use the absolute path when Sterling Connect:Direct is not configured with a directory restriction.

Process name (-PROCNAME) command

The **-PROCNAME** command specifies the name of the process for Sterling Connect:Direct® to run when the adapter calls Sterling Connect:Direct.

This command is required.

-Procname command syntax

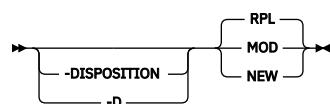

process_name
The name of the Sterling Connect:Direct process that is to run. The Sterling Connect:Direct **Select Statistics** command displays the process names.

File disposition (-DISPOSITION) command

The **-DISPOSITION** command specifies how to open or write to a file.

This command is optional. If you omit it, the default is RPL.

-DISPOSITION command syntax

RPL

Replace the existing file with the current file.

MOD

Add the contents of the current file to the existing file.

NEW

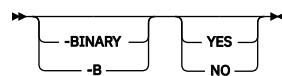

Create the file.

Binary transfer (-BINARY) command

The **-BINARY** command specifies whether files are transferred in binary or text mode.

This command is optional. If you omit it, the adapter does not specify the DATATYPE option On the Sterling Connect:Direct® **SUBMIT** command.

-BINARY command syntax

YES

Use binary file transfer.

NO

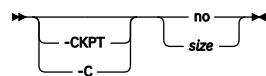

Use text transfer.

Restart checkpoint (-CKPT) command

The **-CKPT** command specifies the byte interval for checkpoint support, which restarts interrupted transmissions at the last valid checkpoint point and reduces the time to retransmit the file.

This command is optional. If you omit it, the default is the value that is specified by the ckpt.interval parameter in the Sterling Connect:Direct® initialization parameters file.

-CKPT command syntax

no

Specifies that no checkpoint is to be taken. See the Sterling Connect:Direct documentation to determine if this keyword is valid for your platform.

size

Specifies the amount data to be transmitted before the transmission is checked for failure.

See the Sterling Connect:Direct documentation for the values that are valid for your platform. Examples of how to specify the size:

100
Specifies 100 bytes.

1K
Specifies 1 KB.

4M
Specifies 4 MB.

1G
Specifies 1 GB.

Wait interval (-WAIT) command

The **-WAIT** command specifies the number of seconds that Sterling Connect:Direct® is to wait for a Sterling Connect:Direct **SUBMIT** process to finish. In addition, the IBM® Transformation Extender Connect:Direct listener uses the wait interval as the polling time for the Launcher.

Coordinate the use of this adapter command with any Sterling Connect:Direct retries that you configure in the Sterling Connect:Direct netmap.cfg file.

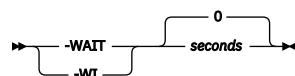

The adapter call fails if the wait interval expires before the **SUBMIT** process finishes.

- On an output card, the IBM Transformation Extender map fails with return code 76: Adapter failed to put data on output. The Sterling Connect:Direct process attempts to complete the copy.
- On an input card, the IBM Transformation Extender map fails with return code 12: Source not available. The Sterling Connect:Direct process attempts to complete the copy.

In each case, the adapter trace file contains the message No successful copy record retrieved from C:D in WAIT time.

This command is optional.

-WAIT command syntax

seconds

The number of seconds that Sterling Connect:Direct is to wait for the **SUBMIT** process to finish.

0

Specifies that Sterling Connect:Direct is to wait for an infinite period of time. This is the default.

When used as a Launcher source event, the **-WAIT** command determines the polling interval. 0 defaults to 10 seconds.

Use this option with caution. It can cause a hang by preventing Sterling Connect:Direct from returning to IBM Transformation Extender. For example, such a hang can occur if the SNODE is not available.

Directory restriction (-DIRRESTRICT) command

The **-DIRRESTRICT** adapter command is required when you configure the Sterling Connect:Direct® property to restrict file uploads or downloads to a specified directory.

This command is required on input cards or GET commands when a directory restriction is configured for the download directory. This command is required on output cards or PUT commands when a directory restriction is configured for the upload directory.

On Microsoft Windows systems, you configure the Sterling Connect:Direct directory restriction property by using the Select window. On Linux® and UNIX systems, you configure the Sterling Connect:Direct directory restriction property in the *C:D_install/ndm/cfg/node_name/userfile.cfg* file.

-DIRRESTRICT command syntax

directory

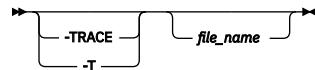

For input cards and GET commands, specifies the download location for the files. For output cards and PUT commands, specifies the upload location for the files.

Create trace file (-TRACE) command

The **-TRACE** command produces a diagnostics file that contains detailed information about adapter activity. The trace file is overwritten each time the trace runs.

This command is optional.

-TRACE command syntax

file_name

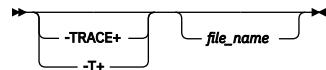

The name and path of the trace file. This parameter is optional. If you omit it, the adapter creates a trace file named m4cd.mtr in the IBM® Transformation Extender map directory.

Append trace file (-TRACE+) command

The **-TRACE+** appends detailed diagnostic information about adapter activity to an existing trace file.

This command is optional.

-TRACE+ command syntax

file_name

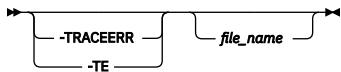

The name and path of the trace file. This parameter is optional. If you omit it, the adapter creates a trace file named m4cd.mtr in the IBM® Transformation Extender map directory.

Trace adapter errors (-TRACEERR) command

The **-TRACEERR** command produces a trace file that contains only the adapter errors that occurred during map execution.

This command is optional.

-TRACEERR command syntax

file_name

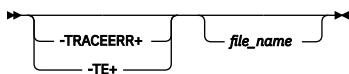

The name and path of the trace file. This parameter is optional. If you omit it, the adapter creates a trace file named m4cd.mtr in the IBM® Transformation Extender map directory.

Append adapter errors (-TRACEERR+) command

The **-TRACEERR+** command appends only the adapter errors that occurred during map execution to an existing trace file.

This command is optional.

-TRACEERR+ command syntax

file_name

The name and path of the trace file. This parameter is optional. If you omit it, the adapter creates a trace file named m4cd.mtr in the IBM® Transformation Extender map directory.

Use translation table (-XLATE) command

The **-XLATE** command specifies whether to use the default Sterling Connect:Direct® translation table.

This command is optional. If you omit it, the adapter does not specify the XLATE option on the **SUBMIT** command.

-XLATE command syntax

YES

Use the default Sterling Connect:Direct translation table.

NO

Do not use the default Sterling Connect:Direct translation table.

DB2 (Windows/UNIX) Adapter overview

Use the DB2® (Windows/UNIX) Adapter to access and manipulate data contained in databases that are DB2 data sources. You can install this adapter on additional systems for remote database connectivity.

Use the adapter with a map in a map rule, or use it with the Command Server, Launcher, or Software Development Kit.

- [System requirements](#)
- [Database columns and types](#)
- [Database Interface Designer settings](#)
- [DB2 \(Windows/UNIX\) Adapter commands](#)
- [Adapter commands for a source](#)
- [Adapter commands for a target](#)
- [Binding values in DBLOOKUP and DBQUERY](#)
- [Bulk copy example files](#)
- [Restrictions and limitations](#)
- [Return codes and error messages](#)

System requirements

The minimum system requirements and operating system requirements for the DB2® (Windows/UNIX) Adapter are detailed in [system requirements](#). See also the [release notes](#). The following tasks are also required:

- Verify that you have installed the DB2 client software.
- Verify that you have configured the DB2 data source or sources. For information about configuring the DB2 data source or sources, see the DB2 documentation.
- Verify that the DB2 environment variables are defined. For information about defining the DB2 environment variables, see your DB2 documentation.
- Set the shared library path environment variable for UNIX.

After installing the adapters on a UNIX platform and running the environment variable setup program (**setup**), add the installation directory to your shared library path environment variable if it is not already there. The following instructions assume your installation directory is defined in the environment variable DTX_HOME_DIR.

Note: After you have initially run the **setup** program, if you make changes to your path and/or library path at a later date, you need to re-run this program.

Note: These instructions assume that your UNIX environment is the Korn (ksh) shell and that the DB2_HOME environment variable points to the DB2 installation directory.

- For HP-UX

```
SHLIB_PATH=$DTX_HOME_DIR/lib:$DB2_HOME/lib:$SHLIB_PATH
export SHLIB_PATH
```

- For Sun Solaris

```
LD_LIBRARY_PATH=$DTX_HOME_DIR/lib:$DB2_HOME/lib:$LD_LIBRARY_PATH
export LD_LIBRARY_PATH
```

- For IBM® RS/6000® AIX®

```
LIBPATH=$DTX_HOME_DIR/lib:$DB2_HOME/lib:$LIBPATH
export LIBPATH
```

Database columns and types

The Database Interface Designer and **mtsmaker** with the Type Tree Maker generate type trees for queries, tables, views, and stored procedures in a DB2® DBMS (Database Management System). Item types will be created in a type tree that represent the data types of the columns of a query, table, view, or stored procedure.

The Database Interface Designer and **mtsmaker** get information about columns by calling DB2 to describe the columns associated with a query, table, view, or stored procedure. DB2 returns the data type, length, and other information to the Database Interface Designer and **mtsmaker**. The Database Interface Designer and **mtsmaker** then map the DB2 data types to types in a type tree.

- [Item type properties](#)
- [Date and Time Formats](#)

Item type properties

The following table lists the DB2® (Windows/UNIX) data types and the values of the item type properties to which they correspond when the type tree is generated.

DB2 Data Type	Interpret as	Item Subclass, Presentation	Length
INTEGER	Character	Number, Integer	11
SMALLINT	Character	Number, Integer	6
FLOAT	Binary	Number, Float	8
REAL	Binary	Number, Float	4
DOUBLE PRECISION	Binary	Number, Float	8
DECIMAL(n) ¹	Character	Number, Integer	*
DECIMAL(n,m) ²	Character	Number, Decimal	*
NUMERIC(n) ¹	Character	Number, Integer	*
NUMERIC(n,m) ²	Character	Number, Decimal	*
CHAR	Character	Text	*
VARCHAR	Character	Text	*
DATE	Character	Date & Time	10
TIME	Character	Date & Time	8
TIMESTAMP	Character	Date & Time	26
GRAPHIC	Binary	Text	*
VARGRAPHIC	Binary	Text	*
BLOB	Binary	Text	*
CLOB	Character	Text	*
DBCLOB	Character	Text	*

¹ $n \geq 1$

² $n \geq 1, m \geq 0$

* The DBMS dictates the length of this type.

Note: The BLOB, CLOB and DBCLOB data types are not supported as parameters for stored procedures.

Date and Time Formats

When using columns defined as date, time or timestamp in DB2® databases, the format for both input and output is:

Column	Format
Date	<code>ccyy-mm-dd</code>
Time	<code>hh:mi:ss</code>
Timestamp	<code>ccyy-mm-dd hh:mi:ss[.fff...]</code>

Formats

Format	Description
cc	two-digit century
yy	two-digit year
mm	two-digit month
dd	two-digit day
hh	two-digit hour
mi	two-digit minute
ss	two-digit second
.fff...	optional fractional seconds
fffff	six-digit fraction of a second
hh24	two-digit hour using a 24-hour day

In the Generate Type Tree from dialog, use the Represent date/time columns as text items check box to define whether to automatically format this information as Date & Time (which is with this check box disabled, the result of which is shown in the Item Subclass, Presentation column) as a text string. When generated as a text string, it might be necessary to use either the TEXTTODATE or TEXTTOTIME function in a map rule to convert the text string to the date and time format required by the database. If you are generating new type trees, it is recommended that you disable this check box.

This Represent date/time columns as text items check box is modal. After it has been disabled, it will remain disabled for all subsequent type tree generations, regardless of source. Therefore, you must be careful in determining this setting.

Database Interface Designer settings

When defining a DB2® (Windows/UNIX) database in the Database Interface Designer, in addition to the common settings available for all of the adapters in the Database Definition dialog, you need to enter information specific to DB2 (Windows/UNIX).

The DB2 (Windows/UNIX) Adapter-specific settings include:

Data Source > Database Interface Designer

The data source you defined in your DB2 (Windows/UNIX) development PC that is used by the Database Interface Designerto access the database information for design-time purposes.

Data Source > Runtime

The data source you defined in your DB2 (Windows/UNIX) database host platform to be used for access to the database for runtime (map execution) purposes both from the Map Designer and Command Server.

Security

- User ID The user ID used to connect to the database.
- Password The authorization password to connect to the DB2 subsystem.
- [Stored procedures native call syntax](#)

Stored procedures native call syntax

A stored procedure can be accessed from within a map by specifying the native call syntax in the following scenarios:

- A query that is specified in an input card.

- The first argument in a DBQUERY or DBLOOKUP function.
This argument does not need to be a literal. The arguments to the stored procedure may be determined at map execution time.
- The SQL Statement adapter command (-**STMT**) in DBQUERY, DBLOOKUP, or GET functions.

For information about using DBLOOKUP or DBQUERY, or for information about using the syntax for device-independent calls to access return values and output adapter commands refer to the Database Interface Designer documentation.

For example, a call to a stored procedure using DB2® in a DBLOOKUP might be:

```
DBLOOKUP ("{call MyAddNameProc(' " + Name:Column + " ',-1)}" ,
"mydb.mdq",
"MyDB")
```

Note: String literals must be contained within single quotation marks; adapter arguments must be separated by commas.

DB2® (Windows/UNIX) Adapter commands

Use the adapter commands when specifying data sources and targets. The applicability of many of the commands depends upon whether you are specifying a source or target, whether a database/query file (.mdq) is used, and the situations in which the usage of the command applies.

Adapter commands can be used in GET->Source->Command or PUT->Target->Command settings in the map designer and Integration Flow Designer, using GET, PUT, DBLOOKUP, or DBQUERY function calls, or overriding a data source or target using execution commands in a **RUN** function or on the command line.

- [Adapter-specific command list](#)

Adapter-specific command list

This documentation lists adapter commands that are DB2-specific database parameters. For a complete listing of all adapter commands, see the Resource Adapters documentation.

- ["Database Adapter Type \(-DBTYPE\)"](#)
- ["Row Count \(-ROWCNT\)"](#)
- ["Data Source \(-SOURCE\)"](#)
- [Database adapter type \(-DBTYPE\) adapter command for DB2 \(Windows/UNIX\)](#)
- [Row count \(-ROWCNT\) adapter command for DB2 \(Windows/UNIX\)](#)
- [Data Source \(-SOURCE\) adapter command for DB2 \(Windows/UNIX\)](#)

Database adapter type (-DBTYPE) adapter command for DB2 (Windows/UNIX)

Use the Database Adapter Type adapter command (-DBTYPE) to specify the database adapter type.

-DBTYPE DB2

Option	Description
DB2®	The database adapter type is DB2 (Windows and UNIX). Note: This command must be specified if the original card is not a database and no database is specified using the Database/Query adapter command (-MDQ) and the Database Name adapter command (-DBNAME).

The database adapter type is DB2 (Windows and UNIX).
Note: This command must be specified if the original card is not a database and no database is specified using the Database/Query adapter command (-MDQ) and the Database Name adapter command (-DBNAME).

Row count (-ROWCNT) adapter command for DB2 (Windows/UNIX)

Use the Row Count adapter command (-ROWCNT) to specify the number of rows to be retrieved per fetch.

-ROWCNT row_count

Option	Description
row_count	The number of rows to be retrieved per fetch. The time to fetch is optimized in accordance with the increase in the number of rows to retrieve. Therefore, a significant performance improvement may be gained by retrieving as many rows as possible in a single fetch.

Note: The number of rows retrieved is limited only by the amount of memory installed on the querying computer.
The default for the number of rows to be retrieved per fetch for the DB2® (Windows/UNIX) Adapter is one row.

Data Source (-SOURCE) adapter command for DB2 (Windows/UNIX)

Use the Data Source adapter command (-SOURCE) to specify the DB2® data source.

-SOURCE datasource

Option

Description

datasource

Specify the DB2 data source.

Adapter commands for a source

This summary shows the syntax of the adapter commands that can be used when defining a data source using an .mdq file or without using one, including both the required and optional adapter commands in the following situations:

- Using the `GET_>Source_>Command` setting in the Map Designer and Integration Flow Designer.
- Overriding a data source using the Input Source Override - Database execution command (`-ID`) using a RUN function or on the command line.
- Using a DBLOOKUP, DBQUERY, or GET function in map or component rules.

Adapter commands for a target

This summary shows the syntax of the adapter commands that can be used when defining a data target using an .mdq file or without using one, including both the required and optional adapter commands in the following situations:

- Using the `PUT_>Target_>Command` setting in the Map Designer and Integration Flow Designer.
- Overriding a data source using the Output Source Override - Database execution command (`-OD`) using a RUN function or on the command line
- Using the PUT function in map or component rules.

Binding values in DBLOOKUP and DBQUERY

When using a DBLOOKUP or DBQUERY function, use the Bind facility to submit similarly constructed SQL statements to the database server so that the statements are syntactically identical. By binding a value to a placeholder in the SQL statement, the actual syntax of the statement can be made static, which may improve performance. For more information about using bind values in database functions, refer to the Database Interface Designer documentation.

- [Limitation when using DB2](#)
- [Specifying the data type](#)

Limitation when using DB2

When binding values using DB2®, a limitation exists because DB2 cannot determine the data type of the column to which the value is being bound at the time the SQL statement executes. Therefore, the data type of the value being passed must be explicitly specified. Because of this DB2 limitation, the DB2 adapter determines the data type of the value according to the following rule:

If the value contains only numeric characters or numeric characters with a decimal point, the value is assumed to be numeric; otherwise, the value is assumed to be text.

This rule provides the expected results in most cases; however, there may be some situations in which the rule may not apply and it may be necessary to specify the exact data type. For example, if the value is a text field consisting solely of numeric characters, the value will be incorrectly interpreted as numeric unless correctly specified.

Specifying the data type

To override the default behavior and to explicitly specify the data type, a data type indicator must precede the bind value. The syntax for this is:

`:bind([T|N], value)`

The following table lists the data type indicators and the relationship between each data type indicator and the DB2® data types.

Data Type Indicator

DB2 Data Type

T or TEXT

Any non-numeric (including DATE, TIME, and TIMESTAMP)

N or NUM or NUMBER

Any numeric (INT, DECIMAL, REAL, and so on)

As an example of specifying a data type, to bind a value that is a text data type containing only digits to a statement, the SQL statement would be entered as:

```
DBLOOKUP ("Select * from Checks where CheckNumber=:bind([TEXT], " +
CheckNumber:Row "+")",
"DB.mdq",
"MyDB")
```

If the [TEXT] data type indicator is not specified, the trace file from the adapter displays the following error message:

```
Message: [IBM] [CLI Driver] [DB2/NT]SQL0301N
The value of a host variable in the EXECUTE or OPEN
```

statement cannot be used because of its data type.
SQLSTATE=07006.

Bulk copy example files

The bulk copy function transfers data between a table and an operation system file at high speeds. It is the most common way to load large amounts of data into a database table.

It is frequently used to transfer data between database vendors, spreadsheet applications, and servers.

The example files are located at *install_dir\examples\adapters\db2*.

Restrictions and limitations

The Database Interface Designer and adapters offer options and functions for accessing and manipulating data contained within a database. However, the following limitations exist:

- Database triggers are not supported. You cannot use a data source as an input event trigger for the Launcher.
- The BLOB, CLOB and DBCLOB data types are not supported as parameters for stored procedures.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages may also be recorded as specified in the audit logs, trace files, execution summary files, and so on.

For information about error codes and messages returned by database-specific adapters, refer to the Resource Adapters documentation.

Various troubleshooting tools are available in case you encounter problems while using the database adapters. For example, if you attempt to run a map that uses the adapter and encounter problems or do not receive the expected results, use the following adapter troubleshooting tools:

- adapter audit log (.log)
- adapter trace file (.mtr)

DB2 (z/OS ODBC) Adapter overview

Use the DB2® adapter for z/OS® (ODBC) for all z/OS environments except CICS®. You can use the adapter with a Command Server, the Platform API, or in a map rule. (For CICS, use the DB2 (z/OS) adapter and see the DB2 (z/OS) Adapter documentation for specific information.) It is recommended that you use the DB2 (z/OS ODBC) Adapter because it is more consistent with the behavior of other platforms, increasing the ease with which maps can be tested on other platforms.

This adapter also eases maintainability by eliminating the need to bind an IBM® Transformation Extender-specific plan each time a new release or maintenance is applied. You can also install these adapters on additional systems for remote database connectivity.

If you plan to only use mtsmaker without an .mdq file to create each type tree, you do not need to use the Database Interface Designer. However, you will still need to use the Database Interface Designer to create maps on the workstation. For information about using mtsmaker, see the Resource Adapters documentation.

The DB2 (z/OS ODBC) Adapter is available for the z/OS operating system with DB2.

- [Using tdfmaker to define update keys](#)
- [Using mtsmaker on z/OS](#)
- [DB2 \(z/OS ODBC\) Adapter limitations](#)
- [Return codes and error messages](#)

System requirements

The minimum system requirements and operating system requirements for the DB2® (z/OS® ODBC) Adapter are detailed in the [system requirements](#). See also the [release notes](#). In addition to these requirements, to install and run the DB2 (z/OS ODBC) Adapter:

- Verify that you have installed the Language Environment/370 runtime library. The adapter is compatible with all supported releases of LE/370.
- Verify that the Command Servers for both Batch and CICS® have been installed prior to using the adapters. For more information, see the Command Server documentation.
- Verify that the DB2 (z/OS ODBC) interface has been installed and the IBM-supplied plans for ODBC have been bound.

Database columns and types

The Database Interface Designer and **mtsmaker** with the Type Tree Maker generate type trees for queries, tables, and views in a DB2-compliant Database Management System (DBMS). Item types are created in a type tree that represents the data types of the columns of a query, table, or view.

The Database Interface Designer and **mtsmaker** get information about columns by calling DB2® to describe the columns associated with a query, table, or view. DB2 returns the data type, length, and other information to the Database Interface Designer and **mtsmaker**. The Database Interface Designer and **mtsmaker** then map the DB2 data types to types in a type tree.

- [How DB2 data types convert to item types in a type tree](#)
- [Date and time formats](#)

How DB2 data types convert to item types in a type tree

The following table lists the DB2® (z/OS® ODBC) data types and the values of the item type properties to which they correspond when a type tree is generated by the Database Interface Designer and mtsmaker. An asterisk (*) in the Length column indicates that the DBMS dictates the length of this type.

DB2 (z/OS ODBC) Data Type	Interpret as	Item Subclass, Presentation	Length
SQL_VARCHAR	Character	Text	*
SQL_CHAR	Character	Text	*
SQL_DECIMAL	Character	Number, Decimal	17
SQL_NUMERIC	Character	Number, Decimal	17
SQL_SMALLINT	Character	Number, Integer	6
SQL_INTEGER	Character	Number, Integer	11
SQL_REAL	Binary	Number, Float	4
SQL_FLOAT	Binary	Number, Float	8
SQL_DOUBLE	Binary	Number, Float	8
SQL_LONGVARCHAR	Character	Text	*
SQL_BIT	Character	Number, Integer	*
SQL_TINYINT	Character	Number, Integer	4
SQL_BIGINT	Character	Number, Integer	20
SQL_BINARY	Binary	Text	*
SQL_VARBINARY	Binary	Text	*
SQL_LONGVARBINARY	Binary	Text	*
SQL_DATE	Character	Date & Time	10
SQL_TIME	Character	Date & Time	8
SQL_TIMESTAMP	Character	Date & Time	19-26
SQL_INTERVAL_HOUR	Character	Text	*
SQL_INTERVAL_MINUTE	Character	Text	*
SQL_INTERVAL_SECOND	Character	Text	*
SQL_INTERVAL_YEAR_TO_MONTH	Character	Text	*
SQL_INTERVAL_DAY_TO_HOUR	Character	Text	*
SQL_INTERVAL_DAY_TO_MINUTE	Character	Text	*
SQL_INTERVAL_DAY_TO_SECOND	Character	Text	*
SQL_INTERVAL_HOUR_TO_MINUTE	Character	Text	*
SQL_INTERVAL_HOUR_TO_SECOND	Character	Text	*
SQL_INTERVAL_MINUTE_TO_SECOND	Character	Text	*
SQL_BLOB	Binary	Text	*
SQL_CLOB	Character	Text	*
SQL_DBCLOB	Character	Text	*

Note: The SQL_BLOB, SQL_CLOB and SQL_DBCLOB data types are not supported as parameters for stored procedures.

Date and time formats

When using columns defined as dates and times in DB2® (z/OS® ODBC) databases, use these formats:

Column	Format
Date	ccyy-mm-dd
Time	hh:mm:ss
Timestamp	ccyy-mm-dd hh:mm:ss[.fff...]

Formats

Format	Description
cc	two-digit century
yy	two-digit year
mm	two-digit month
dd	two-digit day
hh	two-digit hour
mi	two-digit minute
ss	two-digit second
.fff...	optional fractional seconds
ffffff	six-digit fraction of a second
hh24	two-digit hour using a 24-hour day

If the group format is fixed, the field is padded to 26 with trailing spaces.

Example:

2001-08-27 00:00:00 specifies August 27, 2001.

In the Generate Type Tree from dialog, use the Represent date/time columns as text items check box to define whether to automatically format this information as Date & Time (which is with this check box disabled, the result of which is shown in the Item Subclass, Presentation column) as a text string. When generated as a text string, it might be necessary to use either the TEXTTODATE or TEXTTOTIME function in a map rule to convert the text string to the date and time format required by the database. If you are generating new type trees, it is recommended that you disable this check box.

This Represent date/time columns as text items check box is modal. After it has been disabled, it will remain disabled for all subsequent type tree generations, regardless of source. Therefore, you must be careful in determining this setting.

Database Interface Designer settings

When defining a DB2® (z/OS® ODBC) database in the Database Interface Designer, in addition to the common settings available for all of the adapters in the Database Definition dialog, you need to enter information specific to DB2 (z/OS ODBC).

DB2 (z/OS ODBC) Adapter-specific settings include:

- **Data Source > Database Interface Designer**
The data source you defined in your development PC that is used by the Database Interface Designer to access the database information for design-time purposes.
 - **Data Source > Runtime**
The data source you defined in your ODBC database host platform to be used for access to the database for runtime (map execution) purposes both from the Map Designer and a Command Server.
 - **Security**
 - The user ID used to connect to the database.
 - The authorization password to connect to the DB2 subsystem.
- The IBM® DB2 implementation ignores the Security setting values. For more information, see the appropriate IBM documentation for the call-level interface.

Note: To see all common settings, see the Database Interface Designer documentation.

DB2 (z/OS® ODBC) Adapter commands

Use the adapter commands when specifying data sources and targets. The applicability of many of the commands depends upon whether you are specifying a source or target, whether a database/query file (.mdq) is used, and the situations in which the usage of the command applies.

Adapter commands can be used in GET > Source > Command or PUT > Target > Command settings in the Map Designer and Integration Flow Designer, using GET, PUT, DBLOOKUP, or DBQUERY function calls, or overriding a data source or target using execution commands in a RUN function or on the command line.

If connectivity to the mainframe-based DB2® is available, you can:

- View DB2 host database table names directly from Database Interface Designer
- Build type trees for DB2 host tables without using MTSMAKER
- Test maps on your workstation
- [**DB2 \(z/OS ODBC\) Adapter-specific commands**](#)
- [**Database Adapter Type \(-DBTYPE\) adapter command**](#)
- [**Row count \(-ROWCNT\) adapter command for DB2 \(z/OS ODBC\)**](#)
- [**Data Source \(-SOURCE\) adapter command**](#)

DB2® (z/OS® ODBC) Adapter-specific commands

This documentation lists adapter commands that are DB2-specific database parameters. For a complete listing of all adapter commands, see the Resource Adapters documentation.

Database Adapter Type (-DBTYPE) adapter command

Use the Database Adapter Type adapter command (-DBTYPE) to specify the database adapter type.

-DBTYPE ODBC

Option

Description

ODBC

The database adapter type is ODBC. In order to use the ODBC database adapter type, your systems programmer (DBA) must bind the ODBC default package and plans. For more information, see the topic regarding default plans and packages in the *IBM® DB2 Universal Database for z/OS®:ODBC Guide and Reference*.

Row count (-ROWCNT) adapter command for DB2 (z/OS ODBC)

Use the Row Count adapter command (-ROWCNT) to specify the number of rows to be retrieved per fetch.

-ROWCNT row_count

Option

Description

row_count

The number of rows to be retrieved per fetch. The time to fetch is optimized in accordance with the increase in the number of rows to retrieve. Therefore, a significant performance improvement may be gained by retrieving as many rows as possible in a single fetch.

The default for the number of rows to be retrieved per fetch for the DB2® (z/OS® ODBC) Adapter is one row.

Data Source (-SOURCE) adapter command

Use the Data Source adapter command (-SOURCE) to specify the ODBC data source or the data source for an .mdq file. Use this command only when using a non-default (alternate) plan. For more information, see the topic regarding default plans and packages in the *IBM® DB2 Universal Database for z/OS®:ODBC Guide and Reference*.

-SOURCE datasource

Option

Description

datasource

The ODBC data source.

Adapter commands for a source

This summary shows the syntax of the adapter commands that can be used when defining a data source using an .mdq file or without using one, including both the required and optional adapter commands in the following situations:

- Using the GET...Source...Command setting in the Map Designer and Integration Flow Designer.
- Overriding a data source using the Input Source Override - Database execution command (-ID) using a RUN function or on the command line.
- Using a DBLOOKUP, DBQUERY, or GET function in map or component rules.
- [GET > Source > Command setting](#)
- [Database execution command: input source override \(-ID\)](#)
- [DBLOOKUP and DBQUERY functions](#)
- [GET function](#)

GET > Source > Command setting

In an input card, when you specify Database as the value for the GET...Source setting, the Command field is displayed where you can enter adapter commands.

Database command options when there is a database/query file

[-DBTYPE ODBC]
[-SOURCE datasource]
[-STMT SQL_statement]
[-FILE [directory]]

```

[-VAR name=value...]
[-USER user_ID]
[-PASSWORD password]
[-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]]

```

Database command options when there is not a database/query file

```

-DBTYPE ODBC
-STMT SQL_statement
[-SOURCE datasource]
[-FILE [directory]]
[-VAR name=value...]
[-USER user_ID]
[-PASSWORD password]
[-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]]

```

Database execution command: input source override (-ID)

Use the Input Source Override - Database execution command (-ID) to designate a database as the source or you can override one or more of the adapter command settings or database definitions in a RUN function or on the command line.

When you are not using a database/query file (.mdq), the -SOURCE and -STMT commands are mandatory unless there is a default data source specified for DB2® ODBC. For detailed information about DB2 ODBC, see the DB2 Universal Database for z/OS®: ODBC documentation.

The adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

Scenario: compiled map source is a database

Database/query file (.mdq)	No database/query file (.mdq)
'[-MDQ mdq_file -DBNAME database_name] [-QUERY query_name -STMT SQL_stmt] [-FILE [directory]] [-VAR name=value..] [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-ROWCNT row_count] [-AUDIT[G] [+ [full_path]]] [{-TRACE -TRACEERR} [+ [full_path]]]'	'-DBTYPE ODBC -STMT SQL_statement [-SOURCE datasource] [-FILE [directory]] [-VAR name=value...] [-USER user_ID] [-PASSWORD password] [-CCARD -CSTMT [number]] [-ROWCNT row_count] [-AUDIT[G] [+ [full_path]]] [{-TRACE -TRACEERR} [+ [full_path]]]'

Scenario: compiled map source is not a database

Database/query file (.mdq)	No database/query file (.mdq)
'-MDQ mdq_file -DBNAME database_name -QUERY query_name -STMT SQL_stmt [-FILE [directory]] [-VAR name=value..] [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-ROWCNT row_count] [-AUDIT[G] [+ [full_path]]] [{-TRACE -TRACEERR} [+ [full_path]]]'	'-DBTYPE ODBC -STMT SQL_statement [-SOURCE datasource] [-FILE [directory]] [-USER user_ID] [-PASSWORD password] [-CCARD -CSTMT [number]] [-ROWCNT row_count] [-AUDIT[G] [+ [full_path]]] [{-TRACE -TRACEERR} [+ [full_path]]]'

DBLOOKUP and DBQUERY functions

The DBLOOKUP and DBQUERY functions can be used in component rules in the Type Designer and map rules in the Map Designer when creating a map that can be used with a database.

Using DBLOOKUP with a database/query file

```

DBLOOKUP ("SQL_statement",
"-MDQ mdq_file
-DBNAME database_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]]
[{-TRACE|-TRACEERR} [+| [full_path]]]")

```

Using DBQUERY without a database/query file

```
DBQUERY ("SQL_statement",
"-DBTYPE ODBC
[-SOURCE datasource]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]]"
```

GET function

The GET function returns the data from the source adapter.

When you are not using a database/query file (.mdq), the -SOURCE and -STMT commands are mandatory unless there is a default data source specified for DB2® ODBC. For detailed information about DB2 ODBC, see the DB2 Universal Database for z/OS®: ODBC documentation.

Using GET with a database/query file

```
GET ("DB",
"-MDQ mdq_file
-DBNAME database_name
-QUERY query_name|-STMT SQL_stmt
[-FILE [directory]]
[-VAR name=value...]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]]"
```

Using GET without a database/query file

```
GET "DB",
"-DBTYPE ODBC
-STMT SQL_stmt
[-SOURCE datasource]
[-FILE [directory]]
[-USER username]
[-PASSWORD password]
[-ROWCNT row_count]
[-CCARD|-CSTMT [number]]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]]"
```

Adapter commands for a target

This summary shows the syntax of the adapter commands that can be used when defining a data target using an .mdq file or without using one, including both the required and optional adapter commands in the following situations:

- Using the [PUT > Target > Command setting](#) in the Map Designer and Integration Flow Designer.
- Overriding a data source using the Output Source Override - Database execution command (-OD) using a RUN function or on the command line
- Using the PUT function in map or component rules.
- [PUT > Target > Command setting](#)
- [Database execution command: output source override \(-OD\)](#)
- [PUT function](#)

PUT > Target > Command setting

In an output card, when you specify Database as the value for the PUT > Target setting, the Command field is displayed so that you can enter adapter commands.

Database command options when there is a database/query file

```
[-DBTYPE ODBC]
[-SOURCE datasource]
[-PROC procedure_name|-TABLE table_name]
[-USER user_ID]
[-PASSWORD password]
[-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+| full_path]
```

```

[-AUDIT[G] [+]
 [full_path]
[{-TRACE|-TRACEERR} [+]
 [full_path]]]
```

Database command options when there is no database/query file

```

-DBTYPE ODBC
-PROC procedure_name|-TABLE table_name
[-SOURCE datasource]
[-USER user_ID]
[-PASSWORD password]
[-CSTMT [number]]
[-DELETE]
[-BADDATA[+] full_path]
[-AUDIT[G] [+]
 [full_path]]
[{-TRACE|-TRACEERR} [+]
 [full_path]]]
```

Database execution command: output source override (-OD)

Use the Output Source Override - Database execution command (-OD) to designate a database as a target or you can override one or more of the adapter command settings or database definitions in a RUN function or on the command line.

The adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

Scenario: compiled map target is a database

Database/query file (.mdq)	No database/query file (.mdq)
' [-MDQ mdq_file -DBNAME database_name] [-PROC procedure_name -TABLE table_name] [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [-BADDATA[+] full_path] [-AUDIT[G] [+] [full_path]] [{-TRACE -TRACEERR} [+] [full_path]]'	' -DBTYPE ODBC -PROC procedure_name -TABLE table_name [-SOURCE datasource] [-USER user_ID] [-PASSWORD password] [-CCARD -CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [-BADDATA[+] full_path] [-AUDIT[G] [+] [full_path]] [{-TRACE -TRACEERR} [+] [full_path]]'

Scenario: compiled map target is not a database

Database/query file (.mdq)	No database/query file (.mdq)
' -MDQ mdq_file -DBNAME database_name -PROC procedure_name -TABLE table_name [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [-BADDATA[+] full_path] [-AUDIT[G] [+] [full_path]] [{-TRACE -TRACEERR} [+] [full_path]]'	' -DBTYPE ODBC -PROC procedure_name -TABLE table_name [-SOURCE datasource] [-USER user_ID] [-PASSWORD password] [-CCARD -CSTMT [number]] [-DELETE] [-BADDATA[+] full_path] [-AUDIT[G] [+] [full_path]] [{-TRACE -TRACEERR} [+] [full_path]]'

PUT function

Use the PUT function to pass data to the target adapter.

The -SOURCE and -PROC|-TABLE commands when used **Without Database/Query File** are mandatory unless there is a default data source specified for DB2® ODBC. For detailed information on DB2 ODBC, see the DB2 Universal Database for z/OS®: ODBC documentation.

Using PUT with a database/query file

```

PUT ("DB",
"-MDQ mdq_file
-DBNAME database_name
-PROC procedure_name|-TABLE table_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G] [+]
 [full_path]]
[{-TRACE|-TRACEERR} [+]
 [full_path]]")
```

Using PUT without a database/query file

```

PUT "DB",
"-DBTYPE ODBC
-PROC procedure_name|-TABLE table_name
[-SOURCE datasource]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]]")

```

Using tdfmaker to define update keys

To insert the data produced by a mapping operation as new rows into a database table or to update only specific columns, you need to define the key columns and the columns to update. If you have access to your DB2® database through ODBC, use the Database Interface Designer to designate certain columns in a database as key columns in a table. For information about defining update key columns using the Database Interface Designer, see the Database Interface Designer documentation. If you do not have ODBC connectivity to your DB2 database, use the tdfmaker installed on your z/OS® system during the installation of the adapters for DB2.

When you run tdfmaker on your z/OS system, tdfmaker interrogates all of the tables in the library or each specified table name. It derives a listing of the column names defined in the tables and then outputs this information to a table definition file (.tdf).

After tdfmaker completes, transfer the table definition file in TEXT mode to your development PC, specifying the file name extension as .tdf. Then use the Database Interface Designer to process the .tdf so that you can specify update keys. Because you do not have ODBC connectivity when using the Database Interface Designer, when you select Set Update Keys from the Database menu, you are prompted for the name of the .tdf.

- [Using tdfmaker on z/OS](#)

Using tdfmaker on z/OS

When executing tdfmaker on z/OS®, the following adapter commands are required in your JCL (Job Control Language):

- The first adapter command is the DDNAME that identifies the output file.
- The -D adapter command identifies the DB2® subsystem.
- [Sample tdfmaker.JCL file](#)

Sample tdfmaker.JCL file

The following is sample JCL for using tdfmaker:

```

//TDFMAKER EXEC PGM=TDFMAKER,PARM='`-@PARMS'
//-----*
//** Load library containing TDFMAKER and DBUTIL
//**-----*
//STEPLIB DD DSN=<load_library>,DISP=SHR
//-----*
//** Print datasets
//**-----*
//SYSPRINT DD SYSOUT=<sysout_class>
//SYSOUT DD SYSOUT=<sysout_class>
//SYSUDUMP DD DUMMY
//-----*
//** The output TDF file. This must be a variable format file. *
//** Maximum record length is optional; 255 is sufficiently   *
//** large while not being too large to allow viewing in ISPF. *
//**-----*
//OUTPUT DD DSN=<tdf_file>,
//          DISP=(NEW,CATLG,DELETE),
//          DCB=(LRECL=255,RECFM=VB),
//          UNIT=<unit_adapter command>,
//          SPACE=<space_allocation>
//**-----*
//** The -@ option allows TDFMAKER parms optionally to reside  *
//** in a file                                              *
//**-----*
//PARMS DD *
OUTPUT
-D <DB2_subsystem_name>
<table_name>
<table_name>
...
/*
```

Using mtsmaker on z/OS

When using the adapters for DB2® on z/OS®, use mtsmaker to assist with generating a type tree for a query, table, or view when you do not have connectivity between the Database Interface Designer and your database. Note the following when using mtsmaker on z/OS:

- When you use `mtsmaker` and do not specify all required adapter commands, you are not prompted for this information. If an adapter command is missing or incorrect, the program reports this fact and stops running.
 - Typing `-H` or `?` on the command line does not access help for the parameters.
 - You can use a database/query file (`.mdq`) that was created with the Database Interface Designer in your z/OS environment by transferring it, in TEXT mode, to the system hosting your database. Transfer all `.mdq` files and tree script files (`.mts`) in TEXT mode. For example, the following settings are used: ASCII/EBCDIC translation and carriage-return/line-feed delimiters. Use the ASCII and CRLF options of the IND\$FILE transfer program or the ASCII option of FTP.
 - Wherever a file name is coded, it must refer to a DDNAME, never to a dataset name.

• [**mtsmaker parameters for z/OS**](#)

- mtsmaker parameters for z/OS

mtsmaker parameters for z/OS

The following are the additional mtsmaker parameters that are applicable only when used on z/OS®.

Adapter command

Description

-D subsystem_name
Required command when using mtsmaker without a database/query file (.mdq). Used to identify a z/OS DB2® data source. This name should refer to the name of the DB2 subsystem you intend to use.

the DB2 subsystem
Application plan name

The `-i` command is obsolete and is no longer required.

The -L command

The **PRNAME** of a file containing commands that is used (that is, the file) instead of the PARM statement.

- Sample JCL files for mtssmaker on z/OS

Sample JCL files for mtssmaker on z/OS®

The following is sample JCL for using mtsmaker with an .mdq file:

```
//MTSMAKER EXEC PGM=MTSMAKER,
// PARM=-Q <query_name> -M MDQFILE -F <query_name>.MTT -O OUTPUT
//*
//** Load library containing MTSMAKER and DBUTIL *
//*
//STEPLIB DD DSN=<load_library>,DISP=SHR
//*
//** Print datasets *
//*
//SYSPRINT DD SYSOUT=<sysout_class>
//SYSOUT DD SYSOUT=<sysout_class>
//SYSUDUMP DD DUMMY
//*
//** The MDQ file
//*
//MDQFILE DD DSN=<mdq_file>,DISP=SHR
//*
//** The output MTS file. This must be a variable format file.
//** Maximum record length is optional; 255 is sufficiently *
//** large while not being too large to allow viewing in ISPF. *
//*
//OUTPUT DD DSN=<mts_file>,
//          DISP=(NEW,CATLG,DELETE),
//          DCB=(LRECL=255,RECFM=VB),
//          UNIT=<unit_adapter_command>,
//          SPACE=<space_allocation>
```

The following is sample JCL for using mtmaker without an .mdq file:

```
/*MTSMAKER EXEC PGM=MTSMAKER,PARM='`-@PARMS'  
/*  
/*  Load library containing MTSMAKER and DBUTIL *  
/*  
//STEPLIB DD DSN=<load_library>,DISP=SHR  
/*  
/*  Print datasets *  
/*  
//SYSPRINT DD SYSOUT=<sysout_class>  
//SYSOUT DD SYSOUT=<sysout_class>  
//SYSUDUMP DD DUMMY  
/*  
/* The output MTS file. Can be a member of a PDS as long as  
/* the format is variable.  
/*  
//OUTPUT DD DSN=<mts_library>(<member_name>),DISP=SHR  
/*  
/* The -@ option allows MTSMAKER parms to reside in a file  
/*  
//PARMS DD *  
-T <table_name>  
-D <DB2 subsystem name>
```

```
-F <table>.MTT -O OUTPUT  
/*
```

DB2® (z/OS® ODBC) Adapter limitations

The Database Interface Designer and adapters offer options and functions for accessing and manipulating data contained within a database. However, there are some restrictions and limitations of certain functions:

- **Stored Procedures**

Using stored procedures to access adapter commands and return values from stored functions is not supported.

- **Bind Facility**

Using bind values in database functions is not supported.

- **Database Triggers**

Using a data source as an input event trigger for the Launcher is not supported.

The SQL_BLOB, SQL_CLOB and SQL_DBCLOB data types are not supported as parameters for stored procedures.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages can also be recorded as specified in the audit logs, trace files, execution summary files, and so forth.

For information about error codes and messages returned by database-specific adapters, see the Resource Adapters documentation.

Various troubleshooting tools are available in case you encounter problems while using the database adapters. For example, if you attempt to run a map that uses the adapter and encounter problems or do not receive the expected results, use the following adapter troubleshooting tools:

- adapter audit log (.log)
- adapter trace file (.mtr)

DB2 (z/OS) Adapter overview

Use the DB2® (z/OS®) Adapter to access and manipulate data contained in databases that are DB2 data sources in the CICS® and IMS environment. For all other z/OS environments, use the DB2 (z/OS ODBC) adapter. For more information about the DB2 (z/OS ODBC) adapter, see the DB2 (z/OS ODBC) documentation. You can install adapters on additional systems for remote database connectivity.

You can use the DB2 (z/OS) Adapter with a Command Server, the Software Development Kit, or with a map in a map rule.

If you plan to only use **mtsmaker** without an .mdq file to create each type tree, you do not need to use the Database Interface Designer. However, you will still need to use the Database Interface Designer to create maps on the workstation. For information about using **mtsmaker**, see the Resource Adapters documentation.

- [System requirements](#)
- [Binding the application plan](#)
- [Database columns and types](#)
- [Database Interface Designer settings](#)
- [DB2 \(z/OS\) Adapter commands](#)
- [DB2 \(z/OS\) Adapter limitations](#)
- [Return codes and error messages](#)

System requirements

Before installing and running the DB2® (z/OS®) Adapter, verify that you have installed the Language Environment® (LE) runtime library. The DB2 (z/OS) Adapter is compatible with all supported releases of LE.

For more information, see the Command Server documentation.

Binding the application plan

Ensure that the application plan for the adapter you intend to use has been bound. For DB2® (z/OS® ODBC), these plans are supplied by IBM®. If you want to use the native DB2 adapter, the DBUTILE plan must be bound as described in the IBM Transformation Extender z/OS Configuration documentation.

Database columns and types

The Database Interface Designer and **mtsmaker** with the Type Tree Maker generate type trees for queries, tables, and views in a DB2-compliant Database Management System (DBMS). Item types are created in a type tree that represents the data types of the columns of a query, table, or view.

The Database Interface Designer and **mtsmaker** get information about columns by calling DB2® to describe the columns associated with a query, table, or view. DB2 returns the data type, length, and other information to the Database Interface Designer and **mtsmaker**. The Database Interface Designer and **mtsmaker** then map the DB2 data types to types in a type tree.

- [Item type properties](#)
- [Date and time formats](#)

Database Interface Designer settings

When you define a DB2® (z/OS®) database in the Database Interface Designer, in addition to the common settings available for all of the database-specific adapters in the Database Definition dialog, you need to enter information specific to DB2 (z/OS).

DB2 (z/OS) Adapter-specific settings include:

- **DB2 > Plan name**
This is the name used to bind the plan when the IBM® Transformation Extender products were installed.
- **DB2 > Subsystem name**
This is the name used to specify the DB2 subsystem.
- **Have access to DB2 through ODBC**
This check box determines whether you will access your DB2 database through ODBC and Client Access for Windows.
If you do have ODBC access, the remaining fields must be assigned values.
- **ODBC Definition > Data source**
This is the data source you defined in your development computer that is used by the Database Interface Designer to access the database information for design-time purposes.
- **Security > User ID**
This is the user ID to connect to the DB2 subsystem.
This field is used by the Database Interface Designer only. It is ignored when the map is run on z/OS.
- **Security > Password**
This is the authorization password to connect to the DB2 subsystem.
This field is used by the Database Interface Designer only. It is ignored when the map is run on z/OS.

DB2 (z/OS®) Adapter commands

Use the adapter commands when specifying data sources and targets. The applicability of many of the commands depends upon whether you are specifying a source or target, whether a database/query file (.mdq) is used, and the situations in which the usage of the command applies.

Adapter commands can be used in GET > Source > Command or PUT > Target > Command settings in the Map Designer and Integration Flow Designer, using GET, PUT, DBLOOKUP, or DBQUERY function calls, or overriding a data source or target using execution commands in a RUN function or on the command line.

If connectivity to the mainframe-based DB2® is available, you can:

- View DB2 host database table names directly from Database Interface Designer
- Build type trees for DB2 host tables without using MTSMAKER
- Test maps on your workstation
- [DB2 \(z/OS\) Adapter-specific commands](#)
- [Database adapter type adapter command for DB2 \(z/OS\)](#)
- [Database/query file adapter command for DB2 \(z/OS\)](#)
- [DB2 \(z/OS\) Adapter source commands](#)
- [DB2 \(z/OS\) Adapter commands for a target](#)

DB2 (z/OS) Adapter-specific commands

The following section lists and describes those adapter commands that are DB2-specific database parameters. For a complete listing of all database-specific adapter commands, see the DB2® (z/OS®) Adapter.

- [Database Adapter Type \(-DBTYPE\)](#)
- [Database/Query File \(-MDQ\)](#)

Database adapter type adapter command for DB2® (z/OS)

Use the Database Adapter Type adapter command (-DBTYPE) to specify the database adapter type.

-DBTYPE {DB2MVS | ODBC}

Option

Description

DB2MVS

The database adapter type is z/OS® and you must specify an **.mdq** file.

This must be specified if the original card is not a database and no database is specified using the Database/Query adapter command (**-MDQ**) and the Database Name adapter command (**-DBNAME**).

ODBC

The database adapter type is ODBC. In order to use the ODBC database adapter type, your systems programmer (DBA) must bind the ODBC default package and plans. For more information, see the topic regarding default plans and packages in the *IBM® ODBC* documentation.

Database/query file adapter command for DB2® (z/OS®)

Use the **-MDQ** command to specify the DDNAME that identifies the .mdq file.

-MDQ DDNAME

Option**Description****DDNAME**

Specify the DDNAME that identifies the .mdq file.

DB2® (z/OS®) Adapter source commands

This summary shows the syntax of the adapter commands that can be used when defining a data source using an .mdq file or without using one, including both the required and optional adapter commands in the following situations:

- Using the **GET > Source > Command** setting in the Map Designer and Integration Flow Designer.
- Overriding a data source using the Input Source Override - Database execution command (**-ID**) using a RUN function or on the command line.
- Using a DBLOOKUP, DBQUERY, or GET function in map or component rules.
- [GET > source > command for DB2 \(z/OS\) Adapter](#)
- [DB2 \(z/OS\) Adapter database execution command \(input source override\)](#)
- [DBLOOKUP or DBQUERY functions](#)
- [GET function](#)

GET > source > command for DB2® (z/OS®) Adapter

Use the Map Designer or Integration Flow Designer to specify Database as the value for the **GET > Source** setting and enter the database-specific adapter commands as desired for the **Command** setting.

Database command options when there is a database/query file:

```
'' [-DBTYPE DB2MVS]
[-SOURCE datasource]
[-STMT SQL_statement]
[-VAR name=value...]
[-CSTMT [number]]
[{-TRACE [file|ERROR]}]'''
```

Database command options when there is no database/query file:

```
'' -DBTYPE ODBC
-STMT SQL_statement
[-SOURCE datasource]
[-VAR name=value...]
[-CSTMT [number]]
[{-TRACE [file|ERROR]}]'''
```

DB2® (z/OS®) Adapter database execution command (input source override)

Use the Input Source Override - Database execution command (**-ID**) to designate a database as the source or you can override one or more of the adapter command settings or database definitions in a RUN function or on the command line.

The adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

Scenario: compiled map source is a database

Database/query file (.mdq)

No database/query file (.mdq)

Database/query file (.mdq)	No database/query file (.mdq)
'-MDQ DDNAME -DBNAME database_name [-QUERY query_name -STMT SQL_stmt] [-VAR name=value...] [-CCARD -CSTM'T [number]] [{-TRACE [file ERROR]}]'	'-DBTYPE ODBC -STMT SQL_statement [-SOURCE datasource] [-VAR name=value...] [-CCARD -CSTM'T [number]] [{-TRACE [file ERROR]}]'

Scenario: compiled map source is not a database

Database/query file (.mdq)	No database/query file (.mdq)
'-MDQ DDNAME -DBNAME database_name [-QUERY query_name -STMT SQL_stmt] [-VAR name=value...] [-CCARD -CSTM'T [number]] [{-TRACE [file ERROR]}]'	'-DBTYPE ODBC -STMT SQL_statement [-SOURCE datasource] [-CCARD -CSTM'T [number]] [{-TRACE [file ERROR]}]'

DBLOOKUP or DBQUERY functions

The DBLOOKUP and DBQUERY functions can be used in component rules in the Type Designer and map rules in the Map Designer when creating a map that can be used with a database without specifying a database/query file name (.mdq) or a database name.

Using DBLOOKUP with a database/query file:

```
DBLOOKUP
(''SQL_statement'',
'-MDQ DDNAME
-DBNAME database_name
[-CCARD|-CSTM'T [number]]
[{-TRACE [file|ERROR]}]''')
```

Using DBQUERY without a database/query file:

```
DBQUERY
(''SQL_statement'',
'-DBTYPE ODBC
[-SOURCE datasource]
[-CCARD|-CSTM'T [number]]
[{-TRACE [file|ERROR]}]''')
```

GET function

The GET function returns the data from the source adapter.

Using GET with a database/query file:

```
GET (''DB'', ''
-MDQ DDNAME
-DBNAME database_name
[-QUERY query_name|-STMT SQL_stmt
[-VAR name=value...]
[-CCARD|-CSTM'T [number]]
[{-TRACE [file|ERROR]}]''')
```

Using GET without a database/query file:

```
GET ''DB'', ''
-DBTYPE ODBC
-STMT SQL_stmt
[-SOURCE datasource]
[-CCARD|-CSTM'T [number]]
[{-TRACE [file|ERROR]}]''')
```

DB2® (z/OS®) Adapter commands for a target

This summary shows the syntax of the adapter commands that can be used when defining a data target using an .mdq file or without using one, including both the required and optional adapter commands in the following situations:

- Using the PUT > Target > Command setting in the Map Designer and Integration Flow Designer.
- Overriding a data source using the Output Source Override - Database execution command (-OD) using a RUN function or on the command line
- Using the PUT function in map or component rules.
- [PUT > target > command for DB2 \(z/OS\) Adapter](#)
- [DB2 \(z/OS\) Adapter database execution command \(output source override\)](#)
- [PUT function](#)

PUT > target > command for DB2® (z/OS®) Adapter

Use the Map Designer or Integration Flow Designer to specify **Database** as the value for the PUT > Target setting and enter the adapter commands as desired for the **Command** setting.

The adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

Database command options when there is a database/query file	Database command options when there is no database/query file
<pre>''' [-DBTYPE DB2MVS] [-SOURCE datasource] [-TABLE table_name] [-CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [{-TRACE [file ERROR]}]'''</pre>	<pre>''' -DBTYPE ODBC -TABLE table_name [-SOURCE datasource] [-CSTMT [number]] [-DELETE] [{-TRACE [file ERROR]}]'''</pre>

DB2® (z/OS®) Adapter database execution command (output source override)

Use the Output Source Override - Database execution command (-OD) to designate a database as a target or you can override one or more of the adapter command settings or database definitions in a RUN function or on the command line.

The adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

Scenario: compiled map target is a database

Database/query file (.mdq)	No database/query file (.mdq)
<pre>'[-MDQ DDNAME -DBNAME database_name] [-TABLE table_name] [-CCARD -CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [{-TRACE [file ERROR]}]'</pre>	<pre>'-DBTYPE ODBC -TABLE table_name [-SOURCE datasource] [-CCARD -CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [{-TRACE [file ERROR]}]'</pre>

Scenario: compiled map target is not a database

Database/query file (.mdq)	No database/query file (.mdq)
<pre>'-MDQ DDNAME -DBNAME database_name -TABLE table_name [-CCARD -CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [{-TRACE [file ERROR]}]'</pre>	<pre>'-DBTYPE ODBC -TABLE table_name [-SOURCE datasource] [-CCARD -CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [{-TRACE [file ERROR]}]'</pre>

PUT function

Use the PUT function to pass data to the target adapter.

Using PUT with a database/query file	Using PUT without a database/query file
<pre>PUT (''DB'', ''-MDQ DDNAME -DBNAME database_name -TABLE table_name [-CCARD -CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [{-TRACE [file ERROR]}]''')</pre>	<pre>PUT (''DB'', ''-DBTYPE ODBC -TABLE table_name [-SOURCE datasource] [-CCARD -CSTMT [number]] [-DELETE] [{-TRACE [file ERROR]}]'''')</pre>

DB2® (z/OS®) Adapter limitations

The Database Interface Designer and adapters offer options and functions for accessing and manipulating data contained within a database. However, there are some restrictions and limitations of certain functions:

- **Stored Procedures**

Using stored procedures to access adapter commands and return values from stored functions is not supported.

- **Bind Facility**

Using bind values in database functions is not supported.

- **Database Triggers**

Using a data source as an input event trigger for the Launcher is not supported.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages can also be recorded as specified in the audit logs, trace files, execution summary files, and so forth.

For information about error codes and messages returned by database-specific adapters, see the Resource Adapters documentation.

Various troubleshooting tools are available in case you encounter problems while using the database adapters. For example, if you attempt to run a map that uses the adapter and encounter problems or do not receive the expected results, use the following adapter troubleshooting tools:

- adapter audit log (.log)
- adapter trace file (.mtr)

Extreme Scale adapter overview

IBM® Transformation Extender uses the Extreme Scale adapter to connect to an Extreme Scale server to access data or set data, or to run SQL queries to retrieve data. Extreme Scale can improve application performance by scaling processing to serve more users in less time.

Extreme Scale customers can access values from databases that are supported by Extreme Scale and can GET and PUT values that can be shared across multiple instances of IBM Transformation Extender.

- [System requirements](#)
- [Extreme Scale adapter command overview](#)

This table summarizes the adapter commands, syntax, and whether you can use the command with data sources, data targets, or both. You can specify the commands on the adapter command line.

System requirements

See the [system requirements](#) for details about minimum system requirements for IBM® Transformation Extender. See the Extreme Scale documentation for the minimum system requirements for Extreme Scale.

Extreme Scale adapter command overview

This table summarizes the adapter commands, syntax, and whether you can use the command with data sources, data targets, or both. You can specify the commands on the adapter command line.

The commands are not case-sensitive, but the command values are case-sensitive. Choices are separated by the OR symbol /. Optional parameters are enclosed in brackets []. The topics that follow provide the command syntax in railroad track format.

Table 1. Extreme Scale adapter command summary

Command	Syntax	Use with data source (GET)	Use with data target (PUT)
Connection string to connect to the Extreme Scale server	<code>{-CONNSTRING -C} connection_string</code>	Yes	Yes
Grid name	<code>{-GRID -G} grid_name</code>	Yes	Yes
Map that is called as the hash map (located within the grid)	<code>{-HASHMAP -M} map_name</code>	Yes	Yes
Key to look for	<code>{-KEY -K} key</code>	Yes	Yes
Reference of the complex object that is present in the IBM® Transformation Extender Object pool	<code>{-REFERENCE -R} object_reference</code>	No	Yes
Command to apply	<code>{-COMMAND -D} {UPDATE PUT INSERT REMOVE}</code>	No	Yes
Whether to apply a PUT command immediately, instead of waiting until the map completes	<code>{-NOW -N}{YES NO}</code>	No	Yes
SQL statement to retrieve values	<code>{-SQL -S} SQL_statement</code>	Yes	No
Trace	<code>-T [+][file_name]</code>	Yes	Yes
Trace errors	<code>-TE [+][file_name]</code>	Yes	Yes

- [Command aliases](#)

The WES adapter alias for the Extreme Scale adapter can be used on both input and output cards and in GET and PUT map rules.

- [Connection string \(-CONNSTRING\) command](#)

The **-CONNSTRING** adapter command specifies the connection string that is used to connect to the Extreme Scale server.

- [Grid \(-GRID\) command](#)

The **-GRID** adapter command specifies the name of the Extreme Scale Object Grid that the adapter connects to on the Extreme Scale server.

- [Hash map \(-HASHMAP\) command](#)

The **-HASHMAP** adapter command specifies the name of the Extreme Scale hash map to be used by the Extreme Scale server.

- [Key \(-KEY\) command](#)

The **-KEY** adapter command specifies the key to be sought for a GET or PUT to retrieve or set the value for the Extreme Scale hash map key.

- [Reference \(-REFERENCE\) command](#)

The **-REFERENCE** adapter command specifies the reference ID of the complex Java™ object that is in the IBM Transformation Extender Object Pool. When a map uses the JEXIT function to build a Java object, you can use this command to add the object to the Extreme Scale database.

- **Command (-COMMAND) adapter command**
The **-COMMAND** adapter command specifies the command to be run. If the command specified is a PUT, this command can be used with the **-NOW** command. The **-NOW** command indicates that the command specified is to be run immediately, instead of when the map completes.
 - **Now (-NOW) command**
Use the **-NOW** adapter command with the PUT function of the **-COMMAND** adapter command to indicate that the command specified is to be run immediately, instead of when the map completes.
 - **SQL statement (-SQL) command**
The **-SQL** adapter command specifies the SQL statement to be used to retrieve values with a GET function.
 - **Create trace file (-T) command**
The **-T** command produces an adapter trace log file. When you use the **-T** command at the command property card level or within a PUT or GET map rule, it produces the file `m4exscale.log`. The information within the file contains connection information and information on how the map performed.
 - **Trace adapter errors (-TE) command**
The **-TE** command produces a trace file that contains only the adapter errors that occurred during map execution.
-

Command aliases

The `WES` adapter alias for the Extreme Scale adapter can be used on both input and output cards and in GET and PUT map rules.

Specify adapter overrides by using a command string on the command line or in a map rule (either a PUT or a GET). The execution command syntax is as follows:

```
-IA[alias]card_num
-OA[alias]card_num
```

where:

-IA
The Input Source Override execution command.

-OA
The Output Target Override execution command.

alias
The adapter alias `WES`.

card_num
The number of the map card.

To override an input card 1:

```
-IAWES1 'adapter_commands'
```

To override an output card 1:

```
-OAWES1 'adapter_commands'
```

Connection string (-CONNSTRING) command

The **-CONNSTRING** adapter command specifies the connection string that is used to connect to the Extreme Scale server.

This command is required on input cards or GET commands when the Extreme Scale adapter connects to an Extreme Scale server to access data. This command is required on output cards or PUT commands when the Extreme Scale adapter connects to an Extreme Scale server to set data. The connection string argument is used to connect to the Extreme Scale Server. *hostname* is either the loop-back host name or the host name of the operating system that the user is logged in to.

-CONNSTRING command syntax

hostname:port
The connection string for the Extreme Scale server.

Grid (-GRID) command

The **-GRID** adapter command specifies the name of the Extreme Scale Object Grid that the adapter connects to on the Extreme Scale server.

This command is required on input cards or GET commands when the Extreme Scale adapter connects to an Extreme Scale server to access data. This command is required on output cards or PUT commands when the Extreme Scale adapter connects to an Extreme Scale server to set data.

-GRID command syntax

grid_name
The name of the Extreme Scale Object Grid that the adapter connects to on the Extreme Scale server.

Hash map (-HASHMAP) command

The **-HASHMAP** adapter command specifies the name of the Extreme Scale hash map to be used by the Extreme Scale server.

This command is required on input cards or GET commands when the Extreme Scale adapter connects to an Extreme Scale server to access data. This command is required on output cards or PUT commands when the Extreme Scale adapter connects to an Extreme Scale server to set data.

-HASHMAP command syntax

```
▶ [-HASHMAP [hashmap_name] -M]
```

hashmap_name

The name of the Extreme Scale hash map to be used.

Key (-KEY) command

The **-KEY** adapter command specifies the key to be sought for a GET or PUT to retrieve or set the value for the Extreme Scale hash map key.

This command is required on input cards or GET commands when the Extreme Scale adapter connects to an Extreme Scale server to access data. This command is required on output cards or PUT commands when the Extreme Scale adapter connects to an Extreme Scale server to set data.

-KEY command syntax

```
▶ [-KEY [key] -K]
```

key

The key to be sought for a GET or PUT to retrieve or set the value for the Extreme Scale hash map key. This key is a text string.

Reference (-REFERENCE) command

The **-REFERENCE** adapter command specifies the reference ID of the complex Java™ object that is in the IBM® Transformation Extender Object Pool. When a map uses the JEXIT function to build a Java object, you can use this command to add the object to the Extreme Scale database.

This command is not applicable on input cards or GET commands. This command is optional on output cards (PUT commands) when the Extreme Scale adapter connects to an Extreme Scale server to set data.

-REFERENCE command syntax

```
▶ [-REFERENCE [reference_ID] -R]
```

reference_ID

The reference ID of the complex object in the IBM Transformation Extender Object Pool. When a map uses the JEXIT function to build a Java object, you can use this command to add the object to the Extreme Scale database.

Command (-COMMAND) adapter command

The **-COMMAND** adapter command specifies the command to be run. If the command specified is a PUT, this command can be used with the **-NOW** command. The **-NOW** command indicates that the command specified is to be run immediately, instead of when the map completes.

This command is not applicable on input cards. This command is optional on output cards or PUT commands when the Extreme Scale adapter connects to an Extreme Scale server to set data.

-COMMAND command syntax

```
▶ [-COMMAND [UPDATE | PUT | INSERT | REMOVE] -D]
```

UPDATE

Update the referenced data on the Extreme Scale server.

PUT

Put (set) the referenced data to the Extreme Scale server. Optionally, specify the **-NOW** command to indicate that the PUT function is to process immediately rather than when the map completes.

INSERT

Insert the referenced data to the Extreme Scale server.

REMOVE

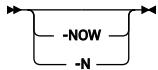

Remove the referenced data from the Extreme Scale server.

Now (-NOW) command

Use the **-NOW** adapter command with the PUT function of the **-COMMAND** adapter command to indicate that the command specified is to be run immediately, instead of when the map completes.

This command is not applicable on input cards or GET commands when the Extreme Scale adapter connects to an Extreme Scale server. This command is optional on output cards or PUT commands when the Extreme Scale adapter connects to an Extreme Scale server to set data.

-NOW command syntax

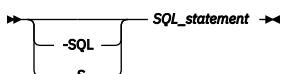

SQL statement (-SQL) command

The **-SQL** adapter command specifies the SQL statement to be used to retrieve values with a GET function.

This command is optional on input cards or GET commands when the Extreme Scale adapter connects to an Extreme Scale server to GET data. This command is not applicable on output cards or PUT commands when the Extreme Scale adapter connects to an Extreme Scale server.

-SQL command syntax

SQL_statement

The SQL statement that is used with a GET command to retrieve values from the Extreme Scale server.

Create trace file (-T) command

The **-T** command produces an adapter trace log file. When you use the **-T** command at the command property card level or within a PUT or GET map rule, it produces the file `m4exscale.log`. The information within the file contains connection information and information on how the map performed.

This command is optional.

-T command syntax

+

Appends trace information to the existing trace file.

`m4exscale.log`

The default trace file that is created.

`file_name`

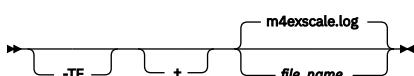

The name and path of the trace file. This parameter is optional. If you omit it, the adapter creates a trace file that is named `m4exscale.log` in the map source directory.

Trace adapter errors (-TE) command

The **-TE** command produces a trace file that contains only the adapter errors that occurred during map execution.

This command is optional.

-TE command syntax

+

Appends trace adapter error information to the `m4exscale.log` adapter trace file.

`file_name`

The name and path of the trace file. This parameter is optional. If you omit it, the adapter appends the error information to a trace file that is named m4exscale.log in the map source directory.

Overview of email adapters

An email adapter automatically receives email messages as sources of a map or sends email messages as targets of a map.

Using email adapters you can:

- Send sales orders to a remote manufacturing facility
- Retrieve notifications of error messages for technical support activities
- Pass notification of a contract price to a component

IBM Transformation Extender supports the following email transport protocols:

- Notes® API (Lotus Notes®)
- Internet email (SMTP/POP3)
- [System requirements](#)
- [Command alias](#)
- [Using adapter commands](#)
- [Commands for email adapters](#)
- [Syntax summary](#)
- [Troubleshooting email adapters](#)
- [Return codes and error messages](#)

System requirements

The computer where the email adapter is installed must be able to access the email servers over a network. It is assumed that a Command Server has already been installed on the computer where the adapter is to be installed for runtime purposes. See the [system requirements](#) and the [release notes](#) for additional details.

Command alias

Specify adapter commands by using a command string on the command line or by creating a command file that contains adapter commands. The command syntax is:

`-IA[alias]card_num`
`-OA[alias]card_num`

In the command syntax, `-IA` is the Input Source Override execution command and `-OA` is the Output Target Override execution command, `alias` is the adapter alias, and `card_num` is the number of the map card. The email adapter alias and corresponding execution commands are listed below.

Adapter	Alias	As Input	As Output
email	EMAIL	<code>-IAEMAILcard_num</code>	<code>-OEMAILcard_num</code>

Using adapter commands

Use an email adapter either as the data source of an input map card, as the data target for an output map card, or both. You can also use an email adapter on the command line or in a map rule using the GET, PUT, or RUN functions.

The IBM Transformation Extender email adapters support email transport protocols for several popular email applications. Use the required Protocol command (`-PROTO`) in the `GET > Source > Command` or `PUT > Target > Command` settings to specify the email transport protocol.

See [Syntax Summary](#) for adapter command syntax.

Commands for email adapters

The following table lists valid commands for the email adapters, the command syntax, and whether the command is supported (✓) for use with data sources, targets, or both.

Name	Syntax	Source	Target
Attachment (-ATT or -ATTACH)	<code>-ATTACH filename</code>	✓	✓
Attachment Name (-AN or -ATTNAME)	<code>-ATTNAME fieldname</code>	✓	✓
Audit (-A or -AUDIT)	<code>-AUDIT[+]S][full_path]</code>	✓	✓
BCC Recipient (-BCC)	<code>-BCC recipient</code>		✓
CC Recipient (-CC)	<code>-CC recipient</code>		✓
From (-FROM) Note: Supported by the internet email transport protocol only	<code>-FROM sender</code>		✓
Header (-HDR)	<code>-HDR[+]</code>	✓	✓

Name	Syntax	Source	Target
Login (-L or -LOGIN) Note: Supported by the internet email transport protocol only	-LOGIN {APOP USERPASS}	✓	
Listen (-LSN)	-LSN seconds	✓	
Markread (-MARKREAD) Note: Supported by the Lotus Notes® email transport protocol only	-MARKREAD		✓
Password (-P or -PASS)	-PASS <i>password</i>	✓	✓
Port (-PORT)	-PORT <i>port_number</i>	✓	✓
Post Office (-PO) Note: Supported by the Lotus Notes email transport protocol only	-PO <i>post_office</i>	✓	✓
Priority (-PRI or -PRIORITY)	-PRIORITY <i>level</i>	✓	✓
Protocol (-PR or -PROTO)	-PROTO {INET LNOTES}	✓	✓
Raw (-RAW)	-RAW	✓	✓
Note: Supported by the internet email transport protocol only			
Receipt (-RCPT or -RECEIPT)	-RECEIPT		✓
Server (-SVR or -SERVER) Note: Supported by the internet email transport protocol only	-SERVER <i>host_name</i>	✓	✓
SSL Protocol (-SPROTO)	-SPROTO {SSLv2 SSLv3 SSLv23 TLSv1 TLSv11 TLSv12}	✓	✓
SSL Encryption Strength (-STR)	-STR {WEAK STRONG ANY}	✓	✓
Subject (-SUB or -SUBJECT)	-SUBJECT <i>subject</i>		✓
Text (-TXT or -TEXT)	-TEXT <i>string</i>	✓	✓
To Recipient (-TO)	-TO <i>recipient</i>		✓
Trace (-T or -TRACE)	-T[E][+][S V] [<i>full_path</i>]	✓	✓
Type (-TYPE) Note: Supported by the internet email transport protocol only	-TYPE <i>content_type</i>		✓
Userid (-UID or -USERID) Note: Supported by the Lotus Notes email transport protocol only	-USERID <i>user_id</i>	✓	✓
Username (-U or -USER)	-USER <i>user_name</i>	✓	✓

- [Attachment \(-ATT or -ATTACH\)](#)
- [Attachment name \(-AN or -ATTNAME\)](#)
- [Audit \(-A or -AUDIT\)](#)
- [BCC recipient \(-BCC\)](#)
- [CC recipient \(-CC\)](#)
- [From \(-FROM\)](#)
- [Header \(-HDR\)](#)
- [Login \(-L or -LOGIN\)](#)
- [Listen \(-LSN\)](#)
- [Markread \(-MARKREAD\)](#)
- [Password \(-P or -PASS\)](#)
- [Port \(-PORT\)](#)
- [Post office \(-PO\)](#)
- [Priority \(-PRI or -PRIORITY\)](#)
- [Protocol \(-PR or -PROTO\)](#)
- [Raw \(-RAW\)](#)
- [Receipt \(-RCPT or -RECEIPT\)](#)
- [Server \(-SVR or -SERVER\)](#)
- [SSL protocol \(-SPROTO\)](#)
- [SSL encryption strength \(-STR\)](#)
- [Subject \(-SUB or -SUBJECT\)](#)
- [Text \(-TXT or -TEXT\)](#)
- [To recipient \(-TO\)](#)
- [Trace \(-T or -TRACE\)](#)
- [Type \(-TYPE\)](#)
- [Userid \(-UID or -USERID\)](#)
- [Username \(-U or -USER\)](#)

Attachment (-ATT or -ATTACH)

The attachment adapter command (-ATT or -ATTACH) processes message attachments.

When used for a data source, you can read attachments (instead of the note text) by omitting the filename.

When used for a data target, this command changes the location of data supplied through the map from the body of the email to a file attachment when you specify the filename. For example, if the map rule is the text literal Hello World, the body of the email contains "Hello World". If you then enter -att sample.txt for the Target, PUT...>Target... Command in the output card, the text literal Hello World will appear in the attachment as a text file with the name sample.txt; the body of the email will be empty.

-ATTACH *filename*

Option

Description

filename

For data targets only, supply the name of the attachment file. For data sources, omit this option.

To generate the name portion of the attachment's filename using the adapter, supply a filename in extension-only format (for example, .ext).

- [Multiple attachments](#)

Multiple attachments

The **-ATTACH** command only supports a single attachment. If you are using the internet email transfer protocol (**-PROTO INET**) and multiple attachments need to be sent or received, you can accomplish this by chaining the MIME adapter with the email adapter, and using the **-RAW** option of the email adapter to map the MIME header fields.

An example of a map that sends and receives multiple attachments is provided in the map source file *emailatt.mms* in the *install_dir\examples\adapters\mime* directory.

Attachment name (-AN or -ATTNAME)

The Attachment Name adapter command (**-AN** or **-ATTNAME**) specifies that the name of the attachment should be returned together with the attachment itself. This command can only be used on input. It results in the name of the attachment being returned as a header to the data.

-ATTNAME *fieldname*

Option	Description
<i>fieldname</i>	Specify the name of the header field that should be returned in the header.

For example, to specify **myfield** as the name of the header field that should be returned in the header:

-ATTNAME *myfield*

When used with the **-HDR** option, the attachment name becomes another header field. For example:

```
From: Mr. X <mrX@mail.net>
Subject: Attachment test
Date: Wed, 3 Apr 2002 10:13:36 -0500
To: mrsX@mail.net
X-Attachment-Name: myday.txt
Breakfast
Kids to school
Go to work
```

The option takes an optional parameter that is the name of the attachment name field. This is provided for two reasons:

- To offer a solution in the event that **X-Attachment-Name** appears in the data, which would cause distinguish ability problems during validation
- To provide a means to offer a user-defined field name that might be more suited to the context of its use than the default name

Audit (-A or -AUDIT)

Use the Audit adapter command (**-A** or **-AUDIT**) to produce a log file in the map directory where the adapters are installed with the default name *m4email.log*. Audit information is recorded detailing files sent or received from each host, elapsed time, file size, and retry count for each file.

-AUDIT[+] [S] [full_path]

Option	Description
+	Append audit information to the existing log file. If a log file does not exist, it is created.
S	Summary mode. Record only minimal information in the log file.
full_path	Create audit file with the specified name in the specified directory. (By default, the directory is where the map is located and the file name is <i>m4email.log</i> .)

BCC recipient (-BCC)

The BCC Recipient adapter command (**-BCC**) identifies a blind courtesy copy (BCC) recipient, but is otherwise identical to the To Recipient adapter command (**-TO**).

-BCC *recipient*

Option	Description
<i>recipient</i>	Specify the BCC recipient.

CC recipient (-CC)

The CC Recipient adapter command (**-CC**) identifies a courtesy copy (CC) recipient, but is otherwise identical to the To Recipient adapter command (**-TO**).

-CC recipient

Option

Description

recipient

Specify the CC recipient.

From (-FROM)

The From adapter command (**-FROM**) uses the specified email address as the sender of the generated message.

-FROM sender

Option

Description

sender

Supply the email address of the sender for outbound messages.

Note: This command is only supported by the internet email transport protocol and is required. You must also specify at least one of the following commands:

- [To recipient \(-TO\)](#)
- [CC recipient \(-CC\)](#)
- [BCC recipient \(-BCC\)](#)

Header (-HDR)

When used on input, the Header command option (**-HDR**) of the email adapter retrieves the message header in the following format:

```
From: originator[originator_address]
Subject: subject text
Date: yyyy/mm/dd hh: mm
To: recipient[recipient_address]; ....;
recipient[recipient_address]
cc: recipient[recipient_address]; ....;
recipient[recipient_address]
bcc: recipient[recipient_address]; ....;
recipient[recipient_address]
```

-HDR [+]

Option

Description

+

Append user-supplied headers

On output, the (**-HDR+**) option can be used to append the user-supplied header fields to the message header. Each header field should be terminated by a CR/LF and an empty line (CR/LF only) delimits the headers from the data.

Note: The (**-HDR+**) option is only compatible with internet email transport protocol (**-PROTO INET**) on output.

For example, use the **-HDR+** command to append the user-supplied header fields to include:

```
X-MyfirstHeader:John
X-MysecondHeader:Paul
X-MythirdHeader:Michael
This is my message.
```

Login (-L or -LOGIN)

The Login adapter command (**-L** or **-LOGIN**) is used for data sources to supply the method(s) used to gain access to the mailbox. When a Login command is not provided, the default setting is **USERPASS**. Consult your System Administrator if you are unsure of the method to use. Generally, the method used is **USERPASS**.

Note: This command is only supported by the internet email transport protocol.

-LOGIN {APOP|USERPASS}

Option

Description

APOP

Sends the APOP command as described in RFC 1939 (<http://www.ietf.org/rfc/rfc1939.txt>).

USERPASS

Sends a plain-text user name and password combination

Listen (-LSN)

Use the listen (**-LSN**) command to specify a time (in seconds) to wait for messages to arrive. If no email is available in the specified listen time, you will receive an error message of **Source not available**.

The command `-LSN 0` means do not wait at all. If no message is immediately available, the adapter returns a warning indicating that no messages were found.

-LSN seconds

Option

Description

seconds

The number of seconds to wait for messages to arrive

Markread (-MARKREAD)

Use the Markread adapter command (`-MARKREAD`) to specify that the messages the adapter is sending have been read. They will be marked as read in the sender's **Sent** folder. This command is not required.

Note: This command is only supported by the Lotus Notes® email transport protocol.

Note: The `-MARKREAD` command can only be used when the `-PROTO` command is specified on the adapter command line as well (used with the `LNOTES` command option of the Protocol adapter command).

-MARKREAD

Password (-P or -PASS)

Use the Password adapter command (`-P` or `-PASS`) to gain authorized access to mailboxes that use security passwords. This command is required unless you are using a mailbox that does not require you to specify the user ID and password to connect to the mailbox.

-PASS password

Option

Description

password

When used for a data source, supply the case-sensitive password required for entry to the source mailbox.

When used for a data target, supply the case-sensitive password required for the target mailbox.

Port (-PORT)

Use the Port adapter command (`-PORT`) to specify the port number used for SMTP and POP3 on exchange server. The `-PORT` accepts integer value.

-PORT port_number

Option

Description

port_number

If `-PORT` is used for SMTP or POP3 communication. Default for SMTP is 465 and 995 for POP3 if not specified. SMTP protocol is used to send a mail and POP3 is used to receive a mail.

Post office (-PO)

Use the Post Office adapter command (`-PO`) to gain authorized access to mailboxes. The Post Office adapter command is required.

-PO post_office

Option

Description

post_office

Required value. When used for a data source, supply the post office (case sensitive) required for entry to source mailbox.

When used for a data target, supply the post office (case sensitive) required for the target mailbox.

Note: The Post Office adapter command (`-PO`) is supported by the Lotus Notes® (`LNOTES`) email transport protocol only.

See [Userid \(-UID or -USERID\)](#) for its use with `LNOTES`.

Priority (-PRI or -PRIORITY)

Use the Priority adapter command (`-PRI` or `-PRIORITY`) to set the priority of the message.

-PRIORITY level

Option

Description

level

Required value. Specify the level of priority:

1. -low or -lo
2. -normal or -nrm
3. -high or -hi

Note: This command is only supported by Lotus Notes® and internet email transport protocols.

Protocol (-PR or -PROTO)

Use the Protocol adapter command (-PR or -PROTO) to specify the email transport protocol.

-PROTO {INET|LNOTES}

Option

Description
INET
Specifies the SMTP email transport protocol for data targets and POP3 for data sources
LNOTES
Specifies the Lotus Notes® email transport protocol

Raw (-RAW)

Use the Raw (-RAW) command in an input card to dump out the received message without interpreting or processing the header fields. Use it on an output card if the data specified contains the header data.

The type tree RawInet.mtt in the examples directory (*install_dir\examples\adapters\email*) can be used to create the header data.

-RAW

The -RAW option is only compatible with internet email transport protocol (-PROTO INET). If used with another protocol, it will be flagged as an error.

Similarly, the -RAW command is incompatible with all other header options:

- -ATTACH
- -BCC
- -CC
- -HDR
- -PRIORITY
- -RECEIPT
- -SUBJECT
- -TEXT
- -TYPE

An error will be flagged if any of these options are used when -RAW is specified.

Note: This command is only supported by the internet email transport protocol.

Receipt (-RCPT or -RECEIPT)

Use the Receipt adapter command (-RCPT or -RECEIPT) to request a return receipt. Valid with data targets only.

-RECEIPT

Server (-SVR or -SERVER)

Use the Server adapter command (-SVR or -SERVER) to identify the host server where the mailbox can be accessed or addressed.

-SERVER host_name

Option

Description
<i>host_name</i> For data sources, supply the internet host name where the mailbox can be accessed. For data targets, supply the internet host name that will forward the outgoing message.

Note: This command is only supported by the internet email transport protocol.

SSL protocol (-SPROTO)

Use the Secure Socket Layer (SSL) protocol adapter command (-SPROTO) to set the SSL protocol level.

This command decides whether to use Secure channel to communicate with the Email server. If `-SPROTO` is not specified, it will be an unsecured communication channel between the map and the Email server.

This command is applicable only when the SSL `secure_mode` setting in the config.yaml configuration file (/runtime/secure_mode) is set to 0 and RSA-based SSL encryption is in effect. This command is superseded by an SSL `secure_mode` setting of 1 or 2.

```
-SPROTO {SSLv2|SSLv3|SSLv23|TLSv1|TLSv11|TLSv12}
```

Option

Option	Description
SSLv2	Specify SSL protocol version 2
SSLv3	Specify SSL protocol version 3
SSLv23	Specify SSL protocol version 2, version 3, TLSv1, TLSv1.1 or TLSv1.2 Whenever the protocol method of <code>SSLv23</code> is specified, the protocol of first choice is <code>TLSv1.2</code> , with fallback to <code>TLSv1.1</code> , then to <code>TLSv1</code> , then to <code>SSLv3</code> , and finally to <code>SSLv2</code> , depending on the loaded GSKit module.
TLSv1	Specify Transport Layer Security (TLS) protocol version 1
TLSv11	Specify Transport Layer Security (TLS) protocol version 1.1
TLSv12	Specify Transport Layer Security (TLS) protocol version 1.2

SSL encryption strength (-STR)

Use the Secure Socket Layer (SSL) encryption strength adapter command (`-STR`) to specify the encryption strength.

The SSL encryption strength adapter command (`-STR`) can be either `WEAK`, only using weak encryption algorithms, or `STRONG`, only using strong encryption algorithms. If not specified, any available encryption algorithm is used.

If `STRONG` encryption algorithm is not available, then `WEAK` encryption algorithm is used. If the export version of the libraries is used, only weak encryption algorithms are available, and this command is ignored.

This command is applicable only when the SSL `secure_mode` setting in the config.yaml configuration file (/runtime/secure_mode) is set to 0 and RSA-based SSL encryption is in effect.

```
-STR {WEAK|STRONG|ANY}
```

Option

Option	Description
WEAK	Use exportable encryption algorithm only
STRONG	Use strong (non-exportable) encryption algorithm only
ANY	Use any available encryption algorithm

Subject (-SUB or -SUBJECT)

The Subject adapter command (`-SUB` or `-SUBJECT`) uses the specified subject text as the subject of the generated message. If no text is specified, the subject field contains `Message Produced by IBM`.

```
-SUBJECT "subject"
```

Option

Option	Description
<code>subject</code>	Supply the text to be placed in the subject field for outbound messages.

Text (-TXT or -TEXT)

Use the Text adapter command (`-TXT` or `-TEXT`) to process the text part(s) of the message.

When used for a data source, it specifies that text parts should be retrieved in addition to attachments if the Attachment adapter command (`-ATTACH`) is specified. In this case, omit `string` and the flag is ignored if `-ATTACH` has not been specified.

When used for a data target, the Text adapter command (`-TEXT`) causes the specified `string` to be sent as the text part of the message. In this case, `string` is required, and if `-ATTACH` has not been specified, the text is prefixed to the data.

```
-TEXT string
```

Option

Description
<i>string</i>
Required value when used for a data target. Specify the string to be sent as the text part of the outbound message. When used for a data source, this option is not required.

To recipient (-TO)

Use the To Recipient adapter command (-TO) to identify a recipient of the message.

-TO *recipient*

Option

Description
<i>recipient</i>

Required value. Supply the name of the recipient.

Note: If you use the INET email transport protocol, only the SMTP type of addressing is applicable for a *recipient* name.

Trace (-T or -TRACE)

Use the Trace adapter command (-T or -TRACE) to produce a diagnostics file that contains detailed information about email adapter activities.

The default filename is m4email.mtr and it is created in the map directory unless otherwise specified.

-T [E] [+|S|V] [*full_path*]

Option

Description
E
Produce a trace file containing only the adapter errors that occurred during map execution.
+
Append trace information to the existing log file.
S
Summary mode. Record only minimal information in the log file. Default value.
V
Verbose mode. Record in the log file all activity occurring while the adapter is retrieving data. If not specified, summary mode is assumed.
<i>full_path</i>
Create a trace file with the specified name in the specified directory. The default directory is the map directory and the default filename is m4email.mtr.

Note: You can override the adapter command line trace options dynamically using the Management Console. See "Dynamic Adapter Tracing" in the *Launcher* documentation for detailed information.

Note: Because summary mode is the default, using -TRACES provides the same output as -TRACE.

Type (-TYPE)

Use the Type adapter command (-TYPE) to specify the MIME content-type for the attachment used in the adapter request. The default content-type is **application/octet-stream**.

-TYPE *content_type*

Option

Description
<i>content_type</i>

Specify the MIME content-type for the attachment used in the adapter request. You can use other types, but do not use compound types such as multipart.

Note: This command can only be used with the -ATTACH command in an output card. In addition, this command is only supported by the internet email transport protocol.

Userid (-UID or -USERID)

Use the Userid adapter command (-UID or -USERID) to specify the user ID file required when you use the LNOTES command option.

-UID *user_id*

Option

Description
<i>user_id</i>

Specify a valid user id file of the specified post office.

Note: This adapter command is required only when the Post Office adapter command (-PO) is used and the Protocol adapter command (-PROTO) is specified with the LNOTES command option.

Username (-U or -USER)

Use the Username adapter command (-U or -USER) to identify the user name associated with the account being accessed. You can omit this command if mailbox session is currently active.

-USER user_name

Option

Description

user_name

Specify a valid user name for the email account being accessed.

When used for a data target and this command is omitted, the default profile is used to log on to the email system. You must be logged-on for the following scenarios:

- A default profile has not been defined.
- The messaging system does not support default profiles.
- -U is not used to specify a profile.

The profile requires a password and the -P command is not used to specify the password.

Syntax summary

This documentation provides syntax summaries for each of the email adapter protocol options that support Lotus Notes® (LNOTES) and internet email (INET) transport protocols.

- [Lotus Notes adapter commands](#)
- [Internet email adapter commands](#)
- [Email adapters example using data sources and targets](#)
- [Example: send mail using the Lotus Notes protocol](#)
- [Example: send mail using internet email protocol](#)
- [Command line example: Lotus Notes override](#)
- [Command line example: internet email override](#)

Lotus Notes adapter commands

The following command syntax summaries are for the email adapter protocol option that supports the Lotus Notes® (LNOTES) email transport protocol.

- [Data sources for LN NOTES](#)
- [Data targets for LN NOTES](#)

Data sources for LN NOTES

The following command syntax summary is for the email adapter protocol LN NOTES option used for data sources.

```
-PROTO LN NOTES
[-PASS password]
[-PO post_office]
[-ATTACH filename]
[-TEXT string]
[-PRIORITY level]
[-HDR]
[-LSN seconds]
[-T[E] [+][S|V] [full_path]]
[-AUDIT[+][S] [full_path]]
[-USER user_name]
[-USERID user_id]
```

Data targets for LN NOTES

The following command syntax summary is for the email adapter protocol LN NOTES option used for data targets:

```
-PROTO LN NOTES
-TO recipient|-CC recipient|-BCC recipient
[-PASS password]
[-PO post_office]
[-SUBJECT subject]
[-PRIORITY level]
[-RECEIPT]
[-ATTACH filename]
[-TEXT string]
[-T[E] [+][S|V] [full_path]]
[-AUDIT[+][S] [full_path]]
[-MARKREAD]
```

```
[-USER user_name]
[-USERID user_id]
```

You must specify at least one of the following commands, in addition to the Protocol (-PROTO) command:

- To Recipient (-TO *recipient*)
- CC Recipient (-CC *recipient*)
- BCC Recipient (-BCC *recipient*)

Internet email adapter commands

The following command syntax summaries are for the email adapter protocol option that supports the internet email transport protocol.

- [Data sources for INET](#)
- [Data targets for INET](#)

Data sources for INET

The following command syntax summary is for the email adapter protocol INET option used for data sources:

```
-PROTO INET
-SERVER host_name [-LOGIN {APOP|USERPASS}]
[-USER user_name]
[-PASS password]
[-ATTACH]
[-PRIORITY level]
[-TEXT string]
[-RAW]
[-HDR]
[-LSN seconds]
[-T[E] [+][S|V] [full_path]]
[-AUDIT[+][S] [full_path]]
```

Data targets for INET

The following command syntax summary is for the email adapter protocol INET option used for data targets:

```
-PROTO INET
-FROM sender
-TO recipient|-CC recipient|-BCC recipient
[-SERVER host_name]
[-PASS password]
[-SUBJECT subject]
[-PRIORITY level]
[-RECEIPT]
[-ATTACH filename]
[-RAW]
[-TEXT string]
[-T[E] [+][S|V] [full_path]]
[-AUDIT[+][S] [full_path]]
```

You must specify at least one of the following commands, in addition to the Protocol (-PROTO) and From (-From) commands:

- To Recipient (-TO *recipient*)
- CC Recipient (-CC *recipient*)
- BCC Recipient (-BCC *recipient*)

Email adapters example using data sources and targets

```
= RUN("XExLogEM.mmc", " -WD -AE=" + GETDIRECTORY( AuditLog ) +
"XExLogEM.log" + " -IFI " + GETFILENAME(AuditLog) + " -
OAEMAIL1 -T -PR "+ Protocol Field:EmailOptionRec + " -U "" +
User Field:EmailOptionRec + " " +
IF(PRESENT(#01 Destination Field:EmailOptionRec), "-TO "" + #01
Destination Field:EmailOptionRec + "", NONE) +
IF(PRESENT(#02 Destination Field:EmailOptionRec), " -TO "" +
#02 Destination Field:EmailOptionRec + "", NONE) +
IF(PRESENT(#03 Destination Field:EmailOptionRec), " -TO "" +
#03 Destination Field:EmailOptionRec + "", NONE) +
" -CC "squentin" -SUB "" + Subject Field:EmailOptionRec + " " +
" -TEXT ""+ Text Field:EmailOptionRec + " " +
" -ATTACH "" + Attachment Field:EmailOptionRec + " " ` " )
```

Example: send mail using the Lotus Notes® protocol

```
-PR LNOTES -MARKREAD -TO name -PASS password  
-CC recipient -PASS password -SUBJECT subject  
-TEXT string -RECEIPT
```

Example: send mail using internet email protocol

```
-PR inet -TO name -FROM name -ATT filename -T
```

Command line example: Lotus Notes override

To override output map card 3 using the email adapter for a Lotus Notes® email system on a Windows platform, send an attachment to a user, and generate a new trace file:

```
-OAEMAIL3 ` -PR lnotes -TO name -P lymdear4 -ATT filename -T`
```

Command line example: internet email override

To override output map card 4 using an adapter for internet email systems on a Windows operating system, send an attachment, and generate a trace file:

```
-OAEMAIL4 ` -PR inet -TO name -FROM name -ATT filename -T`
```

Troubleshooting email adapters

For information about error codes and messages returned by the adapters, see [Return Codes and Error Messages](#).

Various troubleshooting tools are available when you encounter problems using email adapters as data sources or targets for a map. If you attempt to run a map that uses an email adapter and receive a runtime error or do not get the expected output, use any or all of the following troubleshooting tools:

- View the Trace log file (.mtr).
 - View source and target data.
 - [Trace log file](#)
 - [Internet email](#)
 - [Lotus Notes](#)
-

Trace log file

The adapter trace log file contains detailed information provided by the adapter, recording the actions that are taking place such as connections that are established and statements that are executed. The trace log file is produced during the adapter execution and can be used as a debugging aid. To produce a trace file for the adapter, use the **-TRACE** command. The default name for the log is m4email.mtr which is located in the same directory as the compiled map file. You can specify an alternate filename and/or location using the **-TRACE** command.

Internet email

- The 32-bit version of internet email (wsock32.dll, normally installed as part of the Windows operating system) must be installed on the same computer where the adapters are to be installed.)
- Windows or BSD (UNIX) Sockets must be installed on the client computer. The Sockets installation must support TCP/IP.
- The client computer must be able to access an appropriate server. Test this as follows:
 - telnet target-ip 25 (to test a SMTP email target)
 - telnet target-ip 110 (to test a POP3 email source)

where **target-ip** is the IP address of the server. If the test is successful, you will receive a welcome message from the server. To close the session, enter **QUIT** (all caps) and press **Enter**.

Note: You might not be able to see what you are typing on the screen.

Lotus Notes

This section presents troubleshooting information for the email adapter protocol options that support the Lotus Notes® (LNOTES) email transport protocols.)

- The specific version of the Lotus Notes transfer protocol APIs must be installed on the same computer where the adapters are to be installed.
 - For **LNOTES** protocol command option, it is the 32-bit version of the Notes® API, which is nnotes.dll and its associated software.
- Notes must be in the PATH. When using the Launcher, only the System PATH is available. The User PATH is never accessible if the server runs under the appropriate user ID. You might have to manually modify those settings. You might have to copy the Notes PATH settings from the user ID PATH variable to the system PATH

variable. Do not change the user ID for the Launcher; even if running as a specified user ID, user environment variables are not available. You must restart the system so that changes to system environment variables are available to a service.

Note: If there is an active Notes session running on the same computer, errors can occur in the adapter and display the message: Could not open ID file. Close the Notes session to resolve this issue.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages can also be recorded as specified in the audit logs, trace files, execution summary files, and so on.

- [Messages](#)

Messages

The following is a listing of all the codes and messages that can be returned as a result of using the email adapter for sources or targets.

Note: Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Return Code	Message
0	OK
-1	Insufficient memory to continue
-1	Library Initialization Failed
-2	Invalid Entry Point. (AIX® adapters only)
-3LNOTES	Could not load adapter
-3INET	Could not load adapter
-3	Error Sending Data
-4	Error Receiving Data
-5	LNOTES: Insufficient memory to continue
-5	INET: Insufficient memory to continue
0	No Messages
1	No data provided. Create on content specified: no data sent.
-1	Unsupported protocol
-1	Insufficient memory to continue
-1	Invalid protocol selection. (SMTP for Get/POP3 for Put)
-5	Memory Error
-600	Internal Error: Resource Manager Error
-?	Mail Error where -? is an API-specific error code, made negative if >0
-???	???? (SMTP only) where -??? is an error code returned from the server, made negative and where ??? is a server-supplied error message

Excel Adapter

The Excel Adapter reads data from and maps data to a sheet in a Microsoft Excel workbook. In Design Studio, use the Excel importer (File > Import > Excel) to create a type tree based on a specified worksheet in the Excel workbook.

Excel Adapter command aliases

Use **EXCEL** as the adapter command alias on input and output card overrides and in **GET** and **PUT** rules. For example:

Input source override execution command	-IAEXCEL card_num
Output target override execution command	-OAEXCEL card_num

Inbound adapter example

Command line: -W Sheet1 -T

GET rule: =PARSE(GET("EXCEL", "-W Sheet1 -T", Input))

Inbound mapping rules are likely to be based on row number and the **EXTRACT** function:

Figure 1. Inbound mapping rules based on row number and **EXTRACT** function

Figure 1. Inbound mapping rules based on row number and EXTRACT function	
Excel	
sequence	
◆ ID	=GETID(EXTRACT(Rows:ExcelIn, RowNumber Columns:Rows:ExcelIn = 2))
◆ NAME	=GETNAME(EXTRACT(Rows:ExcelIn, RowNumber Columns:Rows:ExcelIn = 2))
▶ Detail (1:s)	=GETDETAILS(EXTRACT(Rows:ExcelIn, RowNumber Columns:Rows:ExcelIn = 2))
	NAME:sequence:Excel:global:XMLOut

Outbound mapping rules can be index-based. RowNumber indicates where to insert the data.

Figure 2. Index-based outbound mapping rules using RowNumber

Figure 2. Index-based outbound mapping rules using RowNumber	
ExcelOut	
Rows [1]	
◆ RowNumber Columns	=2
◆ COL0 Columns (0:1)	="ID"
◆ COL1 Columns (0:1)	=ID:sequence:Excel:global:XMLIn
◆ COL2 Columns (0:1)	=NONE
◆ COL3 Columns (0:1)	="NAME"
◆ COL4 Columns (0:1)	=NAME:sequence:Excel:global:XMLIn
Rows [2]	
◆ RowNumber Columns	=4
◆ COL0 Columns (0:1)	="FULLNAME"
◆ COL1 Columns (0:1)	="TITLE"
◆ COL2 Columns (0:1)	="BIRTH"
◆ COL3 Columns (0:1)	="COUNTRY"
◆ COL4 Columns (0:1)	="ID"
Rows (s)	=FOREACHDETAIL(Detail:sequence:Excel:global:XMLIn, COL4 Columns:Rows[2]:ExcelOut)

- **System requirements**

See the [release notes](#) for the Excel Adapter requirements.

- **Excel Adapter commands**

This documentation describes the functions and use of the Excel Adapter commands.

System requirements

See the [release notes](#) for the Excel Adapter requirements.

Excel Adapter commands

This documentation describes the functions and use of the Excel Adapter commands.

- **Transaction scope and document persistence in memory**

When a document is added using the **-ADOC** command, the Excel Adapter stores the document in memory. Documents stored in memory are identified by a document identifier that is either provided by the user, or generated by the Excel Adapter. The document persists in memory as specified by the transaction scope in the card settings.

- **data_from_map option**

Some of the Excel Adapter commands that are described in this documentation include the **data_from_map** option. The **data_from_map** option represents the data that is passed as the third parameter of a **GET** function. It is not a parameter on the command line.

- **Add document (-ADOC) command**

The **-ADOC** command adds a file on the local file system, or a remote file accessible through **HTTP** protocol, as a document in memory, and returns the document ID to the map. Alternatively, the **-ADOC** command can add dynamic data from a map as a document in memory and return the document ID to the map.

- **Remove document (-RDOC) command**

The **-RDOC** command removes a document from memory. By default, documents are removed from memory when map, or card processing completes. Transaction scope card setting determines the document persistence in memory. Use this command if too many intermediate documents accumulate in memory during map processing.

- **Replace document (-UDOC) command**

The **-UDOC** command replaces an existing document in memory with a new one and returns the new document ID.

- **Get document data (-GDOC) command**

The **-GDOC** command returns data from a document in memory for the given document identifier.

- **Excel workbook (-FILE) command**

The Excel workbook name. Use this command for data sources or data targets.

- **[Worksheet \(-WRKSHEET\) command](#)**
The Excel sheet name in the workbook. This command is required. Use this command for data sources or data targets.
- **[Read Mode \(-READMODE\) command](#)**
The **-READMODE** command specifies the type of read operation to be performed. Use this command for data sources.
- **[Worksheet Identifier \(-IDENTIFIER\) command](#)**
The **-IDENTIFIER** command specifies how to identify a worksheet. Use this command for data sources.
- **[Worksheet Index \(-WRKSHEETINDEX\) command](#)**
The **-WRKSHEETINDEX** command specifies the index of the worksheet. Use this command for data sources.
- **[Template \(-TEMPLATE\) command](#)**
The Excel template workbook name. This command is optional. Use this command for data targets.
- **[Excel transformation \(-XLS\) command](#)**
The **-XLS** command allows the map to transform map data in delimited format to Excel formatted data using the GET map rule. PUT receives map data in delimited format and transforms it to Excel formatted data. This command allows the same with GET, so that it can return Excel formatted data back to the map by performing in-memory transformation. The delimited format data has to conform to the Excel importer generated type tree for the corresponding worksheet in the Excel workbook.

Transaction scope and document persistence in memory

When a document is added using the **-ADOC** command, the Excel Adapter stores the document in memory. Documents stored in memory are identified by a document identifier that is either provided by the user, or generated by the Excel Adapter. The document persists in memory as specified by the transaction scope in the card settings.

- When the transaction scope is MAP, the document is accessible in memory to later map rules in the same map. The document is removed from memory when the map completes processing.
- When the transaction scope is CARD, the document is accessible in memory to later map rules on the same card. The document is removed from memory when the card completes processing, and is not accessible to map rules in later cards.

data_from_map option

Some of the Excel Adapter commands that are described in this documentation include the *data_from_map* option. The *data_from_map* option represents the data that is passed as the third parameter of a **GET** function. It is not a parameter on the command line.

If both the **-FILE** and *data_from_map* options are provided, then *data_from_map* has precedence over the **-FILE** option.

Add document (-ADOC) command

The **-ADOC** command adds a file on the local file system, or a remote file accessible through **HTTP** protocol, as a document in memory, and returns the document ID to the map. Alternatively, the **-ADOC** command can add dynamic data from a map as a document in memory and return the document ID to the map.

-ADOC command syntax

-FILE

Adds a single file, specified by a local file URL (**file:///**), or remote file URL (**http://**), as a document in memory, and returns a document ID to the map. The **-FILE** keyword is optional, but you must specify either the **-FILE**, or the *data_from_map* option on the **-ADOC** command. The **doc_ID** parameter is optional. If specified, the **-ADOC** command associates the user-specified identifier for the document in memory and returns the same. If not specified, the **-ADOC** command generates a unique document identifier for the document in memory.

data_from_map

Adds dynamic data from a map as a document in memory and returns the document ID to the map. The *data_from_map* is optional, but you must specify either the **-FILE**, or the *data_from_map* option on the **-ADOC** command.

Examples

The following example adds the `parsewds.txt` file as a document in memory and returns the adapter generated, unique document ID to the map:

```
=GET("EXCEL", "-FILE file:///C:\parsewds.txt -ADOC")
```

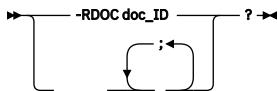

The following example adds the `Hello World!!` text string as a document in memory and returns `mydocid` to the map:

```
=GET("EXCEL", "-ADOC mydocid", "Hello World!!")
```

Remove document (-RDOC) command

The **-RDOC** command removes a document from memory. By default, documents are removed from memory when map, or card processing completes. Transaction scope card setting determines the document persistence in memory. Use this command if too many intermediate documents accumulate in memory during map processing.

-RDOC command syntax

`doc_ID`

doc_ID indicates the document identifier of a document to be deleted from memory, if needed.

Replace document (-UDOC) command

The **-UDOC** command replaces an existing document in memory with a new one and returns the new document ID.

-UDOC command syntax

-FILE

Specifies the local file URL (`file:///`), or remote URL (`http://`), of the document that is to replace the document in memory. Either the **-FILE** or the *data_from_map* option is required.

data_from_map

Replaces the document in memory with dynamic data from a map. Either the *data_from_map*, or the **-FILE** option is required.

Get document data (-GDOC) command

The **-GDOC** command returns data from a document in memory for the given document identifier.

-GDOC command syntax

`doc_ID`

doc_ID indicates the document identifier of a document to be fetched from memory.

Excel workbook (-FILE) command

The Excel workbook name. Use this command for data sources or data targets.

-F *workbook.xls[x]*
-FILE *workbook.xls[x]*

The **-FILE** command is optional for **GET** rules but required on input cards. For example, the workbook name is not required if a map uses the File Adapter to read an Excel workbook and passes the data in memory to the Excel Adapter. The adapter can read from either the .xls or the .xlsx workbook format.

The **-FILE** command specifies a URL to a local file on the file system (`file:///`), or a remote file on a host server (`http://`), or a document in memory (`memory://`). If the workbook file name alone is provided for the **-FILE** command, it is located relative to the **map** directory.

Worksheet (-WRKSHEET) command

The Excel sheet name in the workbook. This command is required. Use this command for data sources or data targets.

-W *sheetname*
-WRKSHEET *sheetname*

Read Mode (-READMODE) command

The **-READMODE** command specifies the type of read operation to be performed. Use this command for data sources.

-RM { *wsl* | *wsd* }
-READMODE { *wsl* | *wsd* }

The **-READMODE** command is optional. Valid values for this command are: *wsl* (worksheet list) and *wsd* (worksheet data). Default is *wsd*.

Worksheet list specification for **-READMODE** command returns the delimited list of worksheet names defined in the Excel workbook. The delimiter between worksheet names is Line feed (<LF>) character. Ignores **-WORKSHEET** command if specified in the command line.

Worksheet Identifier (-IDENTIFIER) command

The **-IDENTIFIER** command specifies how to identify a worksheet. Use this command for data sources.

-I { wsi / wsn }
-IDENTIFIER { wsi / wsn }

The **-IDENTIFIER** command is optional. Valid values for this command are: *wsi* (worksheet by index) and *wsn* (worksheet by name). Default is *wsn*.

Worksheet by index specification for **-IDENTIFIER** command returns worksheet data by index number of the worksheet specified with **-WRKSHEETINDEX** command.

Worksheet Index (-WRKSHEETINDEX) command

The **-WRKSHEETINDEX** command specifies the index of the worksheet. Use this command for data sources.

-WI worksheet_index
-WRKSHEETINDEX worksheet_index

This **-WRKSHEETINDEX** command is required when **-IDENTIFIER wsi** has been specified. Worksheet index number specified must be greater than or equal to 1.

Template (-TEMPLATE) command

The Excel template workbook name. This command is optional. Use this command for data targets.

-P template.xls[x]
-TEMPLATE template.xls[x]

The **-TEMPLATE** command specifies the URL to a local file on the file system (**file:///**), or to a remote file on a host server (**http://**), or to a document in memory (**memory://**). If the workbook file name alone is provided for the **-TEMPLATE** command, it is located relative to the **map** directory. The **-TEMPLATE** command can also be used to add a new worksheet to an existing Excel workbook.

Excel transformation (-XLS) command

The **-XLS** command allows the map to transform map data in delimited format to Excel formatted data using the GET map rule. PUT receives map data in delimited format and transforms it to Excel formatted data. This command allows the same with GET, so that it can return Excel formatted data back to the map by performing in-memory transformation. The delimited format data has to conform to the Excel importer generated type tree for the corresponding worksheet in the Excel workbook.

This command is generally useful in environments where file system access is restricted to the users, and Excel transformations must be performed in memory and then transformed output to be returned to the map for further processing. A stream of Excel formatted data is passed back to the map with GET:

=GET("EXCEL","-XLS -TEMPLATE memory://<template-document-id>,<delimited-map-data>)

A template should also be added to the memory, if it is not a remote file, using the **-ADOC** command when performing in-memory transformation of delimited formatted data to Excel formatted data. The **-ADOC** command returns a user specified document ID, or a system generated ID for the template.

This two step process is shown here:

- **template-document-id=GET("EXCEL",-ADOC <my-template-documentid>,<template-file-data-as-stream>) or template-document-id=GET("EXCEL",-ADOC",<template-file-data-as-stream>)**
- **excel-data-out=GET("EXCEL","-XLS -TEMPLATE memory://<template-document-id>,<delimited-map-data>)**

Store output document in memory

Without the **-XLS** command, instead of streaming to a map, output operation can keep the output document in memory until it is fetched with **-GDOC** command. This is a two step process:

- **=PUT("EXCEL",-FILE memory://<my-output-doc-id> -TEMPLATE memory://<template-document-id>,<delimited-map-data>)** or the adapter command line can be with the output card
- **excel-data-out=GET("EXCEL",-GDOC <my-output-doc-id>")**

Default File URL

It is required to specify **memory://** for memory documents, or **http://** for remote documents, or **file:///** for local file system documents using the **-FILE (-F)** and **-TEMPLATE (-P)** commands. If **file:///** is not specified in the path to the local file system documents, such paths are resolved relative to the map directory.

Reference delimited data

-FILE memory://<delimited-data-document-id> can be specified. Delimited data is in memory and can be referenced instead of passing map data as a third parameter of GET, third parameter has precedence over **-FILE** option.

Google Cloud Storage Adapter

The Google Cloud Storage Adapter provides access to Google Cloud Storage buckets and objects in the Google Cloud Platform.

The adapter supports the following features:

- The Google Cloud Storage adapter provides access to Google Cloud Storage buckets and objects in the Google Cloud Platform.
 - Discovering available buckets and objects with the option to filter objects based on the provided delimiter and prefix values.
 - Authenticating the user using the specified service account credentials file, or automatically by the environment.
 - Reading the specified object in a single chunk or in multiple chunks of the specified size.
 - Keeping or deleting the specified object after reading and processing it successfully, as part of committing the map transaction.
 - Reading the list of objects in the specified bucket, with optional filtering, for further processing the list in a map.
 - Writing an object, with the option to fail or overwrite the target object if it exists already.
 - Writing an object in a single chunk or in multiple chunks by configuring the map inputs to run in burst mode.
 - Writing data to an intermediate (temporary) object and moving it to the target object as part of committing the map transaction.
- **Authenticating Connections**
The Google Cloud Storage adapter supports service account based authentication and authorization. Refer to the **Credentials File** adapter property documentation for more information.
- **Adapter properties and commands**
This section lists the properties supported by the Google Cloud Storage adapter.
- **Examples**

Authenticating Connections

The Google Cloud Storage adapter supports service account based authentication and authorization. Refer to the **Credentials File** adapter property documentation for more information.

Adapter properties and commands

This section lists the properties supported by the Google Cloud Storage adapter.

Credentials File

Property identifier: credentials_file

Adapter command (short syntax): -CF**credentials_file**

Adapter command (long syntax): -CREDENTIALSFILE**credentials_file**

Specifies JSON file with credentials of the service account used to access the Cloud Storage service. When not specified, the authentication is done using the credentials file pointed to by the GOOGLE_APPLICATION_CREDENTIALS environment variable. When running in the Google Cloud environment, where applicable the authentication may be performed automatically by the environment using the default service account for the environment in which the adapter is running. Note that the adapter only supports authentication for Google service accounts. Authentication for Google end-user accounts and API keys is not supported.

Bucket

Property identifier: bucket

Adapter command (short syntax): -B **bucket_name**

Adapter command (long syntax): -BUCKET **bucket_name**

Specifies the name of the bucket to access. The bucket must exist already. When configuring the adapter in Design Server, the list of existing buckets can be fetched, and a bucket can be selected from the list.

Object

Property identifier: object

Adapter command (short syntax): -O **object_name**

Adapter command (long syntax): -OBJECT **object_name**

Specifies the name of the object (blob) to access. When configuring the adapter in the Design Server web UI, the list of existing objects in the specified bucket can be fetched and an object can be selected from the list.

Read mode

Property identifier: read_mode

Adapter command (short syntax): -RM object_data|object_list

Adapter command (long syntax): -READMODE object_data|object_list

The read operation mode. Two modes are supported:

- Object Data - in this mode the adapter retrieves the contents of the specified object. This is the default read mode. The corresponding adapter command value is object_data (case-insensitive).
- Object List - in this mode the adapter retrieves a list of objects in the specified bucket. Each object name in the list is terminated with a linefeed character. If Prefix and Delimiter options are specified, they are used as filters when assembling the list of objects. The corresponding adapter command value is object_list (case-insensitive).

Prefix

Adapter command (short syntax): -PFX **prefix**

Adapter command (long syntax): -PREFIX **prefix**

Specifies object name prefix to use for filtering object names for the object discovery operation, and for listing objects for the Object List mode read operation. When specified, only the object names that start with it are included in the result.

Delimiter

Adapter command (short syntax): -DEL **delimiter**

Adapter command (long syntax): -DELMITTER **delimiter**

Specifies object name delimiter to use for filtering object names for the object discovery operation, and for listing objects for the Object List mode read operation. When specified, it is treated as path delimiter, and for object names that include the delimiter in their name, only the portion of the object name up to and including the specified delimiter is included in the result. Note that if the prefix filter is specified as well, any delimiters present in the prefix position are ignored, and only the delimiters present after the prefix are considered for the delimiter filtering.

Overwrite

Adapter command (short syntax): -OW

Adapter command (long syntax): -OVERWRITE

When selected, it instructs the adapter to overwrite the object is writing data to in case the object with the same name already exists. The default is not to overwrite the object but to report an error if attempt it made to write data to an object that already exists.

Read Success Action

Adapter command (short syntax): -RSA keep|delete

Adapter command (long syntax): -READSUCCESSACTION keep|delete

Specifies the action to perform on the object after successfully reading it. The adapter performs this action when requested to commit the source transaction under which it read the object. The action is performed as part of the transaction commit operation perform. The supported actions are:

- Keep - the adapter does not perform any action and leaves the source object intact. This is the default action. The corresponding adapter command value is keep (case-insensitive).
- Delete - the adapter deletes the object. The corresponding adapter command value is delete (case-insensitive).

Read Chunk Size (Bytes)

Adapter command (short syntax): -RCS **size**

Adapter command (long syntax): -READCHUNKSIZE **size**

Size of chunks, in bytes, in which to retrieve data from the source object. When the property is not specified, or is set to a non-positive value, the entire object data is retrieved in a single chunk.

Intermediate Object Mode

Adapter command (short syntax): -IOM

Adapter command (long syntax): -INTERMEDIATEOBJECTMODE

Instructs the adapter to write data to a uniquely-named intermediate object, and to copy that object to the specified target object when committing the target transaction. The adapter automatically creates a unique name to use for the intermediate object, by generating a universally unique identifier (UUID) value consisting of 68 dash and hex digit characters, to which it appends an underscore character and the specified target object name.

Intermediate Object Prefix

Adapter command (short syntax): -IOP **prefix**

Adapter command (long syntax): -INTERMEDIATEOBJECTPREFIX **prefix**

In addition to the unique name for the intermediate object that the adapter constructs automatically, this property provide option to include additional user-defined prefix in the intermediate object names. This can be used to help identify or filter intermediate objects in the bucket created by the adapter.

Intermediate Object Failure Action

Adapter command (short syntax): -IOFA keep|delete

Adapter command (long syntax): -INTERMEDIATEOBJECTFAILUREACTION keep|delete

Specifies action to perform on the intermediate object in case of a failed write operation. The adapter performs this action on the intermediate object as part of the target transaction rollback operation. Note that this action applies only to the intermediate object, not to the specified target object. The supported actions are:

- Keep - Preserve the intermediate object. This can help with troubleshooting problems and can also be used to force-commit the transaction, by manually copying the object to the target object. The corresponding adapter command value is keep (case-insensitive).
- Delete- Delete the intermediate object. This is the default action. The corresponding adapter command value is delete (case-insensitive).

Logging

Adapter command (short syntax): -T[V|E][+] [log_file]

Adapter command (long syntax): -TRACE[VERBOSE|ERROR][+] [log_file]

This property, along with its two sub-properties, Append Log and Log File Name is used to enable logging at the adapter level. When enabled, the adapter logs messages with details about the operations it is performing on the Cloud Storage service. The default logging level is Info and is used to log informational level messages. The level Error can be specified to enable logging of error level messages only, and the level Verbose can be used to enable logging of all messages. The property Append Log can be set to instruct the adapter to append messages to the log file if the log file exists already, instead of overwriting it, which is the default option. The sub-property Log File Name can be used to specify the file name for the log file. By default the log file name is m4gcstorage.mtr and the file is created in the current map directory.

Convert Data

Specifies to convert data to parsed form. If enabled, support for converting CSV, Avro, Excel, Parquet and JSON documents into sets of data records in the CSV format. This means that the data produced by the converters can be loaded directly into relational databases.

Data Format

Specifies the data format. This is a mandatory property. Select one of the following as per the data format type. This property field is applicable when Convert Data property toggle is enabled.

- CSV
- Excel
- Avro
- Parquet
- JSON

Header

If enabled, specifies whether the CSV data contains a header row.

Quote

Specifies the quote character. Default value is ".

Delimiter

Specifies the field delimiter character. Default value is ,.

Escape

Specifies the escape character.

Separator

Specifies the row separator characters. Default value is \r\n.

Character Set

Specifies the character set of the data. Default value is UTF-8.

Limit

Specifies the maximum number of records to return.

Sample Size

Specifies the number of records to analyze when determining the data structure. Default value is 100.

Worksheet Index

Specifies the index of the worksheet. The index of the first worksheet is 1 (default).

Select Source Tables

Select which arrays of objects in the AVRO data you wish to map to tables in the target.

Find Array

If enabled, specifies that the output will iterate on the first array found in the JSON document.

Array Path

Specifies the path of the JSON array within the document. Omit if the document is an array. For example,"/resources".

Examples

GET function example for fetching message from Cloud Storage subscription

The following is an example of a **GET** map rule used to retrieve data from an object in the Cloud Storage bucket and performing authentication explicitly based on the specified credentials file. Logging is enabled, with verbose level and default log file m4gcstorage.mtr created in the map directory.

Replace *creds_file*, *bucket_name* and *object_name* with the credentials file path, bucket name and object name applicable to your environment.

```
GET("GCSTORAGE", "-CF creds_file -B bucket_name -O object_name -RM OBJECT_DATA -TV")
```

PUT function example for inserting message to a Cloud Storage topic

The following is an example of a **PUT** map rule used to write data to an object in the Cloud Storage bucket and overwrite the object if it exists already. Authentication is performed automatically, such as using the GOOGLE_APPLICATION_CREDENTIALS environment variable. Logging is enabled, with error level and appending messages to the specified log file. The last argument, *input_data* represents the data to be written to the object, and may be a hard-coded data, or, more typically, a reference to a type from another map card.

Replace *log_file*, *bucket_name* and *object_name* with the log file name, bucket name and object name applicable to your environment:

```
PUT("GCSTORAGE", "-B bucket_name -O object_name -OW -TE+ log_file", input_data)
```

Google Pub / Sub Adapter

The Google Cloud Pub/Sub adapter provides access to Google Cloud Pub/Sub topics and subscriptions in the Google Cloud Platform.

The adapter supports the following features:

- Testing the configured connection by authenticating the user and attempting to list the available topics.
- Discovering available topics and subscriptions of the pull kind.
- Authenticating the user using the specified service account credentials file, or automatically by the environment.
- Reading messages from the specified pull subscription, with the option to create the subscription if it does not exist already.

- Option to specify message deadline when creating a new subscription, and separately for the messages retrieved from a subscription.
- Option to acknowledge retrieved messages immediately, never, or when committing the source transaction.
- Option to specify number of messages to poll per request.
- Logical message mode, where multiple Pub/Sub messages are treated as a single logical message.
- Lets you write messages to the specified topic with the option to create the topic automatically if it does not exist.
- Option to batch messages locally before publishing them to the Pub/Sub service.
- Option to specify the publish timeout.
- Configuring the adapter as a listener for triggering flows based on the arrival of messages on the specified pull subscription.

- **[Authenticating Connections](#)**

The Google Cloud Pub/Sub adapter supports username/password-based authentication method.

- **[Adapter properties and commands](#)**

This section lists the properties supported by the Google Cloud Pub/Sub adapter.

Credentials File

Specifies the JSON file with credentials of the service account used to access the Cloud Pub/Sub service. When not specified, the authentication is done using the credentials file pointed to by the GOOGLE_APPLICATION_CREDENTIALS environment variable. When running in the Google Cloud environment, where applicable the authentication may be performed automatically by the environment using the default service account for the environment in which the adapter is running. The adapter only supports authentication for Google service accounts. Authentication for Google end-user accounts is not supported.

The corresponding adapter command is -CF (or -CREDENTIALSFILE) *credentials_file*.

Username

Specifies the username for the connection. This is optional property. For many drivers, you can specify the username as part of the connection string. Some drivers might use authentication other than username and password, and some drivers might not require authentication at all. The corresponding adapter command is -USER *user_name*.

Project

This property identifies the project that hosts the topics and subscriptions accessed by the adapter. The corresponding adapter command is -P (or -PROJECT) *project_id*.

Topic

Specifies the topic to which messages are written. When reading messages and creating the subscription automatically. This is the topic for which the subscription is created. The corresponding adapter command is -TP (or -TOPIC) *topic_id*.

Create Topic

Instructs the adapter to create the specified target topic if the topic does not exist already. This property is applicable only when the adapter is used in target scenario. The corresponding adapter command is -CT (or -CREATETOPIC).

Subscription

This property identifies the subscription from which to read messages. The adapter supports only pull type subscriptions, and it does not support push type subscriptions. When discovering subscriptions, only the subscriptions of pull type are included in the result. The corresponding adapter command is -S *subscription_id*.

Create Subscription

Instructs the adapter to create the specified subscription if the subscription does not exist already. This property is applicable only when the adapter is used in source scenario. The new subscription is created for the specified topic, and it is created as subscription of pull type.

The corresponding adapter command is -CS (or -CREATESUBSCRIPTION).

Batch Count

Specifies the number of messages to store locally in the Pub/Sub client before flushing the buffer. The default value is 1 which implies immediate flushing of the buffer. The flushing of the batch is controlled using a combination of conditions specified in Batch Count, Batch Size (Bytes) and Batch Delay (Milliseconds) properties. When any of those conditions is met, the buffer is flushed.

The corresponding adapter command is -BC (or -BATCHCOUNT) *count*.

Batch Size (Bytes)

Specifies the size in bytes of the buffer in which to store messages locally before flushing the buffer. The default value is 1 which implies immediate flushing of the buffer. The flushing of the batch is controlled using a combination of conditions specified in Batch Count, Batch Size (Bytes) and Batch Delay(Milliseconds) properties. When any of these conditions is met, the buffer is flushed.

The corresponding adapter command is -BS (or -BATCHSIZE) *size*.

Batch Delay (Milliseconds)

Specifies the duration in milliseconds for storing messages locally in a buffer before flushing the buffer. The default value is 1 which implies immediate flushing of the buffer. The flushing of the batch is controlled using a combination of conditions specified in Batch Count, Batch Size (Bytes) and Batch Delay(Milliseconds) properties. When any of those conditions is met, the buffer is flushed.

The corresponding adapter command is -BD (or -BATCHDELAY) *delay*.

Subscription Deadline (Seconds)

Specifies the deadline in milliseconds to set for the messages on the subscription when the subscription is created by the adapter. This is the interval each subscriber is given to acknowledge the retrieval of a message from the subscription. If the message is not acknowledged during this interval and its deadline is not extended, it is automatically made available for redelivery. The default value is 10 seconds.

The corresponding adapter command is -SD (or -SUBSCRIPTIONDELAY) *deadline*.

Acknowledgments

Specifies when the adapter should acknowledge retrieved messages. The supported options are:

- **Never** - the adapter never sends acknowledgments for the messages. After the deadline for acknowledgment expires, the messages are made available for redelivery. This is the default option. It is case-insensitive. The corresponding adapter command value is never.
- **Immediate** - the adapter sends acknowledgment for messages immediately after retrieving them before the messages are processed by the map. It is case-insensitive. The corresponding adapter command value is immediate.
- **Transactional** - the adapter acknowledges the messages as part of committing the source transaction. It is case-insensitive. The corresponding adapter command value is transactional.

The corresponding adapter command is -ACK (or -ACKNOWLEDGMENTS)never|immediate|transactional.

Message Deadline (Seconds)

Specifies the deadline in milliseconds to set for the messages retrieved from a subscription. This becomes the new time interval. The adapter has to acknowledge the messages before they are made available for redelivery. When the value is not specified, the default deadline value is -1, which represents the deadline set at the subscription level. The corresponding adapter command is -MD (-MESSAGEDEADLINE) deadline.

Poll Message Count

Specifies the maximum number of messages to poll from the Pub/Sub service per single request. The default value is 1 which effectively disables retrieving messages in batches. When more than one message is retrieved per request, the messages are stored locally, and the adapter polls the subscription for new messages only after it has exhausted all locally stored messages.

The corresponding adapter command is -PMC (-POLLMESSAGECOUNT)*count*.

Publish Timeout (Seconds)

Specifies the time in milliseconds. The adapter waits for the publish operation to complete, before timing out and reporting error. The default value is -1 which indicates no timeout. The corresponding adapter command is -PT (-PUBLISHTIME) *timeout*.

Logical Message Mode

Specifies that the adapter will run in a mode in which the payload it exchanges with the framework is assumed to consist of one or more Pub/Sub physical messages. When this mode is not used, each payload the adapter exchanges with the framework corresponds to exactly one Pub/Sub message.

In logical message mode, the payload the adapter exchanges with the framework is in the following format:

32-bit integer representing the total remaining payload size (4 bytes) 32-bit integer representing the size of message 1 (4 bytes) message 1 data 32-bit integer representing size of message 2 (4 bytes) message 2 data.

In target context, a single payload (logical message) provided to the adapter may result in multiple Pub/Sub messages published to the target topic. In source context, multiple Pub/Sub messages retrieved from the subscription may be combined and provided to the framework as a single payload (logical message).

The corresponding adapter command is -LMM (or -LOGICALMESSAGEMODE).

Logical Message Count

Specifies the number of Pub/Sub messages to include in a single logical message when reading messages from the subscription in logical message mode. The default value is 1. The size of the logical message provided by the adapter is controlled by the combination of conditions defined by two properties:

- Logical Message Count and
- Logical Message Size (Bytes).

Whichever condition is met first determines the actual size of the logical message.

The corresponding adapter command is -LMC (or -LOGICALMESSAGECOUNT) *count*.

Logical Message Size (Bytes)

Specifies the size in bytes of a single logical message when reading messages from the subscription in logical message mode. When the total size of messages retrieved from the subscription reaches or exceeds this value, the logical message is considered complete. The default value is 0. The size of the logical message provided by the adapter is controlled by the combination of conditions defined by two properties:

- Logical Message Count and
- Logical Message Size (Bytes).

Whichever condition is met first determines the actual size of the logical message.

The corresponding adapter command is -LMS (or -LOGICALMESSAGESIZE) *size*.

Limit

Specifies the number of messages to retrieve from the subscription. The default value is 1. The special value "S" indicates all available messages and the value 0 means no wait. The corresponding adapter command is -QTY *limit*.

Timeout

Specifies the timeout in seconds to wait for a new message to arrive. The default value is "S". This is a special value that indicates unlimited (infinite) wait. The corresponding adapter command is -LSN *timeout*.

Logging

This property specifies the level of logging to use for the log (trace) file produced by the adapter. The default is Off. The value Information means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

The corresponding adapter command is:

-T [E|V] [+|] [file_path]

-T -> Log adapter informational messages.
-TE -> Log only adapter errors.
-TV -> Use verbose (debug) logging. The log file records all activity that occurs while the adapter is producing or consuming messages.
+ -> Appends the trace information to the existing log file. Omit this argument to create a new log file.
file_path -> The full path to the adapter trace log. If you omit this keyword, the adapter creates the m4gcpubsub.mtr log file in the map directory.

Append Log

Flag indicating what to do if the specified log file already exists. When set to true, the log messages are appended to the file. When set to false, the file is truncated, and the messages are written to the empty file. The default value is true.

Examples

GET function example for fetching message from Cloud Pub/Sub subscription

The following is an example of a **GET** map rule used to retrieve messages from a Cloud Pub/Sub subscription and performing authentication explicitly based on the specified credentials file. Messages are acknowledged as part of committing the source transaction.

```
GET("GCPUBSUB", "-CF creds_file -S subscription_name -ACK TRANSACTIONAL -TV")
```

PUT function example for inserting message to a Cloud Pub/Sub topic

The following is an example of a **PUT** map rule used to write messages to a Cloud Pub/Sub topic and create the topic if it does not exist already. Publish timeout is set to 10 seconds. Authentication is performed automatically, such as using the GOOGLE_APPLICATION_CREDENTIALS environment variable.

```
PUT("GCPUBSUB", "-T topic_name -CT -PT 10 -TE+ log_file", input_data)
```

FTP adapter overview

Use the File Transfer Protocol (FTP) Adapter to transport data. When source data arrives at its target, it often must be transformed into a different format for a receiving application to use it successfully.

If you have the Command Server, Launcher, or Software Development Kit on one platform, you can use the FTP adapter to retrieve or send data to another platform.

The adapter can connect to any FTP server that follow RFC 959. For optimal performance, the server should also follows RFC 1123. Noncompliant servers may cause errors in the adapter.

- [FTP adapter introduction](#)
This documentation introduces the File Transfer Protocol (FTP) adapter. You can use this adapter with a Command Server, Launcher, Software Development Kit, or map in a map rule.
- [Adapter Properties and Commands](#)
This section lists the properties supported by the adapter.
- [FTP Adapter command examples](#)
- [Syntax summary](#)
- [Troubleshooting](#)
The FTP adapter can reference up to 1024 temporary files during process execution.
- [Return codes and error messages](#)

FTP adapter introduction

This documentation introduces the File Transfer Protocol (FTP) adapter. You can use this adapter with a Command Server, Launcher, Software Development Kit, or map in a map rule.

System requirements

The minimum system requirements and operating system requirements for the FTP adapter are detailed in the system requirements and the release notes. For runtime purposes, a Command Server is assumed to have already been installed on the computer where the adapter will be installed.

In addition, the following are requirements for installing and running the FTP adapter:

- The FTP adapter must be installed in the same directory as the Command Server for your specific platform.
- TCP/IP must be installed on the machine where the adapter is installed.
- The machine where the FTP adapter is installed must be able to access the FTP servers over a TCP/IP network.

About sockets

Windows or BSD (UNIX) sockets must be installed on the client computer.

- The socket installation must support TCP/IP.
- The client computer must be able to access an appropriate server. To test this, type:
 - telnet target-ip 25 (to test an SMTP e-mail target)
 - telnet target-ip 110 (to test a POP3 e-mail source)

Where *target-ip* is the server IP address, if the test is successful, you will receive a welcome message from the server. To shut down the session, type **QUIT** and press **Enter**.

You might not see what you are typing on the screen.

Access to international VANs

The FTP adapter can access international VANs and communicate with a Trading Manager post office. For detailed configuration information, see the Partner Manager documentation.

Command alias

Specify adapter commands by using a command string on the command line or by creating a command file that contains adapter commands. The command syntax is:

```
-IA[alias] card_num
-OA[alias] card_num
```

In the command syntax, **-IA** is the Input Source Override execution command, and **-OA** is the Output Target Override execution command, *alias* is the adapter alias, and *card_num* is the number of the map card. The FTP adapter alias and corresponding execution commands are listed in the following table.

Adapter	Alias	As Input	As Output
FTP	FTP	-IAFTP <i>card_num</i>	-OAFTP <i>card_num</i>

Adapter Properties and Commands

This section lists the properties supported by the adapter.

FTP adapter commands

The following table lists valid commands for the FTP adapter, the command syntax, and whether the command is supported (✓) for data sources, targets, or both.

Table 1. Adapter properties and commands

Name	Syntax	Source	Target
Account	-ACCT <i>account_id</i>	✓	✓
Audit	-AUDIT [+][S] [full_path]	✓	✓
Client Certificate	-CERT {label}	✓	✓
Code Page Local (z/OS only)	-CPL <i>code_page_name</i>	✓	✓
Code Page Remote (z/OS only)	-CPR <i>code_page_name</i>	✓	✓
Fail	-FAIL <i>error_code[:error_code...]</i>	✓	✓
Firewall Connection Method URL	-FIREWALL <i>FTP://firewall_URL</i>	✓	✓
FTP URL	-URL <i>FTP://ftp_URL</i>	✓	✓
GXS	-GXS	✓	✓
Ignore	-IGNORE <i>error_code[:error_code...]</i>	✓	✓
Implicit	-IMPLICIT	✓	✓
Keep Server	-KS	✓	✓
List Option	-LS <i>sort_type</i>	✓	✓
Make Directory	-MKD	✓	✓
Move	-MOVE [<i>file_name directory_location</i>]	✓	
Passive Mode	-PASV	✓	✓
Port Mode	-PORT	✓	✓
Quantity	-QTY <i>number</i>	✓	
Site	-SITE <i>command_text</i>	✓	✓
SSL Encryption Strength	-STR {WEAK STRONG ANY}	✓	✓
SSL Protocol	-SPROTO {SSLv2 SSLv3 SSlv23 TLSv1}	✓	✓
Stage	-STAGE [<i>file_name</i>]		✓
Success	-SUCCESS <i>error_code[:error_code...]</i>	✓	✓
System	-SYS {WIN32 UNIX UNKNOWN}	✓	✓
Trace	-T[E][+][S V] [full_path]	✓	✓
Timeout	-TIMEOUT (<i>nnn</i>)	✓	✓

Account

Specifies the account required to connect to an FTP server. If the account is required to log on, *account_id* must be specified. The corresponding adapter command is **-AC** or (**-ACCT** *account_id*).

account_id: Specifies the account for connecting to an FTP server.

Audit

Generates a log file in the map directory where the adapter is installed with the default name **m4ftp.log**. The log file records audit information with details such as files sent or received from each host, elapsed time, file size, and retry count for each file.

The corresponding adapter command is: **-AUDIT** or **-A**

-AUDIT[+][S] [full_path]

For example:

+> Appends audit information to the existing log file. If no log file exists, a new one will be created.

S-> Summary mode, recording only minimal information in the log file.

full_path-> Creates an audit file with the specified name in the specified directory. By default, the directory is where the map is located, and the file name is **m4ftp.log**.

Client Certificate

Specifies the label of the client certificate in the key store. This command is applicable only when the **SSL_CLIENT secure_mode** setting in the config.yaml file is set, and SSL/TLS encryption is in effect.

The corresponding adapter command is **-CERT {label}**.

label: The name of the entry in the certificate store, which is specified by the **key_store** field in the config.yaml file.

Note: The certificate store contains all personal and trusted certificates in a PKCS12 format file. To see the examples on how to import private keys and certificate chains into this encrypted file, refer to the readme.txt file located in the <Design Studio installation folder>|examples|secureadapt|ssl folder.

Code Page Local

Specifies the code page of the data on the local system. The local system is the system on which the IBM Sterling Transformation Extender is running.

Use this command with the TYPE=ASCII feature of the **-URL** command. This command must be used if the Code Page Remote adapter command (**-CPR**) is specified.

This command is only valid on z/OS systems. The default value is the default **EBCDIC** code page for your system.

The corresponding adapter command is **-CPL code_page_name**.

code_page_name: Specifies the code page name of the data on the local system.

For more information, see the description of the **atoe_l** function in the *IBM z/OS C/C++ Run-Time Library Reference*.

Code Page Remote

Specifies the code page of the data on the remote system, from which or to which the data is being transferred. This command is only valid on z/OS systems; the default value is ISO **8859-1**.

Use this command with the TYPE=ASCII feature of the **-URL** command. This command must be used if the Code Page Local adapter command (**-CPL**) is specified.

The corresponding adapter command is **-CPR code_page_name**.

code_page_name: Specifies the code page name of the data on the local system.

Fail

Specifies the error codes that cause the adapter to fail and disconnect from the FTP server. This is an optional command.

The default behavior of the FTP adapter is to pass 100 and 200-level error codes and to fail only on 300, 400, and 500-level error codes as defined in RFC 959. Any other error codes returned are ignored. Using the Fail adapter command, you can specify the error codes, such as from third-party data, for which the adapter fails.

The Fail adapter command requires a numerical integer for the error code. If necessary, you can specify multiple error codes.

The corresponding adapter command is **-FAIL**.

-FAIL error_code[:error_code...]

error_code: Any numerical integer return code except 100, 200, 300, 400, and 500 level FTP error codes as defined in RFC 959 that you want the adapter to fail on.

Use a colon (:) to separate multiple error codes. For example, the following command indicates that the adapter will fail on return codes 13 and 24:

-FAIL 13:24

Firewall Connection Method

Specifies the URL for the proxy server (firewall). One of the following connection methods must be specified:

- OPEN
- SITE
- TRANSPARENT
- USER
- USERFW
- USERFWPASS
- USERLOGON or USER
- USERLOGONFW or USERFW

The corresponding adapter command is **-FW** or **(-FIREWALL)**.

Generally, the command format is written as:

-FIREWALL FTP://[fw_user[:fw_pass]@[fw_host[:fw_port]]/method

fw_user: Specifies the username required for connecting to the proxy server. Unless you specify a password, this parameter must be followed by @ if you specify fw_host.

:fw_pass: Specifies the password required to authenticate the username. This parameter must be followed by @ if you are also specifying fw_host.

fw_host: Specifies the name (or address) of the proxy server to which to connect.

:fw_port: Specifies the name (or number) of the port to use for connection.

/method: Required value. The method dictates how the firewall connection is established based on a combination of the connection information provided using - **FIREWALL** (for proxy server URL) and - **URL** (for FTP URL). Select one of the following methods that specifies the corresponding Connection Information.

Method Connection Information

OPEN ftp_host, USER ftp_user, PASS ftp_pass

TRANSPARENT is the only method directly connecting to the FTP server; all other methods connect to the firewall. For more information on the FTP variables shown in the Connect Information column, see the section for the FTP URL (-URL) adapter command.

Adapter behavior when the -FIREWALL command Is present

A firewall isolates and restricts some computers from reaching other computers.

Only a small part of the FTP adapter knows its presence if a firewall is mentioned.

Without a firewall, the start of a file transfer begins with:

- Establish a Socket connection to the remote host.
- Issue the **USER** command over the connection.
- Issue the **PASS** command over the connection.

When a firewall is used, more steps are performed at the beginning of the file transfer.

These steps depend on the *method* specified in the last part of the -FIREWALL command.

OPEN - Establish a Socket connection to the firewall host and issue the following command over the connection in this order:

OPEN ftp_host USER ftp_user PASS ftp_pass

SITE - Establish a Socket connection to the firewall host and issue the following command over the connection in this order:

USER fw_user PASS fw_pass SITE ftp_host USER ftp_user PASS ftp_pass

TRANSPARENT - Establish a Socket connection to the firewall host and issue the following command over the connection in this order:

USER fw_user PASS fw_pass USER ftp_user PASS ftp_pass

USERFW - Establish a Socket connection to the firewall host and issue the following command over the connection in this order:

USER ftp_user@ftp_host fw_user PASS ftp_pass USER ftp_user PASS ftp_pass

USERFWPASS - Establish a Socket connection to the firewall host and issue the following command over the connection in this order:

USER ftp_user@fw_user@ftp_host PASS ftp_pass@fw_pass

USERLOGON or USER - Establish a Socket connection to the firewall host and issue the following command over the connection in this order:

USER fw_user PASS fw_pass USER ftp_user@ftp_host PASS ftp_pass USER

USERLOGONFW or USERFW - Establish a Socket connection to the firewall host and issue the following command over the connection in this order:

USER fw_user@ftp_host PASS fw_pass USER ftp_user PASS ftp_pass

URL syntax

As the syntax for the rest of the URL varies depending on the scheme selected, URL schemes use direct IP-based protocol for a specified host on the Internet follow a common syntax for the scheme-specific data:

//user:password@host:port/url_path

The scheme-specific data may exclude some or all parts of the following components: *user:password@*, *:password*, *:port*, and */url_path*

The scheme-specific data starts with a double slash (//), indicating compliance with the common Internet scheme syntax. The *user:password* component conforms to the following rules:

user: An optional username. Some schemes allow the specification of a username.

password: An optional password. When present, it follows the username and is separated by a colon. The username and password are followed by an at sign (@). Any :, @, or / characters must be encoded. See URL encoding.

The *url_path* of an FTP URL has the following syntax:

cwd1/cwd2/.../ cwdN/name; type = xfer_type

Where *cwd1* through *cwdN* and *name* are possibly encoded strings and *xfer_type* is one of the characters a, i, or d. The part; *type=xfer_type* be omitted. The *cwdx* and *name* parts are empty. The whole *url_path* be omitted, including the /, delimiting it from the prefix containing *user*, *password*, *host*, and *port*.

The *url_path* is interpreted as a series of FTP commands as follows:

- Each *cwd* element will be sequentially supplied as the argument to a **CWD**, change working directory, command.
- If the type code is "d," perform an **NLST**, name list, or command with *name* as the argument and interpret the results as a file directory listing.
- Otherwise, perform a **TYPE** command with *xfer_type* as the argument and then access the file named *name*. For example, using the **RETR** command.
The *xfer_type* argument has been extended beyond what the RFC supports, specifically the D1, D2, D3, and D4 sections. Also, *host:port* be excluded, although it is rarely useful to do so; the *host* defaults to *localhost*.

FTP URL

Specifies the file names to be retrieved (adapter source) or created and appended (adapter target). This command is required to establish a connection to an FTP server.

The corresponding adapter command is **-URL**

Generally, the command format is:

-URL [FTP://][ftp_user[:ftp_pass]@][ftp_host[:ftp_port]]
`[/[...][dir/[dir/...]] [filename] ;type=xfer_type[+]]`

Option	Description
FTP:	Specifies a connection to an FTP server. If not specified, FTP: is assumed, along with the <code>//</code> . If specified, another <code>/</code> must separate the user and host parameters from the file and transfer type.
<code>:ftp_user</code>	Specifies the username to connect to the FTP server. Unless you specify a password, this parameter must be followed by <code>@</code> if you specify <code>ftp_host</code> .
<code>:ftp_pass</code>	Specifies the password that authenticates the username. If you also specify <code>ftp_host</code> , this parameter must be followed by <code>@</code> .
<code>ftp_host</code>	Specifies the name or address of the FTP server to which to connect. If not specified, the default of localhost is assumed.
<code>:ftp_port</code>	Specifies the port name or number to use for connection.
<code>dir/...</code>	Specifies the file's directory path. The ellipsis (...) indicates that this field can repeat, depending on your directory structure.
<code>filename</code>	Specifies the name of the target file. This is required for an adapter target but optional for an adapter source. If not specified, all files in the path are retrieved.
<code>;type=xfer_type</code>	<p>Specifies the transfer type or mode. The supported transfer types vary from server to server. Depending on the server, there might be additional or omitted transfer types. Valid transfer types are:</p> <p><code>A[len][!] ASCII</code></p> <p>Where <code>len</code> specifies the optional record length to pad or truncate the record, and <code>!</code> indicates no line terminator for the record(s).</p> <p>When sending an FTP request to the AS/400, the file must first be created on the AS/400 for the <code>len</code> parameter to pad the record correctly.</p> <p>Description of Transfer type</p> <ul style="list-style-type: none"> • I: Directory (file names only) • LB: Local 8-bit types (usually equivalent to I) • D: Directory (file names only) • D1: Directory (file names only) • D2: Directory (server-defined format) • D3: Directory (easily parsed line format, as defined in Internet draft draft-bernstein-eplf-02.txt) • D4: Directory (machine-readable list format as defined in Internet draft draft-ietf-ftpext-m1st-02.txt)
<code>+</code>	Appends the transferred data to the existing file.

If specified, an additional forward slash (`/`) is required to separate the user and host parameters from the file and transfer type.

GXS

Allows proper connectivity with the GXS VAN using an FTPS connection. The corresponding adapter command is **-GXS**.

When this command is in use, the **-IMPLICIT** adapter command is not necessary.

Generally, the command format is:

-TV -GXS -URL FTPS://john_doe:1234@gxsics.com/send/sendfile;type=A

This command performs several functions:

-TV-> Creates a trace verbose file in the directory where the map is located.

-GXS-> Specifies that a GXS (**-GXS**) secure connection to the server is used.

_URL FTPS://-> Specifies sending the file using **FTPS** to the **URL** address `secure.com`.

User id and Password-> Specifies the **user id** name `John Doe` and a **password** of `1234` is used to login to this account.

/Send/-> Specifies **send** will be the directory where the send file is stored.

sendfile;type=A-> specifies that **sendfile** will be transferred in ASCII mode (**type=A**).

Ignore

Allows the adapter to ignore the specific FTP error codes. The corresponding adapter command is **-I** or (**-IGNORE**).

-IGNORE error_code[:error_code...]

`error_code`: Specifies the FTP error codes that the adapter should ignore. A colon (`:`) should be used to separate multiple error codes.

For example, if you specified the command: **-I450:550**. The adapter ignores errors of type 450 (file busy) and errors of type 550 (file not available) and returns a zero-length file to the map.

Implicit

Specifies implicit FTPS secure connections to a server for sending or receiving data. This command implies the use of port number 990 as the default. If an alternate port number is required, it must be included on the command line after the specified URL. For example, `ftps://secure.com:6377`.

The corresponding adapter command is **-IMPLICIT**.

For example:

-TV -IMPLICIT -URL FTPS://john_doe:1234@secure.com/upload/mail_list;type=A

This command performs several functions:

-TV: Creates a trace verbose file in the directory where the map is located.

-IMPLICIT: Specifies that an implicit (**-IMPLICIT**) secure connection to the server is used.

-URL FTPS://: Specifies sending the file using **FTPS** to the **URL** address *secure.com*.

user id and password: Specifies the **user id** name *John Doe* and a **password** of 1234 are used to login to this account.

upload/mail_list;type=A: Specifies that the send file will be named **mail_list** after being transferred in ASCII mode (**type=A**).

Keep Server

Specifies in a map rule that when retrieving a file from an FTP server, it should not be deleted after transfer. This is an optional command. This option should be used if this behavior is required when using the **GET** mapping function. Alternatively, when running the adapter from an input card, the same behavior can be accomplished using the card property, **OnSuccess**, by setting it to **Keep**.

The corresponding adapter command is **-KS**.

For example:

-KS -URL ftp://user:pass@server/file.txt

List Option

Allows files to be retrieved based on a user supplied sorting preference. This command is used with the existing FTP URL (**-URL**) adapter command and supports a subset of FTP options that control the sequence of file transfers. This is an optional command.

The corresponding adapter command is **-LS**

-LS sort_type

The adapter passes the **-LS** command value to a remote FTP server as an argument when it lists the files in the directory. One of three events happens:

- The FTP server accepts the option and lists the files in the specified order.
- The FTP server ignores the option and lists the files in the default order.
- The FTP server rejects the option, and the adapter returns an error.

For example:

-URL ftp://testftp:test@host/mydir -ls tr

The **-LS** command is issued by the adapter before any file transfer, so that its results are used to control the order of the file transfer. In the example above, all files from *mydir* would be transferred, the oldest file being transferred first.

The following are the command options that are allowed:

t-> Sorts by time stamp.

r-> Reverses the order of sort.

tr-> Reverses the order of sort by time stamp.

rt-> Same as **-LS tr**.

All other list options result in the error message: `invalid ls option logged` in the adapter trace file.

Some FTP servers can ignore the List Option (**-LS**) command options (*t, r, tr, and rt*).

Make Directory

Creates a directory. For instance, if a file specified in a **PUT** operation belongs to a directory that does not exist, this command creates a new directory. If the command is not specified and the file specified on a **PUT** operation points to a directory that does not exist, the adapter will fail. This is an optional command.

The corresponding adapter command is **-MKD**.

For example:

PUT("FTP", "-URL ftp://jdoe:secret@server1/some/folder/ data.txt -MKD", "Some data")

This will force **jdoe/some** and create the **jdoe/some/folder**. A new file called **data.txt** will be added to this new directory.

Move

Moves files from their original location on the source FTP server to a different location on the source FTP server after the files have been transferred to the target server. On the Move adapter command, you can specify a new name for the original source file as a different file name, path, or both.

The FTP Adapter typically provides options for deleting or keeping files on the source FTP server after they are transferred to the target FTP server. The Move command provides additional functionality that permits you to move the files to a different location on the source server, as opposed to, for example, deleting them.

The corresponding adapter command is **-MOVE**.

For example:

-MOVE [file_name | directory_location]

file_name: Specifies the new name on the source FTP server for the transferred original file. This can be specified as the source file's absolute (fully qualified) or relative path.

The following commands demonstrate examples of how you can specify new names for the original file on the source FTP server as absolute and relative path names when the original file name in the FTP command to be downloaded is specified as *myoriginalfilename.txt*:

- **-MOVE /mynewfilename.txt**: This Move command, specified with an absolute path and new file name, moves the *myoriginalfilename.txt* file after it is downloaded from its original location on the source FTP server to your root directory for that FTP client and renames it *mynewfilename.txt*.

- **-MOVE mynewfilename.txt**: This Move command, specified with a new file name, renames the myoriginalfilename.txt file after it is downloaded to mynewfilename.txt on the source FTP server.

directory_location: Specifies the different directory or subdirectory names on the source FTP server for the original or transferred files. The directory name must be terminated with a path separator. Examples include backward slash (\) for Windows and forward slash (/) for UNIX environments.

If the directory does not exist and the **MKD** option is also specified on the command line, the directory will be created relative to the current location of the file or files on the source FTP server that have already been downloaded.

The adapter will fail if the directory does not exist, and the **MKD** option is not specified on the command line.

If you are unsure that the directory exists, use the **MKD** option. When you specify this command option whether the directory exists, the adapter command will avoid a failure result. If the directory does exist, the **MKD** option will not attempt to create the directory and the adapter command will continue.

The following commands demonstrate examples of how you can specify an existing or new subdirectory name for the original file on the source FTP server when the original subdirectory name in the FTP command is specified as myoriginalsubdir:

- **-MOVE /mydiffexistingsubdir/**: This Move command, specified with a different subdirectory that already exists, moves the file after it has been downloaded from its original location on the source FTP server to the mydiffexistingsubdir subdirectory with its original file name.
- **-MOVE /mynewsubdir/ -MKD**: This Move command, specified with a new subdirectory, makes the new mynewsubdir subdirectory in a location that is absolute to the current location and then moves the file after it has been downloaded from its original location on the source FTP server to the new subdirectory with its original file name.

Platform-specific FTP Server limitations

The Move adapter command functionality is subject to platform-specific FTP Server limitations. For example, on z/OS environments, the **-MOVE** option cannot be executed across different file systems. The Hierarchical File System (HFS) on your UNIX System Services (USS) environment cannot move a file to a data set.

Note: The FTP Adapter does not recognize z/OS Partitioned Data Set (PDS) file names.

Passive Mode

Specifies that only passive mode should be used for the FTP data connection. This command is primarily useful for firewalls and is considered a preferred connection method for security reasons.

By default, the adapter attempts to connect using passive mode. If unsuccessful, the adapter uses Port Mode. See the Port Mode adapter command (-PT). During a passive mode connection, the server listens for the connection and dictates where the adapter is to connect. Older servers might not support passive mode.

The corresponding adapter command is **-PV** or (**-PASV**).

Port Mode

Specifies that only port mode should be used for the FTP data connection. This older connection method might be the only way to connect on older servers. The corresponding adapter command is **-PT** or **-PORT**.

By default, the adapter attempts to establish a connection using passive mode. If the adapter is unsuccessful, it uses port mode. See the Passive Mode adapter command **-PV**.

Note: The IBM Sterling Transformation Extender FTP Adapter only supports the FTP secure socket layer (SSL) protocol in passive mode (-PASV). If you specify the **-PORT** option on the command line and the FTP URL specifies the SSL protocol (for example, `ftps://`), the **-PORT** option is ignored, and passive mode is used instead.

Submit command after file transfer

Submits a specified command to the FTP server after each file transfer occurs. The corresponding adapter command is **-PQUOTE**.

-PQUOTE*command*.

command: The command or command string will be submitted to the FTP server.

For example:

The following command records the size of the test.dat file in the adapter trace file after the file transfers:

-PQUOTE 'size test.dat'

Quantity

Specifies the number of files retrieved by the adapter.

In burst mode, each burst might return fewer messages than specified, but the total number of messages returned by the adapter will not exceed the value set by the **-QTY** command. If not specified, the default quantity is the **FetchUnit** size of the burst.

The corresponding adapter command is **-QTY**

-QTY*number*.

number: The number of files to be retrieved by the adapter.

If you want the maximum number of files retrieved in burst mode infinite, you must set the **-QTY** command option number to 's' and specify "`-LSN 0`" on the command line. The `-LSN` command is currently unsupported; however, it must only be used with the `-QTY` command in this scenario.

Submit command before file transfer

Submits a specified command to the FTP server when the connection is established and immediately before each file transfer occurs. The corresponding adapter command is **-QUOTE**.

-QUOTE*command*.

command: The command or command string is to be submitted to the FTP server.

The following command submits the **TYPE B 6** command to a System i® server:

-QUOTE 'TYPE B 6'

Site

Sends an FTP server-specific site command to the FTP server software. The corresponding adapter command is **-SITE**.

-SITE'command_text':

'command_text': Specify the FTP-server-specific site command, enclosed in single quotation marks, to send to the FTP server software.

The following command sends the *namefmt* command to an AS/400 FTP server before files are transferred.

-SITE 'namefmt=1'

To see what commands are accepted by the server, use a BSD-based command line client, typically the FTP command installed with your Windows or UNIX operating system and log in to the server and type the following from the `ftp` prompt: `quote HELP SITE` or `quote SITE HELP`.

The command specified by **-SITE** is executed before the files are transferred.

SSL Encryption Strength

Specifies the encryption strength for FTP connections. It can be set to either WEAK, only using weak algorithms, or STRONG, only using strong algorithms. If not specified, any available algorithm is used. If STRONG is unavailable, then WEAK is used. However, if the export version of the libraries is used, only weak algorithms are available, and this command is ignored.

This command is applicable only when the SSL **secure_mode** setting is in the config.yaml configuration file (/runtime/secure_mode) is set to 0, and RSA-based SSL encryption is in effect.

The corresponding adapter command is **-STR {WEAK/STRONG/ANY}**.

WEAK-> Use strong (non-exportable) encryption only.

STRONG-> Use exportable encryption only.

ANY-> Use any available encryption.

SSL Protocol

Specifies setting the Secure Socket Layer (SSL) protocol level. SSL enables the adapter to process FTPS URLs. The corresponding adapter command is **-SPROTO{SSLv2/SSLv3/SSLv23/TLSv1}**.

SSLv2: Specify SSL protocol version 2.

SSLv3: Specify SSL protocol version 3.

SSLv23: Specify SSL protocol version 2, version 3, TLSv1, TLSv1.1 or TLSv1.2. Whenever the protocol method of **SSLv23** is specified, the protocol of first choice is **TLSv1.2**, with a fallback to **TLSv1.1**, then to **TLSv1**, then to **SSLv3**, and finally to **SSLv2**, depending on the GSKit module that is loaded.

TLSv1: Specify Transport Layer Security (TLS) protocol version 1.

If **-SPROTO** is not specified, the SSL Protocol defaults to **SSLv23**.

This command is applicable only when the SSL **secure_mode** setting is in the config.yaml configuration file (/runtime/secure_mode) is set to 0, and RSA-based SSL encryption is in effect. This command is superseded by an SSL **secure_mode** setting of 1 or 2.

Stage

Use the Stage adapter command to:

- Specify that uploaded data should be staged in a temporary or shadow file.
- Prevent partial updates of a file from being transferred. This is especially important if the FTP server processes uploads in an automated fashion.

During an upload, the FTP server generates a uniquely named temporary file. When the transfer has been completed successfully, the original file is deleted, and the temporary file is renamed. For this process to succeed, you must have access rights associated with your user ID to delete and rename files, and if the optional file name (*file_name*) is omitted, the server must provide a correct Store Unique (STOU) response. The adapter issues a warning if the server response cannot be interpreted. It is recommended that you run a preliminary test to ensure that the process is completed successfully.

The corresponding adapter command is **-STAGE** or **-STG**.

-STAGE[file_name]

file_name: Specifies a unique file name for the temporary file. This option is especially useful if a server does not supply unique file names.

Success

Allows a map to succeed when 300-level error codes, as defined in RFC 959, are returned. If this command option is not specified, the adapter's default behavior of the adapter is to fail on 300-level error codes. This is an optional command.

The corresponding adapter command is **-S** or **(-SUCCESS)**

-SUCCESS error_code[:error_code...]

When you specify **-SUCCESS** on the adapter command line, a numerical integer value between 300 and 399 is required. When this value is returned, the adapter does not fail.

error_code- An FTP error code, defined in RFC 959, between 300 and 399. Separate multiple error codes with a colon (:). For example:

-SUCCESS 301:302:303

System

Specifies the system type when the adapter cannot accurately determine the system type of the FTP server.

The FTP server system type is not necessarily the same as the operating system of the machine it runs on. Some Windows FTP servers use UNIX conventions. If in doubt, consult your server documentation or use the `dir` command to view the results.

The corresponding adapter command line is:

-SYS {WIN32|UNIX|UNKNOWN}

WIN32: The server follows Windows conventions. For example, directories in pathnames are separated by a backward slash (\).

UNIX: The server follows UNIX conventions. For example, directories in pathnames are separated by a forward slash (/).

UNKNOWN: Because the platform is not known, exercise generic code. Do not perform anything specific to a platform.

Trace

Produces a diagnostic file that contains detailed information about FTP adapter activity. The default filename is **m4ftp.mtr**, created in the map directory unless otherwise specified.

The corresponding adapter command is `-T` or `(-TRACE)`

For example:

-T[E][+][S|V] [full_path]

E-> Produces a trace file containing only the adapter errors during map execution.

+-> Appends trace information to the existing log file.

S-> Summary mode. Record only minimal information in the log file. This is the default value.

V-> Verbose mode. Record all activity occurring while the adapter retrieves data in the log file. If not specified, summary mode is assumed.

full_path-> Creates a trace file with the specified name in the specified directory. The default directory is the map directory. The default file name is **m4ftp.mtr**.

You can dynamically override the adapter command line trace options using the Management Console. See "Dynamic Adapter Tracing" in the *Launcher* documentation for detailed information.

Because summary mode is the default, using `-TRACES` provides the same output as `-TRACE`.

Timeout

Specifies the waiting time for the client to connect to the server before the request times out. If this option is not specified, the maximum timeout is 300 seconds, and the connection time for a client varies for different operating systems.

When this option is specified, the connection attempt is made for `-TIMEOUT`, time in seconds, and fails if it is not connected within the specified period.

The corresponding adapter command is `-TIMEOUT`.

-TIMEOUT(nn)

nnn: The number of seconds to wait for activity on the FTP connection before the session ends in error. The default value is 300.

FTP Adapter command examples

Example of the Firewall connection method URL using Userlogon

The following command uses the `USERLOGON` (or `USER`) method to connect to the proxy server `fire` with no port specified, with a username of `jbond` and password of `007`:

```
-FW FTP://jbond:007@fire/userlogon
```

See URL Syntax and URL Encoding for more information.

Example of the input card command in the Map Designer

The following is an example of the input card command in the Map Designer:

```
-T -URL FTP://sales@host/c:/forms/myfile.txt
```

The command causes the `myfile.txt` file to be retrieved from a remote host named `sales`. The `-T` adapter command specifies that the adapter creates a trace file to report adapter activity information during the FTP process.

Syntax summary

Data sources

The following is the command syntax of the FTP adapter commands used for data sources:

```
-URL [FTP://  
  [ftp_user[:ftp_pass]@] [ftp_host[:ftp_port]]  
  [/[/]] [dir/[dir/...]] [filename] ;type=xfer_type[+]
```

```

[-ACCT account_id]
[-AUDIT[+] [S] [full_path]]
[-CERT {label}]
[-CPL code_page_name]
[-CPR code_page_name]
[-FIREWALL FTP://[fw_user[:fw_pass]@][fw_host[:fw_port]]]
[method]
[-GXS]
[-IGNORE error_code[:error_code...]]
[-IMPLICIT]
[-KS]
[-LS sort_type]
[-MKD ]
[-MOVE [file_name|directory_location]]
[-PASV]
[-PORT]
[-QTY number]
[-QUOTE command]
[-SITE command_text]
[-SPROTO {SSLv2|SSLv3|SSLv23|TLSv1}]
[-STR {WEAK|STRONG|ANY}]
[-SYS {WIN32|UNIX|UNKNOWN}]
[-T[E] [+][S|V] [full_path]]

```

Data targets

The following is the command syntax of the FTP adapter commands used for data targets:

```

-URL [FTP://][ftp_user[:ftp_pass]@][ftp_host[:ftp_port]]
    [/[/][dir/[dir/...]] [filename][;type=xfer_type[+]]

```

Using FTP adapter commands

Use the adapter commands from the Map Designer or Integration Flow Designer as the data source of an input map card and as the data target for an output map card. You can also use the adapter on the command line or in a map rule using the functions >GET, PUT, or RUN.

The FTP adapter requires the -URL adapter command for the GET>Source>Command and PUT>Target>Command settings.

See "[FTP Commands](#)" for more information on FTP adapter commands and their syntax. For general information about commands, see the *Resource Adapters documentation*.

Examples of using FTP adapter commands

To retrieve the mine.txt file, located on the host computer, with no port specified, under c:\forms with no username or password specified, enter the following command:

```
-URL FTP://host/c:/forms/mine.txt
```

The following command example would retrieve the entire contents of the **forms** directory because the file name is omitted from the **host** computer:

```
-URL FTP://host/c:/forms/
```

To retrieve the payments.txt file, located on the source FTP server, with no port specified, with a username and password specified, and then move the file from its original location on the source FTP server to your root directory for that FTP client and rename it paymentsbackup.txt, enter the following command:

```
-URL FTP://ftpuser:mypassword@sourceftpserver/payments.txt -MOVE /paymentsbackup.txt
```

To retrieve the invoices.txt file, located on the source FTP server in the billing subdirectory, no port specified, with a user name and password specified, make the new billingbackup subdirectory in a location that is absolute to the current location of the original file, and then move the file from its original location on the source FTP server to the new subdirectory on the source FTP server with its original file name, enter the following command:

```
-URL FTP://ftpuser:mypassword@sourceftpserver/billing/invoices.txt
      -MOVE /billingbackup/ -MKD
```

URL syntax

The syntax for the rest of the URL varies depending on the scheme selected. URL schemes that involve the direct use of an IP-based protocol for a specified host on the Internet use the following common syntax for scheme-specific data:

```
//user:password@host:port/url_path
```

Some or all parts of *user:password@*, *:password*, *:port*, and */url_path* can be excluded. The scheme-specific data starts with a double slash (*//*) to indicate that it complies with the common Internet scheme syntax. The *user:password* component conforms to the following rules:

user: An optional username. Some schemes allow the specification of a user name.

password: An optional password. When present, it follows the user name and is separated by a colon. The user name and password are followed by an at sign (@). Any :, @, or / characters must be encoded, within the user and password field. See "URL Encoding".

The *url_path* of an FTP URL has the following syntax:

cwd1/cwd2/.../ cwdN/ name; type= xfer_type

Where *cwd1* through *cwdN* and *name* are possibly encoded strings and *xfer_type* is one of the characters a, i, or d. The part *; type= xfer_type* be omitted. The *cwdx* and *name* parts are empty. The whole *url_path* be omitted, including the /, delimiting it from the prefix containing *user*, *password*, *host*, and *port*.

The *url_path* is interpreted as a series of FTP commands as follows:

- Each *cwd* element will be sequentially supplied as the argument to a CWD, change working directory, command.
- If the type code is "d," perform an NLST, name list, command with *name* as the argument, and interpret the results as a file directory listing.
- Otherwise, perform a TYPE command with *xfer_type* as the argument and then access the file named *name*. For example, using the RETR command.
The *xfer_type* argument has been extended beyond what the RFC supports, specifically the D1, D2, D3, and D4 sections. Also, *host:port* should be excluded.
Although it is rarely useful to do so, the *host* defaults to localhost.

URL encoding

The URL does not need to be completely 'URL-encoded'. As shown in the following table, you only need to use escape characters for tokens specifically used in an FTP URL. Any FTP URL that contains spaces must be enclosed in quotation marks; for example:

-URL "FTP://Home Machine/FTP Files"

Table 1. The following tokens are replaced with escape characters, respectively.

Tokens	Escape characters
% (percent)	%25
@ (at)	%40
/ (forward slash)	%2F
: (colon)	%3A
; (semicolon)	%3B
& (ampersand)	Escape is not needed; use it as is.
# (pound)	Escape is not needed; use it as is.
8-bit or control characters	Escape is not needed; use it as is.

Troubleshooting

The FTP adapter can reference up to 1024 temporary files during process execution.

For error codes and messages the adapter returns, see Return Codes and Error Messages.

Various troubleshooting tools are available in case of problems using the FTP adapter for data sources or targets for a map. For example, if you attempt to run a map that uses the FTP adapter and encounter problems or do not receive the expected results, use the following adapter troubleshooting tools:

- adapter audit log (.log)
- adapter trace file (.mtr)

Adapter audit log

The adapter audit log is a text file created during the adapter execution that records information about the events that occurred during the adapter activity. Use the adapter command (-AUDIT) to produce adapter audit log. The default log name is **m4ftp.log**, located in the map directory. See Trace (-T or -TRACE) for more information about the Trace command.

The adapter audit log contains information including the following:

- host identifier
- files sent or received
- size of each file
- elapsed time
- retry count for each file

Sample FTP adapter audit log

```
BEGIN FTP AUDIT
Receiving from Host: localhost
Filename      Filesize   Time   Retry
-----
rollback.gif    183 KBytes  000s    0
END FTP AUDIT
```

Adapter trace file

The adapter trace file contains detailed information the adapter provides and records the actions taking place, such as connections established and statements executed. The trace file is produced during the adapter execution and can be used as a debugging aid. To produce a trace file for the adapter, use the (-TRACE) adapter command. The default adapter trace file name is **m4ftp.mtr**, located in the map directory. See Audit (-A or -AUDIT) for more information about the Audit command.

Sample FTP adapter trace file

```
Retry Count is 0. Retry Interval is 0. Rollback is OFF.
Fetch Unit is 0. Burst Mode is OFF
Run Started at 08: 49: 38.911 on 03/28/00.

```

Temporary file limit

During a PUT or output card operation, the FTP adapter transfers files at the end of a successful map execution. When a run map invokes the FTP adapter, and the FTP operation is set to Card scope, the adapter transfers the files after the run map completes.

The default FTP operation is Map scope. When a run map invokes the FTP adapter, and the FTP operation is set to Map scope, the FTP adapter stores the contents in a temporary file. After the top-level map completes successfully, the FTP adapter sends all the temporary files to the target FTP server. If the number of FTP temporary files in all executing maps exceeds the limit of 1024, the adapter writes a message to the trace file and returns an adapter error message.

Return codes and error messages

Return codes and error messages are returned when the particular activity is completed. Return codes and error messages can also be recorded as specified in the audit logs, trace files, and execution summary files,

Messages

The following is a listing of all the codes and messages that can be returned when using the FTP adapter for sources or targets.

Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Table 1. Return Code with Messages

Return Code	Message
0	OK
-1	Insufficient memory to continue
-1	Library Initialization Failed
-2	Invalid Entry Point. (AIX adapters only)

Return Code	Message
-3FTP	Could not load adapter
-3	Error Sending Data
-4	Error Receiving Data
-5	FTP: Insufficient memory to continue
1	No data was provided. Create on content specified: no data sent.
2	Could not interpret the STOU response! The target file will not be renamed.
-1	FTP Setup failed
-1	FTPRRecv() failed
-1	FTPSend() failed
-101	No URL was specified
-102	Invalid SSL protocol
-103	Invalid SSL algorithm strength
-104	Code page values are invalid for this system
-105	Unable to initialize code page description
-106	Specify both -CPR and -CPL or neither
-107	Code page translation results in unequal character counts
-108	Iconv() failed to convert all characters
-109	The move option is missing a value. The move option requires a target directory name or file name.
-110	Move option value exceeds its size limit.
-600	Internal Error: Resource Manager Error
-???	An error code returned from the server made a negative
????	Server-supplied error message

GZIP/ZLIB Adapter

Use the GZIP/ZLIB Adapter to retrieve data in file or memory formats and export data for GZIP, ZLIB and Plain file formats.

- [GZIP/ZLIB Adapter overview](#)
- [System requirements](#)
- [Command alias](#)
- [GZIP/ZLIB Adapter commands](#)
- [Syntax summary](#)
- [Command behavior](#)

GZIP/ZLIB Adapter overview

The GZIP/ZLIB Adapter commands enable you to define the type of input and output streams and the compression actions.

The following data streams can be used for input for the GZIP/ZLIB Adapter:

- GZIP
- ZLIB
- Plain

The following file formats are output as data for the GZIP/ZLIB Adapter:

- GZIP
- ZLIB
- Plain

System requirements

See the system requirements and the release notes for the GZIP/ZLIB Adapter requirements. It is assumed that a Command Server has already been installed on the computer where the adapter is to be installed for runtime purposes.

Command alias

Adapter commands can be specified by using a command string on the command line or creating a command file that contains adapter commands. The execution command syntax is:

```
-IA[alias] card_num
-OA[alias] card_num
```

where **-IA** is the Input Source Override execution command and **-OA** is the Output Target Override execution command, **alias** is the adapter alias, and **card_num** is the number of the input or output card. The following table shows the adapter alias and its execution command.

Adapter	Alias	As Input	As Output
GZIP/ZLIB	GZIP	-IAGZIPcard_num	-OAGZIPcard_num

GZIP/ZLIB Adapter commands

The following table lists valid commands for the GZIP/ZLIB Adapter, the command syntax, and whether the command is supported (✓) for use with data sources, targets, or both.

Command	Syntax	Source	Target
Action (-ACTION)	-ACTION <i>actiontype</i>	✓	✓
File (-FILE)	-FILE <i>filename</i>	✓	✓
Stream (-STREAM)	-STREAM <i>datatype</i>	✓	✓
Trace (-T)	-T[+] [<i>full_path</i>]	✓	✓

- [Action adapter command for GZIP/ZLIB](#)
- [File adapter command for GZIP/ZLIB](#)
- [Stream adapter command for GZIP/ZLIB](#)
- [Trace adapter command for GZIP/ZLIB](#)

Action adapter command for GZIP/ZLIB

Use the Action adapter command (-ACTION) to decompress or compress the data stream before processing it. If an action is not specified as an option to the -ACTION command, the default action is AUTO.

-ACTION [DECOMPRESS | COMPRESSTOGZIP | COMPRESSTOZLIB | AUTO]

Option

Description

DECOMPRESS

Specifies decompression of the data stream.

COMPRESSTOGZIP

Specifies compression of the data stream using the GZIP file format.

COMPRESSTOZLIB

Specifies compression of the data stream using the ZLIB file format.

AUTO

Automatic compression (DECOMPRESS, COMPRESSTOGZIP, or COMPRESSTOZLIB) occurs depending on the type of data stream.

For a complete list of behaviors associated with this command when used with the -STREAM command, see ["Command behavior"](#).

File adapter command for GZIP/ZLIB

Use the File adapter command (-FILE) for data sources and data targets to specify the file that contains the GZIP or ZLIB input stream or output stream.

-FILE [*file_path*] / *file_name*

Option

Description

*[file_path] / *file_name**

Specify the file from which the input stream is read or to which the output stream is written.

A relative file path is relative to the current path of the process.

To specify a file path that is relative to the map directory, use the GETDIRECTORY function to build an absolute path. See the *Functions and Expressions* documentation.

If the File adapter command (-FILE) is not specified for a data source, the memory buffer is the default data source.

The File adapter command is required for data targets.

For example, to specify a data source of **input.gz**, the following adapter command should be used:

-FILE *input.gz*

Stream adapter command for GZIP/ZLIB

Use the Stream adapter command (-STREAM) to specify the input and output data type. If a data type is not specified as an option to the stream command, the default data type is AUTO.

-STREAM [GZIP | ZLIB | PLAIN | AUTO]

Option

Description

GZIP

Specifies a data type of GZIP.

ZLIB Specifies a data type of ZLIB.

PLAIN Specifies the data stream is a sequence of bytes.

AUTO Specifies auto-detection of the data type. The use of this option should be limited because streams that are not GZIP or ZLIB can have a valid GZIP or ZLIB fingerprint.

For a complete list of behaviors associated with this command when used with the **-ACTION** command, see "[Command behavior](#)".

Trace adapter command for GZIP/ZLIB

Use the Trace adapter command (**-T**) to produce a diagnostics file. This file contains detailed information about adapter activity. By default, the **m4gzip.mtr** trace file is created in the directory where the map is located.

-T[+] *[full_path]*

Option

Description

+ Append trace information to the existing trace file.
full_path Creates a trace file with the specified name in the specified directory.

Syntax summary

Data sources

The following is the syntax of the GZIP/ZLIB Adapter commands used for data sources:

```
[-FILE filename]
[-STREAM [GZIP|ZLIB|PLAIN|AUTO]]
[-ACTION [DECOMPRESS|COMPRESSTOGZIP|COMPRESSTOZLIB|AUTO]]
[-T[+] [full_path]]
```

Data targets

The following is the syntax of the GZIP/ZLIB Adapter commands used for data targets:

```
-FILE filename
[-STREAM [GZIP|ZLIB|PLAIN|AUTO]]
[-ACTION [DECOMPRESS|COMPRESSTOGZIP|COMPRESSTOZLIB|AUTO]]
[-T[+] [full_path]]
```

Command behavior

The following commands behave in this manner when used in the following combinations:

-STREAM command	-ACTION command	Data Source	Data Target
GZIP	DECOMPRESS	Input stream is decompressed before it is passed to the map.	Data is decompressed using the GZIP file format and written to the file specified by -FILE command.
GZIP	COMPRESSTOGZIP	Not valid.	Data is decompressed using the GZIP file format and written to the file specified by -FILE command (-ACTION command is ignored).
GZIP	COMPRESSTOZLIB	Not valid.	Data is decompressed using the GZIP file format and written to the file specified by -FILE command (-ACTION command is ignored).
GZIP	AUTO	Input stream is decompressed before it is passed to the map.	Data is decompressed (inflated) and written to the file specified by -FILE command.
ZLIB	DECOMPRESS	Input stream is decompressed before it is passed to the map.	Data is decompressed (inflated) and written to the file specified by -FILE command.
ZLIB	COMPRESSTOGZIP	Not valid.	The -ACTION command is ignored. The data coming from the map is decompressed (inflated) and written to the file that is specified by the -FILE command.
ZLIB	COMPRESSTOZLIB	Not valid.	The -ACTION command is ignored. The data coming from the map is decompressed (inflated) and written to the file that is specified by the -FILE command.

-STREAM command	-ACTION command	Data Source	Data Target
ZLIB	AUTO	Input stream is decompressed before it is passed to the map.	-ACTION command is assumed to be decompressed and the data is decompressed (inflated) and written to the file specified by -FILE command.
PLAIN	DECOMPRESS	Not valid.	Not valid.
PLAIN	COMPRESSTOGZIP	Input stream is compressed using GZIP file format prior to being passed to the map.	Output data received from map is compressed and written to the file specified by -FILE command.
PLAIN	COMPRESSTOZLIB	Input stream is compressed using the ZLIB file format prior to being passed to the map.	Output data received from map is compressed and written to the file specified by -FILE command.
PLAIN	AUTO	The input stream is compressed using GZIP file format prior to be passed to the map.	Output data received from map is compressed and written to the file specified by -FILE command.
AUTO	DECOMPRESS	Type of the input stream is automatically detected and expanded by the adapter. It can be GZIP (COMPRESSTOGZIP), ZLIB (COMPRESSTOZLIB) or PLAIN (COMPRESSTOZLIB). The behavior of the adapter is in accordance with the previously specified cases.	Type of the input stream is automatically detected and expanded by the adapter. It can be GZIP (COMPRESSTOGZIP), ZLIB (COMPRESSTOZLIB) or PLAIN (COMPRESSTOZLIB). The behavior of the adapter is in accordance with the previously specified cases.
AUTO	COMPRESSTOGZIP	Type of the input stream is automatically detected and expanded by the adapter. It can be GZIP (COMPRESSTOGZIP), ZLIB (COMPRESSTOZLIB) or PLAIN (COMPRESSTOGZIP). The behavior of the adapter is in accordance with the previously specified cases.	Type of the input stream is automatically detected and expanded by the adapter. It can be GZIP (COMPRESSTOGZIP), ZLIB (COMPRESSTOZLIB) or PLAIN (COMPRESSTOGZIP). The behavior of the adapter is in accordance with the previously specified cases.
AUTO	COMPRESSTOZLIB	Type of the input stream is automatically detected and expanded by the adapter. It can be GZIP (COMPRESSTOZLIB), ZLIB (COMPRESSTOZLIB) or PLAIN (COMPRESSTOZLIB). The behavior of the adapter is in accordance with the previously specified cases.	Type of the input stream is automatically detected and expanded by the adapter. It can be GZIP (COMPRESSTOZLIB), ZLIB (COMPRESSTOZLIB) or PLAIN (COMPRESSTOZLIB). The behavior of the adapter is in accordance with the previously specified cases.
AUTO	AUTO	Type of the input stream is automatically detected and expanded by the adapter. It can be GZIP (COMPRESSTOZLIB), ZLIB (COMPRESSTOZLIB) or PLAIN (COMPRESSTOZLIB). The behavior of the adapter is in accordance with the previously specified cases.	Type of the input stream is automatically detected and expanded by the adapter. It can be GZIP (COMPRESSTOZLIB), ZLIB (COMPRESSTOZLIB) or PLAIN (COMPRESSTOZLIB). The behavior of the adapter is in accordance with the previously specified cases.

HL7 MLLP Adapter

The HL7 MLLP adapter uses the MLLP protocol over TCP/IP to pass data to and from IBM Transformation Extender. The adapter has a listener interface that can detect the arrival of data on a socket and trigger a map to run. With the HL7 MLLP adapter, remote applications can pass data to IBM Transformation Extender without using additional middleware software.

The HL7 MLLP adapter is implemented as a dynamic-link library (DLL) on Microsoft Windows platforms (m4mllp.dll) and as a shared object on UNIX platforms (m4mllp.sl or m4mllp.so). The type trees that are supplied with the IBM Transformation Extender Pack for HL7 define the message format.

The adapter supports:

- Conversations
- Client or server mode

The adapter provides these functions:

- Gets one or more messages from a socket for input to IBM Transformation Extender
- Puts a message to a socket as output from IBM Transformation Extender
- Listens for messages and triggers maps to run as messages arrive
- **System requirements**
Install a Command Server, Launcher, or other IBM Transformation Extender runtime component on the computer where the adapter is to be installed for runtime purposes.
- **How to use the HL7 MLLP adapter in a map**
You can use the HL7 MLLP adapter on input cards and output cards, and in **GET** and **PUT** map rules.
- **Conversation support**
- **HL7 MLLP adapter command overview**
This table summarizes the adapter commands, syntax, and whether you can use the command with data sources, data targets, or both. You can specify the commands on the adapter command line or through the adapter properties.

System requirements

Install a Command Server, Launcher, or other IBM Transformation Extender runtime component on the computer where the adapter is to be installed for runtime purposes.

See the [system requirements](#) for details about minimum system requirements for the HL7 MLLP adapter.

How to use the HL7 MLLP adapter in a map

You can use the HL7 MLLP adapter on input cards and output cards, and in **GET** and **PUT** map rules.

When used with data sources, the HL7 MLLP adapter listens on a port. When a client socket connects to the port, the server socket creates a connection for the client. When a connection is open, the adapter receives a message if the MLLP leading bytes are present. If the leading bytes are missing, the adapter does not accept the message. The MLLP delimiters indicate the end of the message.

When used with data targets, the adapter constructs a message by wrapping the data from the map with the MLLP leading bytes and trailing delimiters. The adapter delivers the message to the specified host on the specified port.

When used with a three-parameter **GET** rule, the adapter constructs a message, delivers it to the specified host on the specified port, and waits for an acknowledgement. The adapter returns the acknowledgement to the map as output from the **GET** rule.

The adapter reuses a connection when an output card or **PUT** function specifies the same host and port numbers as the input card or **GET** function in the same map. The adapter sends a response message to the client that sent the request message.

Conversation support

The HL7 MLLP adapter supports conversation scenarios in which:

- Input is an event
 1. The listener detects a message
 2. The **GET** rule retrieves the message
 3. An output card sends a response to the same socket
- Input is not an event
 1. The **GET** rule retrieves the message
 2. An output card sends a response to the same socket
- The map uses the **=GET()** mapping function
The third parameter of the function is the data that the adapter is to send to the socket. The **GET** function returns the resulting message.

By default, a single instance of a map has exclusive use of a client connection (**-CCON** command). With an exclusive client connection, you can use the number of event messages (**-NEM** command) to initiate a conversational map instance. The **-NEM** command specifies how many messages the adapter must receive to start an instance of a map. If the map runs in burst mode, each burst can process one or more additional messages from the client, and send one or more responses to the client. In this scenario, the map ends when the client disconnects from the socket.

When the client connection is shared, multiple map instances concurrently use a single client connection. You cannot use the **-NEM** command with a shared connection. Instead, use the Quantity (**-QTY**) and Listen (**-LSN**) commands to determine the number of messages that a single map instance processes. The listener receives the specified number of messages. The map instance processes the messages and sends one or more response messages to the client.

If the client continues to send messages while a map instance is running, the adapter can start another map instance. Both map instances use the same client connection. The client is responsible for associating the request message with any responses from the maps. The **-CCON shared** command does not preclude multiple clients from connecting to the socket.

- [Quantity \(-QTY\) command](#)

HL7 MLLP adapter command overview

This table summarizes the adapter commands, syntax, and whether you can use the command with data sources, data targets, or both. You can specify the commands on the adapter command line or through the adapter properties.

The commands are not case-sensitive, but the command values are case-sensitive. Choices are separated by the OR symbol | . Optional parameters are enclosed in brackets []. The topics that follow provide the command syntax in railroad track format.

Table 1. HL7 MLLP adapter command summary

Command	Syntax	Use with Data Source	Use with Data Target
Client Connection	-CCON [excl shared]	Yes	No
Host	{-H -HOST} host_name IP_addr	Yes	Yes
Listen	-LSN seconds	Yes	No
Number of Event Messages	-NEM number	Yes	No
Port	{-P -PORT} port_number	Yes	Yes
Quantity	-QTY number	Yes	No
Service	{-S -SERVICE} service_name	Yes	Yes
Trace	{-T -TRACE} [E V] [+ file_name]	Yes	Yes

- [Command alias](#)

Use the MLLP adapter alias to use the HL7 MLLP adapter on input and output cards and in GET and PUT map rules.

- **[Client connection \(-CCON\) command](#)**
The client connection command specifies whether a client connection is shared between map instances or exclusively associated with a single map instance.
- **[Host \(-H\) command](#)**
The **-HOST** command specifies the host name or TCP/IP address of the remote host. The **-HOST** command is optional. If you omit it, the adapter uses the name of the local computer as the remote host name.
- **[Listen \(-LSN\) command](#)**
The **-LSN** command specifies the amount of time, in seconds, that the adapter waits for a message to arrive. This command is optional. If you omit it, the adapter waits for an infinite amount of time.
- **[Number of event messages \(-NEM\) command](#)**
Use this command to specify the threshold number of messages that triggers the Launcher to run a map. This command is optional. If you omit it, the threshold is the value specified on the **-QTY** command. The default value of the **-QTY** command is 1.
- **[Port \(-P\) command](#)**
The **-PORT** command specifies the TCP/IP port number of the adapter. In server mode, the port number specifies the port to which remote clients connect. In client mode, the port number specifies the port on the remote host to which the adapter connects. The **-PORT** command is mutually exclusive with the **-SERVICE** command.
- **[Quantity \(-QTY\) command](#)**
The **-QTY** command specifies the number of messages that the adapter is to retrieve. In burst mode, the total number of messages retrieved by the adapter does not exceed the number specified by the **-QTY** command, although a single burst might return fewer messages. The **-QTY** command is optional. If you omit it, the default number of messages is 1.
- **[Service \(-S\) command](#)**
The **-Service** command specifies the service name that is used to map a TCP/IP port number. The **-Service** command is mutually exclusive with the **-PORT** command.
- **[Trace \(-T\) command](#)**
The **-TRACE** command produces a log file of HL7 MLLP adapter activity.

Command alias

Use the MLLP adapter alias to use the HL7 MLLP adapter on input and output cards and in GET and PUT map rules.

Specify adapter commands by using a command string on the command line or by creating a command file that contains adapter commands. The command syntax is:

```
-IA[alias]card_num
-OA[alias]card_num
```

where:

-IA	The Input Source Override execution command
-OA	The Output Target Override execution command
<i>alias</i>	The adapter alias
<i>card_num</i>	The number of the map card

To override an input card:

```
-IAMLLPcard_num
```

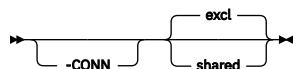

To override an output card:

```
-OAMLLLPcard_num
```

Client connection (-CCON) command

The client connection command specifies whether a client connection is shared between map instances or exclusively associated with a single map instance.

-CCON command syntax

excl

The client connection is exclusive to a particular map instance. When a client connects to an adapter that is running in server mode, the connection is associated with the map instance until the client disconnects. The map can receive multiple requests from the client and return multiple responses. Use this option in an environment where the client connects to the socket, engages in a conversation, and then disconnects.
This is the default client connection mode.

shared

The client connection can be shared by multiple map instances. You can configure the adapter to run a map after the number of messages specified by the **-QTY** command have been received, or when the listening time specified by the **-LSN** command has elapsed. Use this option in an environment where the client connects to the socket and remains connected, feeding a continuous stream of messages to the Launcher.

- [Quantity \(-QTY\) command](#)

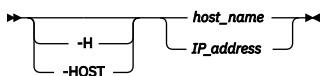

From

- [Conversation support](#)

Host (-H) command

The **-HOST** command specifies the host name or TCP/IP address of the remote host. The **-HOST** command is optional. If you omit it, the adapter uses the name of the local computer as the remote host name.

-HOST command syntax

host_name

Specifies the name of the remote host.

ip_address

Specifies the IP address of the remote host. You can use an Internet Protocol version 4 (IPv4) address or an Internet Protocol version 6 (IPv6) address. For example, use 192.168.1.120 as the IPv4 address or 1080:0:0:0:8:800:200C:417A as the IPv6 address.

Listen (-LSN) command

The **-LSN** command specifies the amount of time, in seconds, that the adapter waits for a message to arrive. This command is optional. If you omit it, the adapter waits for an infinite amount of time.

-LSN command syntax

0

The adapter does not wait. If no message is available, the adapter returns a warning that no messages were found.

seconds

Specifies the amount of time, in seconds, that the adapter is to wait for a message to arrive. If a message does not arrive within the specified timeframe:

- In Command Server mode, the adapter returns a warning.
- In Launcher mode, the Launcher continues to retry.

Number of event messages (-NEM) command

Use this command to specify the threshold number of messages that triggers the Launcher to run a map. This command is optional. If you omit it, the threshold is the value specified on the -QTY command. The default value of the -QTY command is 1.

-NEM command syntax

number_of_msgs

The number of messages that triggers the Launcher to run a map.

- [Quantity \(-QTY\) command](#)
- [Conversation support](#)

From

- [Conversation support](#)

Port (-P) command

The **-PORT** command specifies the TCP/IP port number of the adapter. In server mode, the port number specifies the port to which remote clients connect. In client mode, the port number specifies the port on the remote host to which the adapter connects. The **-PORT** command is mutually exclusive with the **-SERVICE** command.

-PORT command syntax

```
► [ -P ] port_number ►  
  [ -PORT ]
```

port_number
The TCP/IP port number.

To

- [Service \(-S\) command](#)

Quantity (-QTY) command

The **-QTY** command specifies the number of messages that the adapter is to retrieve. In burst mode, the total number of messages retrieved by the adapter does not exceed the number specified by the **-QTY** command, although a single burst might return fewer messages. The **-QTY** command is optional. If you omit it, the default number of messages is 1.

-QTY command syntax

```
► [ -QTY ] [ 1 ] number_of_msgs ►  
  [ -QTY ]
```

number_of_msgs
The number of messages that the adapter is to retrieve. In burst mode, *number_of_msgs* specifies the total number of messages that the adapter is to retrieve. A single burst might contain fewer messages.

From

- [Conversation support](#)

Service (-S) command

The **-Service** command specifies the service name that is used to map a TCP/IP port number. The **-Service** command is mutually exclusive with the **-PORT** command.

-SERVICE command syntax

```
► [ -S ] service_name ►  
  [ -SERVICE ]
```

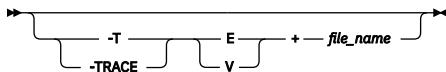

service_name
The service name that is used to map a TCP/IP port number.

From

- [Port \(-P\) command](#)

Trace (-T) command

The **-TRACE** command produces a log file of HL7 MLLP adapter activity.

E

Creates a trace file that contains only the adapter errors that occurred during map execution.

V

Specifies verbose mode. The log file records all activity that occurs while the adapter is retrieving data. The default maximum size of the data that is to be logged is 256 bytes. To trace more or fewer bytes, set the TX_SOCKET_MAX_BYTES_IN_TRACE_MESSAGE environment variable.

+

Appends the trace information to the existing log file. Omit this keyword to create a new log file.

path/file_name

The file name and, optionally, path to the log file. If the file name contains spaces or special characters, enclose the file name in quotation marks (for example, "test-file.txt"). The default log file name is m4mllp.log. By default, the log file is created in the directory where the map is located.

HTTP Adapter overview

The Hypertext Transfer Protocol (HTTP) Adapter provides support for Proxy servers and Secure Socket Layer (SSL) protocol, which is required to process HTTPS (secure) URLs.

Use the HTTP Adapter to transfer data to and from an HTTP(S) Web server. You can transfer data from a Command Server, Launcher, or Software Development Kit on one platform to an HTTP(S) Web server on another platform.

- [HTTP Adapter Introduction](#)

Use the HTTP Adapter to transfer data to and from an HTTP(S) Web server.

HTTP Adapter Introduction

Use the HTTP Adapter to transfer data to and from an HTTP(S) Web server.

System requirements

The release notes detail the HTTP adapter's minimum system requirements and operating system requirements. For runtime purposes, you must have already installed a Command Server on the computer.

Additional requirements for the HTTP Adapter:

- TCP/IP must be installed on the machine where you install the HTTP Adapter.
- The machine where the HTTP Adapter is installed must be able to access the HTTP(S) server over a TCP/IP network.

Automatic HTTP event management

The HTTP Adapter allows the Launcher to directly process HTTP input events without compromising the integrity of the firewall.

Command Alias

You can specify adapter commands by using a command string on the command line or by creating a command file that contains adapter commands. The command syntax is:

```
-IA[alias]card_num
-OA[alias]card_num
```

In the command syntax, **-IA** is the Input Source Override execution command, and **-OA** is the Output Target Override execution command, *alias* is the adapter alias, and *card_num* is the number of the map card. The HTTP Adapter alias and corresponding execution commands are listed below.

Adapter	Alias	As Input	As Output
HTTP	HTTP	-IAHTTP <i>card_num</i>	-OAHHTTP <i>card_num</i>

Known limitations

The HTTP Adapter does not support:

- Document caching
- Content Codings such as x-gzip, x-compress, or deflate
- Multiparts and multipart/byte ranges
- #markers

HTTP Adapter commands

The following table lists valid commands for the HTTP Adapter, their syntax, and whether they are supported (✓) for use with data sources, targets, or both.

Name	Syntax	Source	Target
Client Certificate	-CERT {label}	✓	✓
From	-FROM address	✓	✓
Header	-HDR [+][I]	✓	✓
HTTP(S)	-URL {HTTP HTTPS}://[user[:pass]@] [host[:port]]/[dir]/[file]	✓	✓
Ignore	-IGNORE error_code[:error_code...]	✓	✓
Inline Output	-INLINE		✓
Listen	-LSN seconds	✓	
Method	-METHOD method_name	✓	✓
Modified Since	-MODIFIED http-date	✓	✓
Proxy URL	-PROXY {HTTP HTTPS}://[user[:pass]@] [host[:port]]/[dir]/[file]	✓	✓
Redirections Allowed	-REDIRECT limit	✓	✓
Session	-SESSION session_id [*]	✓	✓
Server Name Indication	-SNI	✓	✓
SOCKS URL	-SOCKS {socks4 socks5}://[user[:pass]@] [host[:port]]	✓	✓
SSL Encryption Strength	-STR {WEAK STRONG ANY}	✓	✓
SSL Protocol	-SPROTO {SSLv2 SSLv3 SSLv23 TLSv1}	✓	✓
Status Code	-STATUS_CODE {map_return_code=HTTP_status_code[,map_return_code=HTTP_status_code...]} map_return_code:map_return_code[:map_return_code...]=HTTP_status_code	✓	
Status Line	-STATUSLINE	✓	
Status Page	-STATUS_PAGE file_name[*].file_type	✓	
Status Page Default	-STATUS_PAGE_DEFAULT file_name,file_type	✓	
Timeout	-TIMEOUT time_in_seconds	✓	✓
Trace	-T[E][+][S V] [full_path]	✓	✓
Tunneling	-TUNNELING	✓	✓
Type	-TYPE content_type [charset=encoding]	✓	✓

Client Certificate

Specifies the label of the client certificate in the key store. This command is applicable only when the **SSL_CLIENT secure_mode** setting in the config.yaml file is set, and SSL/TLS encryption is in effect.

The corresponding adapter command is **-CERT {label}**.

label: The name of the entry in the certificate store, which is specified by the `key_store` field in the config.yaml file.

Note: The certificate store contains all personal and trusted certificates in a PKCS12 format file. To see the examples on how to import private keys and certificate chains into this encrypted file, refer to the `readme.txt` file located in the `<Design Studio installation folder>|examples|secureadapt|ssl` folder.
From

Specifies the email address of a contact person. The adapter sends alerts to the contact person in case of a problem using requests.

The corresponding adapter command is **-FROM**.

-FROMaddress

address: Specifies the e-mail address of a contact person

Header

This command is used to send message headers from data in a map file or to return message headers to the map file. In addition to generating new headers, you can append user-supplied headers, eliminating duplicating all adapter-generated headers to add a new header.

Note: The header and body data must be separated by `<CR><LF><CR><LF>` when sent to the HTTP Adapter. The **Header** and **Headers** groups are in the **http.mtt** example type tree provides a clear illustration of this concept. Each header is terminated by `<CR><LF>`, and the Headers group is terminated by another `<CR><LF>`.
The corresponding adapter command is **-HDR**.

For example:

-HDR[+][I]

+> Appends user-supplied headers. It eliminates the need to duplicate the existing adapter-generated headers by adding a new one.

I-> In a request-reply scenario, indicates headers are provided in the input request but should not be returned in the response.

See also: [HTTP Header Adapter Command \(-HDR\) Example](#).

[HTTP\(S\) URL](#)

This property establishes a connection between the adapter and the HTTP(S) server. Specify the URL to connect to the HTTP(S) server. You must also specify the name of the file you want to transfer.

The corresponding adapter command is **-URL**.

For example:

-URL {HTTP|HTTPS}://[user[:pass]@[host[:port]]]/[dir[/file]]

HTTP: The HTTP application protocol.

HTTPS: The HTTPS application protocol.

Note: This option is only available if the Security Option is installed.

user: Specifies the user name required to connect to the HTTP(S) server. Unless you specify a password, this must be followed by @ if you specify the host.

:pass: Specifies the password required that authenticates the user name. This parameter must be followed by @ if you also specify the host.

host: The HTTP(S) server name or address.

:port: The HTTP(S) server port name or number.

/dir: The directory path for the file.

/file: The file that the HTTP adapter retrieves.

Note: The user and pass arguments extend what the RFC supports for a URL path.

The URL does not need to be completely 'URL-encoded'. As shown in the following table, you only need to use escape characters for tokens specifically used in a URL.

Replace the tokens with escape characters respectively:

Table 1. The following tokens are replaced with escape characters, respectively.

Tokens	Escape characters
% (percent)	%25
@ (at)	%40
/ (forward slash)	%2F
:	%3A
;	%3B
& (ampersand)	Escape is not needed; use it as is.
# (pound)	Escape is not needed; use it as is.
8-bit or control characters	Escape is not needed; use it as is.

Any URL that contains spaces must be enclosed in quotes. For example:

-URL HTTP://Home Machine/HTTP Fil

Ignore

This property is used to ignore specific error codes. The corresponding adapter command is **-IGNORE**.

-IGNORE error_code[:error_code]

error_code: Specifies the HTTP error codes that are to be ignored by the adapter. A colon (:) must separate multiple error codes.

For example, the results for the following command **-I 404:410** is:

- The adapter ignores errors of type 404 (not found).
- The adapter ignores errors of type 410 (gone).

Inline Output

This property is used to append data to the end of a URL. The corresponding adapter command is **-INLINE**.

You can use this command to submit a long query string to a form that uses `method=GET`. In the example below, the `GET` function has three arguments. The third argument is optional.

GET ("HTTP", "-URL HTTP://[www.yahoo.com/cgi-bin/search?]" - INLINE", "widgets")

Result: Gets the URL `http://www.yahoo.com/cgi-bin/search?widgets`.

KEEPALIVE

This command limits the connection reuse time of an HTTP adapter to prevent the reuse of closed connections. For example, when the connection exceeds the HTTP server KeepAlive Timeout setting.

A map reuses a connection under two conditions:

- A running map reuses an *active* HTTP connection when it issues multiple HTTP requests with the same command-line connection options within the same map instance.
- A map also reuses an *idle* HTTP connection when it runs multiple times in different map instances.

The corresponding adapter command is **-KEEPALIVE**.

-KEEPALIVEtimeout

timeout: The number of seconds that can elapse between consecutive reuses of a connection. After the timeout is exceeded, the HTTP adapter does not reuse the connection. Valid values are 0 - 99999. A 0 value specifies no connection reuse.

Example

A map issues multiple HTTP requests and runs multiple times. The HTTP server has a KeepAliveTimeout of 5 seconds. The config.yaml file has an IdleHTTP=10 /runtime/Connections Manager/HTTP/idle setting.

The map processing sequence is as follows:

1. A new instance of Map 1 starts.
2. Map 1, Input Card 1, iteration 1.
3. Map 1, Output Card 1, iteration 1 runs.
 - a. The HTTP adapter establishes **Connection 1** or reuses a connection from a prior map with similar HTTP settings.
 - b. The map issues an HTTP Post operation.
4. Map 1, Input Card 1, iteration 2.
5. Map 1, Output Card 1, iteration 2 runs.
 - a. The HTTP adapter reuses **Connection 1**.
 - b. The map issues an HTTP Post operation.
6. Map 1 is completed.
7. Map 1 runs again with a new instance number and repeats step 1.

Without the **-KEEPALIVE** command, consider these potential failure scenarios:

- More than 5 seconds elapse between HTTP POST operations (steps 3b and 5b):
 - The HTTP server KeepAliveTimeout closes the connection.
 - The HTTP adapter attempts to use the active (but closed) connection in step 5b, and the map fails.
- Less than 10 seconds elapse between step 5b in the first map instance and step 3a in the new map instance:
 - The HTTP adapter reuses the idle connection.
 - Step 3b activates the reused connection.
 - If more than 5 seconds elapse between HTTP POST operations (steps 3b and 5b), the HTTP server KeepAliveTimeout closes the connection. The map fails when the HTTP adapter attempts to use the active (but closed) connection in step 5a.

The **-KEEPALIVE 5** adapter command prevents the HTTP adapter from reusing a connection if more than 5 seconds elapsed since the last time the map used the connection. Consider these successful scenarios:

- More than 5 seconds elapse between HTTP POST operations (steps 3b and 5b):
 - The HTTP server KeepAliveTimeout closes the active connection.
 - The **-KEEPALIVE 5** adapter command prevents the HTTP adapter from reusing the active (but closed) connection.
 - The HTTP adapter establishes a new connection, and the map completes successfully.
- The connection's idle time between map instances (steps 6 and 7) is between 5 - 9 seconds:
 - The idle time is less than 10 seconds, so the idle connection qualifies for reuse.
 - The time between requests exceeds the server KeepAliveTimeout value. The HTTP server closes the connection.
 - The **-KEEPALIVE 5** adapter command prevents the HTTP adapter from reusing the idle (but closed) connection in step 3a.
 - The HTTP adapter establishes a new connection, and the map completes successfully.

Listen

Specifies a time (in seconds) to wait for messages to arrive. Suppose the URL does not become available in the specified listen time. In that case, you will receive an error message, Source not available.

The corresponding adapter command is **-LSN**.

-LSNseconds

seconds: The number of seconds to wait for messages to arrive.

The command **-LSN 0** means do not wait at all. If no message is immediately available, the adapter returns a warning indicating no messages were found.

Method

Specifies the transfer method to use in an HTTP request. The HTTP request method can be any request the HTTP(S) server can process. Typical method names are PUT, GET, and POST. If the transfer is not specified, the default value for **-METHOD** is GET for input cards (to retrieve data) and POST for output cards (to store data).

The corresponding adapter command is **-M** or (**-METHOD**).

-METHODmethod_name

method_name: Transfer method used in an HTTP request.

Modified Since

This command generates the *If-Modified-Since* header information used during a GET request. The HTTP Adapter then adds the date to the request.

The corresponding adapter command is **-MOD** Or (**-MODIFIED**).

-MODIFIEDhttp-date

http-date: Dates supported by *RFC 1123* and *RFC 850*. The date can also be in the form of {*wkday date time*}, where:

- *wkday* is Mon | Tue | Wed | Thu | Fri | Sat | Sun
- *date* is month day (for example, JUN 06)
- *time* is 00:00:00 to 23:59:59

Proxy URL

This property specifies the URL to connect to a proxy server and a file name for transferring the file.

The corresponding adapter command is **-PROXY**

For example:

-PROXY {HTTP|HTTPS}://[user[:pass]@[host[:port]]]/[dir[/file]]

HTTP: The HTTP application protocol.

HTTPS: The HTTPS application protocol.

user: Specifies the user name required to connect to the proxy server. Unless you specify a password, this must be followed by @ if you specify a host.

:pass: Specifies the password required that authenticates the user name. This parameter must be followed by @ if you specify the host.

host: The proxy server name or address.

:port: The proxy server port name or number.

/dir: The directory path for the file.

/file: The file that the HTTP Adapter retrieves.

Redirections Allowed

This property specifies the maximum number of redirections or file-moved messages allowed before the transfer request fails. The request fails if the adapter cannot locate the file within the limit. Use a value of 0 to prevent the adapter from following redirections.

The corresponding adapter command is **-REDIRECT**.

-REDIRECT*limit*

Session

This property is used to coordinate the request and response of an HTTP. The corresponding adapter command is **-SESSION**.

-SESSION *session_id*[*]

session_id: Specifies the session identifier used for matching purposes. When receiving the HTTP request in a map, this contains the agent-assigned identifier. This identifier must be returned in the HTTP response.

*-> Permits all HTTP session IDs to be passed from the input card to the output card. You must enter a space between the **-SESSION** command and the asterisk (*) option for it to process correctly.

Generally, this command is written as:

-url *localhost:8080/example -session * -type text/html -tv+*

This command specifies the following:

- Specifies the entry to search for the HTTP server called *localhost* on port 8080 and request the */example* page.
- Allows all session id's to be passed from the input card to the output card
- Specifies *text/html* as the MIME Content-Type for the file used in the adapter request
- Enables a verbose trace file called **m4http.mtr** in append mode

SOCKS URL

This property is used to connect to a SOCKS proxy server. The corresponding adapter command is **-SOCKS**

Generally, the command is written as:

-SOCKS {**socks4|socks5**}://[**user[:pass]@[host[:port]]**]

socks4: The SOCKS protocol version 4.

socks5: The SOCKS protocol version 5.

user: Specifies the user name required to connect to the SOCKS server.

pass: Specifies the password required that authenticates the user name.

host: Specifies the server name or address of SOCKS.

port: Specifies the server port name or number of SOCKS.

Examples to connect to a SOCKS:

- To connect to a SOCKS server named **myhost** using SOCKS protocol version 4, use the command:
-SOCKS socks4://myhost
- To connect to a SOCKS server named **hmss** with a user name of **jbond** and password of **007** using SOCKS protocol version 5, use the command:
-SOCKS socks5://jbond:007@hmss

SSL Encryption Strength

Specifies the encryption strength for FTP connections. It can be set to either WEAK, which uses only weak algorithms, or STRONG, which uses only strong algorithms. If not specified, any available algorithm is used. If STRONG is unavailable, then WEAK is used. However, if the export version of the libraries is used, only weak algorithms are available, and this command is ignored.

This command is applicable only when the SSL **secure_mode** setting is in the config.yaml configuration file (/runtime/secure_mode) is set to 0, and RSA-based SSL encryption is in effect.

The corresponding adapter command is **-STR**.

-STR{WEAK/STRONG/ANY}

WEAK-> Use strong (non-exportable) encryption only.

STRONG-> Use exportable encryption only.

ANY-> Use any available encryption.

SSL Protocol

Specifies setting the Secure Socket Layer (SSL) protocol level. SSL enables the adapter to process FTPS URLs. The corresponding adapter command is **-SPROTO**.

-SPROTO{SSLv2/SSLv3/SSLv23/TLSv1}.

SSLv2: Specifies SSL protocol version 2.

SSLv3: Specifies SSL protocol version 3.

SSLv23: Specifies SSL protocol version 2, version 3, *TLSv1*, *TLSv1.1* or *TLSv1.2*. Whenever the protocol method of *SSLv23* is specified, the protocol of first choice is *TLSv1.2*, with a fallback to *TLSv1.1*, then to *TLSv1*, then to *SSLv3*, and finally to *SSLv2*, depending on the GSKit module that is loaded.

TLSv1: Specifies Transport Layer Security (TLS) protocol version 1.

If *-SPROTO* is not specified, the SSL Protocol defaults to *SSLv23*.

This command is applicable only when the SSL **secure_mode** setting is in the config.yaml configuration file (/runtime/secure_mode) is set to 0 and RSA-based SSL encryption is in effect. An SSL **secure_mode** setting of 1 or 2 supersedes this command.

Status Code

Returns an HTTP status code through the HTTP listener to the external HTTP client that requested a particular URL. The HTTP status code is associated with one or more map return codes. You can customize the HTTP status codes or use the default codes defined in the /runtime/M4HTTP/StatusCode path of the config.yaml configuration file. The corresponding adapter command is **-STATUS_CODE**.

Unable to insert image

- *map_return_code*: The numeric code indicating the map execution result. See the Map Designer description of map execution and warning messages for a list of execution codes.
- *HTTP_status_code*: An official HTTP status code maintained by the Internet Assigned Numbers Authority (IANA).

To specify multiple p return code/HTTP status code combinations on a single **-STATUS_CODE** keyword, separate each combination with a comma (,) character. For example:

-STATUS_CODE "30 = 400 Bad Request, 12 = 404 Not Found"

To link multiple map return codes to a single HTTP status code, delineate each map code with a colon (:) character. For example:

-STATUS_CODE "8:9:30 = 400 Bad Request"

Status Line

Allows the initial HTTP response line to be returned to the map. The response line will be pre-pended to the regular data returned by the HTTP Adapter.

If the *-STATUSLINE* command is specified on the command line, the HTTP Adapter behaves like the Header (*-HDR*) command was also specified.

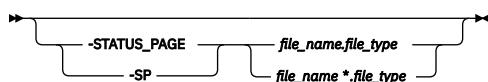

Status line is an optional command. The corresponding adapter command is **-STATUSLINE**.

For example, if you specify: **-URL http://www.google.com -STATUSLINE**

The command would return the complete HTTP response from Google, including HTTP headers and the HTTP Response status as the first line.

Status Page

Returns a text file containing the execution results of a session-specific map to an external HTTP client. The map can dynamically construct the file using predefined variables that resolve at map run time. The corresponding adapter command is **-SP** or **-STATUS_PAGE**.

file_name,file_type

file_name.file_type*

The file name of the status page file that the HTTP listener returns to the HTTP client. If the file name is not qualified, the map directory is used as the file path.

Optionally, you can generate a session-specific file name by appending an asterisk (*) wildcard character at the end of the file name. The wildcard character resolves to the Launcher session ID and timestamp.

Status page variables

With predefined status page variables, a map can dynamically create the status page the HTTP listener returns to the external HTTP client. When the map runs, the variables in the status page resolve to map execution details such as error code and map name. The variables are as follows:

- %TX_ADAPTER_STATUS_CODE%: The selected status code from the "-status_code" option.
- %TX_MAP_ERROR_CODE%: The map error code.
- %TX_MAP_ERROR_MSG%: The map error message.
- %TX_MAP_NAME%: The map name
- %TX_MAP_INSTANCE%: The map instance number
- %TX_MAP_SESSION_ID%: The unique ID assigned by the HTTP listener to this instance of the triggered input card

- %TX_TIMESTAMP%: The timestamp when the HTTP listener sends the response to the external HTTP client

Status page files for multi-threaded maps

To support multi-threaded maps, append an asterisk (*) character to the file name of the HTTP adapter status page. The asterisk is a wildcard character that generates a unique file name for the status page to ensure that other instances of the same map do not overwrite the file contents.

The wildcard character resolves to `session_ID`, `timestamp`. The session_ID is a unique alphanumeric string that the HTTP listener associates with an instance of a triggered input card.

For example, a multi-threaded map's input card can include the following command:

```
-status_page http_response_*.html
```

When the map runs, the wildcard character resolves to a unique file name, such as:

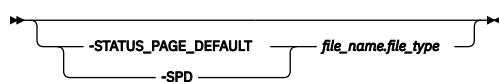

```
http_response_NEED-SESSION-ID,NEED-TIMESTAMP-FORMAT.html
```

Status Page Default

Specifies a backup status page to be returned to an external HTTP client when the page specified by the `-STATUS_PAGE` option fails. The `/runtime/M4HTTP/StatusPage` path of the config.yaml configuration file defines a single default status page.

The corresponding adapter command is `-STATUS_PAGE_DEFAULT`. This option allows you to create a custom default page for each watch.

`-STATUS_PAGE_DEFAULT` is optional. If you omit it, the HTTP listener returns the default status page defined in the `/runtime/M4HTTP/StatusPage` path of the config.yaml configuration file.

`file_name,file_type`

`file_name*.file_type`

The file name of the status page file that the HTTP listener returns to the HTTP client. If the file name is not qualified, the map directory is used as the file path.

Timeout

This property sets the socket timeouts to a specified number of seconds. The default timeout is 300 seconds.

The corresponding adapter command is `-TIMEOUT`.

-TIMEOUT time_in_seconds

`time_in_seconds`: Specifies the number of seconds for the sockets timeout to be set. The default timeout is set to 300 seconds.

Trace

Produces a diagnostics file that contains detailed information about HTTP Adapter activity. The corresponding adapter command is `-T` or `(-TRACE)`.

The default filename is `m4http.mtr`, created in the map directory unless otherwise specified.

Generally, the command is written as:

-T[E][+][S/V] [full_path]

E: Produces a trace file containing only the adapter errors during map execution.

+: Appends trace information to the existing log file.

S: Summary mode. Default value. Record only minimal information in the log file.

V: Verbose mode. Record all activity occurring while the adapter retrieves data in the log file. If not specified, summary mode is assumed.

full_path: Creates a trace file with the specified name in the directory.

Note: Because summary mode is the default, using `-TRACES` provides the same output as `-TRACE`.

Note: You can dynamically override the adapter command line trace options using the Management Console. See "Dynamic Adapter Tracing" in the *Launcher* documentation for detailed information.

Tunneling

Establishes a clean TCP connection to the proxy server and then upgrades to SSL using the `CONNECT` method. This command should only be used in cases where the specified proxy URL is non-secure (http), and the request URL is secure (https). The corresponding adapter command is `-TUNNELING`.

Generally, the command is written as:

-url <https://secure-server:8080/example> -proxy <http://user@proxy-server:2888> -tunneling

This command specifies:

- The entry to search for the HTTPS server called a `secure-server` on port `8080` and request the `/example` page.
- The proxy server called a `proxy-server` with a plain (non-secure) HTTP connection.
- The tunneling mechanism should be used to upgrade the non-secure proxy connection to a secure one for accessing the given URL.

Type

Specifies the type of content that is contained in the body of the HTTP request. The default type is `application/octet-stream`. See "Known Limitations" for additional information. The corresponding adapter command is `-TY` or `(-TYPE)`.

When you send a SOAP-based HTTP request, encoding the HTTP request's content might require you to specify the charset parameter of the **-TYPE** command. The default encoding is ISO-8859-1, as originally specified by RFC 2616. The SOAP adapter requires a UTF-8 encoded response from the HTTP server. However, the request can be in any Western or UTF-8 encoded format.

-TYPE *content_type* [**charset=encoding**]

- *content_type*: The default content type is **application/octet stream**. You might use other types. However, do not use compound types such as multipart.
- **charset**: Specifies the encoding of the content in the HTTP request's body. The charset keyword is optional. If you omit it, the default encoding is ISO-8859-1.

When you specify the charset keyword on a SOAP adapter command line, enclose both the *content_type* and the charset keyword and value pair within two sets of double quotation marks (" "**content_type**
charset=encoding" ") to avoid parsing errors.

The following command line notifies the HTTP Server that the content is UTF-8 data:

-TYPE "text/xml; charset=utf-8"

The following command line uses a SOAP adapter GET request and notifies the HTTP Server that the content is UTF-8 data. Note that both the *content_type* and the **charset** keyword and value pair are enclosed within two sets of double quotation marks:

```
=GET("SOAP", "-T -SA http://localhost/WebService/test -TRANSPORT 'HTTP(-HDR+ -T -TYPE ""text/xml; charset=utf-8"" -METHOD POST -URL http://localhost/WebService/test)' ", PACKAGE(SoapRequest))
```

Syntax summary

Data sources

The following is the command syntax of the HTTP Adapter commands used for data sources:

```
-URL {HTTP|HTTPS}://[user[:pass]@][host[:port]][/dir[/file]]  
[-CERT {label}]  
[-FROM address]  
[-HDR[+] [I]]  
[-IGNORE error_code[:error_code]]  
[-INLINE]  
[-LSN seconds]  
[-METHOD [method_name]]  
[-MODIFIED http-date]  
[-PROXY {HTTP|HTTPS}://[user[:pass]@][host[:port]][/dir[/file]]]  
[-REDIRECT limit]  
[-SESSION session_id [*]]  
[-SOCKS {socks4|socks5}://[user[:pass]@][host[:port]]]  
[-SPROTO {SSLv2|SSLv3|SSLv23|TLSv1}]  
[-STATUSLINE]  
[-STR {WEAK|STRONG|ANY}]  
[-TIMEOUT time_in_seconds]  
[-T[E] [+][S|V] [full_path]]  
[-TUNNELING]  
[-TYPE content_type [charset=encoding]]
```

Data targets

The following is the command syntax of the HTTP Adapter commands used for data targets:

```
-URL {HTTP|HTTPS}://[user[:pass]@][host[:port]][/dir[/file]]  
[-CERT {label}]  
[-FROM address]  
[-HDR[+] [I]]  
[-IGNORE error_code[:error_code]]  
[-INLINE]  
[-LSN seconds]  
[-METHOD [method_name]]  
[-MODIFIED http-date]  
[-PROXY {HTTP|HTTPS}://[user[:pass]@][host[:port]][/dir[/file]]]  
[-REDIRECT limit]  
[-SESSION session_id [*]]  
[-SOCKS {socks4|socks5}://[user[:pass]@][host[:port]]]  
[-SPROTO {SSLv2|SSLv3|SSLv23|TLSv1}]  
[-STR {WEAK|STRONG|ANY}]  
[-TIMEOUT time_in_seconds]  
[-T[E] [+][S|V] [full_path]]  
[-TUNNELING]  
[-TYPE content_type [charset=encoding]]
```

Using HTTP Adapter commands

Use the HTTP Adapter commands from the Map Designer or Integration Flow Designer as the data source of an input map card and as the data target for an output map card. You can also use the adapter as part of the M4HTTP_OPT environment variable, on the command line, or in a map rule using GET, PUT, or RUN functions.

The HTTP Adapter requires the **-URL** command in the value field of the GET>Source>Command and PUT>TARGET>Command settings. See the *Resource Adapters* documentation for general information about commands.

Example files

An example of this adapter is located at *install_dir/examples/adapters/http*.

Using the Map Designer, select HTTP from the *Source* setting in an Input Card dialog. In the GET Source>Command field, type the **-URL** command to specify the uniform resource locator (URL), specifying the HTTP server, the file to transfer, and other required adapter commands. In this input card example, the HTTP Adapter retrieves the

test.htm file from the host server **puff**:

```
-URL HTTP://user1:test@puff:8080/c:/test/tst.htm
```

Using the Integration Flow Designer to override the HTTP Adapter settings for an input card, enter the following for the Source>GET>Source>Command setting in the Launcher settings:

```
-TV -REDIR 3 -URL HTTP://user1:pass@puff:8080/c:/orb/original.htm
```

The adapter specifies the **original.htm** file to be used as the data source. The **-TV** adapter command specifies that the adapter generates a verbose trace file containing a log of all activity and events occurring while the adapter retrieves data. The **-REDIR 3** adapter command specifies that the HTTP Adapter will follow three file redirections (or "document moved" messages) before the file transfer request fails.

Using the Input Source Override - Application Execution Command (**-IA**), this command string example can be used to override the adapter commands defined in output card 1:

```
-IAHTTP1 '-URL HTTP://user1:test@puff:8080/c:/test/test.htm'
```

This example command string causes the file **test.htm** to be retrieved from the host server **puff**.

Use the **M4HTTP_OPT** environment variable to specify commands to the HTTP Adapter or a command file containing adapter commands.

Note: Commands specified in the input or output card settings override commands specified in the environment variable.

The format for specifying commands is:

M4HTTP_OPT=adaptercommands

The *adapter commands* are the HTTP Adapter commands in the list of commands.

The format for specifying a command file is:

M4HTTP_OPT=@filename.txt

Where *filename.txt* is the file containing HTTP Adapter commands, always precede the command file name with @.

HTTP header adapter command (-HDR) example

Process cookies by mapping **Set-Cookie** headers of **Cookie** headers.

This example uses the Header adapter command (-HDR), **Http.mtt** type tree, and the **HTTPGetCookie** map. It retrieves a form that sets cookies and then submits the form. The form includes user name and password fields typical of the forms found on many websites and uses cookies to maintain this login information.

In the input card, the GET > Source > Command in the Source setting uses the **-HDR** command to map the cookies in the **Set-Cookie** headers on the form that is returned.

In the output card, the PUT > Target > Command in the **Target** setting manages the cookie state information by mapping the **Set-Cookie** headers in the form of **Cookie** headers. The **-HDR** command indicates that the user is providing the headers; the target is form data submitted with:

Content-Type application/x-www-form-urlencoded

See *RFC 2109* for more information about cookies. For more information about submitting forms and the **x-www-form-urlencoded** format, see Section 17 of the HTML 4.01 specification.

Create a type tree

In this example, the group type **Message** contains the components needed for the **HTTPGetCookie** map, and the group type **Header(s)** contains the item types **HeaderName** and **HeaderText**.

Configure the Map Input and Output Cards

The **HTTPGetCookie** map input and output cards specify the **http.mtt** file as its type tree in the **TypeTree** setting. The input and output cards use the group type **Message** from that type tree in the **TypeName** setting. Both cards also use the **-HDR** command to specify that the map will operate on headers in the HTTP path in the **-URL** command.

For example, the GET > Source > Command in the **Source** setting of the input card is:

```
-HDR -URL HTTP://www.ilost.com/home/login/1,23456,,00.html -TV
```

The **PUT > Target > Command** in the **Target** setting of the output card is:

```
-HDR -URL HTTP://www.ilost.com/user_registration/manual_login/process_sign_in/1,23456,,00.html -TV
```

Enter the map rules

The **HTTPGetCookie** map output card specifies a functional map named **xCookieExtractor**, which searches for **Set-Cookie** headers.

If a **Set-Cookie** header is found, the map changes it to **Cookie** and submits cookie parameters such as a username and password.

Troubleshooting

For error codes and messages the adapters return, see [Return Codes and Error Messages](#).

Various troubleshooting tools are available if you encounter problems using the HTTP Adapter for data sources or targets for a map. If you run a map that uses the adapter and encounter problems or do not receive the expected results, use the adapter trace file (.mtr) as a troubleshooting tool.

Adapter trace file

The adapter trace file contains detailed information provided by the adapter and records its actions, such as connections established and statements executed. This trace file is generated during the adapter's execution and can be used as a debugging aid. To produce a trace file for the adapter, use the adapter command **-TRACE**. The default adapter trace file name is located in the map directory. See Trace (**-T** or **-TRACE**) for more information.

The adapter trace file contains detailed information the adapter provides, which records the actions, such as connections established and statements executed. The trace file is produced during the adapter execution and can be used as a debugging aid. To produce a trace file for the adapter, use the adapter command **-TRACE**. The default adapter trace file name is located in the map directory. See Trace (**-T** or **-TRACE**) for more information.

Sample adapter trace file

```

Return codes and error messages

Return codes and messages are returned when the particular activity is completed. Return codes and messages might also be recorded as specified in the audit logs, trace files, execution summary files, etc.

Messages

The following lists all the codes and messages that can be returned when using the HTTP Adapter for sources or targets.

Note: Adapter return codes with positive numbers are warning codes that indicate a successful operation, while those with negative numbers are error codes that indicate a failed operation.

-??-> Sever specific error message.

-1-> doHTTP failed.

IBM MQ adapter overview

The IBM® MQ adapter works with IBM MQ to accomplish the task of maintaining data compatibility, handling all kinds of data transformations from the simplest to the most complex. The IBM MQ adapter can be used at either the source or target application, or at both. There is an adapter for IBM MQ client software and an adapter for IBM MQ server software.

IBM MQ software transports data between applications. For the receiving application to be able to successfully use data, the data must be transformed. IBM MQ can successfully move data in heterogeneous computer networks, allowing systems of dissimilar computers to move data to and from each other. Although data successfully arrives at a target, it often cannot be used in its native form and must be transformed into a format acceptable for the receiving application's use.

-

IBM MQ message content

The IBM® MQ message data content can be any content type. Under some conditions, message data contains a message header known as an IBM MQ Message Descriptor structure. For example, if you use the IBM MQ Link for R/3, the input message data always contains a header and a header must be created for an output message.

Use the IBM MQ adapter to include the message header in the data using the optional Header adapter command (-HDR). When the command is specified for an input message, the message header appears before the message content. If the command is specified for an output message, the adapter assumes that the first block of data supplied for the target consists of the appropriate size and values of a valid IBM MQ Message Descriptor structure. When the Header adapter command (-HDR) is specified, any of the message header components can be included in mapping rules.

For mapping purposes, definitions for the message descriptors and the IBM MQ Link for the R/3 header are provided in the **mq.mtt** type tree, located in the **examples\adapters\mq** folder.

Transmission queues

An IBM® MQ transmission queue is a local queue that stores messages destined for a remote queue. The messages are forwarded to their destination queue through a message channel when a communication program and link are available. The channel provides a one-way link to the remote queue manager. Messages are queued at the transmission queue until the channel can accept them. A message channel agent (channel program) that actually transmits the message must be associated with the transmission queue and the remote queue manager. When the message has been transmitted, it is deleted from the transmission queue. The channel definition must specify a transmission queue name at the transmitting end of the message channel.

The IBM MQ adapter supports the definition of transmission queues for data targets with the Transmission Queue Name adapter command (-XQN) and the Transmission Error Queue Name adapter command (-XEQN).

IBM MQ client or server adapter

IBM® MQ supports both client and server modes either from a single platform or distributed across multiple platforms. To select the correct client or server adapter, you must specify the adapter to use for a source or target in map cards, execution settings, or on the command line.

If you do not know the version of IBM MQ software you are running, contact your system administrator.

System requirements

The adapters for the IBM® MQ messaging system can be installed and operated in a Windows environment. The minimum system requirements and operating system requirements for this adapter are detailed in the release notes. The adapters must be installed on a machine running the IBM MQ client or server software.

This section identifies the requirements to install and run the IBM MQ adapter in an environment running IBM MQ client software or IBM MQ server software.

- [Client system](#)
 - [Server system](#)
-

Client system

IBM® MQ client system and configuration requirements include:

- IBM MQ client software is installed and configured. One or more queue managers and queues must have been defined on the system. For information about how to configure IBM MQ, see the IBM MQ documentation.
- The access methods for the IBM MQ adapter follow standard IBM MQ authentication guidelines and do not require any special permissions to work with IBM MQ. The adapter requires permission to those IBM MQ functions used in the IBM MQ adapter. Although registering the user account as a member of the IBM MQ Group (mqm) would simplify the configuration (because of not having to set individual user or group permissions), it is not a requirement. Permissions can be set at the user account level to connect to, get messages from, and put messages on queues. These minimal permissions are: Connect, Put, Get, Browse, and Inq. The Set permission is not required because the maps do not alter queue managers or queues.

Server system

IBM® MQ server system and configuration requirements include:

- IBM MQ server software is installed and configured. One or more queue managers and queues must have been defined on the system. For information about how to configure IBM MQ, see the IBM MQ documentation.
- The access methods for the IBM MQ adapter follow standard IBM MQ authentication guidelines and do not require any special permissions to work with IBM MQ. The adapter requires permission to those IBM MQ functions used. Although registering the user account as a member of the IBM MQ Group (mqm) would simplify the configuration (because of not having to set individual user or group permissions), it is not a requirement. Permissions can be set at the user account level to connect to, get messages from, and put messages on queues. These minimal permissions are: Connect, Put, Get, Browse, and Inq. The Set permission is not required because the maps do not alter queue managers or queues.

Command aliases

Adapter commands can be specified by using a command string on the command line or by creating a command file that contains adapter commands. The execution command syntax is:

```
-IM[ alias ] card_num  
-OM[ alias ] card_num
```

where **-IM** is the Input Source - Override execution command and **-OM** is the Output Target - Override execution command, **alias** is the adapter alias, and **card_num** is the number of the input or output card, respectively. The following table shows the adapter aliases and execution commands.

Adapter	Alias	As Input	As Output
IBM® MQ (client)	MQSC	-IMMQSCcard_num	-OMMQSCcard_num
IBM MQ (server)	MQS	-IMMQScard_num	-OMMQScard_num

When using an adapter alias with the execution command, the IBM MQ adapter commands can be issued on the command line or in a command file. Use the adapter commands to specify adapter functions such as:

- specifying a particular message identifier
- allowing output data to be broken up into multiple messages
- retrieving a logical message from a source queue with a correlation identifier

For example, to override the adapter commands defined in output card 1, the command string for the adapter in an IBM MQ server environment might be:

```
-IMMQS1 '-QM1 queuemgr -QN topqueue -T'
```

This sample execution command string specifies the queue manager named **queuemgr** and the queue named **topqueue** as the source for this card's data. The **-T** command dictates that a trace file be created to report adapter activity information, recording the events that occur while the adapter is retrieving this data.

- [GET > Source settings](#)
- [PUT > Target settings](#)

GET > Source settings

Use the Map Designer **GET** settings to configure options for input map cards that use the IBM® MQ (client) or IBM MQ (server) adapters. For the **Source** setting, select the data source as either **MQSeries® (client)** or **MQSeries (server)** to use the IBM MQ adapter.

- [GET > Source > Command setting](#)
- [Source > Transaction > OnSuccess setting](#)
- [Source > Transaction > OnFailure setting](#)
- [Source > Transaction > Scope setting](#)
- [Source > Transaction > Warnings setting](#)

GET > Source > Command setting

Use the **Command** setting to enter adapter commands.

Source > Transaction > OnSuccess setting

Use the **OnSuccess** setting with adapter sources to prevent deletion of the source message(s) from the server from which the messages originate. The default value is **Delete**.

Value

Description

Keep

Keep messages on the source queue.

Delete

Delete messages on the source queue depending upon the map completion status and the value of **OnFailure**.

For example, if the Source->Transaction->OnSuccess setting is **Delete** and the Source->Transaction->OnFailure setting is **Rollback** and the map fails, the message is rolled back and is left on the input queue. If the setting is **Rollback** and the map succeeds, the transaction is committed.

If **Rollback** is not set, there is no IBM® MQ transaction syncpoint control activation. The message remains deleted, regardless of the completion status of the map.

Source > Transaction > OnFailure setting

Use the **OnFailure** setting with adapter sources to select the rollback or commit behavior if the map does not successfully complete. The default value is Rollback.

Value

Description

Rollback

If the map does not complete successfully, sources retrieved through the messaging adapter are not deleted.

Commit

The adapter behaves as if the map was successful and the action specified by the **OnSuccess** setting is taken.

For example, if the Source->Transaction->OnSuccess setting is **Delete** and the Source->Transaction->OnFailure setting is **Rollback** and the map succeeds, the messages processed on the input queue are deleted. If the map fails, the messages are rolled back and left on the input queue.

However, if the Source->Transaction->OnSuccess setting is **Delete** and Source->Transaction->OnFailure setting is **Commit**, there is no IBM® MQ transaction syncpoint control activation. The message remains deleted, regardless of whether the map is completed. The point is that if the Source->Transaction->OnFailure setting is not **Rollback**, a message can be deleted even if a map fails.

Source> Transaction> Scope setting

Use the **Scope** setting to specify when to check for success (**OnSuccess**) or failure (**OnFailure**) at the completion of the processing of either a map, burst, or card. This is so that the rollback and retry actions can be performed as specified. The default value is Map.

Value

Description

Map

Check for success or failure at the completion of each map. If the map successfully completes, use the **OnSuccess** setting. If the map fails, use the **OnFailure** setting.

Burst

Check for success or failure at the completion of each burst. If the burst is successful, use the **OnSuccess** setting. If the burst fails, use the **OnFailure** setting.

Card

Check for success or failure at the completion of each card. If the card is successfully processed, use the **OnSuccess** setting. If the card fails, use the **OnFailure** setting.

The Burst and Card transaction scope settings cause subsequent MQ read-only GET operations within the same map to start from the beginning of the queue. This can be useful when you perform multiple consecutive ad-hoc searches (by using a RUN map or GET calls) for messages that are not in any specific order on the queue.

Source> Transaction> Warnings setting

Use the **Warnings** setting to determine whether to fail the map or ignore warning conditions for the specific input map card. The warning messages are written to the execution audit log. The default value is Ignore.

Value

Description

Ignore

Ignore warnings for this map card.

Fail

Fail the map upon receiving a warning for this map card.

Warning messages have a positive return code.

PUT > Target settings

Use the Map Designer **PUT** settings to configure options for output map cards that use the IBM® MQ (client) or IBM MQ (server) adapters. Use the **PUT->Target** setting to select the data target. Select **MQSeries** (client) or **MQSeries® (server)** to use the IBM MQ adapter.

- [PUT > Target > Command setting](#)
- [Target > Transaction > OnSuccess setting](#)
- [Target > Transaction > OnFailure setting](#)
- [Target > Transaction > Scope setting](#)
- [Target > Transaction > Warnings setting](#)
- [PUT > Target > Retry settings](#)

PUT > Target > Command setting

Use the `PUT > Target > Command` setting to enter adapter commands.

Target > Transaction > OnSuccess setting

Use the **OnSuccess** setting with adapter targets to prevent a message from being unnecessarily created during any processes. The default value is Create.

Value

Description

Create

Upon successful completion of the burst, map, card, or rule (determined by **Scope** settings), send the message.

CreateOnContent

Upon successful completion of the burst, map, card, or rule (determined by **Scope** settings), send the message only if it has content.

Target > Transaction > OnFailure setting

Use the **OnFailure** setting with adapter targets to select the rollback or commit behavior if the map does not complete successfully. The default value is Rollback.

Value

Description

Rollback

If the map does not complete successfully, the message is not sent.

Commit

The adapter behaves as if the map was successful and the action (**Create** or **CreateOnContent**) specified by the **OnSuccess** setting is taken.

Target > Transaction > Scope setting

Use the **Scope** setting to specify when to check for success (**OnSuccess**) or failure (**OnFailure**) of a card so that the actions specified with the **OnSuccess/OnFailure** settings can be performed. The default value is Map.

Value

Description

Map

Check for success or failure at the completion of each map. If the map completes successfully, use the **OnSuccess** setting. If the map fails, use the **OnFailure** setting.

Burst

Check for success or failure at the completion of each burst. If the burst is successful, use the **OnSuccess** setting. If the burst fails, use the **OnFailure** setting.

Card

Check for success or failure at the completion of each card. If the card is processed successfully, use the **OnSuccess** setting. If the card fails, use the **OnFailure** setting.

Target > Transaction > Warnings setting

Use the **Warnings** setting to determine whether to fail the map or ignore warning conditions for the specific output map card. The warning messages are written to the execution audit log. The default value is Ignore.

Value

Description

Ignore

Ignore warnings for this map card.

Fail

Fail the map upon receiving a warning for this map card.

Warnings have a positive return code.

PUT > Target > Retry settings

Use the **Retry** settings to specify the adapter response to a failure to establish a connection to a queue manager or queue. **Retry** settings include **Switch**, **MaxAttempts**, and **Interval**.

If adapter errors occur, such as failure to attach to a queue and retry is specified (**Switch** is set to ON), the adapter process is retried at the interval specified in the **Interval** setting, up to as many times as requested in the **MaxAttempts** setting.

- [Target > Retry > Switch setting](#)
- [Target > Retry > MaxAttempts setting](#)
- [Target > Retry > Interval setting](#)

Target > Retry > Switch setting

Use the **Switch** setting to determine whether to activate **Retry** for the specific adapter (ON) or not (OFF). The default value is OFF.

Value

Description

ON

This activates **Retry** for the specific adapter.

OFF

Retry is inactive.

Target > Retry > MaxAttempts setting

Use the **MaxAttempts** setting to specify the maximum number of times that **Retry** is attempted. The default value is 0.

Value

Description

0 - value

This is an integer representing the maximum number of times that **Retry** is attempted.

Target > Retry > Interval setting

Use the **Interval** setting to specify the number of seconds to wait before attempting **Retry** again. The default value is 0.

Value

Description

0 - value

This is an integer representing the number of seconds to wait before attempting **Retry** again.

IBM MQ adapter commands

The following table lists valid commands for the IBM® MQ adapter, the command syntax, and whether the command is supported (✓) for use with sources, targets, or both:

Name	Syntax	Source	Target
Channel Definition (-CD) (use with Client side only)	-CD <i>channel_name/transport_type/connection_name</i>	✓	✓
Cluster Queue Manager Name (-CQMN)	-CQMN [<i>cluster_manager_name</i>]		✓
Coded Character Set ID (-CCSID)	-CCSID <i>numeric_identifier</i>	✓	✓
Complete Message (-CMMSG)	-CMMSG	✓	
Convert (-CVT)	-CVT	✓	
Correlation ID (-CID)	-CID [<i>correlation_ID</i>]	✓	✓
Default Header (-DH)	-DH		✓
Error Queue Manager Name (-EQMN)	-EQMN <i>error_queue_mgr</i>	✓	✓
Error Queue Name (-EQN)	-EQN <i>error_queue_name</i>	✓	✓
Message expiration	-EXPIRY <i>time</i>		✓
Global Transaction Management (-GTX)	-GTX	✓	✓
Group Message (-GRP)	-GRP [<i>group_ID</i>]	✓	
Group Message 2 (-GRP2)	-GRP2	✓	
Header (-HDR)	-HDR	✓	✓
Hex Correlation ID (-HCID)	-HCID <i>hex_correlation_ID</i>	✓	✓
Hex Group Message ID (-HGRP)	-HGRP <i>hex_group_ID</i>	✓	
Hex Message ID (-HMID)	-HMID <i>hex_message_ID</i>	✓	✓
Ignore Group Message (-XGRP)	-XGRP	✓	
Listen (-LSN)	-LSN {0 S <i>wait_time_in_sec</i> }	✓	
Message Buffer Size (-MBS)	-MBS <i>bytes</i>	✓	
Message Format (-FORMAT)	-FORMAT <i>message_format</i>		✓
Message ID (-MID)	-MID [<i>message_ID</i>]	✓	✓
MQOPEN Options (-MQOO)	-MQOO <i>option_number</i>	✓	✓
Packet (-PKT)	-PKT <i>packet_size</i>		✓
Password (-P)	{-PASSWORD -P} <i>password</i>	✓	✓
Quantity (-QTY)	-QTY { <i>value</i> S}	✓	
Queue Manager Name (-QMN)	-QMN <i>queue_manager</i>	✓	✓
Queue Name (-QN)	-QN <i>queue_name</i>	✓	✓
Refresh Message Cursor (-REFRESH)	-REFRESH [<i>reset_time</i>]	✓	

Name	Syntax	Source	Target
Require All Messages (-ALLMSG)	-ALLMSG	✓	
Require All Segments (-ALLSEG)	-ALLSEG	✓	
Trace (-T)	-T[E S] [full_path]	✓	✓
Transmission Error Queue Name (-XEQN)	-XEQN x_err_queue_name	✓	✓
Transmission Queue Name (-XQN)	-XQN x_queue_name		✓
User (-U)	{-USERID -U} user_ID	✓	✓
Version 2 (-V2)	-V2	✓	✓
Wait Interval (-WI)	-WI {0 S wait_interval_in_milliseconds}	✓	

- [Channel definition \(-CD\)](#)

- [Cluster queue manager name \(-CQMN\)](#)

- [Coded character set identifier \(-CCSID\)](#)

Use the Coded Character Set ID (-CCSID) adapter command to identify or transform the character set encoding of message data.

- [Complete message \(-CMMSG\)](#)

- [Convert \(-CVT\)](#)

- [Correlation ID \(-CID\)](#)

- [Default header \(-DH\)](#)

- [Error queue manager name \(-EQMN\)](#)

- [Error queue name \(-EQN\)](#)

- [Message expiration \(-EXPIRY\)](#)

The **-EXPIRY** command specifies the amount of time that a message can spend on a queue before it becomes eligible for the queue manager to discard it.

- [Global transaction management \(-GTX\)](#)

- [Group message \(-GRP\)](#)

- [Group message 2 \(-GRP2\)](#)

- [Header \(-HDR\)](#)

- [Hex correlation ID \(-HCID\)](#)

- [Hex group message ID \(-HGRP\)](#)

- [Hex message ID \(-HMID\)](#)

- [Ignore group message \(-XGRP\)](#)

- [Listen \(-LSN\)](#)

- [Message buffer size \(-MBS\)](#)

- [Message format \(-FORMAT\)](#)

- [Message ID \(-MID\)](#)

- [MQOPEN options \(-MQOO\)](#)

- [Packet \(-PKT\)](#)

- [Password \(-P\)](#)

The **-PASSWORD** command specifies the password that the IBM MQ adapter uses to authenticate its connection to the IBM MQ queue manager.

- [Quantity \(-QTY\)](#)

- [Queue manager name \(-QMN\)](#)

- [Queue name \(-QN\)](#)

- [Refresh message cursor \(-REFRESH\)](#)

- [Require all messages \(-ALLMSG\)](#)

- [Require all segments \(-ALLSEG\)](#)

- [Trace \(-T\)](#)

- [Transmission Error queue name \(-XEQN\)](#)

- [Transmission queue name \(-XQN\)](#)

- [User \(-U\)](#)

The **-USERID** command specifies the user ID that the IBM MQ adapter uses to authenticate its connection to the IBM MQ queue manager.

- [Version 2 \(-V2\)](#)

- [Wait Interval \(-WI\)](#)

-

Channel definition (-CD)

Use the optional Channel Definition adapter command (-CD) to specify the client-connection channel definition, which is used by the IBM® MQ Client adapter at runtime to establish the connection to the queue manager.

Note: The Channel Definition adapter command (-CD) can be used only with the IBM MQ Client adapter. (The connection will fail if the IBM MQ Server adapter is used.) If this command is used, the MQSERVER, MQCHLLIB, and MQCHLTAB environment variables are ignored by the adapter for connecting to the IBM MQ Queue Manager.

By defining this adapter command, it is possible to connect to multiple queue managers from the same map using the MQ Client adapter, because each connection will be specified using a different -CD adapter command.

-CD channel_name/transport_type/connection_name

Option

Description

channel_name

Specify the name of the server-connection channel that must be set up on the queue manager to which the IBM MQ Client adapter is connecting.

transport_type

Specify the name of the communication protocol used to establish the connection with the queue manager on the IBM MQ server. The following values are valid:

- LU62
- TCP
- NETBIOS
- SPX
- DECNET

It is the user's responsibility to correctly specify this value. The chosen transport protocol must be supported in the underlying IBM MQ environment.

connection_name

Specify the name of the connection. The format of this value depends on the communication protocol that was selected with *transport_type*. For example, for the TCP communication protocol, the connection name consists of the IP address and the port number on which the MQ listener on MQ server host is waiting for the client requests.

For example:

```
-CD CHANNEL1/TCP/127.0.0.1(1414)
```

This command specifies the following:

- **CHANNEL1** is the name of the server-connection channel.
- **TCP** is the name of the communication protocol used to establish the connection.
- **127.0.0.1(1414)** is the name of the connection. The IP address can be in IPv4 (for example, 1.2.3.4) or IPv6 (for example, a:b:c:d:0:1:2:3) format.

Cluster queue manager name (-CQMN)

Use the Cluster Queue Manager Name adapter command (-CQMN) to put messages to a queue accessible from a cluster queue manager.

```
-CQMN [cluster_manager_name]
```

where *cluster_manager_name* is the optional name of the cluster queue manager upon which the target queue exists. If *cluster_manager_name* is not specified, IBM® MQ selects the queue manager from the cluster.

To put a message to a specific instance of a cluster queue (that is, a queue instance that resides on a particular queue manager), specify the name of that queue manager as the argument for the Cluster Queue Manager Name adapter command (-CQMN). This forces the local queue manager to send the message to the specified destination queue manager.

The Cluster Queue Manager Name adapter command (-CQMN) must be accompanied by the Queue Name adapter command (-QN) and the local Queue Manager Name adapter command (-QMN).

If the argument to -QN is the name of a cluster queue and the -CQMN argument is not supplied, the actual destination of messages sent using the queue handle returned by the MQOPEN call is chosen by the queue manager (or by a cluster workload exit if one exists) according to the value of the DefBind queue attribute. This attribute may have one of two values:

- If MQOO_BIND_ON_OPEN is specified, the queue manager selects a particular instance of the cluster queue during the processing of the MQOPEN call, and all messages put using this queue handle are sent to that instance.
- If MQOO_BIND_NOT_FIXED is specified, the queue manager may choose a different instance of the destination queue (residing on a different queue manager in the cluster) on each successive MPUT call that uses this queue handle.

For more information about setting these options, see "[MQOPENoptions \(-MQOO\)](#)".

- [Examples](#)

Examples

To put a message to a queue named **q1** (which exists on the cluster queue manager **cqm1**) where the adapter is connecting to the cluster queue manager **cqm_default**, enter:

```
-QMN cqm_default -QN q1 -CQMN cqm1
```

To put a message to a queue named **q2** residing on a cluster queue manager, for which the local queue manager of the cluster is **cqm_default**, enter:

```
-QMN cqm_default -QN q2 -CQMN
```

The Cluster Queue Manager Name adapter command (-CQMN) applies only to data targets. IBM® MQ does not support gets (data sources) from remote queues not residing on the local queue manager, which include cluster queues.

Coded character set identifier (-CCSID)

Use the Coded Character Set ID (-CCSID) adapter command to identify or transform the character set encoding of message data.

For data targets, the *numeric_identifier* parameter identifies the character set encoding of the message data that is being put on the queue.

For data sources, the *numeric_identifier* parameter identifies the character set encoding to which the message data is to be transformed. To use this function, you must also specify the -CVT adapter command.

```
-CCSID numeric_identifier
```

Option

Description
<i>numeric_identifier</i> The decimal coded-character-set identifier (CCSID).

Complete message (-CMMSG)

Use the Complete Message adapter command (-CMMSG) for data sources to specify retrieval of complete logical messages within group messages.

-CMMSG

The Complete Message adapter command (-CMMSG) specifies that only a complete logical message can be returned by the MQGET call. If the logical message is segmented, the queue manager reassembles the segments and returns the complete logical message.

The Complete Message adapter command (-CMMSG) is the only adapter command that causes the queue manager to reassemble message segments. Using the Complete Message adapter command (-CMMSG) directs the messaging adapter to set the **MQGMO_COMPLETE_MSG** flag in the **MQGMO.Options** field.

If the queue contains segmented messages with some of the segments missing (perhaps the messages were delayed in the network and have not yet arrived), use the Complete Message adapter command (-CMMSG) to prevent retrieval of segments belonging to incomplete logical messages.

For information about incomplete message groups contributing to the size of **CurrentQDepth**, see "[Incomplete message segments](#)".

The Complete Message adapter command (-CMMSG) implies that all segments in a logical message must be available for retrieval. Therefore, it is not necessary to specify the Require All Segments adapter command (-ALLSEG).

Convert (-CVT)

Use the Convert adapter command (-CVT) for data sources to enable the IBM® MQ server queue manager to perform a data conversion based upon the client-server coded character set identifier (CCSID) settings, or to execute data conversion user exits. For example, you can use this command to convert from the EBCDIC character set to the ASCII character set to implement distributed messaging using IBM MQ.

-CVT

To satisfy all the requirements for IBM MQ when using this command, see your IBM MQ documentation.

Correlation ID (-CID)

Use the Correlation ID adapter command (-CID) to specify a particular correlation identifier (CID) for a source or target. Use this adapter command for a data source to retrieve messages from a queue with a specific correlation ID. You can also use it for a data target to assign a correlation ID to a message when placing it on a queue. A correlation identifier can be up to 24 bytes long and is expected to contain printable characters.

-CID [*correlation_ID*]

Spaces can also be specified in values. However, if the value contains a space, it must be enclosed with double quotation marks as shown in the example below:

-CID "my ID"

The double quotation mark character can also be used as part of a value. To do this, the double quotation mark value must be represented by a pair of double quotation marks. For example, if you wanted to specify a correlation ID of **My "New" ID**, you would need to enter the following:

-CID "My ""New"" ID"

When a correlation identifier is specified for a source, the adapter retrieves the first message on the queue with that correlation ID. If no argument is supplied, the correlation ID of the first message retrieved is used.

If the Correlation ID adapter command (-CID) is specified and is used with the Message ID adapter command (-MID), the retrieved messages begin with the first message on the queue that has the specified message ID and the correlation ID. Additional messages are retrieved that have the same message ID and correlation ID. If no correlation ID is specified, the message is identified only by the message ID.

When a correlation identifier is specified for a data target, the adapter places the message on the queue with the assigned correlation identifier.

Related reference

- [Wildcard support](#)

Default header (-DH)

The Default Header adapter command (-DH) specifies that the default IBM® MQ Message Descriptor (MQMD) is used as the message descriptor for data targets.

-DH

Any null rules (=NONE) in the mapped header field are ignored and the default MQMD values generated by the queue manager are used. Any non-null header fields are set in the MQMD to replace the default MQMD values. The only exception to this is fields that describe the origin and identity context of the message.

Fields describing the origin context of the message are the following (listed in the order in which they appear in the example type tree, **mq.mtt**):

- PutApplType
- PutApplName
- PutDate
- PutTime
- ApplOriginData

Fields describing the identity context of the message are the following (listed in the order in which they appear in the example type tree, **mq.mtt**):

- UserIdentifier
- AccountingToken
- ApplIdentityData

Do not try to specify values for these fields if you use the **-DH** option in the adapter command. Using that option causes values you provided in these fields to be ignored by the adapter and replaced with the default IBM MQ values. If you need to explicitly specify values for these fields, use the **-HDR** option in the adapter command (without the **-DH** option).

The Default Header adapter command (**-DH**) overrides the Header adapter command (**-HDR**).

The appropriate header information must be mapped if the Default Header adapter command (**-DH**) is used. If the header information is not mapped and the Default Header adapter command (**-DH**) is used, the mqseries trace shows that the map fails with the following error:

```
<1476-2248>: [m4mqspPut]
<1476-2248>: | [intm4mqsobtainQueueNode]
<1476-2248>: | | Queue node found: QNAME
<1476-2248>: | [intm4mqsobtainQueueNode] (rc = 0) OK
<1476-2248>: | Adapter error rc = -1011 [Invalid message format]
<1476-2248>: [m4mqspPut] (rc = -1011) *** ERROR ***
<1476-2248>: [m4mqspEndTransaction]
<1476-2248>: | Rolling back unit of work
<1476-2248>: [m4mqspEndTransaction] (rc = 0) OK
```

Error queue manager name (-EQMN)

Use the Error Queue Manager Name adapter command (**-EQMN**) for data sources and data targets to specify the name of the queue manager for the error queue.

-EQMN error_queue_manager_name

Only use the Error Queue Manager Name adapter command (**-EQMN**) when the Error Queue Name adapter command (**-EQN**) is specified and you want to designate a different queue manager for the error queue than the default. The default queue manager is specified with the Queue Manager Name adapter command (**-QMN**).

Only use this adapter command when using the IBM® MQ Client adapter; using it with the IBM MQ Server adapter causes an error. This is because only the IBM MQ Client application can be connected to more than one queue manager at the same time.

Error queue name (-EQN)

Use the Error Queue Name adapter command (**-EQN**) for data sources and data targets to specify the error queue to which messages are copied when errors occur. If a message has the rollback option set and a map does not successfully complete, the message is copied to the designated error queue. The original message is removed from the source queue.

-EQN error_queue_name

The name of the error queue must be specified. By default, the queue manager used is the one specified with the Queue Manager Name adapter command (**-QMN**).

Message expiration (-EXPIRY)

The **-EXPIRY** command specifies the amount of time that a message can spend on a queue before it becomes eligible for the queue manager to discard it.

-EXPIRY time

Option

Description

time

Expiry time in tenths (0.1) of a second. The default value (-1) specifies no message expiration.

Global transaction management (-GTX)

Use the Global Transaction Management adapter command (**-GTX**) to indicate that the transactions for this card (whether input or output) should be processed as global transactions.

-GTX

For more information about global transaction management, see the Global Transaction Management documentation.

Group message (-GRP)

Use the Group Message adapter command (-GRP) for data sources to specify retrieval of messages from a single group from the source.

-GRP [group_ID]

Option	Description
group_ID	This is the GroupId field of the MQ Message Descriptor (MQMD)

For example, to specify a message group with the GroupId of **GroupA**, the syntax would be:

-GRP GroupA

If the Quantity adapter command (-QTY) is not specified, only one message belonging to the group will be retrieved. If *group_ID* is not specified, the first message group encountered is considered the active message group and is retrieved. You can explicitly specify the number of messages to retrieve using the Quantity adapter command (-QTY). The group name has a maximum size of 24 bytes and may contain spaces. If the value contains a space, it must be enclosed with double quotation marks as shown in the example below:

-GRP "Group A"

The double quotation mark character can also be used as part of a value. To do this, the double quotation mark value must be represented by a pair of double quotation marks. For example, if you wanted to specify a message group with the GroupId of **Group "A"**, you would need to enter the following:

-GRP "Group ""A"""

If the Group Message adapter command (-GRP) is used with an event source queue, the adapter will initially browse the queue and look for a message that belongs to the group whose *group_ID* was provided. If *group_ID* was not provided, the first message that belongs to any group will be retrieved and the adapter will keep note of the ID of that group. From that point on, only messages that belong to the same group to which the first message belonged will be retrieved.

Related reference

- [Wildcard support](#)

Group message 2 (-GRP2)

Use the Group Message 2 adapter command (-GRP2) for data sources to specify retrieval of message groups and non-group messages from the source queue.

-GRP2

The -GRP2 adapter command enables better control over group messages than the -GRP adapter command. The biggest difference between the -GRP2 and -GRP adapter commands is that -GRP2 can be used to process multiple message groups on the source queue. In addition to this, message groups are processed as a unit with -GRP2 and not as individual messages.

While the -GRP adapter command detects a group on the queue and then starts retrieving messages that belong only to that group, the -GRP2 adapter command detects a group on the queue, retrieves all the messages from that group in a single block of data, and keeps looking for other message groups on the queue and other individual non-group messages.

The following restrictions apply to the -GRP2 adapter command:

- It has no arguments.
- It can only be used on input (input cards and GET map function).
- It cannot be combined with the -GRP adapter command.
- It assumes usage of the -XGRP, -ALLSEG, and -ALLMSG adapter commands. Whether explicitly specified or not, these three adapter commands will be automatically included by the -GRP2 adapter command.
- It can be used with the -EQMN and -EQN adapter commands. In case of an error, all messages from the retrieved groups as well as all retrieved non-group messages are moved to the specified error queue.
- in the Launcher scenario, it can be combined with the -REFRESH adapter command. This is particularly useful when there is a possibility that an incomplete message group gets skipped by the queue cursor in order to obtain another complete message group (or non-group message), and the skipped group later becomes complete.

The following table lists some examples of the -GRP2 adapter command usage.

Presume that the following content of queue **QUEUE1** is defined under queue manager **QMNAME**:

Message ID	Message in a group?	Group ID	Logical Sequence Number	Last message in the group?	Segmented message?	Offset	Last Segment?	Data
1	NO							PhysMess01
2	YES	1	1	NO	NO			PhysMess02
3	YES	1	2	YES	NO			PhysMess03
4	NO							PhysMess04
5	YES	1	3	NO	NO			PhysMess05
6	YES	2	1	NO	NO			PhysMess06
7	NO							PhysMess07
8	NO							PhysMess08
9	YES	2	2	NO	YES	0	NO	PhysMess09

Message ID	Message in a group?	Group ID	Logical Sequence Number	Last message in the group?	Segmented message?	Offset	Last Segment?	Data
10	YES	2	2	NO	YES	10	NO	PhysMess10
11	YES	2	2	NO	YES	20	YES	PhysMess11
12	YES	2	3	YES	NO			PhysMess12
13	YES	3	1	YES	NO			PhysMess13
14	NO							PhysMess14

There are few important things to note in this table:

- Physical messages on positions 1, 4, 7, 8 and 14 are logical messages that do not belong to any group.
- Physical messages on positions 2, 3 and 5 are logical messages that belong to a group with the group ID equal to "1".
- Physical messages on positions 6, 9, 10, 11 and 12 belong to a group with the group ID equal to "2". Physical messages on positions 6 and 12 are logical messages, and physical messages on positions 9, 10 and 11 are message segments that together form a single logical message. Physical message on position 11 is the last segment of the logical message. Physical message on position 12 is the last logical message of the group.
- Physical message on position 13 is a logical message and it belongs to a group with the group ID equal to "3". This message is the only logical message in the group.

Presume that a map has one input card and one output card. The input card is of IBM® MQ type, and the output card is of "File" type. The data content obtained in the input card is stored to a file specified in the output card.

- [Example 1](#)
- [Example 2](#)

Example 1

For example, enter the following command:

```
-QMN QMNAME1 -QN QUEUE1 -GRP2 -QTY 2
```

The data returned will be:

```
PhysMess01PhysMess02PhysMess03PhysMess05
```

Explanation:

-QTY 2 required two message units to be retrieved from the queue. The first message on the queue is PhysMess01. This message does not belong to a group and is returned as a single message. It contributes to one unit in the -QTY 2 value.

The next message on the queue is PhysMess02. This message belongs to a complete group with the group id "1". The adapter retrieves the whole group (messages PhysMess02, PhysMess03 and PhysMess05) and returns them as a chunk of data that contributes to the second unit in the -QTY 2 adapter command.

If the -GRP2 adapter command was omitted, the returned data would be:

```
PhysMess01PhysMess02
```

Example 2

For example, enter the following command:

```
-QMN QMNAME1 -QN QUEUE1 -GRP2 -QTY 4
```

The data returned will be:

```
PhysMess01PhysMess02PhysMess03PhysMess05PhysMess04  
PhysMess06PhysMess09PhysMess10PhysMess11PhysMess12
```

Explanation:

-QTY 4 required four message units to be retrieved from the queue. The adapter first retrieved PhysMess01, and then PhysMess02, PhysMess03 and PhysMess05, as in the previous example. After that, there are two more message units that need to be retrieved.

The third message unit is message PhysMess04. It is a non-group message, and the adapter retrieves it after retrieving the message group "1". Finally, the forth unit is message group "2" that consists of the following physical messages:

```
PhysMess06, PhysMess09, PhysMess10, PhysMess11 and PhysMess12
```

If -GRP2 adapter command was omitted, the returned data would be:

```
PhysMess01PhysMess02PhysMess03PhysMess04
```

Header (-HDR)

Use the Header adapter command (-HDR) to specify the inclusion of the IBM® MQ message descriptor in the source and target data.

-HDR

When Header adapter command (-HDR) is used for a data source, the message descriptor appears first, before the message content. Use the Header adapter command (-HDR) to include any of the message descriptor components in mapping rules.

When the Header adapter command (-HDR) is used for a data target, the message descriptor must be the first component of the output type. Mapping rules for the message descriptor components must be provided.

Included in the **examples** folder is a type tree that can be used when specifying this command. For more information, see ["Example files"](#).

For data targets only, if the Header adapter command (-HDR) is used in conjunction with the Message ID adapter command (-MID), the Header command (-HDR) takes precedence over the Message ID command, which is ignored. If the Header adapter command (-HDR) is used in conjunction with the Version 2 adapter command (-V2), then the version information mapped in the header is ignored.

Hex correlation ID (-HCID)

Use the Hex Correlation ID adapter command (-HCID) to specify correlation identifiers using hexadecimal pair notation. This passes to the adapter the exact correlation ID to locate, even if that correlation ID contains non-printable values, spaces, or even null characters.

-HCID hex_correlation_ID

Option

Description
<i>hex_correlation_ID</i>
This is the hexadecimal correlation identifier. For example, the ASCII correlation ID My Msg is represented as 4D79204D7357 when specified with the Hex Correlation ID adapter command (-HCID). The space character must be encoded in the hex pair notation.

The hexadecimal correlation ID wildcard notation is not encoded in the hex pair notation. The wildcard character * is entered literally. For example, the hexadecimal pair notation for x*z is 78*7A, not 782A7A. The Hex Correlation ID (-HCID) cannot be used with the Correlation ID adapter command (-CID).

Related reference

- [Wildcard support](#)

Hex group message ID (-HGRP)

Use the Hex Group Message ID adapter command (-HGRP) for data sources to specify group message identifiers using hexadecimal pair notation. This passes to the adapter the exact group message ID to locate, even if that group message ID contains non-printable values, spaces, or even null characters.

-HGRP hex_group_ID

Option

Description
<i>hex_group_ID</i>
This is the hexadecimal group message identifier. For example, the ASCII group message ID My Msg is represented as 4D79204D7357 when specified with the Hex Group Message ID adapter command (-HGRP). The space character must be encoded in the hex pair notation.

The hexadecimal group message ID wildcard notation is not encoded in the hex pair notation. The wildcard character * is entered literally. For example, the hexadecimal pair notation for x*z is 78*7A, not 782A7A. The Hex Group Message ID (-HGRP) cannot be used with the Group Message adapter command (-GRP).

Related reference

- [Wildcard support](#)

Hex message ID (-HMID)

Use the Hex Message ID adapter command (-HMID) to specify message identifiers using hexadecimal pair notation. This passes to the adapter the exact message ID to locate, even if that message ID contains non-printable values, spaces, or even null characters.

-HMID hex_message_ID

Option

Description
<i>hex_message_ID</i>
This is the hexadecimal message identifier. For example, the ASCII message ID My Msg is represented as 4D79204D7357 when specified with the Hex Message ID adapter command (-HMID). The space character must be encoded in the hex pair notation.

The hexadecimal message ID wildcard notation is not encoded in the hex pair notation. The wildcard character * is entered literally. The hexadecimal pair notation for x*z is 78*7A, not 782A7A.

The Hex Message ID (-HMID) cannot be used with the Message ID adapter command (-MID).

Related reference

- [Wildcard support](#)

Ignore group message (-XGRP)

Use the Ignore Group Message adapter command (-XGRP) for data sources to ignore the group messages on the queue and not to treat them as individual, physical messages. The default behavior of the IBM® MQ adapter is to process all physical messages, including group messages, as individual events.

-XGRP

The Ignore Group Message adapter command (-XGRP) causes the adapter to ignore any group messages on that queue for the source event card. If both groups and non-group messages are to be processed as events from the same source queue, the Group Message 2 (-GRP2) command can be used as described on page [Group message 2 \(-GRP2\)](#).

If the Group Message adapter command (-GRP) is used with an event source queue, the adapter ignores non-group messages on that queue. It only processes the messages from the group specified with the -GRP adapter command, or, if no group was specified, the first group that it locates on the queue.

If neither -XGRP nor -GRP is used, all messages are treated as non-group messages and processed individually.

Listen (-LSN)

Use the Listen adapter command (-LSN) for data sources to dictate the length of time (in seconds) that the IBM® MQ queue manager allows the adapter to wait for a message to be received. Map execution is suspended until the message is received or until the specified time lapses.

-LSN {0|S|wait_time_in_sec}

Option

Description

0

Do not wait at all. If there is no input available, the adapter does not wait for more messages.

S

This is an infinite wait time.

wait_time_in_sec

This is the number of seconds that the adapter waits (in seconds) for a message.

If the Listen adapter command (-LSN) is not issued and the message is not available for the adapter to retrieve immediately, the map completes, but returns the following warning in the audit log:

(2033) MQSeries Warning: No message available.

Message buffer size (-MBS)

Use the Message Buffer Size adapter command (-MBS) to specify the size of the message buffer. The adapter allocates this message buffer size for retrieving messages from a source queue. If the buffer size is insufficient, the buffer is automatically reallocated to accommodate the messages.

-MBS bytes

Option

Description

bytes

This is the size of the message buffer in bytes. The default buffer size is 4096 bytes.

Message format (-FORMAT)

Use the Message Format adapter command (-FORMAT) for data targets to specify the format of the application data in the message. Either pre-existing (defined by IBM® MQ) or custom (user-defined) message formats can be used.

-FORMAT message_format

Option

Description

message_format

A message format, either pre-existing (predefined by IBM MQ) or custom (user-defined). The format can contain up to eight (8) characters. If less than eight, it will be padded with spaces.

For example, to specify MQFMT_STRING as the format of the message, the following adapter command should be used:

-FORMAT MQSTR

where MQSTR is the value of the MQFMT_STRING message format. For information about other built-in message formats, see your IBM MQ documentation.

You must always specify a value when using the -FORMAT adapter command. Failure to do so will result in map failure and a corresponding error message is generated.

If you use a user-defined format, you must also provide the corresponding data-conversion exit so that receiving applications can read the message using the MQGMO_CONVERT option. For IBM Transformation Extender applications, this means using the -CVT adapter command for the IBM MQ inputs.

If the message format is not provided (either with the usage of the -FORMAT adapter command or through the message descriptor type tree with the -HDR/-DH adapter command), the MQFMT_STRING message format is used as a default value.

To specify a format value that has spaces interleaved with text (or all spaces), use double quotes.

For example:

```
-FORMAT "ab cd"
```

or

to specify a blank format (all spaces), you can insert eight (8) spaces in double quotes:

```
-FORMAT "     "
```

Note that the value of the -FORMAT adapter command is the value of the predefined format constant, not the name of the constant.

For example, use:

```
-FORMAT MQSTR
```

or:

```
-FORMAT "MQSTR "
```

and not:

```
-FORMAT MQFMT_STRING
```

MQFMT_STRING is the name of the predefined IBM MQ message format constant, and its value is "MQSTR "

Message ID (-MID)

Use the Message ID adapter command (-MID) to specify a particular message ID for a data source or target.

```
-MID [message_ID]
```

Option

Option	Description
message_ID	A message ID can be up to 24 bytes long and may contain spaces.

If the value contains a space, it must be enclosed with double quotation marks as shown in the example below:

```
-MID "my ID"
```

The double quotation mark character can also be used as part of a value. To do this, the double quotation mark value must be represented by a pair of double quotation marks. For example, if you wanted to specify a message ID of My "New" ID, you would need to enter the following:

```
-MID "My ""New"" ID"
```

When using the Launcher, the message ID can be specified with wildcard notation. For more information about wildcard notation, see the Launcher documentation.

When a message ID is specified for a data source, the adapter retrieves the first message with the designated message ID. If no argument is supplied, the message ID of the first message retrieved will be used.

When a message ID is specified for a target, the adapter places the message on the queue with that message ID assigned. If this command is not specified for a target, the message is put on the queue using a unique message identifier generated by the queue manager.

For targets only, if the Header adapter command (-HDR) is used in conjunction with the Message ID adapter command (-MID), the Header adapter command (-HDR) takes precedence over the Message ID adapter command (-MID), which is ignored.

Related reference

- [Wildcard support](#)

MQOPEN options (-MQOO)

Use the MQOPEN Options adapter command (-MQOO) to explicitly set the numeric value of the Options parameter in the MQOPEN API call made by the adapter to the MQSeries® library when opening a queue.

```
-MQOO option_number
```

Option

Option	Description
option_number	Valid values are any positive integer that represents the value of the option parameter in the MQOPEN API call made when opening a queue.

As an example of the required option usage, if you want to specify an open option for the queue to be used on the output side with an MQOO_FAIL_IF_QUIESCING property, you must specify more than the MQOO_FAIL_IF_QUIESCING value (8192). You must also add the MQOO_OUTPUT option value (16), which indicates that the queue will be opened for output (storing messages). The correct syntax for this example would be:

```
-MQOO 8208
```

because MQOO_OUTPUT + MQOO_FAIL_IF_QUIESCING = 16+8192 = 8208.

The valid value is important; otherwise, the MQOPEN, MQGET, or MQPUT calls made by the adapter may fail. For the options and their corresponding values that can be used with the -MQOO adapter command, see the MQ Open Options section in the *IBM® MQ Application Programming Reference*.

The MQOPEN Options adapter command (-MQOO) must be accompanied by the Queue Name adapter command (-QN) and the Queue Manager Name adapter command (-QMN).

For example, to specify the target queue named **target_q** under the queue manager **qmgr** for message outputs (where 16 is the numeric value of the MQOO_OUTPUT option), the syntax would be:

```
-QMN qmgr -QN target_q -MQOO 16
```

To specify the source queue named **source_q** under the queue manager **qmgr**, for message input in browse mode with shared access (where 10 is the numeric superposition of the MQOO_INPUT_SHARED (2) and MQOO_BROWSE (8) options), the syntax would be:

```
-QMN qmgr -QN source_q -MQOO 10
```

Packet (-PKT)

Use the Packet adapter command (-PKT) for data targets to break output data into multiple messages and to put these messages on the target queue with the same message identifier.

```
-PKT packet_size
```

Option

Description

packet_size

The packet size must be specified in units of 1000 bytes with a minimum of one unit.

For example, to specify a packet size of 3000 bytes, the syntax would be:

```
-PKT 3
```

If one of the following conditions is met:

- If the -HDR or -DH command is used on output, and the message header has the **Version** field set to a value of one (1).
- If the Version 2 (-v2) command is used (which enforces the use of the Version 1 header from MQSeries® 2.x). For more information about this command, see ["Version 2 \(-V2\)"](#).

The created physical messages will be independent logical messages that will have the same message id. These messages cannot be automatically reassembled on input, however, this can be achieved through the proper map design.

On the other hand, if BOTH of the following conditions are met:

- If -HDR or -DH is used on output and if the message header has **Version** field set to a value of two (2).
- If the Version 2 (-v2) command is omitted (which would enforce the use of Version 1 header from MQSeries 2.x). For more information about this command, see ["Version 2 \(-V2\)"](#).

The created physical messages will be message segments of the original message. The Offset property of the message will provide information about the relative position of each of the segments in the original message. In this case, -CMMSG adapter command can be used on input to automatically reassemble the original message.

The Packet adapter command (-PKT) is ignored for a message source.

Password (-P)

The **-PASSWORD** command specifies the password that the IBM® MQ adapter uses to authenticate its connection to the IBM MQ queue manager.

```
{-PASSWORD | -P} password
```

Option

Description

password

The password to authenticate.

You must issue both the **-USER** command and the **-PASSWORD** command to initiate authentication and to store the user ID and password information in the IBM MQ MQCSP structure.

Related information

- [User \(-U\)](#)

Quantity (-QTY)

Use the Quantity adapter command (-QTY) to specify the number of messages to retrieve from the source queue, without regard to message IDs. If the Quantity adapter command (-QTY) is not specified, the default value is 1.

```
-QTY {value|S}
```

Option	Description
S	This returns all messages on the queue.
value	This is a positive integer representing the number of concurrent multiple messages to be retrieved.
For example, to specify a quantity of ten messages, the syntax would be:	
-QTY 10	
The Quantity adapter command (-QTY) defines the maximum number of messages across all bursts for a map.	
The number of bursts in a single map execution can be controlled using the combination of values set in the Map Designer Source > FetchAs > FetchUnit setting and the Quantity adapter command (-QTY).	
When using the Quantity adapter command (-QTY) with the S option through either the Launcher or the Command Server, the Listen adapter command (-LSN) is also required with a value specified other than S.	

Queue manager name (-QMN)

Use the Queue Manager Name adapter command (-QMN) to specify the name of the queue manager on which the queue (specified by the -QN command) exists.

-QMN queue_manager_name

Option	Description
queue_manager_name	This is the name of the queue manager. This name is case-sensitive.
When the Queue Manager Name adapter command (-QMN) is not specified, the default queue manager is used.	

Queue name (-QN)

Use the Queue Name adapter command (-QN) to specify the name of the queue from which the message(s) are to be retrieved or to which the message(s) are to be sent.

-QN queue_name

Option	Description
queue_name	This is the name of the queue. This name is case sensitive.
The Queue Name adapter command (-QN) is a required adapter command.	

Refresh message cursor (-REFRESH)

Use the Refresh Message Cursor adapter command (-REFRESH) to ensure that higher-priority messages are enqueued in front of any existing messages with a lower priority so that the higher-priority messages can trigger the associated maps to run. This command is only used when using an IBM® MQ event input with the Launcher. If messages of a higher priority are enqueued after messages of a lower priority, the default behavior is that the higher priority messages would not trigger the maps.

-REFRESH [reset_time]

Option	Description
reset_time	This is a non-negative integer defining the number of seconds that elapse before the message cursor is reset to the head of the queue.
The Refresh Message Cursor adapter command (-REFRESH) resets the message cursor of the source queue message event listener to the head of the queue after every listener cycle (detection of all messages currently on the queue) is completed. You can optionally specify a non-negative integer argument (reset_time) that defines the number of seconds that elapse before the messages cursor is reset to the head of the queue. If reset_time is set to zero, the message cursor will be constantly reset to the beginning of the queue after each event. Thus, the higher priority messages are processed as soon as possible. However, frequent repositioning of the cursor will degrade overall performance.	

The Refresh Message Cursor adapter command (-REFRESH) is only needed when using an IBM MQ event input with the Launcher, and only in two specific situations:

- When messages of higher priority are placed at the beginning of the queue that are not recognized because the message cursor has already begun moving towards the bottom of the queue.
- When there is a possibility of the message cursor skipping the uncommitted messages on the queue. As an example, suppose that two applications, APP1 and APP2, simultaneously place messages on an empty queue and the following sequence of operations occurs (a possibility because APP1 and APP2 are independent and are executing concurrently):
 - TO: APP1 PUT(M1)
 - T1: APP2 PUT(M2)
 - T2: APP2 COMMIT(M2)
 - T3: APP1 COMMIT(M1)

After T1 occurs, both messages have already been placed on the queue (with M1 in front of M2). However, they are not being recognized by the message cursor.

After T2 occurs, the message cursor recognizes message M2 and it positions itself on that message. After T3 occurs, message M1 is also committed, but it is now beyond the message cursor. The message cursor will never be able to recognize that message unless it is repositioned to the beginning of the queue. Use the Refresh Message Cursor adapter command (-REFRESH) to accomplish this repositioning.

Using the Refresh Message Cursor adapter command (-REFRESH) may degrade event notification and mapping performance and should only be used when necessary. The adapter must be careful not to trigger the map more than once for the same input message. To ensure this, the adapter maintains a list of messages that have already been seen by the cursor. Each time the cursor is repositioned to the beginning of the queue, each message that the cursor finds on the queue is compared with all of the messages in this list. Only in situations in which this message is not in the adapter list is that message considered to be a new message to be used for the event notification. As part of this process, this new message will be added to the adapter list. To ensure that this list does not grow infinitely, there are two important limitations for the input cards that use the -REFRESH adapter command:

- The **Rollback** option for the **OnFailure** setting should not be used.
- The **Keep** option for the **OnSuccess** setting should also not be used.

If either of these two options is specified, running the Launcher for a long period of time with many messages being processed may cause excessive memory usage and may slow down processing time significantly, and eventually may cause the system to stop.

The reason for this is that messages once seen by the cursor are added to the internal list, and as long as they are not removed from the source queue, they are also not removed from the internal adapter's list so that they are not processed more than once. Messages are freed from the internal list only after they have been removed from the source queue.

In situations in which it is necessary to use the Refresh Message Cursor adapter command (-REFRESH) and to preserve the messages for the failed map, it is recommended that you use Error Queue Name adapter command (-EQN) in combination with -REFRESH adapter command for the input card. In this case, the Source->Transaction->OnSuccess setting should be **Delete** and the Source->Transaction->OnFailure setting should be **Rollback**. The messages for the map failure will be placed on the error queue and removed from the source queue. Thus, messages will be preserved (on the error queue), and no memory leak will occur because it will be possible to remove messages from the internal adapter's list upon moving them to the error queue. Note, however, that if, for some reason, messages cannot be stored on the error queue (for example, PUT is disabled for the error queue), the messages will remain on the input queue and in the internal adapter's list which again provides the possibility of a memory leak.

Require all messages (-ALLMSG)

Use the Require All Messages adapter command (-ALLMSG) for data sources to specify retrieval of messages in a group only when all messages in that group are available.

The use of the -ALLMSG adapter command automatically sets the requirement that group messages are returned in their logical order and that segments of logical messages are returned in the order of their offsets.

This must be considered when specifying additional selection criteria (such as the -MID or -CID adapter commands). It may be possible that the message which satisfies this additional criteria is not the message with the smallest sequence number and/or the smallest offset in its group, which will prevent it from being retrieved from the queue.

-ALLMSG

If the source queue contains an incomplete message group, the Require All Messages adapter command (-ALLMSG) prevents retrieval of any messages belonging to the incomplete groups.

For information about incomplete message groups contributing to the size of **CurrentQDepth**, see "[Incomplete message segments](#)".

The Require All Messages adapter command (-ALLMSG) implies that all segments in a logical message must be available for retrieval. Therefore, it is not necessary to specify the Require All Segments adapter command (-ALLSEG) in conjunction with -ALLMSG.

Require all segments (-ALLSEG)

Use the Require All Segments adapter command (-ALLSEG) for data sources to specify retrieval of segments in a logical message group only when all segments in the logical message are available.

The use of the -ALLSEG adapter command automatically sets the requirement that group messages are returned in their logical order and that segments of logical messages are returned in the order of their offsets.

This must be considered when specifying additional selection criteria (such as the -MID or -CID adapter commands). It may be possible that the message which satisfies this additional criteria is not the message with the smallest sequence number and/or the smallest offset in its group, which will prevent it from being retrieved from the queue.

-ALLSEG

If the source queue contains segmented messages with some missing segments, the Require All Segments adapter command (-ALLSEG) prevents retrieval of the message segments belonging to incomplete logical messages.

For information about incomplete message groups contributing to the size of **CurrentQDepth**, see "[Incomplete message segments](#)".

Trace (-T)

Use the Trace adapter command (-T) to produce a trace file that contains information about connections to IBM® MQ, message sizes, IBM MQ error messages, and adapter error messages.

The default filename is **mqstrace.log** and it is created in the map directory unless otherwise specified.

For z/OS® Batch and CICS® environments, **mqstrace.log** does not conform to the naming convention. For z/OS Batch and CICS environments, the trace output is written to the dataset indicated by the ddname **MQTRACE** that is (in most cases) defined in the JCL as : //MQTRACE DD SYSOUT=*

If the trace file does not already exist, it is created. If it already exists it is automatically appended.

-T[E|S] [full_path]

Option

Description
E
Error mode. Produces a trace file containing only the adapter errors that occurred during map execution.
S
Summary mode. Use this option to reduce the size of the trace file. The summary trace file excludes polling information and function entries and exits-reporting only minimal information, such as the activity that occurs within a function (when applicable).
<i>full_path</i>
Create a trace file with the specified name in the specified directory. By default, the directory is where the map is located and the file name is mqstrace.log .

You can override the adapter command line trace options dynamically using the Management Console. For detailed information, see "Dynamic Adapter Tracing" in the *Launcher* documentation .

Transmission Error queue name (-XEQN)

Use the Transmission Error Queue Name adapter command (-XEQN) for data sources and targets to specify the name of the transmission queue for the remote error queue to which messages are copied when errors occur. For more information about using the IBM® MQ adapter with IBM MQ transmission queues, see "[Transmission Queues](#)".

-XEQN x_err_queue_name

Option

Description
<i>x_err_queue_name</i>

This is the name of the transmission queue. The transmission queue name is case-sensitive.

For example, to specify that the transmission queue xmit.q should be used as the transmission queue for a remote error queue whose remote queue definition is named error.q, the syntax would be:

-QMN** qmlocal -QN qlocal -EQN error.q -XEQN xmit.q**

In this syntax, **qmlocal** is the name of the queue manager and **qlocal** is the name of the queue that is used as data source or data target in the map.

If a local transmission queue specified with the Transmission Error Queue Name adapter command (-XEQN) exists, it is used. If it does not exist, the queue specified by the IBM MQ DefaultXmitQ attribute (DEFXMITQ in MQSC) on the local queue manager is used.

Transmission queue name (-XQN)

Use the Transmission Queue Name adapter command (-XQN) for data targets to specify the name of the transmission queue that holds messages destined for a remote queue. For more information about using the IBM® MQ adapter with IBM MQ transmission queues, see "[Transmission queues](#)".

-XQN x_queue_name

Option

Description
<i>x_queue_name</i>

This is the name of the transmission queue. The transmission queue name is case sensitive.

For example, to specify that the local transmission queue **xmit.q** be used as the data target for a remote queue named **dest.q** and the local queue manager of **qmlocal**, the syntax would be:

-QMN** qmlocal -QN dest.q -XQN xmit.q**

For this command to work as intended, the local transmission queue must have the same name as the remote queue manager. If the local object **xmit.q** is not defined, the queue manager default transmission queue will be used.

If a local transmission queue exists with the same name as the transmission queue specified with the Transmission Queue Name adapter command (-XQN), the local transmission queue is used. If the transmission queue specified with the Transmission Queue Name adapter command (-XQN) does not exist, the queue specified by the MQSeries® DefaultXmitQ attribute (DEFXMITQ in MQSC) on the local queue manager is used.

User (-U)

The **-USERID** command specifies the user ID that the IBM® MQ adapter uses to authenticate its connection to the IBM MQ queue manager.

{-USERID | -U} user_ID

Option

Description
<i>user_ID</i>

The user ID to authenticate.

You must issue both the **-USERID** command and the **-PASSWORD** command to initiate authentication and to store the user ID and password information in the IBM MQ MQCSP structure.

Related information

- [Password \(-P\)](#)

Version 2 (-V2)

Use the Version 2 adapter command (-V2) to set all message descriptor and option structure version fields to _VERSION_1, which corresponds to IBM® MQ version 2.x.

-V2

If the Version 2 adapter command (-V2) is not specified, the default is _VERSION_2, which corresponds to IBM MQ version 5.x.

The Version 2 adapter command (-V2) is used with sources and targets.

If the Header adapter command (-HDR) is used in conjunction with the Version 2 adapter command (-V2), then the version information mapped in the header is ignored.

Wait Interval (-WI)

Use the Wait Interval adapter command (-WI) to set the length of time (in milliseconds) that the IBM® MQ queue manager allows the adapter to wait for a message to be received. Map execution is suspended until the message is received or until the specified time lapses.

-WI {0|S|wait_interval_in_milliseconds}

Option

Description

0

Do not wait at all. If there is no input available, the adapter does not wait for more messages.

S

This is an infinite wait time.

wait_interval_in_milliseconds

This is the number of milliseconds that the adapter waits for a message.

If the Wait Interval adapter command (-WI) is not issued, the default time that the adapter waits for a message is once for each second.

If the Wait Interval adapter command (-WI) is issued, the Launcher cannot be paused or shut down for the length of time you specified in the *wait_interval_in_milliseconds* command option. Do not specify the S command option and attempt to pause or shut down the Launcher. This will cause the Launcher to stop responding.

Syntax summary

- [Data sources](#)
- [Data targets](#)
- [Wildcard support](#)

Data sources

Syntax of the IBM® MQ adapter commands used for data sources:

```
-QN queue_name
[-ALLMSG]
[-ALLSEG]
[-CD channel_name/transport_type/connection_name]
[-CCSID numeric_identifier]
[-CID [correlation_ID] | -HCID hex_correlation_ID]
[-CMMSG]
[-CVT]
[[-EQMN error_queue_manager_name] [-EQN error_queue_name]]
[[-GRP [group_ID]] [-HGRP hex_group_ID] [-XGRP]]
[-GTX]
[-HDR]
[-LSN {0|S|wait_time_in_sec}]
[-MBS]
[-MID [message_ID] | -HMID hex_message_ID]
[-MQOO option_number]
[(-PASSWORD | -P) password]
[-QMN queue_manager_name]
[-QTY value]
[-REFRESH [reset_time]] [-T[E|S] [full_path]]
[(-USER | -U) user_ID]
[-V2]
[-WI {0|S|wait_interval_in_milliseconds}]
[-XEQN x_err_queue_name]
```

Data targets

Syntax of the IBM® MQ adapter commands used for data targets:

```
-QN queue_name [-CD channel_name/transport_type/connection_name]
[-CQMN [cluster_manager_name]]
[-CCSID numeric_identifier]
[-EXPIRY time]
[-GTX]
[-HDR |-DH
    | [-MID [message_ID] |-HMID hex_message_ID]
    | [-CID [correlation_ID] |-HCID hex_correlation_ID]
    | [-FORMAT message_format]
]
[-MQOO option_number]
[(-PASSWORD | -P) password]
[-PKT packet_size]
[-QMN queue_manager_name]
[-TE(S) [full_path]]
[(-USER | -U) user_ID]
[-V2]
[-XEQN x_err_queue_name]
[-XQN x_queue_name]
```

Wildcard support

Wildcards are supported for the following adapter commands:

- Message ID (-MID)
- Hex Message ID (-HMID)
- Correlation ID (-CID)
- Hex Correlation ID (-HCID)
- Group Message (-GRP)
- Hex Group Message ID (-HGRP)

For more information about using wildcards, see the Launcher documentation.

Related reference

- [Message ID \(-MID\)](#)
- [Hex message ID \(-HMID\)](#)
- [Correlation ID \(-CID\)](#)
- [Hex correlation ID \(-HCID\)](#)
- [Group message \(-GRP\)](#)
- [Hex group message ID \(-HGRP\)](#)

Using the messaging adapter

When you use the IBM® MQ adapter as a source, by default messages are served from the queue in a first-in-first-out (FIFO) manner unless you specify a particular message by using a message identifier, correlation identifier, or group identifier. When you use the adapter as a target, messages are placed on the queue that you specify.

When you use the IBM MQ adapter in a Launcher environment, the user account that starts the Launcher service must be registered in the MQM group.

If more than one thread or process updates the watched queue with new messages, specify the **-REFRESH** and **-EQN** adapter commands on the command line of an input card. The **-REFRESH** command enables the IBM MQ adapter listener to process all messages on the queue, particularly when the messages are inserted and committed at different time intervals by multiple threads. The **-EQN** adapter command identifies a queue to which messages are copied when an error occurs.

By default, the IBM MQ adapter listener enables cooperative browsing. Cooperative browsing enables multiple IBM MQ adapter watches to monitor the same queue. When you deploy additional IBM MQ adapter listeners to watch the same queue from different Launchers, message handling is automatically coordinated and load-balanced with fail-over support.

Cooperative browsing requires no additional command line settings. To disable cooperative browsing, set the WTX_ADAPTER_MQS_DISABLE_COOP environment variable to any value before you start the Launcher.

Cooperative browsing is designed to process physical messages. The IBM MQ adapter listener automatically disables cooperative browsing when the command line of the watched input card specifies any of these commands:

- **-ALLMSG**
- **-ALLSEG**
- **-CMMSG**
- **-GRP2**
- [Threading for IBM MQ](#)
- [Synchronizing multiple watches on the same queue](#)

You can synchronize multiple watches on the same queue to help ensure that only one MQ Adapter attempts to process a message. If multiple adapters do attempt to process the same message, only one adapter processes the message. The other adapters cannot access the message and report a failure. Synchronize the time frame for processing pending maps with the mark interval of the queue to prevent multiple adapters from attempting to process the same message.

Threading for IBM MQ

The IBM® MQ adapter is thread-safe on the Windows, AIX®, Sun, and HP platforms. However, due to the IBM MQ default system configuration parameters for queues and queue managers, the default IBM MQ resources might be insufficient to support multithreading with the IBM MQ adapter.

When operating in the multithreaded mode, the Launcher executes one thread for each map being concurrently executed. In addition to the map thread, the IBM MQ queue manager connection for each distinct queue manager on a source or target card requires a separate connection thread. Because IBM MQ does not allow connection sharing between threads, each map thread maintains its own set of connection threads.

In addition to the map and connection threads, the IBM MQ system spawns threads to service internal requests and processes. The result is that, as the number of concurrent maps increases, the use of IBM MQ and system resources multiplies. When the system resources exceed a threshold based upon the IBM MQ and system configuration settings, the excessive thread context-switching and system memory resource allocation can significantly reduce the efficiency of the overall IBM MQ message throughput.

In addition to the reduction in efficiency, it is possible that when the IBM MQ systems resources are exceeded, the IBM MQ behavior can become unpredictable and can result in messages being ignored on event queues.

To address these limitations, the following recommendations should be implemented:

- Limit the number of concurrent messaging adapter threads to 20. This is a configuration parameter (/runtime/launcher/MaxThreads) set in the **config.yaml** file.
- Ensure that the maximum number of handles (queue and queue manager connections) supported by the queue manager exceeds the total number of messaging adapter and IBM MQ threads. This value can be changed by using an MQSC command at the **runmqsc** prompt as:

```
alter qmgr MAXHANDS(2048)
```

- Set the maximum number of uncommitted messages allowed by the queue manager to an acceptably large value:

```
alter qmgr MAXUMSGS(100000)
```

- Set the maximum number of messages allowed on a queue to an acceptable value:

```
alter ql(my.queue.name) MAXDEPTH(200000)
```

The limit on non-z/OS® Batch and CICS® systems is 640K. The queue manager can enforce smaller actual limits based upon DASD resource limitations.

Synchronizing multiple watches on the same queue

You can synchronize multiple watches on the same queue to help ensure that only one MQ Adapter attempts to process a message. If multiple adapters do attempt to process the same message, only one adapter processes the message. The other adapters cannot access the message and report a failure. Synchronize the time frame for processing pending maps with the mark interval of the queue to prevent multiple adapters from attempting to process the same message.

1. On the input card of the watched queue, set the Pending Instance Thresholds - High Launcher setting to a value that limits the number of messages that can be processed within a particular time frame.
2. Set the mark interval of the watched queue to a time (in milliseconds) that is, at a minimum, long enough for the Launcher to process the maximum number of pending messages that you set in step 1. Run the following command within the IBM® MQ **runmqsc** application to set the mark interval of the watched queue:
ALTER QMGR MARKINT [time in milliseconds | NOLIMIT]

Group message support

The adapter for IBM® MQ supports retrieval of IBM MQ group messages as data source objects. The group message feature allows multiple messages to be placed on a message queue while retaining an organizational connection through the **GroupId** field of the MQ Message Descriptor (MQMD).

- A message group consists multiple logical messages.
- A logical message consists of one or more physical messages.
- When a logical message contains more than one physical message, the logical message is segmented. Each physical message is a segment.
- Each logical message has the same **GroupId** and a distinct **MsgSeqNumber**.
- Each physical message has distinct MQ Message Descriptor (MQMD).
- Each segment has the same **GroupId** **MsgSeqNumber** and a distinct **Offset**.
- [Physical message](#)
- [Logical message](#)
- [Incomplete message segments](#)

Physical message

A physical message is the smallest unit of information that can be placed on or removed from a queue. A physical message often corresponds to the information specified in or retrieved from a single MQPUT or MQGET call. Each physical message has a unique message descriptor (MQMD).

Generally, physical messages are distinguished by differing values for the message identifier (**MsgId** field in the MQMD) although this is not enforced by the queue manager.

Logical message

A logical message is a single unit of application information. In the absence of system constraints, a logical message is the same as a physical message. Logical messages can be extremely large; system constraints might make it advisable or necessary to split a logical message into two or more physical messages known as segments.

A logical message that has been segmented consists of two or more physical messages that have the same non-null group identifier (**GroupId** field in MQMD) and the same message sequence number (**MsgSeqNumber** field in MQMD). The segments are distinguished by differing values for the segment offset (**Offset** field in MQMD), which gives the offset of the data in the physical message from the start of the data in the logical message.

- [Message group](#)

Message group

A message group is a set of one or more logical messages that have the same non-null group identifier. The logical messages in the message group are distinguishable by differing values for the message sequence number. The message sequence number is an integer in the range 1 to n , where n is the number of logical messages in the group. If one or more of the logical messages is segmented, the group will contain more than n physical messages in the group.

Incomplete message segments

If the queue contains segmented messages with some of the segments missing (perhaps the messages were delayed in the network and have not yet arrived), specifying the Complete Message adapter command (-CMMSG) prevents the retrieval of segments belonging to incomplete logical messages.

However, those message segments belonging to incomplete logical messages still contribute to the value of the **CurrentQDepth** queue attribute. This segmentation could result in no retrievable logical messages, even when **CurrentQDepth** is greater than zero.

- [Reassembly of segments](#)
- [Retrieval of group messages](#)

Reassembly of segments

Each physical message that is a segment has a unique message descriptor. For segments that comprise a single logical message, most of the fields in the message descriptor are the same for all segments in the logical message. Usually, it is only the **MsgId**, **Offset**, and **MsgFlags** fields that differ between segments in the logical message. However, when segments take different paths through the network, and some of those paths have MCA sender conversion enabled, it is possible for the **CodedCharSetId** and **Encoding** fields to differ between segments when the segments eventually arrive at the target queue.

A logical message consisting of segments in which the **CodedCharSetId** and/or **Encoding** fields differ cannot be reassembled by the queue manager into a single logical message. Instead, the queue manager reassembles and returns the first few consecutive segments at the start of the logical message having the same character-set identifiers and encodings, and the MQGET call completes with completion code **MQCC_WARNING** and reason code **MQRC_INCONSISTENT_CCSIDS** or **MQRC_INCONSISTENT_ENCODINGS**, as appropriate.

When the queue manager reassembles a logical message, the message descriptor is returned with the values from the message descriptor for the first segment; the only exception is the **MsgFlags** field, which the queue manager sets to indicate that the reassembled message is the only segment.

Retrieval of group messages

The IBM® MQ adapter selects group messages for retrieval based upon three possible selection criteria:

- group ID (GroupID)
- message ID (MsgId)
- correlation ID (CorrelId)

When the Group Message adapter command (-GRP) is specified, the GroupId is used as the sole selection criteria for group message retrieval. If the Message ID adapter command (-MID) or the Correlation ID adapter command (-CID) is specified, the respective selection criteria are also used.

Be sure to organize message segments and groups on output when you specify the **GroupId**, **MsgSequenceNumber**, **Offset**, and **MsgFlags** fields in the **MessageDescriptor** type. Improper use of these fields could result in incomplete message groups and illogical messages on the output queue.

Example files

The IBM® MQ type tree (named **mq.mtt**) is provided in the **examples\adapters\mq** folder. Types describing different IBM MQ message formats are provided so that you can easily select the message types needed for input or output or the descriptor that you need to include with any message data you want.

When mapping information to or from the message descriptor, you must include the message descriptor in your data by using the Header adapter command (-HDR).

- [Using the sample type tree](#)

Using the sample type tree

Depending on how you want to map, select one of the **Message** types as input or output or add a message content type as a **MessageData** component.

The **mq.mtt** type tree is arranged so that you can easily integrate the provided definitions with any message data that you want to define.

The **mq.mtt** type tree has definitions for:

- **MQSeries® Header MessageDescriptor**

The MessageDescriptor Header type defines the components and format of the message descriptor.

- **MQSeries Header MessageDescriptor2**

The MessageDescriptor2 Header type defines the components and format of the message descriptor for IBM® MQ 5.x.

- **MQSeries Header MQSLink4R3**

The MQSLink4R3 Header type defines the components and format of the IBM MQ Link for R/3 Header. When the IBM MQ Link for R/3 is used for source data, the input message data always contains a header; however, you must create the header for an output message. The IBM MQ Link for R/3 Header is not optional. It always appears in your input data and it must be included when mapping output data.

The **mq.mtt** type tree is organized so that you can drag the **MQSeries** root type to another type tree to easily use any of the IBM MQ-specific headers.

- [Mapping message data only](#)
- [Mapping the message descriptor](#)
- [Mapping the IBM MQ Link for R/3 header](#)

Mapping message data only

By default, the adapter does not use message descriptors. On input, it returns only the body of the received message, and on output, it treats the data that it receives as the message body.

Even if you do not need to use message descriptors, you can still use this same example tree to define the content of the message.

To use the type tree for mapping message data only:

1. Define the message content for your message (shown below as **Message** group under **CreditInfo** category).
2. Add it as a component of **MessageData**. By default, **MessageData** contains **Text** item that represents plain textual message content. The **Text** item should be replaced with your own message content type, such as **Message** group under **CreditInfo** category in this example.
3. Use **MessageData** as an input or output card type.

Mapping the message descriptor

If the Header (-HDR) or Default Header (-DH) adapter command is specified, the message descriptor appears in the data, immediately preceding the message data when used for a source.

For a target, you must provide the message descriptor (all components (for -HDR), or components of interest [for -DH]), which is included as the first part of your output data.

Mapping the IBM MQ Link for R/3 header

If you use IBM® MQ to send and receive data from an SAP R/3 system, you might want to use the IBM MQ Link for R/3. This link communicates with R/3 using inbound and outbound server queues.

When using the IBM MQ Link for R/3, message data is in IDoc format, prefixed by the IBM MQ Link for R/3 Header.

The **mq.mtt** type tree includes the definition of this header. You also need the IDoc Importer to automatically generate the types that describe the format of your IDoc data.

Troubleshooting

For information about error codes and messages returned by the adapters, see ["Return codes and error messages"](#).

- [Trace log](#)

Trace log

Use the Trace adapter command (-T) to create a trace file to report adapter activity information, recording events that occur while the adapter is retrieving and sending data. The trace command produces a log file with the default name **mqstrace.log** in the map execution directory.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages may also be recorded as specified in the audit logs, trace files, execution summary files, and so on.

- [Messages](#)
- [IBM MQ and error code relationships](#)

Messages

The following is a listing of all the codes and messages that can be returned as a result of using the IBM® MQ adapter for sources or targets.

In addition to these codes, the IBM MQ adapter can return IBM MQ error codes. Consult the IBM MQ documentation for descriptions of these codes.

Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Return Code	Message
-1001	Trace file could not be accessed
-1002	Adapter command is incorrect
-1003	Queue could not be opened
-1004	Message could not be stored on the queue
-1005	Message could not be retrieved from the queue
-1006	Connection could not be closed
-1007	Global transaction could not be started
-1008	Transaction could not be rolled back explicitly
-1009	Transaction could not be committed
-1010	Queue could not be closed
-1011	Invalid message format
-1012	Transaction monitor not supported
-1013	Error queue operation could not complete
-1014	Unable to Begin Commitment Control (HP NonStop ZLE)
-1015	Unable to Backout (HP NonStop ZLE)
-1016	Unable to Commit (HP NonStop ZLE)
-1017	Segmentation not supported (HP NonStop ZLE)

See [IBM MQ and error code relationships](#) for more information.

IBM MQ and error code relationships

The IBM® MQ adapter returns various error codes when it encounters a problem during code execution. Some of these error codes are related to the errors returned by the MQ calls (such as MQCONN, MQGET) and some of them are not.

The following table lists all MQ calls made by the adapter, and how errors from these calls are mapped to error codes:

IBM MQ Native Function

Action Taken by Adapter

MQCONN

If MQCONN fails while trying to connect to the queue manager specified in the -QMNN adapter command, the error code returned by the adapter is MPIRC_E_BAD_CONNECTION (-13). However, if MQCONN fails while trying to connect to the error queue manager specified by the -EQMNN adapter command, the adapter returns error code MPIRC_E_MQS_EQUEUE_OPERATION (-1013) to indicate that the error occurred while transferring messages to the error queue.

MQOPEN

If MQOPEN fails while trying to open the queue specified in the -QN adapter command, the error code returned by the adapter is MPIRC_E_MQS_OPEN_QUEUE (-1003). However, if MQOPEN fails while trying to open the error queue specified by the -EQMNN adapter command, the error code returned by the adapter is

`MPIRC_E_MQS_EQUEUE_OPERATION` (-1013) to indicate that the error occurred while transferring messages to the error queue. Additionally, if the `MQOPEN` call issued for opening the queue manager object fails (this is done as part of the connection validation process), the returned error code is `MPIRC_E_BAD_CONNECTION` (-13) to indicate to the Resource Manager that the connection is invalid.

`MQGET`

If `MQGET` call fails and this error cannot be corrected or handled by the adapter, the adapter returns error code `MPIRC_E_MQS_GET_MESSAGE` (-1005).

Additionally, if `MQGET` call fails inside of the listener thread, and the MQ reason code is `MQRC_CONNECTION_BROKEN` (2009L), the adapter returns error code `MPIRC_E_BAD_CONNECTION` (-13) to signal that the connection is broken and needs to be reestablished.

`MQPUT`

If `MQPUT` call fails and this error cannot be corrected or handled by the adapter, the adapter returns error code `MPIRC_E_MQS_PUT_MESSAGE` (-1004).

`MQCMIT`

If `MQCMIT` call fails while committing the messages upon successful map completion, the adapter returns error code `MPIRC_E_MQS_COMMIT` (-1009).

`MQBACK`

The adapter does not return an error code as a result of `MQBACK` failure. This is because if the `MQBACK` is called, that means that the map has already failed for another reason.

`MQBEGIN`

This function is called only when the global transactions are used (-GTX adapter command). If `MQBEGIN` fails, the adapter returns `MPIRC_E_MQS_BEGIN_GTX` (-1007). On NonStop ZLE, if the `BEGINTRANSACTION()` call fails, the adapter returns error code `MPIRC_E_MQS_BEGINUOW_ERR` (-1014).

`MQCLOSE`

A failure in `MQCLOSE` does not cause the map to fail (but a textual message indicating this will be traced). The only time a failure in `MQCLOSE` results in an error code returned by the adapter, is when the queue manager connection is being validated. If `MQCLOSE` fails for the previously opened queue manager object for validation, the adapter returns error code `MPIRC_E_BAD_CONNECTION` (-13).

`MQDISC`

If `MQDISC` fails, the returned error code is `MPIRC_E_MQS_DISCONNECT` (-1006).

`MQINQ`

If `MQINQ` fails, the adapter does not return any error.

`MQCONN`

If `MQCONN` fails while trying to connect to the remote queue manager specified in the (-QMN) adapter command, the error code returned by the adapter is `MPIRC_E_BAD_CONNECTION` (-13). Note that the `MQCONN` command is used only by the IBM MQ (client) adapter, and only if the (-CD) adapter command is specified.

`MQPUT1, MQSET`

Not used by the adapter.

Informix Adapter overview

Use the Informix Adapter to access and manipulate data contained in databases that are Informix® data sources. You can also install this adapter on additional systems for remote database connectivity.

You can use the Informix Adapter with the Command Server, Launcher, Software Development Kit, or with a map in a map rule.

- [System requirements](#)
- [Database columns and types](#)
- [Database Interface Designer settings](#)
- [Informix Adapter commands](#)
- [Adapter commands for a source](#)
- [Adapter commands for a target](#)
- [Binding values in DBLOOKUP/DBQUERY](#)
- [Configuring DSN for Launcher startup](#)
- [Restrictions and limitations](#)
- [Return codes and error messages](#)

System requirements

It is assumed that a Command Server has already been installed on the computer where the Informix® adapters are to be installed for runtime purposes. In addition, the following requirements exist for installing and running the Informix adapters on a supported Windows platform:

- Informix ODBC 3.30 32-bit driver or later. Verify that you have installed the required drivers and configured your data source(s). Refer to the documentation included with your driver(s) for more information.

Database columns and types

The Database Interface Designer and **mtsmaker** with the Type Tree Maker generate type trees for queries, tables, views, and stored procedures in an Informix-compliant RDBMS (Relational Database Management System). Item types will be created in a type tree that represent the data types of the columns of a query, table, view, or stored procedure.

The Database Interface Designer and **mtsmaker** obtain information about columns by calling the Informix® Driver Manager that calls the Informix driver for your RDBMS to describe the columns associated with a query, table, view, or stored procedure. The Informix driver for the RDBMS has mapped the data types in each column to Informix data types as appropriate. From the RDBMS, the Informix Driver Manager returns the data type, length, and other information to the Database Interface Designer and **mtsmaker**. The Informix data types are then mapped to types in a type tree by the Database Interface Designer and **mtsmaker**.

- [Item type properties](#)
- [Date and time formats](#)

Item type properties

The following table lists the Informix® data types and the values of the item type properties to which they correspond when the type tree is generated.

Informix Data Type	Interpret as	Item Subclass, Presentation	Length
BYTE	Text	Binary	*
CHAR(n) ¹	Text	Character	*
CHARACTER(n) ¹	Text	Character	*
CHARACTER VARYING(m,r) ²	Text	Character	*
DATE	Text	Character	10
DATETIME	Text	Character	19
DEC(p,s) ³	Number	Character, Decimal	*
DECIMAL(p,s) ³	Number	Character, Decimal	*
DOUBLE PRECISION	Number	Binary, Float	8
FLOAT	Number	Binary, Float	8
INT	Number	Character, Integer	11
INTEGER	Number	Character, Integer	11
INTERVAL	Text	Character	*
MONEY(p,s) ³	Number	Character, Decimal	*
NCHAR(n) ¹	Text	Character	*
NUMERIC(p,s) ³	Number	Character, Decimal	*
NVARCHAR(m,r) ²	Text	Character	*
REAL	Number	Binary, Float	4
SERIAL	Number	Character, Integer	11
SMALLFLOAT	Number	Binary, Float	4
SMALLINT	Number	Character, Integer	6
TEXT	Text	Binary	*
VARCHAR(m,r) ²	Text	Character	*

*The DBMS dictates the length of this type.

¹n=1 £ n £ 32, 67

²m=maximum size of the column: 1-255, r=minimum reserved space: 0-255; r £ m

³p=precision, s=scale

Date and time formats

When using columns defined as dates and times in Informix® databases, specify the input and output formats for date, time, and timestamp listed below.

Date

`yyyy-mm-dd`

Time

`hh:mi:ss`

Timestamp

`yyyy-mm-dd hh:mi:ss[.fff...]`

Formats

Format	Description
cc	two-digit century
yy	two-digit year
mm	two-digit month
dd	two-digit day
hh	two-digit hour
mi	two-digit minute

ss	two-digit second
.fff...	optional fractional seconds
fffff	six-digit fraction of a second
hh24	two-digit hour using a 24-hour day

If the group format is fixed, the field is padded to 26 with trailing spaces.

Example:

2001-08-27 00:00:00 specifies August 27, 2001.

In the Generate Type Tree from dialog, use the Represent date/time columns as text items check box to define whether to automatically format this information as Date & Time (which is with this check box disabled, the result of which is shown in the Item Subclass, Presentation column) as a text string. When generated as a text string, it might be necessary to use either the TEXTTODATE or TEXTTOTIME function in a map rule to convert the text string to the date and time format required by the database. If you are generating new type trees, it is recommended that you disable this check box.

This Represent date/time columns as text items check box is modal. After it has been disabled, it will remain disabled for all subsequent type tree generations, regardless of source. Therefore, you must be careful in determining this setting.

If you have a Date & Time type with a presentation format of month-to-hour, you should enable the **Represent date/time columns as text** items check box so that these values can be treated as text items. Otherwise, these types will be interpreted erroneously using an hour-to-second presentation format.

Note: Not all variations of Informix interval and date/time columns are supported.

Database Interface Designer settings

When you define an Informix® database in the Database Interface Designer, in addition to the common settings available for all of the database adapters in the Database Definition dialog box, enter the information specific to Informix.

- [Database Definition dialog box](#)
- [Stored procedures native call syntax](#)

Database Definition dialog box

The Informix Adapter-specific settings are described in the following table:

Setting	Description
Data Source	<p>Database Interface Designer The data source you defined in your Informix® development PC that is used by the Database Interface Designer to access the database information for design-time purposes.</p> <p>Runtime The data source you defined in your Informix database host platform to be used for access to the database for run-time (map execution) purposes both from the Map Designer and either a Command Server or an Launcher.</p>
Security	<p>User ID The user ID to connect to the database.</p> <p>Password The authorization password to connect to the database.</p>

Stored procedures native call syntax

A stored procedure can be accessed from within a map by specifying the native call syntax in the following:

- A query that is specified in an input card.
- The first argument in a DBQUERY or DBLOOKUP function.
This argument does not need to be a literal. The arguments to the stored procedure may be determined at map execution time.
- The SQL Statement adapter command (-STMT) in DBQUERY, DBLOOKUP, or GET functions.

For information about using DBLOOKUP or DBQUERY or about using the syntax for device-independent calls to access return values and output adapter commands see the Database Interface Designer documentation.

For example, a call to a stored procedure using Informix® in a DBLOOKUP might be:

```
DBLOOKUP("{call MyAddNameProc('" + Name:Column + "','-1')}",
          "mydb.mdq",
          "MyDB")
```

String literals must be contained within single quotation marks; adapter arguments must be separated by commas.

Note: There could be issues with running a stored procedure using data values that are bound at map runtime (for example, input or output card stored procedure calls). As an alternative, run these same stored procedures using DBLOOKUP or DBQUERY.

Informix Adapter commands

Use the adapter commands when specifying data sources and targets. The applicability of many of the commands depends upon whether you are specifying a source or target, whether a database/query file (.mdq) is used, and the situations in which the usage of the command applies.

Adapter commands can be used in GET->Source->Command or PUT->Target->Command settings in the Map Designer and Integration Flow Designer, using GET, PUT, DBLOOKUP, or DBQUERY function calls, or overriding a data source or target using execution commands in a RUN function or on the command line.

If connectivity to the mainframe-based DB2® is available, you can:

- View DB2 host database table names directly from Database Interface Designer
- Build type trees for DB2 host tables without using MTSMAKER
- Test maps on your workstation
- [Adapter-specific command list](#)
- [Database adapter type \(-DBTYPE\)](#)
- [Row count \(-ROWCNT\)](#)
- [Data source \(-SOURCE\)](#)

Adapter-specific command list

This documentation describes those adapter commands that are Informix-specific database parameters. For a complete listing of all adapter commands, see the Resource Adapters documentation.

Database adapter type (-DBTYPE)

Use the Database Adapter Type adapter command (-DBTYPE) to specify the database adapter type.

-DBTYPE IFMX

Option	Description
IFMX	The database adapter type is Informix®. Note: This command must be specified if the original card is not a database and no database is specified using the Database/Query adapter command (-MDQ) and the Database Name adapter command (-DBNAME).

Row count (-ROWCNT)

Use the Row Count adapter command (-ROWCNT) to specify the number of rows to be retrieved per fetch.

-ROWCNT row_count

Option

Description

row_count

The number of rows to be retrieved per fetch. The time to fetch is optimized in accordance with the increase in the number of rows to retrieve. Therefore, a significant performance improvement may be gained by retrieving as many rows as possible in a single fetch.

The factor limiting the number of rows that can be retrieved is the memory requirement because the return buffer must be large enough to hold the rows retrieved.

The default for the number of rows to be retrieved per fetch for the Informix Adapter is one row.

Data source (-SOURCE)

Use the Data Source adapter command (-SOURCE) to specify the Informix® data source.

-SOURCE datasource

Option	Description
datasource	Specify the Informix data source.

Adapter commands for a source

This summary shows the syntax of the adapter commands that can be used when defining a data source using an .mdq file or without using one, including both the required and optional adapter commands in the following situations:

- Using the GET > Source > Command setting in the Map Designer and Integration Flow Designer.
- Overriding a data source using the Input Source Override - Database execution command (-ID) using a RUN function or on the command line.
- Using a DBLOOKUP, DBQUERY, or GET function in map or component rules.
- [GET > Source > Command setting](#)
- [Database execution command: input source override \(-ID\)](#)
- [DBLOOKUP or DBQUERY functions](#)
- [GET function](#)

GET > Source > Command setting

In an input card, when you specify Database as the value for the GET > Source setting, the Command field is displayed where you can enter adapter commands.

Database command options when there is a database/query file

```
[-DBTYPE IFMX]
[-SOURCE datalink]
[-STMT SQL_statement]
[-FILE [directory]]
[-VAR name=value...]
[-USER user_ID]
[-PASSWORD password]
[-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+]] [full_path]
[{-TRACE|-TRACEERR} [+]] [full_path]]
```

Database command options when there is no database/query file

```
-DBTYPE IFMX
-SOURCE datalink
-STMT SQL_statement
[-FILE [directory]]
[-VAR name=value...]
[-USER user_ID]
[-PASSWORD password]
[-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+]] [full_path]
[{-TRACE|-TRACEERR} [+]] [full_path]]
```

Database execution command: input source override (-ID)

Use the Input Source Override - Database execution command (-ID) to designate a database as the source or you can override one or more of the adapter command settings or database definitions in a RUN function or on the command line.

The adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

Scenario: compiled map source is a database

Database/query file (.mdq):

```
'[-MDQ mdq_file -DBNAME database_name]
[-QUERY query_name] [-STMT SQL_stmt]
[-FILE [directory]]
[-VAR name=value...]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+]] [full_path]
[{-TRACE|-TRACEERR} [+]] [full_path]]'
```

No database/query file (.mdq):

```
'-DBTYPE IFMX
-SOURCE datalink
-STMT SQL_statement
[-FILE [directory]]
[-VAR name=value...]
[-USER user_ID]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]'
```

Scenario: compiled map source is not a database

Database/query file (.mdq):

```
'-MDQ mdq_file
-DBNAME database_name
-QUERY query_name|-STMT SQL_stmt
[-FILE [directory]]
[-VAR name=value...]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]]
```

No database/query file (.mdq):

```
'-DBTYPE IFMX
-SOURCE datalink
-STMT SQL_statement
[-SOURCE datasource]
[-FILE [directory]]
[-USER user_ID]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]]
```

DBLOOKUP or DBQUERY functions

The DBLOOKUP and DBQUERY functions can be used in component rules in the schema designer and map rules in the map designer when creating a map that can be used with a database.

Using DBLOOKUP with a database/query file

```
DBLOOKUP ("SQL_statement",
"-MDQ mdq_file
-DBNAME database_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]])
```

Using DBQUERY without a database/query file

```
DBQUERY ("SQL_statement",
"-DBTYPE IFMX
-SOURCE datalink
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]])''
```

GET function

The GET function returns the data from the source adapter.

Using GET with a database/query file

```
GET ("DB",
"-MDQ mdq_file
-DBNAME database_name
-QUERY query_name|-STMT SQL_stmt
[-FILE [directory]]
[-VAR name=value...]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]])
```

Using GET without a database/query file

```
GET "DB",
"-DBTYPE IFMX
-SOURCE datalink
-STMT SQL_stmt
```

```

[-SOURCE datasource]
[-FILE [directory]]
[-USER username]
[-PASSWORD password]
[-ROWCNT row_count]
[-CCARD|-CSTMT [number]]
[-AUDIT[G] [+][full_path]]
[{-TRACE|-TRACEERR} [+][full_path]]"

```

Adapter commands for a target

This summary shows the syntax of the adapter commands that can be used when defining a data target using an .mdq file or without using one, including both the required and optional adapter commands in the following situations:

- Using the PUT->Target->Command setting in the Map Designer and Integration Flow Designer.
 - Overriding a data source using the Output Source Override - Database execution command (-OD) using a RUN function or on the command line
 - Using the PUT function in map or component rules.
 - [PUT > Target > Command setting](#)
 - [Database execution command: output source override \(-OD\)](#)
 - [PUT function](#)
-

PUT > Target > Command setting

In an output card, when you specify Database as the value for the PUT > Target setting, the Command field is displayed so that you can enter adapter commands.

Database command options when there is a database/query file

```

[-DBTYPE IFMX]
[-SOURCE datalink]
[-PROC procedure_name| -TABLE table_name]
[-USER user_ID]
[-PASSWORD password]
[-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G] [+][full_path]]
[{-TRACE|-TRACEERR} [+][full_path]]"

```

Database command options when there is no database/query file

```

-DBTYPE IFMX
-SOURCE datalink
-PROC procedure_name| -TABLE table_name
[-USER user_ID]
[-PASSWORD password]
[-CSTMT [number]]
[-DELETE]
[-BADDATA[+] full_path]
[-AUDIT[G] [+][full_path]]
[{-TRACE|-TRACEERR} [+][full_path]]"

```

Database execution command: output source override (-OD)

Use the Output Source Override - Database execution command (-OD) to designate a database as a target or you can override one or more of the adapter command settings or database definitions in a RUN function or on the command line.

The adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

Scenario: compiled map target is a database

Database/query file (.mdq):

```

' [-MDQ mdq_file -DBNAME database_name]
[-PROC procedure_name| -TABLE table_name]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G] [+][full_path]]
[{-TRACE|-TRACEERR} [+][full_path]]'

```

No database/query file (.mdq):

```
'-DBTYPE IFMX
-SOURCE datalink
-PROC procedure_name|-TABLE table_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]]'
```

Scenario: compiled map target is not a database

Database/query file (.mdq):

```
'-MDQ mdq_file
-DBNAME database_name
-PROC procedure_name|-TABLE table_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]]'
```

No database/query file (.mdq):

```
'-DBTYPE IFMX
-SOURCE datalink
-PROC procedure_name|-TABLE table_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]]'
```

PUT function

Use the PUT function to pass data to the target adapter.

Using PUT with a database/query file

```
PUT ("DB",
"-MDQ mdq_file
-DBNAME database_name
-PROC procedure_name|-TABLE table_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]])"
```

Using PUT without a database/query file

```
PUT ("DB",
"-DBTYPE IFMX
-SOURCE datalink
-PROC procedure_name|-TABLE table_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]])"
```

Binding values in DBLOOKUP/DBQUERY

When using a DBLOOKUP or DBQUERY function, use the Bind facility to submit similarly constructed SQL statements to the database server so that the statements are syntactically identical. By binding a value to a placeholder in the SQL statement, the actual syntax of the statement can be made static, which may improve performance. For more information about using bind values in database functions, see the Database Interface Designer documentation.

- [Limitation when using ODBC](#)
- [Specifying the data type](#)

Limitation when using ODBC

When binding values using Informix®, a limitation exists because Informix cannot determine the data type of the column to which the value is being bound at the time the SQL statement is executed. Therefore, the data type of the value being passed must be explicitly specified. Because of this Informix limitation, the Informix database adapter determines the data type of the value according to the following rule:

If the value contains only numeric characters or numeric characters with a decimal point, the value is assumed to be numeric; otherwise, the value is assumed to be text.

This rule provides the expected results in most cases; however, there may be some cases in which the rule may not apply and it may be necessary to specify the exact data type. For example, if the value is a text field consisting solely of numeric characters, the value will be incorrectly interpreted as numeric unless correctly specified.

Specifying the data type

To override the default behavior and to explicitly specify the data type, a data type indicator must precede the bind value. The syntax for this is:

```
:bind([T|N|D], value)
```

The following table shows the data type indicators and the correspondence between each data type indicator and the Informix® data types.

Data Type Indicator	Informix Data Type
T or TEXT	SQL_CHAR
N or NUM or NUMBER	SQL_NUMERIC
D or DATE	SQL_DATETIME

For information about item formats and interpretation, refer to ["Item properties"](#).

As an example of specifying a data type, if you want to bind a date value to a statement, it is always necessary to specify that the value is of data type DATETIME. The SQL statement would be entered as:

```
DBLOOKUP("select Age from Person where DateOfBirth=:bind([DATE], " +  
        DateItem:Row + ")", "DB.mdq", "MyDB")
```

Configuring DSN for Launcher startup

Note: For information about configuring data sources on UNIX systems, refer to your UNIX documentation.

When using the Informix Adapter on a Windows platform, you need to configure data sources. For information about how to do this, see the ODBC Adapter documentation.

Restrictions and limitations

The Database Interface Designer and database adapters offer options and functions for accessing and manipulating data contained within a database. However, there is one restriction for this adapter: database triggers are not supported. You cannot use a data source as an input event trigger for the Launcher.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages may also be recorded as specified in the audit logs, trace files, execution summary files, and so on.

For information about error codes and messages returned by database-specific adapters, see the database-specific adapter message section of Resource Adapters documentation.

Various troubleshooting tools are available in case you encounter problems while using the database adapters. For example, if you attempt to run a map that uses the adapter and encounter problems or do not receive the expected results, use the following adapter troubleshooting tools:

- adapter audit log (**.log**)
- adapter trace file (**.mtr**)

Java Class Adapter overview

Use the Java Class Adapter to instantiate a Java™ object and to invoke a sequence of methods on the object.

This adapter accesses Java classes from maps. This means, that maps can be created to instantiate objects of a specified class, set values of the public fields for that object and invoke the specified class methods with the specified arguments and retrieve the results that these methods return (as well as public field values that can be modified) so that they can be reused in the map.

You can use the adapter with a Command Server, Launcher, Software Development Kit, or map in a map rule.

-

System requirements

The minimum system requirements and operating system requirements for the Java Class Adapter are detailed in the [system requirements](#). See also the [release notes](#). It is assumed that a Command Server has already been installed on the computer where the adapter is to be installed for runtime purposes.

Adapter capabilities

The following are Java Class Adapter capabilities:

- A card (or GET or PUT rule) represents a Java™ object. If multiple objects are required, multiple cards or rules must be specified.
 - The adapter provides access to public fields that can be set directly in the map.
 - Any (but naturally one) public constructor can be invoked.
 - Any public methods may be invoked on the object, in the order specified in the type tree.
 - Any public static methods may be invoked on the class (even if no object was constructed).
 - Objects created in one card can be used as parameters to methods in subsequent calls. These objects can be created either explicitly, or by invoking a method that returns an object.
 - Objects are identified by reference labels. The "this" attribute is used to assign a label to an explicitly created object. Objects that are returned from method calls are assigned a label by the adapter. This label is of the form "Ref.nn", where nn is a number which uniquely identifies the object.
 - Return values of any of the methods can be returned from a GET call. The importer provides a mechanism to allow the user to select which methods the return values should be provided. These return values can be primitive types (for example, int) or objects. If objects, the public fields are returned together with a reference to the object so that the object can be used in a subsequent call.
 - The public fields of the object after all methods have been invoked on it can be returned.
-

Java Class Adapter limitations

Multidimensional arrays are not supported.

Command alias

Adapter commands can be specified by using a command string on the command line or creating a command file that contains adapter commands. The execution command syntax is:

```
-IM[alias] card_num
-OM[alias] card_num
```

where -IM is the Input Source Override execution command and -OM is the Output Target Override execution command, alias is the adapter alias, and card_num is the number of the input or output card. The following table shows the adapter alias and its execution command.

Adapter	Alias	As Input	As Output
Java™ Class	JAVA	-IMJAVAcard_num	-OMJAVAcard_num

Java Class Adapter commands

The following table lists valid commands for the Java Class Adapter, the command syntax, and whether the command is supported (✓) for use with data sources, targets, or both.

This adapter does not support listening for events.

Note: A command line entry is required for this adapter. If you do not require any commands, enter a single space instead to override this restriction. (In this case the command line would appear empty.)

Command	Syntax	Source	Target
Deserialize (-DS)	-DS		✓
Serialize (-S)	-S		✓
Trace (-T)	-T[+] [full_path]		✓
Trace Error (-TE)	-TE[+] [full_path]		✓

- [Deserialize \(-DS\)](#)
- [Serialize \(-S\)](#)
- [Trace \(-T\)](#)
- [Trace error \(-TE\)](#)

Deserialize (-DS)

Use the Deserialize adapter command (-DS) to deserialize the input data. The adapter returns a deserialized object and stores it in the pool of objects.

-DS

Serialize (-S)

Use the Serialize adapter command (-S) to serialize the input object. Before serialization the adapter checks whether or not the object is in the pool. The object must be in the pool. The adapter then returns the serialized data.

-S

Trace (-T)

Use the Trace adapter command (-T) to produce a diagnostics file. This file contains detailed information about adapter activity. By default, the **javatrace.log** trace file is created in the directory where the map is located.

-T[+] [*full_path*]

Option

Description

+

Append trace information to the existing trace file.

full_path

Creates a trace file with the specified name in the specified directory

Trace error (-TE)

This adapter command produces a trace file containing only the adapter errors that occurred during map execution.

When this adapter command is specified, an adapter trace file is produced by default in the map directory, using the full name of the map file with an **.mtr** filename extension.

You can use this command in the output card (target) and in a GET or PUT function. Use the options listed below to append the trace information to an existing trace file or to specify a filename and path other than the default.

-TE[+] [*full_path*]

Value

Description

+

Append trace information to an existing trace file. (There is no space between TE and +.)

full_path

Create a trace file with the specified name in the specified directory. If you do not specify a directory (path) and filename, the adapter trace file (*map_name.mtr*) is created in the map directory by default.

The Trace Error adapter command (-TE) and the Trace adapter command (-T) are mutually exclusive.

Syntax summary

- [Data sources and targets](#)
- [Using the Java Class Adapter](#)

Data sources and targets

The Java Class Adapter cannot be used for data sources.

The following is the command syntax of the Java Class Adapter commands used for data targets:

[-DS]
[-S]
[-T[+] [*full_path*]]
[-TE[+] [*full_path*]]

Using the Java Class Adapter

Use the Java Class Adapter to instantiate a Java™ object and to invoke a sequence of methods on the object.

Adapter scenarios

The Java Class Adapter cannot be invoked from an input card. The adapter requires data to be passed to it (as defined by a type tree) to enable it to determine what to do. There are therefore two scenarios for using the adapter:

- If no data is required to be returned from the adapter: call the adapter in an output card. Typical scenarios include:
 - Creating an object (invoking its constructor, and optionally setting its fields) to be used in a subsequent card.
 - Invoking methods on an object that do not return data. The success of these methods is typically monitored through the use of exceptions.
 - Data is required to be returned from the adapter: call the adapter in a **GET** function call. The approach here is to build the data to be passed to the adapter in an output card, setting the output adapter to **sink**. Then, in an additional output card, map the root object of this card to the third parameter of the **GET** using the **PACKAGE** call to pass the XML data as a text item.
- [Simple Java class example](#)
[Complex Java class example](#)
[Return values](#)
-

Simple Java class example

The information that the user selects through the Java™ Class Importer is reflected in the type tree that is generated. The type tree contains several elements:

- Class name and options
- Constructor call
- Public fields
- Method calls

The following code is an example of the simple class SubClass (**SubClass.java**):

```
public class SubClass
{
    public int _intField;
    public byte _byteArrayField[];

    public SubClass(int intPar1)
    {
        _intField=intPar1;
        _byteArrayField = new byte[5];
    }
}
```

Install_dir\examples\adapters\javaclas\subclass.mtt reflects this simple example.

- [Type tree elements](#)
 - [Adapter action sequence](#)
-

Type tree elements

The **SubClass.mtt** type tree contains elements for the constructor and the public fields. When used in a map, the **SubClass** group is chosen as the root element.

The purpose of the identifier is so that a reference to this object can be used in subsequent cards (such as passing this object as a parameter to a method call of another object).

Adapter action sequence

This section describes the sequence of actions that the adapter is performing on the Java™ object.

The constructor is mapped followed by the public fields. This represents the order that the adapter considers these elements: it first invokes the constructor to create the object and then sets the public fields according to the values in the type tree.

When this card is executed, the object will be created by calling the constructor with 1 as the value of the constructor's single parameter. Then the public fields are set to the values defined in the map. The object is given the reference **id1**, which may be used in any subsequent card.

If this map is executed, and the output is directed to a file instead of to the Java Class Adapter, it can be seen that the type tree generates an XML representation of the object and its methods:

```
<SubClass inherited="no" returnFields="no" this="id1">
  <Constructor>
    <p1_int type="int">1</p1_int>
  </Constructor>
  <Fields>
    <_intField type="int">5</_intField>
    <_byteArrayField type="byte[]">
      <element>8</element>
      <element>9</element>
    </_byteArrayField>
  </Fields>
</SubClass>
```

Complex Java™ class example

A more complex example is given by the class MainClass (**Mainclass.java**):

```
public class MainClass
{
    public boolean _booleanField;
    public SubClass _SubClassField;
    public String _StringField;

    public MainClass(int intPar1)
    {
        _booleanField = intPar1 > 0 ? true : false;
        _SubClassField = new SubClass((short)0);
    }
    public MainClass(int intPar1, SubClass SubClassPar2)
    {
        _booleanField = intPar1 > 0 ? true : false;
        _SubClassField=SubClassPar2;
    }
    public int function1()
    {
        if (_SubClassField._byteArrayField == null)
            return 0;
        else
            return _SubClassField._byteArrayField.length;
    }
    public SubClass function2(int intPar1)
    {
        SubClass returnValue = new SubClass(2);
        for (int index = 0; index < 5; index++)
        {
            returnValue._byteArrayField[index] = (byte)intPar1;
        }
        return returnValue;
    }
    public char function2(short[] shortArrayPar1)
    {
        return 'A';
    }
    public void function3(int intPar1)
    {
        _StringField = "Value " + intPar1 + "was passed";
    }
    public byte[] function4(SubClass SubClassPar1, String StringPar2)
    {
        _StringField = StringPar2;
        return SubClassPar1._byteArrayField;
    }
}
```

Notice that this class has a field, a constructor parameter and a method parameter that are of the type **SubClass**.

In the type tree (*install_dir\examples\adapters\javaclasses\mainclass.mtt*), the following aspects are noteworthy:

- There is a field of type **SubClass**, the value of which is a reference. This object must be created in a previous card and its reference mapped to the **ref._SubClassField** item.
- The 2 parameter constructor was selected by the user. The second parameter is of type **SubClass** (item **ref._P2_SubClass**). Its value is a text item that is the object reference. This object must be created in an earlier card and assigned a reference value that is then mapped into this item.
- Methods **function1**, **function2**, and **function3** were selected by the user, **function4** was not.
- All the methods were selected by the user to be invoked by the adapter.
- **function1** has no parameters. Since it is represented as a group, and groups must have components, it has a single component called **#NullArgList**. This should be assigned NONE in the map.
- It is possible that two methods with the same name (but different parameter lists) can be invoked within the same card. To facilitate this, the importer will change the names of the groups to unique names by appending .nn, where .nn is a unique number.

For example, if we wanted to invoke two different methods named **function2**, they would appear in the type tree as **function2.1** and **function2.2**.

Return values

When the user chooses to return the return values from method calls, a category entitled **ReturnValues** is created in the type tree.

The **ReturnValues** category includes a group, also called **ReturnValues** which has as components the individual return values from the methods. An example follows:

This data reflects the following, when mapped to a file:

```
<ReturnValues>
<function1.int>2</function1.int>
<function2.1.char>A</function2.1.char>
<function2.2.SubClass>
<ref>Ref.977366</ref>
<intField type="int">2</intField>
<byteArrayField type="byte[]">
<element>3</element>
<element>3</element>
<element>3</element>
<element>3</element>
```

```

<element>3</element>
</_byteArrayField>
</function2.2.SubClass>
<function4.byte_array>
<element>8</element>
<element>9</element>
</function4.byte_array>
<this.MainClass>
<_booleanField type="boolean">true</_booleanField>
<_SubClassField type="SubClass">
<_intField type="int">5</_intField>
<_byteArrayField type="byte[]">
<element>8</element>
<element>9</element>
</_byteArrayField>
</_SubClassField>
<_StringField type="java.lang.String">Another</_StringField>
</this.MainClass>
</ReturnValues>

```

- [Return value rules](#)
-

Return value rules

The following rules apply to return values:

- When only one return value is selected in the importer, and that value is a primitive type (for example, int) or a string. That value is returned without any other syntax. This simplifies mapping, since that value does not require further parsing.
 - When more than one value is returned then the values are decorated with XML tags (as in the above example). To parse this generally requires passing it to another map through a RUN function call.
 - When an object is returned it will always be decorated with XML tags. Its public fields are output, and a unique object reference is returned as an attribute so that this object may be used in subsequent cards.
 - When in the importer the user opted to return the public fields of the object corresponding to the card (the top-level object), then these are returned in the **this** group of the return values.
-

Java Class Importer

Use the Java™ Class Importer to define the methods that will be executed on the object.

The Java Class Importer allows the user to create a type tree that can be used to manipulate Java objects from within a map using the Java Class Adapter. The structure of the type tree explains the sequence of operations that the adapter is performing: constructing the Java object, setting public fields and invoking public methods.

- [Configuring JVM options in the config.yaml file](#)
 - [Running the Java Class Importer](#)
-

Configuring JVM options in the config.yaml file

Importers with the Java™ native interfaces use the JVM options specified in the **config.yaml** (/runtime/JVM Options) file to create Java virtual machine (JVM). You can use the JVM options to tune the importer's behavior, such as setting up big initial or maximum heap size.

Running the Java Class Importer

Use the Java™ Class Importer to create a type tree in order to manipulate Java objects from within a map using the Java Class Adapter.

To run the Java Class Importer:

1. Open the Type Designer.
2. Select Import a type tree in the Startup window and click Next. Or select Import from the Tree menu at anytime while the Type Designer is running. The Importer Wizard dialog appears.
3. Select Java Class and click Next.
The **Java Class Importer Wizard** appears. Follow the steps to automatically generate a type tree for a java class.
4. Type a fully qualified class name of the class (in this example, **java.awt.Scrollbar**) that you want to import and click Next.
Optionally, select the **Include inherited members from the super classes** check box if you want to include inherited members.
5. Select a constructor from the dialog. Click Next.
Note: It is possible to proceed to the next step without selecting a constructor. In that case, only static methods can be involved, or you may use the class instance obtained in the preceding cards to invoke the non-static methods through the **this** item in the type tree.
6. Optionally, select the **Check here if you wish to return the public fields of the object** check box, if you want the adapter to return the public fields of the object. Click Next.
7. Select the methods that you want to be executed by the adapter. Click Next.
You must reorder the methods into the order that you want them to be executed. To execute a method more than once, right-click on it, select Copy, position your cursor where you want to place the method, right-click again and select Paste.

8. Select the methods for which you want return values to be returned by the adapter (in a **GET** call). Click Next.
 9. Enter the name of (or browse for) the type tree that you want to create. Click Next.
The type tree is created and displayed in the Importer Wizard.
 10. Click Finish. The following window appears.
 11. Click Yes if you want to open the generated type tree(s). Click No to close the Importer Wizard and return to the Type Designer application.
-

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages may also be recorded as specified in the audit logs, trace files, execution summary files, and so on.

- [Java Class Adapter messages](#)
-

Java Class Adapter messages

The following is a listing of all the codes and messages that can be returned as a result of using the Java Class Adapter for sources or targets.

Note: Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Return Code	Message
-1001	<p>Java™ exception occurred: <i>exception_description</i> The variable <i>exception_description</i> represents the exception error returned by the Java language.</p>

JAXB Adapter

The JAXB adapter converts Java™ objects to XML and converts XML to Java objects. With the JAXB adapter, you can build Java objects that can be represented with XML, parse the objects, and use them in maps. The JAXB adapter supports all JAXB properties for marshalling and unmarshalling an XML document.

You can use the JAXB adapter on input cards and output cards, and in GET and PUT map rules. A card, GET rule, or PUT rule represents a single Java object. You must use multiple cards to specify multiple objects.

This documentation assumes that you are familiar with Java Architecture for XML Binding (JAXB).

- [System requirements](#)
The command server must be installed on the computer where the adapter is installed for runtime purposes.
 - [Java class requirements](#)
The generated Java classes must be serializable. The `@XmlRootElement` element must be specified in the Java classes that represent the schema.
 - [JAXB adapter command overview](#)
This table summarizes the adapter commands, syntax, and whether you can use the command with data sources, data targets, or both. You can specify the commands on the adapter command line or through the adapter properties.
-

System requirements

The command server must be installed on the computer where the adapter is installed for runtime purposes.

See the [system requirements](#) for details about minimum system requirements for the JAXB adapter.

Java class requirements

The generated Java™ classes must be serializable. The `@XmlRootElement` element must be specified in the Java classes that represent the schema.

You can use the URL location (-U command) to read and write Java objects only when your objects are serializable. To generate serializable objects, specify `<serializable uid="..._home_markdown_jenkins_workspace_Transform_in_SSVSD8_11.0.1_com.ibm.websphere.dtx.adapjaxb.doc_references_r_jaxb_Java_Classes_Requirements_1"/>` in a bindings file under `<globalBindings>` and pass it to the XJC binding compiler with the -b option. For example:

```
xjc -b bindings.xjb
```

The -C adapter command points to the root class. You can annotate your root class with the `@XmlElement`, or the XJC binding compiler can do it for you. To use the XJC binding compiler to annotate the root class, add `<xjc:simple/>` to your bindings file under `<globalBindings>`. Pass the bindings file to the XJC binding compiler by using the -b option.

An example bindings file follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<bindings xmlns="http://java.sun.com/xml/ns/jaxb"
```

```

xmlns:xsi="http://www.w3.org/2000/10/XMLSchema-instance"
xmlns:xjc="http://java.sun.com/xml/ns/jaxb/xjc"
xsi:schemaLocation="http://java.sun.com/xml/ns/jaxb
http://java.sun.com/xml/ns/jaxb/bindingschema_2_0.xsd"
version="2.1">
<globalBindings>
<serializable uid="_home_markdown_jenkins_workspace_Transform_in_SSVSD8_11.0.1_com.ibm.websphere.dtx.adapjaxb.doc_references_r_>
<xjc:simple/>
</globalBindings>
</bindings>

```

The XJC binding compiler produces Java files (.java) from the schema. You manually package the Java files into Java Archive (JAR) files. You must modify the CLASSPATH environment variable for all Java-based adapters that rely on external JAR files. You can edit the CLASSPATH directly, or you can add the JAR files to the config.yaml configuration file. Add JAR file entries to the /runtime/External Jar Files path of config.yaml file and specify the full path to the JAR file. For example:

```

External Jar Files:
jar1: c:/J2EE/lib/j2ee.jar
jar2: c:/mypath/myjar.jar

```

Note: For Windows, use either a forward slash "/" or two back-slashes "\\\" for the directory delimiter in config.yaml.

JAXB adapter command overview

This table summarizes the adapter commands, syntax, and whether you can use the command with data sources, data targets, or both. You can specify the commands on the adapter command line or through the adapter properties.

The commands are not case-sensitive, but the command values are case-sensitive. Choices are separated by the OR symbol | . Optional parameters are enclosed in brackets []. The topics that follow provide the command syntax in railroad track format.

Table 1. JAXB adapter command summary

Command	Syntax	Use with Data Source	Use with Data Target
Class name	-C Java_class_name	Yes	Yes
File location	-U {URL file_name}	Yes	Yes
Object ID	-I ID	Yes	Yes
Encoding	-jaxb.encoding encoding_name	Yes	Yes
Schema location	-jaxb.schemaLocation URI [URI]	Yes	No
No namespace location	-jaxb.noNamespaceSchemaLocation location	Yes	No
Fragment	-jaxb.fragment {true false}	Yes	No
Trace	-T [+] [file_name]	Yes	Yes
Trace errors	-TE [+] [file_name]	Yes	Yes

- Command alias**

Use the JAXB adapter alias to use the JAXB adapter on input and output cards and in GET and PUT map rules.

- Class name (-C) command**

The -C command specifies the Java class name that the new context object must recognize.

- File location (-U) command**

The -U command specifies the URL or the name of a serialized Java object file. The file can be either a source or a target.

- Object ID (-I) command**

The -I command specifies the object ID of the Java object in the IBM Transformation Extender object pool. Use the object pool to save objects and retrieve them later for further map processing.

- Encoding (-jaxb.encoding) command**

The -jaxb.encoding command specifies the character encoding that the adapter is to use when it marshals the XML data.

- Schema location (-jaxb.schemaLocation) command**

The -jaxb.schemaLocation command specifies the xsi:schemaLocation attribute value to place in the marshalled XML output.

- No namespace schema location (-jaxb.noNamespaceSchemaLocation) command**

The -jaxb.noNamespaceSchemaLocation command specifies the xsi:noNamespaceSchemaLocation attribute value to place in the marshalled XML output.

- Generate document-level events (-jaxb.fragment) command**

The -jaxb.fragment command determines whether the marshaller generates document-level events in the XML data.

- Create trace file (-T) command**

The -T command produces a diagnostics file that contains detailed information about adapter activity. The trace file is overwritten each time the trace runs.

- Trace adapter errors (-TE) command**

The -TE command produces a trace file that contains only the adapter errors that occurred during map execution.

Command alias

Use the JAXB adapter alias to use the JAXB adapter on input and output cards and in GET and PUT map rules.

Specify adapter commands by using a command string on the command line or by creating a command file that contains adapter commands. The command syntax is:

```

-IA[alias]card_num
-OA[alias]card_num

```

where:

-IA

The Input Source Override execution command

-OA

The Output Target Override execution command

alias

The adapter alias

card_num

The number of the map card

To override an input card:

-IAJAXB*card_num*

To override an output card:

-OAJAXB*card_num*

Class name (-C) command

The **-C** command specifies the Java™ class name that the new context object must recognize.

-C command syntax

►► -C — *class_name* ►►

class_name

The Java class name that the new JAXBContext class must recognize.

File location (-U) command

The **-U** command specifies the URL or the name of a serialized Java™ object file. The file can be either a source or a target.

-U command syntax

►► -U — *file_name* — *URL* — ►►

file_name

The name of the serialized Java object file.

URL

The location of the serialized Java object file, specified with URL notation. If you omit the URL notation, the location is treated as a file name.

Object ID (-I) command

The **-I** command specifies the object ID of the Java™ object in the IBM Transformation Extender object pool. Use the object pool to save objects and retrieve them later for further map processing.

-I command syntax

►► -I — *object_ID* ►►

object_ID

The object ID of the Java object in the IBM Transformation Extender object pool.

Encoding (-jaxb.encoding) command

The **-jaxb.encoding** command specifies the character encoding that the adapter is to use when it marshals the XML data.

This command is optional. If you omit it, the adapter uses UTF-8 encoding.

-jaxb.encoding command syntax

►► — *encoding* — — *-jaxb.encoding* — — ►►

encoding

The character encoding that the adapter is to use when it marshals XML data. Specify the value as a java.lang.String object class. See your JAXB documentation.

Schema location (-jaxb.schemaLocation) command

The **-jaxb.schemaLocation** command specifies the xsi:schemaLocation attribute value to place in the marshalled XML output.

This command is optional.

-jaxb.schemaLocation command syntax

xsi:schemaLocation

The xsi:schemaLocation attribute to specify in the generated XML data. Specify the value as a java.lang.String object class. See your JAXB documentation.

No namespace schema location (-jaxb.noNamespaceSchemaLocation) command

The **-jaxb.noNamespaceSchemaLocation** command specifies the xsi:noNamespaceSchemaLocation attribute value to place in the marshalled XML output.

This command is optional.

-jaxb.noNamespaceSchemaLocation command syntax

xsi:noNamespaceSchemaLocation

The xsi:noNamespaceSchemaLocation attribute to specify in the generated XML data. Specify the value as a java.lang.String object class. See your JAXB documentation.

Generate document-level events (-jaxb.fragment) command

The **-jaxb.fragment** command determines whether the marshaller generates document-level events in the XML data.

This command is optional. If you omit it, the default is false. Document-level events are not generated in the XML data.

-jaxb.fragment command syntax

true

false

This value must be a java.lang.Boolean object class. The implications of the value depend on which marshaller you use. See your JAXB documentation.

Create trace file (-T) command

The **-T** command produces a diagnostics file that contains detailed information about adapter activity. The trace file is overwritten each time the trace runs.

This command is optional.

-T command syntax

+

Appends trace information to the existing trace file.

file_name

The name and path of the trace file. This parameter is optional. If you omit it, the adapter creates a trace file named m4jaxb.mtr in the IBM Transformation Extender map directory.

Trace adapter errors (-TE) command

The **-TE** command produces a trace file that contains only the adapter errors that occurred during map execution.

This command is optional.

-TE command syntax

+

Appends trace information to the existing trace file.

file_name

The name and path of the trace file. This parameter is optional. If you omit it, the adapter creates a trace file named m4jaxb.mtr in the IBM Transformation Extender map directory.

JDBC Adapter

Overview

Use the Java Database Connectivity (JDBC) adapter to query or update a database through the appropriate JDBC driver for the database.

- [Introduction](#)
Input and output cards and actions of JDBC connection type can be used to access relational database resources.
- [JDBC adapter command overview](#)
- [Authenticating Connections](#)
The adapter supports username/password-based authentication method.
- [Adapter properties and commands](#)
This section lists the properties supported by the adapter.
- [Examples](#)

Introduction

Input and output cards and actions of JDBC connection type can be used to access relational database resources.

JDBC adapter command overview

The following table lists the JDBC adapter commands by function, and specifies whether each command is valid on input and output cards and GET and PUT functions.

Table 1. JDBC adapter functions and commands

Function	Command	Input card	GET function	Output card	PUT function
Configure the JDBC connection and driver	-URL <i>connection_string</i>	✓	✓	✓	✓
	-USERNAME	✓	✓	✓	✓
	-PASSWORD	✓	✓	✓	✓
	-DRIVER	✓	✓	✓	✓
	-AUTOCOMMIT {default on off}	✓	✓	✓	✓
Identify a database table or columns or stored procedure	-CATALOG	✓	✓	✓	✓
	-SCHEMA	✓	✓	✓	✓
	-PROCEDURE	✓	✓	✓	✓
	-TABLE	✓	✓	✓	✓
	-COLUMNS column [, column [, ...]]	✓	✓	✓	✓
Define how to write to or fetch from a database	-DATEFORMAT	✓	✓	✓	✓
	-TIMEFORMAT	✓	✓	✓	✓
	-TIMESTAMPFORMAT	✓	✓	✓	✓
	-WRITEMODE {insert insert_first update update_first}			✓	✓

Specify the number of rows fetched from the database to concatenate and return as a single fetch unit (managed automatically by the adapter)	-ARRAYSIZE array_size	✓	✓		

Authenticating Connections

The adapter supports username/password-based authentication method.

JDBC adapter as a source

The JDBC adapter as a source supports:

- Reading rows from a table.
- Reading rows for a custom database query statement.
- Reading values and rows from a stored procedure.
- Running custom static SQL statements before and after reading rows.

JDBC adapter as a target

The JDBC adapter as a target supports:

- Writing rows to a table, in insert, update and delete modes.
- Writing rows using a custom data manipulation language (DML) statement.
- Invoking stored procedures with passing arguments from input data.
- Running custom static SQL statements before and after writing rows.
- Truncating table before writing rows.

Adapter properties and commands

This section lists the properties supported by the adapter.

URL

Defines the JDBC driver-specific connection to a database. See the JDBC driver documentation for details. Generally, the command format is:

`-URL jdbc:driver://host:port/database[?custom_settings]`

The corresponding adapter command is `-URL connection_string`.

User

Specifies the username for the connection. This is optional property. For many drivers, you can specify the username as part of the connection string. Some drivers might use authentication other than username and password, and some drivers might not require authentication at all. The corresponding adapter command is `-USR user_name` (or `-USER user_name`).

Password

Specifies the password for the connection. This command is optional for the reasons described in the `-USER` command. The corresponding adapter command is `-PWD password` (or `-PASSWORD password`).

Driver

Specifies the fully-qualified Java™ class name for the java.sql.Driver interface implementation in the JDBC driver, typically provided in the driver documentation. This command is optional. If you omit the `-DRIVER` command, the adapter searches all available drivers to locate the driver specified in the URL connection string. The corresponding adapter command is `-DRV driver_class` (or `-DRIVER driver_class`).

Autocommit

Instructs the adapter how to configure the driver in respect to automatic commit of SQL statements performed by the driver. Default is off. Use the default setting specific to the driver and database.

When set to on, the adapter explicitly requests the driver to enable and perform auto-commit.

When set to off, the adapter explicitly requests the driver to disable and not perform auto-commit.

The corresponding adapter command is -AC (or - AUTOCOMMIT).

Catalog

Specifies the name of the database catalog. It is case-sensitive. The adapter does not include quotation marks around the catalog name. This is an optional property.

The corresponding adapter command is -CAT *catalog_name* (or -CATALOG *catalog_name*).

Schema

Specifies the name of the database schema. It is a case-sensitive. The adapter does not include quotation marks around the schema name. This is an optional property.

The corresponding adapter command is -SCH *schema_name* (or -SCHEMA *schema_name*).

Procedure

Specifies the name of the stored procedure to execute. It is case-sensitive and does not include quotation marks around the procedure name. This command overrides the -TABLE command.

- When used in an input card, do not specify any input arguments. The procedure can return a result set or a single set of values through output arguments and a return value.
- When used in an output card and the procedure returns data, the card is automatically configured for a request and response exchange using schema types that represent input and output data.
- When used in a PUT function, any specified output arguments or return values are ignored, because there is no mechanism to provide those values back to the map.

The corresponding adapter command is -PROC *procedure_name* (or -PROCEDURE *procedure_name*).

Table

Specifies the name of the table or view to access. It is case-sensitive and does not include quotation marks around the table name. The corresponding adapter command is -TBL *table_name* (or -TABLE *table_name*).

Columns

Specifies the name of the columns to access. It is case-sensitive and does not include quotation marks around the column name. The corresponding adapter command is -COLUMNS *column [, column [, ...]]* where column is a comma separated list of columns. The corresponding adapter command is -COL (or -COLUMNS).

Date Format

Specifies the alternate string format for date columns. If not specified, the format is the JDBC default yyyy-mm-dd. The corresponding adapter command is -DF (or -DATEFORMAT).

Time Format

Specifies the alternate string format for time columns. If not specified, the format is the JDBC default hh:mm:ss.[fff...]. The corresponding adapter command is -TF (or -TIMEFORMAT).

Time Stamp Format

Specifies the alternate string format for timestamp columns. If not specified, the format is the JDBC default yyyy-mm-dd hh:mm:ss.[fff...]. The corresponding adapter command is -TSF (or -TIMESTAMPFORMAT).

Write Mode

Specifies the mode of operation to use in PUT map function and output card when the Table property is specified. The default value is Insert. The meaning of the values is as follows:

- Insert: Each input row is inserted to the target table. The corresponding adapter command value is *insert*.
- Update: Each input row is used to update the corresponding row in the target table. The corresponding adapter command value is *update*.
- Insert First: Each input row is inserted to the target table. If the operation fails due to an integrity constraint error (such as a primary key violation), use the input row data to update the matching row in the target table. The corresponding adapter command value is *insert_first*.
- Update First: Each input row is used to update the matching row in the target table. If the table does not contain a matching row, insert the input row into the target table. The corresponding adapter command value is *update_first*.
- Delete: Each input row is used to delete the matching row in the target table. The corresponding adapter command value is *delete*.

The corresponding adapter command is -WM (or -WRITEMODE).

Query

Specifies the text of the query statement to execute when fetching the data. When GET map function is used with the adapter, the query statement text may contain query bind parameters (as '?' characters), and the values for the parameters are provided as the third argument of the GET function, with '|' character used as the value separator. The corresponding adapter command is -QRY (or -QUERY *statement_text*).

Query File

This property is used as an alternative to provide query statements through a file. The SELECT statement for fetching rows from the database is provided through file. Generally, the command format is:

```
-URL jdbc_connection_url -USR username -PWD password -QUERYFILE file_path
```

The corresponding adapter command is -QRYF (or -QUERYFILE).

DML

Specifies the custom Data Manipulation Language (DML) statement to use for writing rows to the database. When specified, the schema, table and write mode properties are ignored. The number of bind parameters in the statement must match the number of fields in the records pushed to the adapter. The corresponding adapter command is -DML *statement_text*.

DML File

This property is used as an alternative to provide DML statements through a file. The custom DML statement for writing rows to the database is provided through file. Generally, the command format is:

```
-URL jdbc_connection_url -USR username -PWD password -DMLFILE file_path
```

The corresponding adapter command is -DMLF (or -DMLFILE).

Key

Specifies the list of column names to use in the WHERE clause of SELECT and UPDATE statements that the JDBC adapter generates automatically in the following scenarios:

- By a GET function when the -TABLE command is specified. The adapter assumes that the fields in the records match the number and order of columns in the generated WHERE clause.
- By a PUT function or output card when the -TABLE command is specified and the -WRITEMODE command specifies INSERT_FIRST, UPDATE, or UPDATE_FIRST. The adapter assumes that the fields in the records match the number and order of columns in the target table.

The -KEY command is ignored in all other scenarios. If not specified, the JDBC adapter inspects the table in the database (specified by the combination of catalog, schema and table properties), determines the columns that comprise the primary key of the table, and lists those columns in the WHERE clause. If a column name in the list contains the exclamation point (!) or comma (,), use the exclamation point (!) as the release character.

The corresponding adapter command is -KEY *name [,name[, ...]]*.

Bind

A list of comma-separated index [type] entries that specify how to bind input-record field values to parameters in the user-defined statement that the adapter performs on the database. The index value specifies the position of the respective parameter in the statement, starting with position 1. The type value specifies the data type to use for binding input data values to the statement parameter indicated by the index position, and is one of the following: TEXT, BINARY, INT8, INT16, INT32, INT64, DECIMAL, FLOAT32, FLOAT64, DATE, TIME, TIMESTAMP. The default value is TEXT. A single space character should be specified between each index value and the corresponding type value. No other whitespace characters are allowed in the list. The -BIND command applies only to the following scenarios:

- A GET function or output card that specifies the -QUERY command.
- A PUT function or output card that specifies the -DML command.

The corresponding adapter command is -BIND *index[type][,index[type][, ...]]*.

Row Limit

Specifies the maximum number of records to return from the database. The value 0 means all available records.

The corresponding adapter command is -RL (or -ROWLIMIT).

Named Parameters

If set parameters in the statement can be named instead of using ? placeholder. Named Parameters should be specified as {name}. This is applicable with QUERY and DML.

The corresponding adapter command is -NP (or -NAMEDPARAMS).

Exclude Read-Only Columns

Decides whether to exclude or include read-only columns, when to generate the schema or when to perform the table operations. It is enabled when source or target object is table. When specified, the read-only columns would be excluded while generating table queries or statements.

The corresponding adapter command is -ERO (or -EXCLUDEREADONLY).

Here is an example of the adapter command line that includes the Exclude Read-Only Columns command:

```
-URL jdbc_connection_url -USR username -PWD password -ERO -CAT catalog_name -SCH schema_name -TBL table_name
```

Set Columns

Specifies the comma-separated list of column names to be included in SET clause. Whitespace characters should not be included unless they are part of the actual column names.

The corresponding adapter command is -SETCOL (or -SETCOLUMNS).

Use Column Labels

Column labels are typically available when importing schemas for SELECT statements which include AS keyword with the columns in the list. This setting is applicable only when generating schemas.

The corresponding adapter command is -UCL (or -USECOLUMNLABELS).

Truncate

This property is applicable only on target action and can only be used with target as Table and Write Mode as Insert and Insert First. When the value is set to true, the adapter truncates the specified table prior to inserting rows to it.

The corresponding adapter command is -TRC (or -TRUNCATE).

Here is an example of the adapter command line that includes the Truncate command:

```
-URL jdbc_connection_url -USR username -PWD password -WM insert -TRC -MVM null_value -CAT catalog_name -SCH schema_name -TBL table_name -BS 1
```

Missing Value Mode

Determines whether to treat missing (empty) string values in the delimited input data as Null value or empty string value. The corresponding adapter command is -MVM (or -MISSINGVALUemode). The supported property values are Null Value and Empty String, and the corresponding adapter command values are *null_value* and *empty_string*.

-LSN {seconds | 0 | S}

Specifies the amount of time, in seconds, that the adapter is to wait to retrieve a database row.

0

The adapter does not wait. If no rows are available to retrieve (for example, if the database table is empty), the adapter returns a warning message. This is currently the only supported value and should always be set when fetching data from the database.

S

The adapter waits for an infinite period.

Pre SQL

Specifies one or more SQL statements to execute after connecting to the database and prior to fetching any rows from the database or writing any rows to the database. The statements are committed by the adapter after the last one is executed, or automatically if Autocommit is specified or the statements are non-transactional (e.g. DDL statements). Bind parameters are not supported – the statements must be static statements. The adapter assumes that individual statements are separated by a semicolon. Each semicolon and backslash character that is integral part of a statement needs to be escaped by a backslash character.

The corresponding adapter command is -PRESQL.

Pre SQL File

This property is used to provide Pre-SQL statements through a file. The file contains one or more SQL statements to execute after connecting to the database and before fetching any rows from the database or writing any rows to the database.

The corresponding adapter command is -PRESQLF (or -PRESQLFILE).

Here is an example of the adapter command line that includes the Pre SQL File command:

```
-URL jdbc_connection_url -USR username -PWD password -WM insert -MVM null_value -CAT catalog_name -SCH schema_name -TBL table_name -BS 1 -PRESQLF file_path
```

Post SQL

Specifies one or more SQL statement to execute after fetching or writing all rows and prior to disconnecting from the database. The statements are committed by the adapter after the last one is executed, or automatically if Autocommit is specified or the statements are non-transactional (e.g. DDL statements). Bind parameters are not supported – the statements must be static statements. The adapter assumes that individual statements are separated by a semicolon. Each semicolon and backslash character that is integral part of a statement needs to be escaped by a backslash character.

The corresponding adapter command is -POSTSQL.

Post SQL File

This property is used as an alternative to provide Post-SQL statements through a file. Specifies one or more SQL statement to execute after fetching or writing all rows and before disconnecting from the database, through file. The corresponding adapter command is -POSTSQLF (or -POSTSQLFILE).

```
-URL jdbc_connection_url -USR username -PWD password -WM insert -MVM null_value -CAT catalog_name -SCH schema_name -TBL table_name -BS 1 -POSTSQLF file_path
```

Fetch Size

Specifies the number of rows per fetch that the JDBC driver retrieves from the database. The fetch size must be a non-negative number. This is an optional property. If you omit it or specify a fetch size of 0, the JDBC driver determines the optimal fetch size.

The corresponding adapter command is -FS *fetch_size* (or -FETCHSIZE *fetch_size*).

Batch Size

Specifies the number of rows of data the adapter writes to the database in a single batch. If the Write Mode property specifies Insert First or Update First, the adapter ignores the specified batch size and uses a batch size of 1 row. The batch size must be a non-negative integer. When the batch size is 0, the adapter collects all records from the transformation engine and sends them to the database in a single batch. This command is optional.

- When batch size is not specified on an output card, the adapter uses a default value of 1 row.
- When batch size is not specified for a PUT function, the adapter uses a default value of 0 and sends all records from the transformation engine to the database.

The corresponding adapter command is -BS *batch_size* (or -BATCHSIZE *batch_size*).

Quantity

Specifies the number of rows to retrieve from a database table. This command is optional. If you omit it, the default is one row. A value of S retrieves all rows. The -QTY adapter command is used when fetching data from the database and it specifies the maximum number of rows to fetch from the database. The default value is 1, and the value S means all available rows. The -QTY command must always be accompanied by the -LSN 0 command. The -QTY and -LSN commands are managed automatically when the adapter is utilized in input card in the Design Server web UI. But when the adapter command line is specified directly, the -QTY and -LSN commands must be included in it manually.

Fetch As

Whether to read from the source in bursts or read the source in its entirety.

Fetch Unit

Specifies the fetch unit. 0 means Fetch All.

When using an API to create or overwrite an input JDBC card:

- When Fetch As is set to Integral mode, set the Fetch Unit to 1 and specify the following commands so that adapter reads and returns all available rows at one time:
 - -QTY 1
 - -LSN 0
 - -ARRAYSIZE 0
- When Fetch As is set to Burst mode, set the Fetch Unit to 1 and specify the following commands so that adapter reads and returns one row per burst:
 - -QTY S
 - -LSN 0

Note: The -ARRAYSIZE command instructs the adapter to concatenate rows that it fetched from the database and return them as a single fetch unit. The special value 0 means concatenate all fetched rows. This command is set automatically by the adapter and does not have a corresponding property in the Design Server.

Error Row Handling

Select the Error Row Handling to set the mode on how the error data would be handled. Three modes supported are:

- None - Error records will be ignored and will not be recorded.
- Error Table - Enables the parameters to record the errors in an error table.
- Error File - Enables the parameters to record the errors in an error file.

The corresponding adapter command are -EROWH (or -ERRORROWHANDLING).

The corresponding adapter command values are *none*, *error_table* and *error_file*.

Error Catalog

Specifies the name of the error-table database catalog. It is case-sensitive and does not include quotation marks around the name.

The corresponding adapter command is -ECAT *catalog_name* (or -ERRORCATALOG *catalog_name*).

Error Schema

Specifies the name of the error-table database schema. It is case-sensitive and does not include quotation marks around the name.

The corresponding adapter command is -ESCH *schema_name* (or -ERRORSCHEMA *schema_name*).

Error Table

Specifies the name of the error table where the JDBC adapter stores invalid input records. This is an optional property. When the error table is specified, the adapter stores the invalid input record as part of the current transaction and continues to process subsequent input records. When the adapter cannot insert an invalid record into the error table, the adapter reports the error and the map stops executing. When the error table is not specified, the adapter reports the first invalid record and the map stops executing.

The corresponding adapter command is -ETBL *table_name* (or -ERRORTABLE *table_name*).

Define the error table columns to accommodate the following data:

Error table column	Size	Content
1	Variable	The row number as an integer
2	Variable	The error code as an integer
3	16 characters	The SQLstate as string
4	1024 characters	The text of the error message reported by either the JDBC driver or the JDBC adapter.
5	Variable	The raw bytes of the entire invalid input record, including delimiters.

For example:

```
create table error_table (
    rowNum      number,
    vendorCode   number,
    SQLState    varchar2(16 char),
    reason      varchar2(1024 char),
    rawData     blob
);
```

Error File Name

Specifies the name of the Error File in which error records will be captured.

The corresponding adapter command is -EFILEN *error_file_name* (or -ERRORFILENAME *error_file_name*).

Error Row Data

Specifies the Error Row Data in the error file.

The corresponding adapter command is -EROWD (or -ERRORROWDATA).

Charset

Specifies the character-set encoding to convert character data between native (core engine) and Java (adapter) components. By default, the adapter uses the default system locale encoding. In most cases, you do not need to change the character-set encoding. Custom encoding is applicable only in advanced scenarios. For example, when you exchange binary data with the adapter directly, the data is interpreted as text data and is encoded in a non-default encoding.

The corresponding adapter command is -CS (or -CHARSET).

SQL Files Charset

Specifies the character set for converting contents of SQL statement files between native format and driver Java format. By default the current system locale charset is used.

The corresponding adapter command is -SFCS (or -SQLFILESCCHARSET).

Optional Fields Mode

Specifies the cardinality of field components of the row group in the imported schema. The default value is Always, resulting in fields being always marked as optional (0:1). When set to Mandatory, the fields are always marked as mandatory (1:1). When set to Nullable Columns, the fields are marked optional only if they are found to be nullable. This property applies only to schema generation operation in the Design Server UI. It is not applicable to read and write operations performed during a map run.

Logging

This property specifies the level of logging to use for the log (trace) file produced by the adapter. The default is Off. The value Informational means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

The corresponding adapter command is:

-T [E|V] [+] *[file_path]*

-T -> Log adapter informational messages.

-TE -> Log only adapter errors.

-TV -> Use verbose (debug) logging. The log file records all activity that occurs while the adapter is producing or consuming messages.

+ -> Appends the trace information to the existing log file. Omit this argument to create a new log file.

file_path -> The full path to the adapter trace log. If you omit this keyword, the adapter creates the m4jdbc.mtr log file in the map directory.

Log file path

Specifies the location of the log file to which to write log messages. If not specified, the default log file name m4jdbc.mtr is used, and the file is stored to the directory in which the executed compiled map resides.

Failure Action

Specifies the action to perform on the transaction when the transaction fails. The default value is Rollback.

The following actions are supported:

- Commit: This option will commit the transaction in case of transaction failure.
- Rollback: This option will roll back the transaction in case of transaction failure.

Examples

[JDBC adapter -KEY command examples](#)

These JDBC adapter examples illustrate the effect of the **-KEY** command in a **GET** function and in an output card.

[JDBC adapter -BIND command examples](#)

These JDBC adapter examples illustrate the effect of the **-BIND** command in a **GET** function and in an output card and custom Data Manipulation Language (DML) statement.

JDBC adapter -KEY command examples

These JDBC adapter examples illustrate the effect of the **-KEY** command in a **GET** function and in an output card.

Example of the -KEY command used in a GET function

Assume the table in the database is defined as follows:

```
table1(c1 int, c2 varchar(10), c3 date, primary key(c1, c3))
```

The adapter is used in the following **GET** function:

```
GET("JDBC", "-URL connection -USER username -PASSWORD password -TABLE table1", inputdata)
```

Because the **-KEY** command is not specified, the adapter uses columns **c1** and **c3** from the primary key of **table1**, and generates a **SELECT** lookup statement as follows. The fully qualified table name and quoted identifiers are omitted for clarity.

```
SELECT c1, c2, c3 FROM table1 WHERE c1 = ? and c3 = ?
```

The adapter assumes that the input data is a record with fields that match the order and names of the columns in the primary key, meaning the **c1** field followed by the **c3** field.

However, when the adapter command line includes the **-KEY** command as follows:

```
GET("JDBC", "-URL connection -USER username -PASSWORD password -TABLE table1 -KEY c2,c3", inputdata)
```

The adapter generates the **SELECT** lookup statement as follows. The fully qualified table name and quoted identifiers are omitted for clarity.

```
SELECT c1, c2, c3 FROM table1 where c2 = ? and c3 = ?
```

The adapter assumes that input data is a record with the fields that match the order and names of the columns in the **-KEY** command, meaning the **c2** field followed by the **c3** field.

Example of the -KEY command used in an output card

Assume the table in the database is defined as follows:

```
table1(c1 int, c2 varchar(10), c3 date, primary key(c1, c3))
```

The JDBC adapter is used in an output card with the adapter command line defined as follows:

```
-URL connection -USER username -PASSWORD password -WRITEMODE INSERT_FIRST -TABLE table1
```

Because the **-KEY** command is not specified, the adapter uses columns **c1** and **c3** as the primary key of **table1**, and generates **INSERT** and **UPDATE** statements as follows. The fully qualified table name and quoted identifiers are omitted for clarity.

```
INSERT INTO table1(c1, c2, c3) VALUES (?, ?, ?)
UPDATE TABLE table1 SET c2 = ? WHERE c1 = ? AND c3 = ?
```

However, if the adapter command line in the output card includes the **-KEY** command as follows:

```
-URL connection -USER username -PASSWORD password -WRITEMODE INSERT_FIRST -TABLE table1 -KEY c2,c3
```

The adapter generates the following **INSERT** and **UPDATE** statements. The fully qualified table name and quoted identifiers are omitted for clarity.

```
INSERT INTO table1(c1, c2, c3) VALUES (?, ?, ?)
UPDATE TABLE table1 SET c1 = ? WHERE c2 = ? AND c3 = ?
```

Regardless of whether the **-KEY** command is specified, the adapter assumes that input data consists of records with fields that match the order and names of the columns in the target table, meaning **c1**, followed by **c2** followed by **c3**.

JDBC adapter -BIND command examples

These JDBC adapter examples illustrate the effect of the **-BIND** command in a **GET** function and in an output card and custom Data Manipulation Language (DML) statement.

Example of the -BIND command used in a GET function

The JDBC adapter is used in a **GET** function as follows:

```
GET("JDBC", "-URL connection -USER username -PASSWORD password -QUERY ""SELECT C1, C2, C3 FROM table1 WHERE c4 = ? AND c1 = ?""", inputdata)
```

Because the **-BIND** command is not specified, the adapter assumes that the input data consists of a record with two fields:

- The first field is mapped to the first parameter. It corresponds to the column **c4** in the **WHERE** clause.
- The second field is mapped to the second parameter. It corresponds to the column **c1** in the **WHERE** clause.

The adapter interprets both fields and binds both parameters as text values.

When the **GET** function is defined with the **-BIND** command as follows:

```
GET("JDBC", "-URL connection -USER username -PASSWORD password -QUERY ""SELECT C1, C2, C3 FROM table1 WHERE c4 = ? AND c1 = ?"" -BIND ""2 INT32,1 FLOAT64""", inputdata)
```

The adapter assumes that the input data consists of a record with two fields:

- The first field is mapped to the second parameter. It corresponds to column **c1** in the **WHERE** clause.
- The second field is mapped to the first parameter. It corresponds to column **c4** in the **WHERE** clause.

The adapter interprets the first field as a 32-bit integer (in text representation). It interprets the second field as a double-precision floating-point number (value 8 in text representation, followed by the pipe (|) delimiter, followed by 8 bytes representing the number in binary format).

Example of the -BIND command used in an output card and custom DML

The JDBC adapter is used in an output card with the adapter command line defined as follows:

```
-URL connection -USER username -PASSWORD password -DML "INSERT INTO table1 VALUES (? + 10, TO_TEXT(?), ? + ?)"
```

Because the **-BIND** command is not specified, the adapter assumes that the input data consists of records with four fields each:

- The first field is mapped to the first parameter.
- The second field is mapped to the second parameter.
- The third field is mapped to the third parameter.
- The fourth field is mapped to the fourth parameter.

The adapter interprets all four fields and binds all four parameters as text values. It's likely that this statement will fail to run (depending on the driver) because the plus (+) operator used with some of the parameters might not work with text values.

Now assume the adapter command line is defined with the **-BIND** command as follows:

```
-URL connection -USER username -PASSWORD password -DML "INSERT INTO table1 VALUES (? + 10, TO_TEXT(?), ? + ?)" -BIND "1 INT8,2 DATE,4 INT16,3 INT64"
```

The adapter assumes that the input data consists of records with four fields each:

- The first field is mapped to the first parameter.
- The second field is mapped to the second parameter.
- The third field is mapped to the *fourth* parameter.
- The fourth field is mapped to the *third* parameter.

The adapter interprets the fields and binds the parameters as follows:

- The first field is bound to the first parameter as an 8-bit integer.
- The second field is bound to the second parameter as a date.
- The third field is bound to the fourth parameter as a 16-bit integer.
- The fourth field is bound to the third parameter as a 64-bit integer.

JMS Adapter overview

Use the Java™ Message Service (JMS) Adapter as a client to any JMS-compliant messaging system provider.

JMS is part of the Java™ 2 Platform Enterprise Edition (J2EE) standards. It defines a standard API for accessing enterprise-messaging systems. Its purpose is to insulate an application from the underlying messaging system in much the same way that Java Database Connectivity (JDBC) insulates an application from a specific database.

A number of JMS implementations exist for messaging-oriented middleware (MOM) systems. Some provide a JMS layer on top of existing systems, for example, MQ Series from IBM® and TIB Rendezvous from TIBCO, while others MOM systems are implemented in Java, and whose primary interface is JMS, for example, FioranoMQ from Fiorano. The JMS API standard allows Java applications to interact with MOM systems that have implemented the JMS-compliant interfaces.

System requirements

The minimum system requirements and operating system requirements for the Java™ Message Service adapter are detailed in the release notes. It is assumed that a Command Server has already been installed on the computer where the adapter is to be installed for run-time purposes.

Messaging modes

In JMS, a connection factory is the precursor to a connection and this connection is the precursor to a session. It is in the session that messages, message producers and message consumers are created. The message producer sends messages to a destination while a message consumer receives messages from a destination. A destination can be either a topic or a queue.

JMS provides two messaging models as described in the following sections:

- [Point-to-Point \(PTP\)](#)
 - [Publish and Subscribe \(Pub/Sub\)](#)
 - [Point-to-Point \(PTP\)](#)
 - [Publish and subscribe \(Pub/Sub\)](#)
-

Point-to-Point (PTP)

When the destination is a queue, the messaging mode is said to be point-to-point, PTP or P2P, where it is possible to have one or more producers or senders but only one consumer (receiver).

In other words, the possible sender-receiver configurations in this mode are one-to-one and many-to-one. In the PTP mode, the receiver might or might not be active at the time the message is sent. The messaging provider will store the message until the intended consumer has retrieved the message or until the message expires. An important characteristic of this mode is that the consumer always acknowledges the successful processing of a message.

As designed, the JMS API classes are clearly grouped around messaging modes (PTP or Pub/Sub), which makes for easier programming and understanding of the model.

For example, if we know that the destination is a queue, the corresponding QueueConnectionFactory, QueueConnection, QueueSession, QueueSender and QueueReceiver classes must be available to perform messaging operations (send and receive) for the queue destination.

Publish and subscribe (Pub/Sub)

When the destination is a topic, the messaging mode is said to be publish and subscribe (or Pub/Sub) where each message sent by a producer (publisher) can have zero, one, or many consumers (subscribers). The possible publisher-subscriber configurations in this mode are one-to-one, one-to-many, many-to-many and many-to-one.

In the Pub/Sub mode, a message is deleted as soon as it expires or as soon as it has been delivered to all its active subscribers.

There is also a special mode in which we can have a durable subscriber. With this feature, an un-expired message will be delivered to a durable subscriber as soon as it becomes active as long as it was registered as a durable subscriber before the message was published.

Unlike the PTP mode, a provider is not obligated to store a message in the Pub/Sub mode if the intended destination has no active subscriber and no registered durable subscriber.

Successful processing of a message might or might not be acknowledged in this mode. As designed, the JMS API classes are clearly grouped around messaging modes (PTP or Pub/Sub), which makes for easier programming and understanding of the model.

For example, if we know that the destination is a topic, the corresponding TopicConnectionFactory, TopicConnection, TopicSession, TopicPublisher, TopicSubscriber classes must be available to perform messaging operations for the topic destination.

Command Alias

Adapter commands can be specified by using a command string on the command line or creating a command file that contains adapter commands. The execution command syntax is:

```
-IM[alias] card_num  
-OM[alias] card_num
```

where -IM is the Input Source Override execution command and -OM is the Output Target Override execution command, alias is the adapter alias, and card_num is the number of the input or output card. The following table shows the adapter alias and its execution command.

Adapter	Alias	As Input	As Output
JMS	JMS	-IMJMScard_num	-OMJMScard_num

JMS Adapter commands

The following table lists valid commands for the JMS Adapter, the command syntax, and whether the command is supported (✓) for use with data sources, targets, or any combination therein.

Commands can be specified on the adapter's command line or through adapter properties. Note that the commands are not case sensitive but that each value is case sensitive.

For ease of use, most commands have a short form and a long form that is described in the specific command text.

Note: The following commands are all valid in both JMS modes, Publish-and-Subscribe (Pub/Sub) and Point-to-Point (PTP) except where noted.
[1] PTP only

[2] Pub/Sub only

Command	Syntax	Source	Target
ConnectionFactoryName (-CFN)	-CFN <i>factory_name</i>	✓	✓
CorrelationID (-CID)	-CID <i>correlation_id</i>		✓
DeliveryMode (-DM)	-DM !P P		✓
DurableSubscriber (-DS)[2]	-DS <i>sub_name</i>	✓	
Expiration (-E)	-E <i>time_milliseconds</i>		✓
GroupID (-GID)	-GID <i>group_id</i>		✓
Header (-HDR)	-HDR	✓	
InitContextFactory (-ICTXF)	-ICTXF <i>factory_name</i>	✓	✓
InitContextFactoryURL (-ICTXFURL)	-ICTXFURL <i>factory_url</i>	✓	✓
JNDI Method (-JM)	-JM <i>sys env</i>	✓	✓
Listen (-LSN)	-LSN <i>timeout_value</i>	✓	
Priority (-PRI)	-PRI <i>msg_priority</i>		✓
Property (-PRP)	-PRP	✓	
Password (-PW)	-PW <i>password</i>	✓	✓
Queue (-QN)[1]	-QN <i>queue_dest</i>	✓	✓
Quantity (-QTY)	-QTY <i>num_of_messages</i>	✓	
Reply (-R)	-R <i>topic_name queue_name</i>		✓
Selector (-SEL)	-SEL "sel_expression"	✓	
Text (-TT)	-TT		✓
Topic (-TN) [2]	-TN <i>topic_dest</i>	✓	✓
Trace (-T)	-T[E][+] [<i>filename</i>]	✓	✓
UserName (-UN)	-UN <i>user_name</i>	✓	✓

- [ConnectionFactoryName \(-CFN\)](#)
- [CorrelationID \(-CID\)](#)
- [DeliveryMode \(-DM\)](#)

ConnectionFactoryName (-CFN)

Use the ConnectionFactoryName adapter command (-CFN or -CONNECTIONFACTORYNAME) to indicate the Java™ Naming and Directory Interface (JNDI) lookup name of a valid connection factory in an administered object store.

In Point-to-Point (PTP) mode, the *factory_name* is a valid QueueConnectionFactory lookup name. In Publish-and-Subscribe (Pub/Sub) mode, the *factory_name* is a valid TopicConnectionFactory lookup name.

This is a required command.

```
-CFN factory_name
```

Option**Description**

factory_name

Required value. Specify the name of a valid connection factory name.

For example, to specify **PhoenixRising** as the connection factory:

```
-CFN PhoenixRising
```

CorrelationID (-CID)

Use the CorrelationID adapter command (-CID or -CORRELATIONID) to specify a string to send with the message.

This is an optional command. The default is a null CorrelationID.

```
-CID correlation_id
```

Option**Description**

correlation_id

Specify a correlation ID to send with the message.

For example, to specify **Washington** as the correlation ID:

```
-CID Washington
```

DeliveryMode (-DM)

Use the DeliveryMode adapter command (-DM or -DELIVERYMODE) to indicate the mode of delivery for messaging. For non-persistent messaging, the value is !P. For persistent messaging the value is P.

This is an optional command. The default is javax.jms.Message.DEFAULT_DELIVERY_MODE, making the behavior provider-specific.

```
-DM !P | P
```

Option**Description**

!P

Specifies non-persistent delivery mode for sent messages.

Indicates no guarantee that a sent message will be delivered and it is acceptable that intended receivers miss messages arising from provider failure.

P

Specifies once-only persistent delivery mode for sent messages. This guarantees once-only delivery of messages.

For example, to specify **persistent** as the delivery mode value:

```
-DM P
```

DurableSubscriber (-DS)

Use the DurableSubscriber adapter command (-DS or -DURABLESUBSCRIBER) to specify the name of the durable subscription. Useful only in Pub/Sub mode—that is, when the destination is a topic. It is ignored when the destination is a queue.

This is an optional command. The default is no durable subscriber (that the subscription spans the current session only).

```
-DS sub_name
```

Option**Description**

sub_name

Specify the durable subscription name for the current session.

For example, to specify **Reuters** as the durable subscription name:

```
-DS Reuters
```

Expiration (-E)

Use the Expiration adapter command (-E or -EXPIRATION) to specify the time-to-live in milliseconds for how long an undelivered message might be retained by the provider before it expires. The value is **t \$ 0**.

t = 0 specifies no expiration (message lives "forever").

t > 0 specifies that a sent message can live up to t milliseconds after it is sent before it expires.

This is an optional command. The default is javax.jms.Message.DEFAULT_TIME_TO_LIVE, which implies infinite message life in most cases.

-E time_milliseconds

Option

Description

time_milliseconds

Specify the time-to-live in milliseconds for how long an undelivered message might be retained by the provider.

For example, to specify **3000** milliseconds as the expiration time for an undelivered message to be retained:

-E 3000

GroupID (-GID)

Use the GroupID adapter command (-GID or -GROUPID) to specify the ID that marks multiple messages as belonging to a group.

This is an optional command. The default is a null GroupID.

The -GID adapter command only assigns a specified **group_id** value to the **JMSXGroupID** property of the message. If it is necessary to track the sequence numbers for the messages, the **JMSGroupSeq** property of Java™ **int** type must be utilized. In other words, a type tree with the **JMSXGroupSeq** property must be used.

Additionally, if it is necessary to specify the *last* message of the group, additional properties must be used, and this is defined by the message provider.

For example, to specify the last message in a group sequence in IBM® MQ, the IBM MQ JMS-specific property, **JMS_IBM_Last_Msg_In_Group** of Java **boolean** type must be used.

Note that if you need to use the type tree with JMS properties to specify grouped messages (for example, to specify sequence numbers), you have a choice of using the -GID adapter command or the **JMSXGroupID** property of **java.lang.String** type to specify the group identifier value.

-GID group_id

Option

Description

group_id

Specify the ID that marks multiple messages as belonging to a group.

For example, to specify an ID of **JMSTotal** for the group:

-GID JMSTotal

Header (-HDR)

Use the Header adapter command (-HDR or -HEADER) to extract standard header fields to include them in the output in addition to the body of the message. This is valid only in source context.

This is an optional command. Default is null, that is, header fields are not added to the retrieved message.

-HDR

For example, to extract the header fields and include them in the output:

-HDR

InitContextFactory (-ICTXF)

Use the InitContextFactory adapter command (-ICTXF or -INITIALCTXFACTORY) to indicate the initial context factory provider needed to build the starting point of all required JNDI services.

This is a required command.

-ICTXF factory_name

Option

Description

factory_name

Required value. Specify the factory name of the initial context provider. There are no restrictions on the factory name; it can be any string.

For example, to specify an LDAP provider:

```
-ICTXF com.sun.jndi.ldap.LdapCtxFactory
```

InitContextFactoryURL (-ICTXFURL)

Use the InitContextFactoryURL adapter command (-ICTXFURL or -INITIALCTXFACTORYURL) to indicate the initial context factory server URL needed to build the starting point of all required JNDI services.

This is a required command.

```
-ICTXFURL factory_url
```

Option

Option	Description
factory_url	Required value. Specify the factory URL name of the initial context server.

For example, to specify a file based directory:

```
-ICTXFURL file:///localhost/mydir/STORE
```

JNDI Method (-JM)

Use the optional JNDI (Java™ Naming and Directory Interface) Method adapter command (-JM or -JNDIMETHOD) to indicate how the JNDI environment properties are configured. For system properties the value is **sys**. For local environment properties, use the value **env** (default).

This is an optional command.

```
-JM sys|env
```

Option

Option	Description
env	Specify use of the environment properties for the Internet service provider. This is the default value.
sys	Specify use of the system properties (JNDI SPI is the J2EE reference server) for the provider.

For example, to specify **J2EE system properties** as the reference server:

```
-JM sys
```

Listen (-LSN)

Use the Listen adapter command (-LSN) to provide a timeout value in source contexts for retrieving messages.

This is an optional command. The default is infinity.

Note: The -LSN S and -QTY S commands cannot be used together. If you specify -LSN S, you need to specify a specific value for -QTY.

```
-LSN timeout_value
```

Option

Option	Description
timeout_value	Specify the time out value in seconds.

For example, to specify **60** seconds as the timeout value for retrieving messages:

```
-LSN 60
```

Priority (-PRI)

Use the Priority adapter command (-PRI or -PRIORITY) to specify the priority of a message. The value must be an integer between 0 (lowest priority) and 9 (highest priority).

This is an optional command. The default is **message.DEFAULT_PRIORITY**.

-PRI msg_priority

Option

Description

msg_priority

Specify the message priority integer.

For example, to specify **5** as the message priority for a message:

-PRI 5

Property (-PRP)

Use the Property adapter command (**-PRP** or **-PROPERTY**) to extract message properties to include them in the output in addition to the body of the message. This is valid only in source context.

This is an optional command. Default is null, that is, properties are not added to the retrieved message.

-PRP

For example, to extract the message properties and include them in the output:

-PRP

Password (-PW)

Use the Password adapter command (**-PW** or **-PASSWORD**) to indicate an acceptable password to be used for authentication when connecting to the service provider.

This is an optional command. The default is null.

-PW password

Option

Description

password

Specify the password for authentication purposes.

For example, to specify **wizards** as the password:

-PW wizards

Note: The **-PW** command can be used only if the JMS provider supports user authentication.

Queue (-QN)

Use the Queue adapter command (**-QN** or **-QUEUENAME**) to indicate the JNDI lookup name of a valid queue in the administered object store.

All messaging operations for this parameter are conducted in the PTP mode. The value is the JNDI name of an actual queue object (administered object).

This is a required command for PTP mode.

-QN queue_dest

Option

Description

queue_dest

Required value. Specify the JNDI name of an actual queue object (administered object).

For example, to specify **BigDog** as the actual queue object (administered object):

-QN BigDog

Quantity (-QTY)

Use the Quantity adapter command (**-QTY**) to provide the number of messages to return in source contexts.

This is an optional command. The default is **1**.

Note: The `-LSN S` and `-QTY S` commands cannot be used together. The default for `-LSN` is infinity. Therefore, if you specify `-QTY S`, you need to specify a specific value for `-LSN`.

`-QTY num_of_messages`

Option

Description

`num_of_messages`

Specify the number of messages to return in integer form.

For example, to specify **50** as the number of messages to return in source contexts:

`-QTY 50`

Note that when the JMS Adapter is used in the Map Designer to retrieve messages from the queue, every map that executes will leave the message cursor behind the last retrieved message.

For example, if `-QTY 3` is used in input card, and there are 5 message on the queue, the first execution of the map will receive three messages from the queue. If the same map is run again in the same Map Designer session, it will not complete since there will be only two messages left behind the cursor. Only when an additional message arrives to the queue will the map complete because the `-QTY 3` condition is then satisfied.

The second map would also complete if an `LSN` value was specified, in which case only two messages would be returned. For example, if `-LSN 10` was specified, the second map would try to receive the third message for 10 seconds in order to satisfy the `-QTY 3` condition, however, after 10 seconds it would complete and return only two messages because the `-LSN 10` condition was met first.

Reply (-R)

Use the Reply adapter command (`-R` or `-REPLY`) to specify the destination to send a reply.

In source context, the value is a string to send to the non-null destination found in the `JMSReplyTo` header.

In target context, the value is the topic name or queue name (an administered object) to which a receiver sends a reply.

This is an optional command. The default is a null Reply.

`-R topic_name|queue_name`

Option

Description

`topic_name`

Specify the name to which a receiver sends a reply.

`queue_name`

Specify the name (an administered object) to which a receiver sends a reply.

For example, to specify **irongate** as the topic name (for target context only) to which a receiver sends a reply:

`-R irongate`

Selector (-SEL)

Use the Selector adapter command (`-SEL`) to specify a valid message selector expression. The value is a valid selector expression. Since this might contain spaces and single quotes, the value should be surrounded by double quotes in order to not confuse the parser.

This is an optional command. The default is no selector that implies select all.

`-SEL "sel_expression"`

Option

Description

`"sel_expression"`

Specify the selector expression being used.

For example, to specify to selectively process all messages whose application-specific property is **Age minus 20 greater than 4** as the selector expression:

`-SEL "Age - 20 > 4"`

Trace (-T)

Use the Trace adapter command (`-T` or `-Trace`) to produce a diagnostics file that contains detailed information about JMS Adapter activity.

The default filename is **m4java.mtr** and it is created in the map directory unless otherwise specified.

-T [E] [+] [*filename*]

Option

Description

E

Produce a trace file containing only the adapter errors that occurred during map execution.

+

Append trace information to the existing trace file.

filename

Create a trace file with the specified name in the specified directory.

Note: You can override the adapter command line trace options dynamically using the Management Console. See "Dynamic Adapter Tracing" in the *Launcher* documentation for detailed information.

Text (-TT)

Use the Text adapter command (-TT or -TEXT) to instruct the adapter to treat the data that is passed as text and send it as a text message.

If this option is *not* specified and the data does not start and end with <Message> and </Message>, respectively (noting that the double quotes do not count, but the space character after the <Message> value does), the data is assumed to be a byte stream. The message is sent as a Bytes message. Otherwise, the operation fails. This command should be used only for a target (for sending messages).

This is an optional command.

-TT

For example, to treat the data that is passed as text and send it as a text message:

-TT

Topic (-TN)

Use the Topic adapter command (-TN or -TOPICNAME) to indicate the JNDI lookup name of a valid topic in the administered object store.

All messaging operations for this parameter are conducted in the Pub/Sub mode. The value is the JNDI name of an actual topic object (administered object).

This is a required command for the Pub/Sub mode.

-TN *topic_dest*

Option

Description

topic_dest

Required value. Specify the JNDI name of an actual topic object (administered object).

For example, to specify **BigDog** as the actual topic object (administered object):

-TN **BigDog**

UserName (-UN)

Use the UserName adapter command (-UN or -USERNAME) to indicate an acceptable user name to use for authentication when connecting to the service provider.

This is an optional command. The default is null.

-UN *user_name*

Option

Description

user_name

Specify the user name for authentication purposes.

For example, to specify **JamesBond** as an acceptable user name to be used for authentication purposes:

-UN **JamesBond**

Note: The -UN command can be used only if the JMS provider supports user authentication.

Syntax summary

- [Data sources](#)
 - [Data targets](#)
-

Data sources

The following is the command syntax of the JMS Adapter commands used for data sources:

```
-CFN factory_name
-ICTXF factory_name -ICTXFURL factory_url
-QN queue_dest| -TN topic_dest [-DS sub_name]
[-HDR]
[-JM sys|env]
[-LSN timeout_value]
[-PRP]
[-PW password]
[-QTY num_of_messages]
[-SEL "sel_expression"]
[-T[E][+] [filename]]
[-UN user_name]
```

- [Example 1](#)
-

Example 1

For the GET > Source setting in an input card, select JMS. In the GET > Source > Command field, enter:

```
-T -HDR -ICTXFURL file:///C:/jdkmq/STORE -ICTXF
com.sun.jndi.fscontext.RefFSContextFactory -CFN myQueueCF1 -QN
myQ1
```

This command creates a trace file and outputs a header. In addition, it specifies the following:

- the initial context factory URL as file-based object **STORE**
 - the initial context factory as **com.sun.jndi.fscontext.RefFSContextFactory**
 - the connection factory JNDI lookup name as **myQueueCF1**
 - sets the JNDI queue lookup name as **myQ1**
-

Data targets

The following is the command syntax of the JMS Adapter commands used for data targets:

```
-CFN factory_name
-ICTXF factory_name -ICTXFURL factory_url
-QN queue_dest| -TN topic_dest
[-CID correlation_id]
[-DM !PIP]
[-E time_milliseconds]
[-GID group_id]
[-JM sys|env]
[-PRI msg_priority]
[-PW password]
[-R topic_name|queue_name]
[-T[E][+] [filename]]
[-TT]
[-UN user_name]
```

- [Example 2](#)
-

Example 2

For the PUT > Target setting in an output card, select JMS. In the PUT > Target > Command field, enter:

```
-CID 12345 -ICTXFURL file:///C:/jdkmq/STORE -ICTXF
com.sun.jndi.fscontext.RefFSContextFactory -CFN
"cn=myQueueCF1" -QN "cn=myQ1"
```

This command sets the correlation ID value to **12345**. In addition, it specifies the following:

- the initial context factory URL as file-based object **STORE**
- the initial context factory as **com.sun.jndi.fscontext.RefFSContextFactory**
- the connection factory JNDI lookup name as **myQueueCF1**
- sets the JNDI queue lookup name as **myQ1**

Using the Adapter

Use the JMS Adapter to act as a client to any JMS-compliant messaging system provider.

- [Message content](#)
- [Message Selection](#)
- [Example Files](#)

Message content

A JMS message content is made up of the following three sections:

- Header ([Header](#))
 - Properties ([Properties](#))
 - Body or Payload ([Body or Payload](#))
-
- [Header](#)
 - [Properties](#)
 - [Body or Payload](#)

Header

The header fields are present in every message and common to all JMS implementations.

If the `-HDR` command is used in a source, the header fields are returned from the adapter. If the header group is used in the type tree of a target, then values can be mapped to the header fields.

Note that any adapter commands will override any values that are mapped to these fields and that all fields are passed between the engine and the adapter as UTF-8 data.

- [Header Fields Table](#)

Header Fields Table

The following table indicates how these fields are set and used:

Field	Set by	Significant Context
JMSDestination	Provider	Target
JMSDeliveryMode	Sender	Target
JMSMessageID	Provider	Source
JMSTimestamp	Provider	Source
JMSCorrelationID	Sender	Source, Target
JMSReplyTo	Sender	Source, Target
JMSRedelivered	Provider on receipt	Source
JMSType	Sender	Target
JMSExpiration	Provider ¹	Target
JMSPriority	Provider	Target

¹The **JMSExpiration** field is set by the Provider based on the current GMT time and the **TimeToLive** setting input by the sender.

Only those fields that can be set by the sender can be set in a target. If values are passed to other fields, they will be ignored.

Properties

Properties are a mechanism to add application and provider specific properties to extend the header. Properties enable the JMS provider or the user with the capability to attach more information to a message. Properties are subdivided into the following three categories:

- application-specific ("[Application-specific Properties](#)")
 - JMS-specific ("[JMS-specific Properties](#)")
 - vendor-specific ("[Vendor-specific Properties](#)")
-
- [Application-specific Properties](#)
 - [JMS-specific Properties](#)
 - [Vendor-specific Properties](#)
 - [Using Message Properties](#)

Application-specific Properties

This category includes properties set by the user using the application developer (the adapter). Users can set as many user-defined properties as permitted by resources and the provider. The user nomenclature for application-specific properties must avoid using the contiguous set of characters "JMSX" or "JMS_" that are reserved for JMS-specific and vendor-specific properties, respectively.

JMS-specific Properties

This category includes properties, both required and optional, that are predefined by the JMS specification. These properties are named using the format JMSX<property>, that is, each key begins with the prefix "JMSX".

Required properties must be supported by all JMS-compliant providers. The required properties include:

- JMSXGroupID
- JMSXGroupSeq

Optional properties are currently defined and can be set by the provider. The optional properties include:

- JMSXUserID
- JMSXAppID
- JMSXProducerTXID
- JMSXConsumerTXID
- JMSXRcvTimestamp
- JMSXDeliveryCount
- JMSXState

These properties are not required to be supported by providers.

JMS-specific Properties Table

The following table lists the properties and their significant contexts:

Field	Set by	Significant Context
JMSXUserID	Provider on send	Source
JMSXAppID	Provider on send	Source
JMSXDeliveryCount	Provider on receipt	Source
JMSXGroupID	Sender	Target
JMSXGroupSeq	Sender	Target
JMSXProducerTXID	Provider on send	Source
JMSXConsumerTXID	Provider on receipt	Source
JMSXRcvTimestamp	Provider on receipt	Source
JMSXState	Provider	None

Vendor-specific Properties

The third category of properties is the vendor specific properties. The JMS specification makes it easy to identify this category of properties as each, if any, must follow a nomenclature that begins with the prefix "JMS_".

A provider might define as many provider-defined "JMS_" type properties as its resources permit.

Using Message Properties

If the `-PRP` command is used in a source, all the available properties (application-specific, vendor-specific and JMS-specific) are returned from the adapter. If the properties group is used in the type tree of a target, then values can be mapped to the property fields.

Note that any adapter commands will override any values that are mapped to these fields and that all fields are passed between the engine and the adapter as UTF-8 data.

When a type tree is generated using the JMS Importer, the **Properties** group contains a dummy text item, since it is not possible to know which properties will be contained within the JMS message. Therefore, it is necessary to manually create the items in the property group.

The example type tree, `Text_in.mtt` (located in the examples folder) shows an example set of properties that can be used as a template.

Perform the following steps to add properties to a type tree.

To add properties to a Type Tree

1. Create an item in the **Properties** category. The **Item Subclass** should be set according to the following table:

Java" Type	Item Subclass	Type Attribute in Initiator
boolean	Number->Integer	"boolean"
byte	Number->Integer	"byte"
short	Number->Integer	"short"
int	Number->Integer	"int"
long	Number->Integer	"long"

Java™ Type	Item Subclass	Type Attribute in Initiator
float	Number->Decimal	"float"
double	Number->Decimal	"double"
java.lang.String	Text	"java.lang.String"

For all properties except for the properties of java.lang.String type, the initiator of the item that is representing it should be:

```
<Property_Name type="type">
```

and the terminator of the item type should be:

```
</Property_Name>
```

For the properties of java.lang.String type, the initiator should be:

```
<Property_Name type="type"><![CDATA[
```

and the terminator should be:

```
]]></Property_Name>
```

Property_Name is the actual name of the property, and type is one of the values listed in the above table.

<![CDATA[and]]> enable XML content to appear as a string value for the property of java.lang.String type. They ensure that the XML parser ignores the value of this property, that is, that it does not treat it as part of the XML document that represents the JMS message structure. Note further that the property value should not contain the "]]>" substring because it serves as a closing marker for the CDATA section.

2. Add the item to the **Properties** unordered group.

Body or Payload

The third section of a message is its body, also known as the payload. The JMS specification expects JMS providers to implement and support six message interface types. The adapter supports all six of the following types.

- Message ([Message](#))
- Bytes Message ([Bytes Message](#))
- Stream Message ([Stream Message](#))
- MapMessage ([MapMessage](#))
- TextMessage ([TextMessage](#))
- ObjectMessage ([ObjectMessage](#))

- [Message](#)
- [Bytes message](#)
- [Stream message](#)
- [MapMessage](#)
- [TextMessage](#)
- [ObjectMessage](#)

Message

This is a message with an empty body. It is the base interface for all the other message forms. Because it has no payload, it is useful as a control message.

If data of zero length is passed to the adapter the adapter will create a message with no payload.

A message with no payload can have header and property values.

When sending a message with no payload that has specified header and property values, the opening tag of the <Body> element must be specified in one of the following formats:

- <Body>
- <Body type="">
- <Body type="Message">

When the adapter receives a message with no payload, it always omits the "type" attribute of the <Body> element in the returned XML data.

Bytes message

The body is a stream or an array of uninterpreted bytes. The adapter is able to handle data to and from a Bytes message type.

When the adapter receives a Bytes message, it always base64 encodes the body of the message.

When sending a message:

- If -TEXT command is not specified and if the adapter fails to parse the received data as XML, and if this data does not start and end with "<Message " and "</Message>", respectively (the double quotes do not count, but the space character after the <Message value does), it interprets it as binary data, not base64 encoded, and dumps the data into a Bytes message.

- If the adapter locates the <Body> element in the data and it has the type attribute set to "Bytes", the content of the <Body> element is always interpreted as base64 encoded data.

To base64 encode a message to be sent in an output card, use the **TEXTTOBASE64** engine function.

To base64 decode a message received from an input card, use the **BASE64TOTEXT** engine function.

For more information about these engine functions, see the *Functions and Expressions* documentation.

Stream message

The body is a stream of Java™ primitive types that are filled and read sequentially. The essential characteristics is that the primitives must be read in the same order they were written. The adapter can handle data to and from a StreamMessage type.

MapMessage

Here, the body is a set of name-value pairs where the names are always strings but the values can be any Java™ primitive type, their wrapper object, or even strings. The values can either be accessed sequentially or randomly by name. The adapter is able to handle data to and from a MapMessage type.

TextMessage

The body is of type `java.lang.String`. Users can choose this type to process plain text messages such as XML documents. The adapter can handle data to and from a TextMessage type. A text message is represented in a map as UTF-8 data.

ObjectMessage

The payload is a serializable Java™ object. The adapter package can handle data to and from an ObjectMessage type.

Message Selection

JMS provides an SQL-like language to define "selectors". These selectors operate on the headers and properties (user-defined properties, JMS-defined properties and even provider-specific properties) of the message to select only messages that return **TRUE** for the given expression.

For example:

```
JMSMessageID='sj2j22j' AND MyType='payroll'
```

Note: See the [Selector \(-SEL\)](#) command on page [page 1-11](#) for more information.

Example Files

To access an example for this adapter, from the Start menu, select the **Examples** option for this product. In the Examples menu, select the **Resource Adapters** page from the Table of Contents listing and then select the link for this adapter.

JMS Importer

Use the JMS Importer to create type trees that represent the public fields and constructors of Java™ classes that are sent as objects using JMS messages. The generated type tree reflects the selections the user makes, and includes the fields required for the JMS header and properties.

The importer has no relevance for message types other than the *Object* message type. Metadata is not available for *Text*, *Bytes*, *Stream* and *Map* message types. Only template type trees are provided that can be manually modified to reflect the specific messages being processed.

For detailed information on the structure of the type tree as created by the JMS Importer, review the **readme.txt** file located in the JMS example folder. To access this file, from the Start menu, select the **Examples** option for this product. In the Examples menu, select the **Resource Adapters** page and then select the link for this adapter. Open the **readme.txt** file.

- [Configuring JVM Options in the config.yaml File](#)
- [Running the JMS Importer](#)

Configuring JVM Options in the config.yaml File

Importers with the Java™ native interfaces use the JVM options specified in the **config.yaml (/runtime/JVM Options)** file to create Java virtual machine (JVM). You can use the JVM options to tune the importer's behavior, such as setting up big initial or maximum heap size.

See the similarly named chapter in the *Type Tree Importers documentation* for detailed information.

Running the JMS Importer

Use the JMS Importer to create a type tree in order to manipulate Java™ objects from within a map using the JMS Adapter.

To run the JMS Importer:

1. Open the Type Designer application.
2. Select Import a type tree in the Startup window and click Next. Or select Import from the Tree menu at anytime while the Type Designer is running. The Importer Wizard dialog box appears.
3. Select Java Message Service (JMS) and click Next.
The **JMS Importer Wizard** appears. Follow the steps to automatically generate a type tree for a Java class.
4. Enter a fully qualified class name for the Java class file (in this example, **Book**) that you want to import. Click Next. The Java code for the **Book** class is:

```
public class Book implements java.io.Serializable { public String title; public String author; public float price; public boolean instock; public Book(String title, String author) { this.title = title; this.author = author; } public Book(String title, String author, float price, boolean instock) { this(title, author); this.price = price; this.instock = instock; } }
```

When using the JMS importer, the specified Java class (the one you are importing) must implement the `java.io.Serializable` interface; otherwise, the import process will fail.

Note: **Book** class is in the default package for this example. If it were in a named package, the name of the package would precede the name of the class. For example, `com.ibm.mypack.Book`.

JMS Adapter dependent jars

JMS Adapter dependent jars activemq-all-5.16.2.jar and log4j-1.2.17.jar have been added within the config.yaml file.

Return Codes and Error Messages

Return codes and messages are returned when the particular activity completes. Return codes and messages might also be recorded as specified in the audit logs, trace files, execution summary files, and so on.

- [Messages](#)

Messages

The JMS Adapter reports faults with intuitively annotated Java™ exceptions. Execution flow and error messages, if any, are in the ***.mal** file which the user can obtain via the "[Trace \(-T\)](#)" command on page [page 1-11](#).

Please see the ***.mal** file for error and execution flow information.

JNDI Adapter overview

Use the Java™ Naming and Directory Interface (JNDI) Adapter to enable maps to look up, add, modify and delete entries in external directories, and retrieve the results that these operations return so that they can be reused in a map.

The following JNDI service providers are supported:

- LDAP
- COS Naming
- RMI
- DNS
- File System
- WebLogic

Supporting a service provider involves the adapter recognizing it as a valid protocol, and the availability of a supported schema.

The adapter uses XML parsing to parse the stream passed to an output card. The JNDI Adapter uses a standard Java-based XML parser (Xerces).

See your [Oracle documentation](#) for an overview of the JNDI architecture.

- [System requirements](#)
- [Command alias](#)
- [JNDI commands](#)

- [Syntax summary](#)
- [Using the adapter](#)

System requirements

The JNDI Adapter requirements are detailed in the system requirements and the release notes. It is assumed that a Command Server has already been installed on the computer where the adapter is to be installed for runtime purposes.

Command alias

Adapter commands can be specified by using a command string on the command line or creating a command file that contains adapter commands. The execution command syntax is:

```
-IM[alias] card_num
-OM[alias] card_num
```

where **-IM** is the Input Source Override execution command and **-OM** is the Output Target Override execution command, *alias* is the adapter alias, and *card_num* is the number of the input or output card. The following table shows the adapter alias and its execution command.

Adapter	Alias	As Input	As Output
JNDI	JNDI	-IMJNDI <i>card_num</i>	-OMJNDI <i>card_num</i>

JNDI commands

This documentation describes the functions and use of the JNDI Adapter commands and their options.

- [List of commands](#)

List of commands

The following table lists valid commands for the JNDI Adapter, the command syntax, and whether the command is supported (✓) for use with data sources, targets, or both.

Command	Syntax	Source	Target
Authentication Method (-AM)	-AM SSL	✓	✓
InitContextFactory (-ICTXF)	-ICTXF <i>factory_name</i>	✓	✓
InitContextFactoryURL (-ICTXFURL)	-ICTXFURL <i>factory_url</i>	✓	✓
Max Hits (-MAXHITS)	-MAXHITS <i>hits</i>	✓	
Timeout (-TIMEOUT)	-TIMEOUT <i>milliseconds</i>	✓	
Trace (-T)	-T[E][+] [<i>file_name</i>]	✓	✓

- [Authentication Method \(-AM\)](#)
- [InitContextFactory \(-ICTXF\)](#)
- [InitContextFactoryURL \(-ICTXFURL\)](#)
- [Max Hits \(-MAXHITS\)](#)
- [Timeout \(-TIMEOUT\)](#)
- [Trace \(-T\)](#)

Authentication Method (-AM)

Use the Authentication Method adapter command (**-AM** or **-AUTHENTICATION_METHOD**) to use the secure sockets layer (SSL) security protocol for an LDAP connection. This command is optional.

-AM SSL

Option

Description

SSL

Use the SSL protocol for the LDAP connection.

InitContextFactory (-ICTXF)

Use the InitContextFactory adapter command (**-ICTXF** or **-INITIALCTXFACTORY**) to indicate the initial context factory provider needed to build the starting point of all required JNDI services. If the command is omitted, the adapter examines the URL and attempts to load the appropriate initial context factory provider.

This is a required command.

```
-ICTXF factory_name
```

Option

Description

factory_name

Required value. Specify the factory name of the service provider. There are no restrictions on the factory name; it can be any string.

For example, to specify an LDAP provider:

```
-ICTXF com.sun.jndi.ldap.LdapCtxFactory
```

InitContextFactoryURL (-ICTXFURL)

Use the InitContextFactoryURL adapter command (-ICTXFURL, -INITIALCTXFACTORYURL or -URL) to indicate the initial context factory server URL needed to build the starting point of all required JNDI services.

This is a required command.

```
-ICTXFURL factory_url
```

Option

Description

factory_url

Required value. Specify the factory URL name of the initial context provider.

For example, to specify a file-based directory:

```
-ICTXFURL file:///localhost/mydir/STORE
```

Max Hits (-MAXHITS)

Use the Max Hits adapter command (-MAXHITS) to specify the maximum number of hits to be returned in a search request. If not specified, all hits are returned.

```
-MAXHITS hits
```

Option

Description

hits

Specify the maximum number of hits to be returned in a search request.

For example, to specify **10** as the number of hits to be returned in a search request:

```
-MAXHITS 10
```

Timeout (-TIMEOUT)

Use the Timeout adapter command (-TIMEOUT) to specify the time limit for lookup operations in milliseconds. If not specified the timeout is infinite. Not all service providers support user-defined timeouts.

```
-TIMEOUT milliseconds
```

Option

Description

milliseconds

The time limit in milliseconds

For example, to specify **10,000** milliseconds as the time limit for lookup operations.

```
-TIMEOUT 10000
```

Trace (-T)

Use the Trace adapter command (-T) to produce a diagnostics file. This file contains detailed information about adapter activity. By default, the **m4jndi.mtr** trace file is created in the directory where the map is located.

```
-T[E] [+] [file_name]
```

Option	Description
E	Produce a trace file containing only the adapter errors that occurred during map execution.
+	Append trace information to the existing trace file.
file_name	Creates a trace file with the specified name in the specified directory

Trace (-T) and Trace Error (-TE) adapter commands are mutually exclusive.

Syntax summary

This section of the documentation discusses the JNDI syntax summary and how the command syntax is used.

- [Data sources](#)
 - [Data targets](#)
 - [Example 1](#)
 - [Example 2](#)
-

Data sources

The following is the command syntax of the JNDI Adapter commands used for data sources:

```
-ICTXF factory_name -ICTXFURL factory_url -MAXHITS hits -TIMEOUT milliseconds
[-T[E] [+]] [file_name]] [-AM SSL]
```

Data targets

The following is the command syntax of the JNDI Adapter commands used for data targets:

```
-ICTXF factory_name -ICTXFURL factory_url [-T[E] [+]] [file_name]] [-AM SSL]
```

Example 1

For the GET->Source setting in an input card, select JNDI. In the GET->Source->Command field, enter:

```
-TRACE+ myfile.mtr -Timeout 10000
-MAXHITS 10
-url "ldap://localhost/cn=Test, o=IBM Software,c=
US??base?objectclass=*"
```

This command specifies the following:

- enables a trace file called **myfile.mtr** in append mode
 - sets a time limit for lookup operations to 10,000 milliseconds
 - specifies the maximum number of hits to be returned in a search request to ten.
 - specifies the entries to search for on the LDAP server called localhost
-

Example 2

In a GET map function call enter:

```
=GET("JNDI",
"-T+ myfile.mtr
-ICTXF com.sun.jndi.rmi.registry.RegistryContextFactory
-ICTXFURL rmi:// localhost:2500 ", PACKAGE( MyPackage ))
```

This GET map function call will:

- enable a trace file called **myfile.mtr** in append mode
- load the **InitialContextFactory** *com.sun.jndi.rmi.registry.RegistryContextFactory*
- connect to the **RMI server** running on the local machine on port 2500
- perform the JNDI operations that have been defined in Output Card **MyPackage**

Using the adapter

Use the JNDI Adapter to enable maps to look up, add, modify and delete entries in external directories, and retrieve the results that these operations return so that they can be reused in a map.

- [Theory of operation](#)
- [Adapter capabilities](#)
- [Adapter limitations](#)
- [Adapter scenarios](#)
- [Return values](#)
- [Schemas](#)
- [JNDI service providers](#)
- [Interoperability between JNDI adapter and other adapters](#)
- [Binary data](#)
- [Example files](#)

Theory of operation

The adapter uses the Initial Context Factory, which might be explicitly or implicitly supplied on the command line, to initialize the JNDI API. The mandatory url supplied on the command line identifies the host and optionally the port, user, password and which domain to connect to.

There are two major types of JNDI service providers, Naming Services and Directory Services.

- Naming Services such as the RMI Registry are generic enough to share most of their functionality. They are capable of performing lookup, add, delete and modify operations; they do not use attributes; their lookups might return one, zero or many objects.
- Directory Services, such as LDAP and DNS require specific implementations due to their complexity.

The adapter command line can be used to load a specific service provider at runtime.

The adapter uses Java™ Reflection to dynamically load the service provider implementation. Communication between the adapter and the remote server is handled transparently by JNDI.

Adapter capabilities

The JNDI Adapter has the following capabilities:

- A card or `GET` or `PUT` rule represents a JNDI operation. JNDI operations include lookup, add, modify or delete.
- The adapter provides access to records and attributes that can be set in the map, assuming the underlying service provider supports add, modify and delete.
- RDN modification, including renaming, is not supported. However, RDNs can be deleted and added in a modified state, assuming the service provider supports delete and add. An RDN is analogous to the name of the file in a hierarchical file system in Windows or UNIX.
- Objects created in one card can be used as parameters to methods in subsequent calls. These objects must be created by invoking an operation that returns an object.
- Reference labels identify objects. Objects that are returned from method calls are assigned a label by the adapter. The label is of the form `Ref.nn`, where `nn` is a number which uniquely identifies the object.
- The return values of any of the methods can be returned from a `GET` call. The schemas provide a mechanism allowing the user to select which methods the return values should be provided for. These return values can be primitive types, for example, `int`, strings, arrays, or local or remote objects. In the case of remote objects, the reference label is returned so that the object can be used in a subsequent call.
- Objects can be shared between the JNDI, JMS, Java™ Class adapters.

Adapter limitations

The JNDI Adapter has the following limitations:

- Only simple authentication is supported in bind requests.
- Attributes are always retrieved in search requests.
- Aliases are always de-referenced.
- The JNDI Adapter does not support Compare Requests.
- Basic Encoding Rule (BER) values are not supported in modify requests.

Adapter scenarios

The JNDI Adapter can be used in an input or output card. In an input card, the adapter can only perform lookup operations. Data is passed to the adapter on the URL command line option. Each provider implementation uses a different URL format. When used as an output card, data is passed, as defined by a schema, to enable it to determine what to do.

Therefore, there are two scenarios for using the adapter.

- If no data is required to be returned from the adapter, call the adapter in an output card. Typical scenarios include:
 - Add operations

- Modify operations
- Delete operations
- If data is required to be returned from the adapter, call the adapter in a `GET` function call. Build the data to be passed to the adapter in an output card and set the output adapter to 'sink'. Map the root object of this card to the third parameter of the `GET` function using the `PACKAGE` call to pass the XML data as a text item. See ["Return Values"](#) for more information on the format of the data returned from the `GET` function call.

Return values

Lookup operations are expected to return values. The format of the return data is described below.

	No Hits	One Hit	Multiple Hits
Directories	DSML	DSML	DSML
Naming Repositories	No data	Raw data	DSML

Lookups on a specific name in a naming repository might only return one hit. Lookups on a general domain within a naming repository return a collection of hits.

Each object returned from any lookup naming and directories is examined by the adapter. If it is a simple object, its value is returned. If it is not a simple object, it is stored in the Object Pool and its reference id is returned.

Multiple values return data similar to the following:

```
<dsml:dsml xmlns:dsml="http://www.dsml.org/DSML">
<dsml:directory-entries>
  <dsml:entry dn="cn=Test, o=IBM Software, c=US">
    <dsml:objectclass>
      <dsml:oc-value>
        <![CDATA[ top ]]>
      </dsml:oc-value>
    </dsml:objectclass>
    <dsml:attr name="homepage">
      <dsml:value>
        <![CDATA[ www.ibm.com ]]>
      </dsml:value>
    </dsml:attr>
    <dsml:attr name="someObject">
      <dsml:value>
        <![CDATA[ Ref. 786542 ]]>
      </dsml:value>
    </dsml:attr>
  </dsml:entry>
</dsml:directory-entries>
</dsml:dsml>
```

Return data for a single value in a naming context is similar to the following:

Ref. 786542

or

www.ibm.com

Schemas

The following schemas are provided with the JNDI Adapter installation:

- [LDAP](#)
- [DNS](#)
- Generic Naming

The Generic Naming schema can be used to perform [RMI](#) Repository, [WebLogic](#) and [File System](#) operations. It can also be used to perform user-specific naming operations. If the URL command line option does not contain a *supported* protocol such as LDAP, FILE, RMI, IIOP, DNS, or WebLogic it is assumed that the adapter is performing a generic naming operation.

All protocols are processed by the JNDI Adapter, however, if an *unsupported* protocol is used and the adapter does not recognize it, an exception is thrown and the adapter fails with the following message:

```
"WARNING: unsupported protocol " + protocol_name
```

The use of schemas is required in add, modify and delete operations. Schemas can be used in lookup operations when the adapter is used in an output card (a three (3) parameter `GET`). If lookup parameters are supplied in both a schema and the command line's URL parameter, the parameters in the schema are used and the corresponding URL parameters are ignored.

JNDI service providers

This section provides examples of how the JNDI Adapter handles service provider scenarios.

- [LDAP](#)
- [COS naming](#)
- [RMI](#)

- [DNS](#)
 - [File system](#)
 - [WebLogic](#)
-

LDAP

The JNDI Adapter is designed to mimic the functionality of the existing LDAP adapter. The advantage of the JNDI Adapter is that it is Java-based, and therefore capable of running on UNIX platforms as well as Windows platforms.

The adapter treats LDAP as a directory implementation.

- [Operations supported](#)
 - [Command line options supported](#)
 - [URL format](#)
 - [Initial Context factory](#)
 - [LDAP schema](#)
-

Operations supported

The **LDAP** provider supports the following operations:

Lookup	Add	Delete	Modify
✓	✓	✓	✓

Command line options supported

The following command line options are supported for LDAP connections:

Command Option	Lookup	Add	Modify	Delete
AM	Optional	Optional	Optional	Optional
ICTXF	Optional	Optional	Optional	Optional
ICTXFURL	Required	Required	Required	Required
MAXHITS	Optional			
TIMEOUT	Optional			
TRACE	Optional	Optional	Optional	Optional

URL format

`LDAP://[user:pass@]host[:port]/[rdn[?attr[?scope[?filter]]]]`

Option	Description
<i>user</i>	Specify the user name to connect to the LDAP server.
<i>pass</i>	Specify the password that authenticates the user name.
<i>host</i>	Specify the LDAP server name or address. The default name is localhost .
<i>port</i>	Specify the LDAP server port number. The default port name is 389 .
<i>rdn</i>	Specify the LDAP distinguished names. <i>rdn</i> is used during LDAP search operations. For add, replace, and modify operations it is optional. You can find examples of distinguished name abbreviations and formats in RFC 1779. Examples of distinguished name abbreviations include CN (common name), O (organization), and C (country). The following examples are from the RFC: CN=Christian Huitema, O=INRIA, C=FR CN=Christian Huitema; O=INRIA; C=FR CN=James Hacker L=Basingstoke O=Widget Inc C=GB OU=Sales + CN=J. Smith, O=Widget Inc., C=US CN=L. Eagle, O="Sue, Grabbit and Runn", C=GB CN=L. Eagle, O=Sue, Grabbit and Runn, C=GB
<i>attr</i>	

Specify the search attributes. *attr* is used during LDAP search operations. For add, replace, and modify operations, it is optional. This might be a single value or a comma-separated list.

scope

Specify the scope of the search. The default scope is **base**. Use this option only during an LDAP search operation. It is only valid when it is used in the [GET...Source](#) [...Command setting](#).

The **scope** options are:

- **base** - indicates a base object search
- **one** - indicates a single-level search
- **sub** - indicates a subtree search

filter

Specify the search filter as defined in RFC 1558. For example:
(!(cn=Tim Howes))

returns any common name except **Tim Howes**.

Initial Context factory

If no Initial Context factory is specified on the command line, the following service provider is used:

com.sun.jndi.ldap.LdapCtxFactory

LDAP schema

When used as an input card, the **Results LDAP** group should be selected. For all operations, the **Results LDAP** group should be selected.

The meaning of each node is described below:

Name	Description
Field/Data	A single attribute value
Field/Name	A single attribute name
Field/Operation	Used to instruct the adapter to perform a modify, add or delete operation. Valid values are add , modify , delete and replace . Replace and modify are identical. If the adapter is being used in a PUT rule and no operation is specified, modify is assumed.
Field/Operation/U	During a modify operation on an entry, its individual attributes can be added, modified or deleted. The <i>U</i> node applies to specific attributes. Valid values are add , modify , delete and replace . Replace and modify are identical. If left blank, modify is assumed.
Field/RDN	Overrides the RDN (<i>ldap_DN</i>) on the URL
Group/Attribute/Attribute	Corresponds to the <i>attr</i> parameter on the URL
Group/Attribute/ObjectClass	Represents the LDAP special attribute <i>objectclass</i>
Group/Attribute/ObjectClassU	Represents the LDAP special attribute <i>objectclass</i> in a modify request
Group/Entry	Represents a single directory entry
Group/Entries	Represents a collection of directory entries
Group/Value/Attribute	Contains the value or reference id of one attribute
Group/Value/ObjectClass	Contains the value or reference id of the LDAP specific <i>objectclass</i> attribute
Results	Represents the output from a lookup operation.

COS naming

The Common Object Services (COS) Name Server is the name server for storing Common Object Request Broker Architecture (CORBA) object references. It can be accessed from CORBA applications using the COS Naming package (*org.omg.CORBA.COSNaming*).

The JNDI/IOP service provider implements the **javax.naming.Context** interface on top of the COS Naming package in order to allow applications to use JNDI to access the COS Name Server.

The adapter treats COS Naming as a naming implementation.

- [**Operations supported**](#)
- [**Command line options supported**](#)
- [**URL format**](#)
- [**Initial Context factory**](#)

- [Generic naming type tree \(COS Naming\)](#)

Operations supported

The **COS Naming** provider supports the following operations:

Lookup	Add	Delete	Modify
✓	✓	✓	✓

Command line options supported

The following command line options are supported:

	Lookup	Add	Modify	Delete
TRACE	Optional	Optional	Optional	Optional
ICTXF	Optional	Optional	Optional	Optional
ICTXFURL	Required	Required	Required	Required
MAXHITS				
TIMEOUT				

URL format

`IIOP://[host[:port]]/[cosnaming_name] [?rdn]`

Option	Description
host	Specify the CORBA Naming Server name or address. The default name is localhost .
port	Specify the LDAP CORBA Naming Server port number. The default port is 900 .
cosnaming_name	Specify the root naming context (if any).
rdn	The name of the object to lookup, add, delete or modify

Initial Context factory

If no Initial Context factory is specified on the command line, the following service provider is used:

`com.sun.jndi.cosnaming.CNCtxFactory`

Generic naming type tree (COS Naming)

The COS Naming implementation uses the generic **Naming Repository** type tree.

When used as an input card the **Results JNDI** group should be selected. For all operations, the **Results JNDI** group should be selected.

The meaning of each node is described below:

Name	Description
Field/Data	Stores arbitrary input or output data
Field/Name	A single entry name
Field/Operation	Used to instruct the adapter to perform a modify, add or delete operation. Valid values are add , modify , delete and replace . Replace and modify are identical. If the adapter is being used in a PUT rule and no operation is specified, modify is assumed.
Group/Entry	Represents a single directory entry
Group/Entries	Represents a collection of directory entries
Group/Value	Contains the value or reference id of one entry
Results	Represents the output from a lookup operation

RMI

The RMI registry service provider allows JNDI applications to access remote objects registered with the RMI registry. Given the location of a registry, the provider will create a naming context with bindings for the objects registered there.

With this service provider installed, JNDI subsumes the functionality of the **java.rmi.Naming** class.

The adapter treats RMI as a naming implementation.

- [Operations supported](#)
- [Command line options supported](#)
- [URL format](#)
- [Initial Context factory](#)
- [Generic naming type tree \(RMI\)](#)

Operations supported

The **RMI** provider supports the following operations:

Lookup	Add	Delete	Modify
✓	✓	✓	✓

Command line options supported

The following command line options are supported:

	Lookup	Add	Modify	Delete
TRACE	Optional	Optional	Optional	Optional
ICTXF	Optional	Optional	Optional	Optional
ICTXFURL	Required	Required	Required	Required
MAXHITS				
TIMEOUT				

URL format

`rmi://[host[:port]][/[object]][?rdn]`

Option

Description

host

Specify the RMI registry name or address. The default name is **localhost**.

port

Specify the RMI registry port number. The default port is **1099**.

object

If the object name is absent, then the URL names the registry at the given host and port. Otherwise, it names the remote object registered at that registry under the name provided.

rdn

The name of the object to lookup, add, delete or modify

Initial Context factory

If no Initial Context factory is specified on the command line the following service provider is used:

`com.sun.jndi.rmi.registry.RegistryContextFactory`

Generic naming type tree (RMI)

The RMI implementation uses the generic **Naming Repository** type tree.

When used as an input card, the **Results JNDI** group should be selected. For all operations, the **Results JNDI** group should be selected.

The meaning of each node is described below:

Name

Description
Field/Data Stores arbitrary input or output data
Field/Name A single entry name
Field/Operation Used to instruct the adapter to perform a modify, add or delete operation. Valid values are add , modify , delete and replace . Replace and modify are identical. If the adapter is being used in a PUT rule and no operation is specified, modify is assumed.
Group/Entry Represents a single directory entry
Group/Entries Represents a collection of entries
Group/Value Contains the value or reference id of one entry
Results Represents the output from a lookup operation

DNS

The DNS service provider allows JNDI applications to access information stored in the Internet Domain Name System. The provider presents the DNS namespace as a tree of JNDI directory contexts, and DNS resource records as JNDI attributes.

The adapter treats DNS as a directory implementation.

TIMEOUT				

URL format

`dns://[host[:port]][/domain][[?rdn]?attr]`

Option

Description
<i>host</i> Specify the RMI registry name or address. The default name is localhost .
<i>port</i> Specify the RMI registry port number. The default port is 53 .
<i>domain</i> The domain is the DNS domain name of the context, and is not necessarily related to the domain of the server; it defaults to ". ", the root domain.
<i>rdn</i> The IP host name of the object to lookup
<i>attr</i> DNS resource record class and type names are mapped onto JNDI attribute identifiers. If a record is in the internet class, the corresponding attribute ID is simply the record's type name. If the type is an unsupported one, its integer value is used instead. If the record is not in the internet class, the class name or integer class value is pre-pended to the attribute ID and separated by a space.

For example, the attribute identifier "AAAA" represents an IPv6 address record, and the attribute identifier "HS 97" represents a resource record of type 97 in the **Hesiod** class.

Superclass attribute identifiers are also defined. These can be useful when querying records using the `DirContext.getAttributes()` method. If an attribute name has "*" in place of a type name or class name, it represents records of any type or class. For example, the attribute identifier "IN *" might be passed to the `getAttributes()` method to find all **internet** class records.

The default attribute identifier "* *" represents records of any class or type.

Attribute identifiers are case-insensitive.

Initial Context factory

If no Initial Context factory is specified on the command line, the following service provider is used:

`com.sun.jndi.dns.DnsContextFactory`

DNS Type Tree

The DNS implementation uses the following type tree.

When used as an input card, the **Results DNS** group should be selected. For all operations, the **Results DNS** group should be selected.

The meaning of each node is described below:

Name	Description
Field/Data	A single attribute value
Field/Name	A single attribute name
Field/RDN	A single entry name
Group/Attribute	A single attribute
Group/Entry	Represents a single entry
Group/Entries	Represents a collection of entries
Group/Value	Represents a collection of attributes
Results	Represents the output from a lookup operation

File system

JNDI offers a universal naming API and a standardized way to store objects in a namespace. The file system service provider supports these features for a local or networked file system. Its purpose is two-fold. It allows clients to:

- traverse the file system namespace using JNDI's context interface.
- store Java™ objects in the file system.

These two separate functions are handled by two different providers, that is, classes. The first class handles accessing the file system and can be used independently of the second. The second class handles storage of Java objects and is used with the first. It is a subclass of the first.

The adapter treats the **File** provider as a naming implementation.

- [**Operations supported**](#)
- [**Command line options supported**](#)
- [**URL format**](#)
- [**Initial Context factory**](#)
- [**Generic naming schema \(file system\)**](#)

Operations supported

The **File** provider supports the following operations:

Lookup	Add	Delete	Modify
✓	✓	✓	✓

Command line options supported

The following command line options are supported:

	Lookup	Add	Modify	Delete
TRACE	Optional	Optional	Optional	Optional
ICTXF	Optional	Optional	Optional	Optional
ICTXFURL	Required	Required	Required	Required
MAXHITS	Optional			
TIMEOUT				

URL format

`file:///qualified_file_name[?rdn]`

Option

Description

`qualified_file_name`

Specifies the file to be used as the root context. It must be a file URL representing a directory in the file system.

For example:

`file:///home/kafka`

This URL causes the provider to use the directory named `kafka` in the `home` directory of the root directory as the base context. Performing a `list()` on the initial context would be equivalent to typing the UNIX command `ls` in the `/home/kafka` directory. If this property is not set, it defaults to the root of the local file system.

`rdn`

The name of the file or object to lookup, add, delete or modify.

Initial Context factory

If no Initial Context Factory is specified on the command line, the following service provider is used:

`com.sun.jndi.fscontext.RefFSContextFactory`

It is expected that users will typically specify a different Initial Context Factory (`com.sun.jndi.fscontext.FSContextFactory`) which performs slightly differently. The default provider stores Objects on the file system. The optional provider provides access to the file system itself.

Generic naming schema (file system)

The **File** implementation uses the generic **Naming Repository** schema.

When used as an input card, the **Results JNDI** group should be selected. For all operations, the **Results JNDI** group should be selected.

The meaning of each node is described below:

Name

Description

Field/Data

Stores arbitrary input or output data

Field/Name

A single entry name

Field/Operation

Used to instruct the adapter to perform a modify, add or delete operation. Valid values are **add**, **modify**, **delete** and **replace**. **Replace** and **modify** are identical. If the adapter is being used in a `PUT` rule and no operation is specified, **modify** is assumed.

Group/Entry

Represents a single directory entry

Group/Entries

Represents a collection of entries

Group/Value

Contains the value or reference id of one entry

Results

Represents the output from a lookup operation

WebLogic

The WebLogic service provider allows JNDI applications to access remote objects registered with the WebLogic registry.

The adapter treats WebLogic as a naming implementation.

- [Operations supported](#)
 - [Command line options supported](#)
 - [URL format](#)
 - [Initial Context factory](#)
 - [Generic naming type tree \(WebLogic\)](#)
-

Operations supported

The **WebLogic** provider supports the following operations:

Lookup	Add	Delete	Modify
✓	✓	✓	✓

Command line options supported

The following command line options are supported:

	Lookup	Add	Modify	Delete
TRACE	Optional	Optional	Optional	Optional
ICTXF	Optional	Optional	Optional	Optional
ICTXFURL	Required	Required	Required	Required
MAXHITS				
TIMEOUT				

URL format

`t3://[host[:port]][/[object]][?rdn]`

Option	Description
<code>host</code>	Specify the WebLogic registry name or address. The default name is localhost .
<code>port</code>	Specify the WebLogic registry port number. The default port is 1099 .
<code>object</code>	If the object name is absent, then the URL names the registry at the given host and port. Otherwise, it names the remote object registered at that registry under the name provided.
<code>rdn</code>	The name of the object to lookup, add, delete or modify

Initial Context factory

If no Initial Context factory is specified on the command line the following service provider is used:

`weblogic.jndi.WLInitialContextFactory`

Generic naming type tree (WebLogic)

The WebLogic implementation uses the generic **Naming Repository** type tree.

When used as an input card, the **Results JNDI** group should be selected. For all operations, the **Results JNDI** group should be selected.

The meaning of each node is described below:

Name	Description
Field/Data	Stores arbitrary input or output data
Field/Name	A single entry name
Field/Operation	Used to instruct the adapter to perform a modify, add or delete operation. Valid values are add , modify , delete and replace . Replace and modify are identical. If the adapter is being used in a PUT rule and no operation is specified, modify is assumed.
Group/Entry	

	Represents a single directory entry
Group/Entries	Represents a collection of entries
Group/Value	Contains the value or reference id of one entry
Results	Represents the output from a lookup operation

Interoperability between JNDI adapter and other adapters

The Object Pool used by the JNDI Adapter is shared by some other adapters, notably the Java™ Class and JMS adapters. Objects created in one adapter can be passed by reference to another adapter.

The Object Pool is also useful for creating local Objects, such as Referenceable Objects. A Java class can have a method that returns an Object which is a Referenceable Object. This locally generated Object can be stored, for example, in an RMI registry by passing its reference id to the JNDI Adapters add or modify operation.

Objects retrieved from JNDI operations and stored in the pool usually need to be narrowed before they can be used outside of JNDI. Narrowing objects is beyond the scope of the JNDI Adapter since it might require external third-party software or services. For example, to narrow the result of a COS Naming operation, you need a fully initialized ORB.

Adapters that aim to share Objects with the JNDI Adapter should take this into account.

Binary data

The JNDI Adapter will not process any text/binary conversion. If binary data needs to be passed from a map to a JNDI service provider, it can be done in any supported way. For example, using a sequence of octets, or using a Base64-encoded string.

Example files

You can find an example of this adapter in the `tx_install_dir\examples\adapters` directory.

Memory Link Adapter

The Memory Link adapter is only used by the Launcher, and provides additional workflow support for Launcher watches to be triggered without traditional transformation adapters (such as file, MQ, or database adapters) and therefore does not add any file system, messaging, or database overhead. The watches can be triggered based on the outcome of other watches, and can also be used in **PUT** rules to trigger other watches. The Memory Link adapter has the ability to run watches inline, when the transactional handling of a watch might depend on another watch that is triggered by a Memory Link event.

Overview

Table 1. Memory Link adapter overview. The following table provides an overview of the Memory Link adapter:

Characteristic	Definition
Adapter Name	Memory Link
Description	This adapter provides additional workflow support and allows Launcher watches to be triggered without traditional adapters (such as file, MQ, or database adapters). The watches can be triggered based on the outcome of other watches, and can also be used in PUT rules to trigger other watches.
Business usage	The Memory Link adapter can queue a memory link trigger immediately during a PUT rule in a map, using the -NOW option. Additionally, you can configure input and output cards of a Launcher watch to use the Memory Link adapter. For output, you can use the Memory Link adapter in target cards, PUT rules, RUN map target cards, and RUN map PUT rules. Memory link outputs can trigger multiple watches if the watches are configured with the same memory link name source event.
Preconfigured?	The the adapter is installed with Transformation Extender. However, you add information to the config.yaml file before using the Memory Link adapter.
Requires third-party files?	No. All required components are shipped with the product.
Platform availability	<ul style="list-style-type: none"> • Windows • Linux®
Application requirements	This adapter requires Transformation Extender version 9.0.0.1 or later.
Invocation	This adapter can be invoked via the command line.
Returned status values	If a map fails, the failure is reported to the top watch map, which fails with the new error code 79 – Linked map failure.

Characteristic	Definition
Restrictions	<ul style="list-style-type: none"> You must define a memory link name as a single string for input cards, output cards, and PUT rules. Wildcard characters are not allowed in the memory link name. Valid characters for a memory link name are: <ul style="list-style-type: none"> o 0 - 9 o a - z o A - Z o dot (.) o dash (-) o underscore (_) The maximum length is 64 bytes, and another 63 bytes are reserved for wildcard and index values. An input memory link must be a source event and contain only the valid memory link name.
Testing considerations	<ul style="list-style-type: none"> Triggered maps must run sequentially inline. Maps should be queued to run concurrently if MaxThreads allow. Maps should be queued to run concurrently when using the PUT rule.

Memory Link configuration in the config.yaml file

The following section in the config.yaml file controls the Memory Link adapter.

```
runtime:
  Memory Link:
    # How many simultaneous active watches that write to memory link. Consider Initialize Pending maps that are
    # queued up to trigger along with InitPendingHigh setting in Launcher section. Default is 2000.
    ActiveTableSize: 2000
    # How many memory link instances per an active watch (each output card / PUT instance). Default is 5.
    UniqueTableSize: 5
```

The use of the **ActiveTableSize** and **UniqueTableSize** properties depends on the workflow and map design, but they increase automatically if needed.

ActiveTableSize

The number of Memory Link source events that are queued to run, including Initialize Pending maps.

UniqueTableSize

The number of unique Memory Link targets in a single Transformation Extender map instance.

PUT rule command line options

Use the following command line options when using the **PUT** rule with this adapter:

-SCOPE

The scope of the **PUT** command. Valid values are MAP and CARD.

-NOW

Trigger the **PUT** rule immediately.

MIME Adapter

This documentation introduces the Multipurpose Internet Mail Extensions (MIME) Adapter. You can use the adapter with a Command Server, Launcher, Software Development Kit, or map in a map rule.

- [MIME Adapter overview](#)
- [System requirements](#)
- [Command alias](#)
- [MIME commands](#)
- [Syntax summary](#)
- [Using the adapter](#)

MIME Adapter overview

Use the MIME Adapter to package, on output, and decode, on input, generic MIME messages.

The adapter does not handle the transporting of messages. Typically, SMTP is the transport of choice, but HTTP is another alternative.

The MIME Adapter is an encode and decode adapter. That is, it receives a stream of data, performs encoding or decoding and returns a stream of data. It is designed to be used with other adapters to transport the data.

Typical uses for this adapter include:

- **RosettaNet** - Full MIME support, including nested multipart messages, encryption and enveloping. The MIME Adapter can either be chained with a transport adapter such as HTTP or invoked through a **GET** function.
- **Multiple attachments for e-mail** - The MIME Adapter, when chained with the E-mail adapter provides a means to support multiple attachments.
- General MIME encoding and decoding for use with other transports such as HTTP.
- Generating unique IDs, using the **-GENID** command, for content IDs and other purposes.
- Calculating message digests, using the **-DIGEST** command.

System requirements

The minimum system requirements and operating system requirements for the MIME Adapter are detailed in the release notes. It is assumed that a Command Server has already been installed on the computer where the adapter is to be installed for run-time purposes.

Command alias

Adapter commands can be specified by using a command string on the command line or by creating a command file that contains adapter commands. The execution command syntax is:

```
-IM[alias] card_num  
-OM[alias] card_num
```

where **-IM** is the Input Source Override execution command and **-OM** is the Output Target Override execution command, *alias* is the adapter alias, and *card_num* is the number of the input or output card. The following table shows the adapter alias and its execution command.

Adapter	Alias	As Input	As Output
MIME	MIME	-IMMIMEcard_num	-OMMIMEcard_num

MIME commands

This documentation describes the functions and use of the MIME Adapter commands and their options.

- [List of commands](#)

List of commands

The following table lists valid commands for the MIME Adapter, the command syntax, and whether the command is supported (✓) for use with data sources, targets, or both.

The MIME Adapter can only be used in an input card if it is chained with a transport adapter.

Command	Syntax	Source	Target
Decode (-DECODE)	-DECODE	✓	
Encode (-ENCODE)	-ENCODE		✓
Generate ID (-GENID)	-GENID [filename]	✓	
Message Digest (-DIGEST)	-DIGEST [OPGP SMIME] [MD5 SHA1]	✓	
Session (-SESSION)	-SESSION alias(commands)	✓	✓
Trace (-T)	-T[E][+][filename]	✓	✓
Transport (-TRANSPORT)	-TRANSPORT 'adapter_name (adapter_command_line)'	✓	✓

- [Decode \(-DECODE\)](#)
- [Encode \(-ENCODE\)](#)
- [Generate ID \(-GENID\)](#)
- [Message Digest \(-DIGEST\)](#)
- [Session \(-SESSION\)](#)
- [Trace \(-T\)](#)
- [Transport \(-TRANSPORT\)](#)

Decode (-DECODE)

Use the Decode adapter command (-DECODE) to instruct the adapter to decode the MIME data into XML format. This is performed implicitly if the MIME Adapter is chained with a transport adapter in an input card.

-DECODE

For example, to decode MIME data received over HTTP:

```
GET ("MIME", "-DECODE -TRANSPORT 'HTTP (-URL http://myurl/ )'"")
```

The -DECODE option is optional since it is implied by the invocation of the MIME Adapter in an input card or GET function.

For more information on encoding and decoding data, see the Encoding and Decoding Data section in the *Resource Adapters documentation*.

Encode (-ENCODE)

Use the Encode adapter command (-ENCODE) to instruct the adapter to encode the XML data into MIME format. This is performed implicitly if the MIME Adapter is chained with a transport adapter in an output card.

-ENCODE

For example, to encode MIME data before transporting over HTTP:

```
PUT("MIME", "-ENCODE -TRANSPORT 'HTTP (-URL http://myurl/)'"
  MimeRequest )
```

The -ENCODE option is optional since it is implied by the invocation of the MIME Adapter in an output card or PUT function.

For more information on encoding and decoding data, see the Encoding and Decoding Data section in the *Resource Adapters documentation*.

Generate ID (-GENID)

Use the Generate ID adapter command (-GENID) to return a *unique* ID. Its primary purpose being for Content-ID attributes.

The command uses a file to track the current ID, and serializes access to this file. The file contains a single number which is incremented with each call to the adapter with the -GENID command.

The -GENID cannot be used with any other adapter commands.

This is an optional command.

-GENID [filename]

where *filename* is the file used to track the current ID. The *filename* is optional and if not specified, defaults to *install_dir\genid.dat*.

For example, to generate a unique ID for a Content-ID:

```
ContentID = "ContextSensitivestem" + GET("MIME", "-GENID"
  c:\genid.dat")
```

Message Digest (-DIGEST)

Use the Message Digest adapter command (-DIGEST) to obtain the message digest for the specified message. The MD5 and SHA1 message digests can be calculated. The syntax is:

-DIGEST [OPGP|SMIME] [MD5|SHA1]

where SMIME is the default adapter to invoke for backwards compatibility, and MD5 is the default algorithm.

This is an optional command.

If this command is specified in an input card, the message digest will be calculated and returned back to the map. The rules for specifying the algorithm parameter are:

- If the original message is signed and the algorithm is not specified, the algorithm that was used in signing the message will be used to calculate the digest.
- If the original message is not signed and the algorithm is not specified, MD5 shall be used.
- If the algorithm is specified, this algorithm shall be used regardless of the algorithm used to sign the message.

Session (-SESSION)

Use the Session adapter command (-SESSION) to specify encryption session commands. These commands are appended to any encryption commands provided in the data.

This is an optional command.

-SESSION alias (commands)

where *alias* is the alias of the encoder to invoke to perform encryption or other operations, and *commands* contains the commands to be passed to that adapter.

For example:

```
-SESSION SMIME (-USER marcel -PASSWORD **** )
```

It is possible to have multiple -SESSION commands on the command line, if multiple encoders need to be invoked.

For example:

```
-SESSION SMIME(-USER marcel) -SESSION OPGP (-USER marcel)
```

In an output card, if the mapped data contains parameters for these encoders, the values of the mapped data override those of the command line.

The commands specified in the -SESSION command are appended to those specified in the data.

- [Example](#)

Example

If the data passed to the MIME Adapter contains the following message part:

```
<MIME-Message-Part>
<Header>
Content-Type: application/pkcs7-mime
Content-Transfer-Encoding: base64
Content-Disposition: attachment; filename=something.p7m
Encryption: SMIME (-ENCODE -ACTION ENCRYPT)
</Header>
```

```
</MIME-Message-Part>
```

and the MIME Adapter is called with the following command line:

```
-SESSION SMIME(-USER marcel -PASSWORD ****)
```

the command line is appended to any occurrence of *Encryption: SMIME* in the MIME data, and the command sent to the SMIME encoder is:

```
-ENCODE -ACTION ENCRYPT -USER marcel -PASSWORD ****
```

Trace (-T)

Use the Trace adapter command (-T) to produce a diagnostics file that contains detailed information about MIME Adapter activity.

The default filename is **m4mime.mtr** and it is created in the map directory unless otherwise specified.

```
-T[E][+] [filename]
```

Option

Description
E
Produce a trace file containing only the adapter errors that occurred during map execution.
+
Append trace information to the existing trace file.
filename
Creates a trace file with the specified name in the specified directory

You can override the adapter command line trace options dynamically using the Management Console. See "Dynamic Adapter Tracing" in the *Launcher* documentation for detailed information.

Transport (-TRANSPORT)

Use the Transport adapter command (-TRANSPORT) to specify which transport adapter to use and the command line for the transport adapter.

The syntax of the command must include the single quotes and parentheses as shown below.

```
-TRANSPORT 'adapter_name ( adapter_command_line )'
```

Option

Description
adapter_name
Specify the transport adapter to use.
adapter_command_line
Specify the command line for the transport adapter. You must enclose this option within parentheses () .

For example, to specify the **HTTP** adapter as the transport adapter, and to send the MIME request to the **www.myws.com/DoWS** URL, enter the following command:

```
-TRANSPORT 'http (-URL http://www.myws.com/DoWS -T)'
```

Syntax summary

This documentation discusses the MIME Adapter syntax summary and how it is used.

- [Data sources](#)
 - [Data targets](#)
 - [Example](#)
-

Data sources

The following is the command syntax of the MIME Adapter commands used for data sources:

```
-SESSION alias ( commands )
[-TRANSPORT 'adapter_name (adapter_command_line)']
[-DECODE]
[-DIGEST [OPGP|SMIME] [MD5|SHA1]]
[-GENID [filename]]
[-T[E] [+]] [filename]
```

If the -GENID command is specified, no other commands can be used.

Data targets

The following is the command syntax of the MIME Adapter commands used for data targets:

```
-SESSION alias ( commands )
[-TRANSPORT 'adapter_name (adapter_command_line)']
[-ENCODE]
[-T[E] [+]] [filename]
```

See the Encode/Decode Scenarios section in the *Resource Adapters documentation* for more information about the -DECODE, -ENCODE and -TRANSPORT commands.

Example

For the GET->Source setting in an input card, select MIME. In the GET->Source->Command field, enter:

```
-DECODE -SESSION SMIME(-U 1121 -PW cat12 -UE 1121@foo.com) -T+
-TRANSPORT 'HTTP (-URL http://myurl.com -METHOD GET)'
```

This command specifies that:

- the input stream is MIME and therefore should be decoded (-DECODE)
 - if the data contains SMIME encrypted or signed data, the session defined by the -SESSION command should be used
 - the adapter trace should be appended to the **m4mime.mtr** file
 - the data passed to the MIME Adapter originates from the transport adapter (HTTP) by getting the document from the URL *http://myurl.com*. See the Encoding and Decoding Data section in the *Resource Adapters documentation* for more information on the -TRANSPORT command.
- The MIME Adapter can only be used in an input card if it is chained with a transport adapter.
-

Using the adapter

Use the MIME Adapter to package, on output, and decode, on input, generic MIME messages. The adapter does not handle the transporting of messages. A transport adapter, such as HTTP, performs this action.

The MIME Adapter uses S/MIME, OpenPGP or another encoder to encode parts of the message and to handle signatures. Hence, the adapter directly invokes the S/MIME, OpenPGP or another encoder for this purpose.

The MIME Adapter gets its instructions for encryption, decryption, signing and verifying from within the header of the message parts, and additionally from the -SESSION command line.

The data mapped to an output card includes commands for encryption in the <Header> element of the message part. The MIME Adapter invokes the specified encoder and passes the specified commands to that encoder. Typically, this encoder is either the S/MIME or OpenPGP adapter.

- [MIME structure](#)
 - [Representing MIME data in type trees](#)
 - [Using the type tree example](#)
-

MIME structure

The following documentation describes the format of a MIME message. The specification RFC 2046 should be consulted for full description of the MIME format.

- [MIME header fields](#)

- [Multipart messages](#)
-

MIME header fields

This section defines the fields used in MIME headers. MIME headers consist of the following fields:

- MIME Version Header field
 - Content-Type Header field
 - Content-Transfer-Encoding Header field
 - Content-ID Header field
 - Content-Description Header field
 - [MIME version header field](#)
 - [Content-type header field](#)
 - [Content-transfer-encoding header field](#)
 - [Content-ID header field](#)
 - [Content-description header field](#)
-

MIME version header field

The header field must be included in the MIME message:

```
MIME-Version: 1.0<CR><LF>
```

A comment might be included in the header field.

For example:

```
MIME-Version: (produced by John Doe) 1.0<CR><LF>
```

This comment can appear anywhere.

Content-type header field

This header field contains media-type and subtype values. The media type is the general type of the data, and the subtype is a specific format.

Media type can have the following values:

- text
- image
- audio
- video
- application
- message
- multipart
- x-* - where * can be any token

The values are *not* case sensitive.

The Content-Type header field can be followed by any number of attributes.

For example:

```
Content-Type: text/plain; charset=us-ascii <CR><LF>
```

The value of the attributes can be enclosed in double quotes.

If the Content-Type is not specified it defaults to:

```
text/plain, charset=us-ascii
```

Content-transfer-encoding header field

This header field defines the content encoding of the message.

Valid values include:

- 7bit
- 8bit
- binary
- quoted-printable

- base64
- x-* - where * represents any token

If not specified, the Content-Transfer-Encoding defaults to 7bit.

7bit, 8bit and binary indicate that NO encoding has been applied. "x-token" permits additional encoding schemes, but its use is discouraged by the standard (RFC 2045).

If this field is used in the message header, it applies to the entire body of the message. If it appears in an entity header, then it applies only to that entity. If an entity is of type *multipart* then the encoding can only have values of 7bit, 8bit or binary.

Content-ID header field

This header field uniquely identifies MIME entities in several contexts.

For example:

```
Content-ID: 123132
```

Content-description header field

This header field permits descriptive text to be included in the header..

For example:

```
Content-Description: this is my message.
```

Multipart messages

Of special interest are messages with a media-type *multipart*. These are messages that contain one or more different sets of data in a single body.

A multipart message consists of the following parts in the order listed here:

- **Header** - The Content-Type is *multipart*. A required parameter is *boundary* that defines the boundary parameter value. The boundary value can be enclosed in quotes. This is always good practice, but not required. It can not exceed 70 characters. The boundary value is used to delimit each part. By making this a parameter, an application can ensure that there is no chance that the boundary value appears in any of the entities of the message.
- **Preamble** - This is optional and can be ignored.
- **Boundary Delimiter** - This is two hyphens, the boundary parameter, optional whitespace and a CRLF terminator.
- **Message Part (Entity)** - The entity might include a header. If it does, then this header can only include fields that describe the content and which begin with "Content-". The header is followed by a blank line, and then the body.
- **Closing Delimiter** - This is two hyphens, the boundary parameter, two more hyphens, optional whitespace and a CRLF terminator.
- **Epilogue** - This is optional and can be ignored.

Here is a sample multipart message:

```
From: Nathaniel Borenstein <nsb@bellcore.com>
To: Ned Freed <ned@innosoft.com>
Date: Sun, 21 Mar 1993 23:56:48 -0800 (PST)
Subject: Sample message
MIME-Version: 1.0
Content-type: multipart/mixed; boundary="simple boundary"

This is the preamble. It is to be ignored, though it
is a handy place for composition agents to include an
Explanatory note to non-MIME conformant readers.

--simple boundary

This is implicitly typed plain US-ASCII text.
It does NOT end with a linebreak.
--simple boundary
Content-type: text/plain; charset=us-ascii

This is explicitly typed plain US-ASCII text.
It DOES end with a linebreak.

--simple boundary--

This is the epilogue. It is also to be ignored.
```

Representing MIME data in type trees

The MIME Adapter accepts a datastream and produces a corresponding MIME stream for an output card, it then parses a MIME stream and creates a decoded datastream for an input card.

This datastream could contain binary data that needs encoding, for example, using Base64 or Quoted-Printable encoding. In addition, parts or all of the stream might need to be secured, either through S/MIME or PGP encoding.

Therefore, the input stream needs to contain not only the data, but the processing instructions that determine what to do with the various message parts.

The format of this data is largely XML-based, however, since the adapter can represent binary data, it is not well-formed XML.

- [Message](#)
 - [Header](#)
 - [Message Parts](#)
-

Message

A typical message can include several encrypted and non-encrypted parts.

The top level message contains one or more parts. A message is represented in the stream in the following example.

```
<MIME-Message>
<Header>
...
</Header>
<Preamble>
</Preamble>
<MIME-Message-Part>
...
</MIME-Message-Part>
...
<MIME-Message-Part>
...
</MIME-Message-Part>
<Epilogue>
</Epilogue>
</MIME-Message>
```

The message always contains a `Header`. See "[Header](#)" for more information. But some of the fields of the header are optional. Following this is the `Preamble`, which can be omitted in its entirety. Following this are one or more `Message Parts`, and finally an optional `Epilogue`.

If the message is a simple single-part MIME message, then no `Preamble` or `Epilogue` is permitted, and the single message part cannot have a `Header`.

If a `Boundary` `Header` field is specified in a multipart message, then this is used as the `Boundary` value in the final MIME message.

If the message is a simple single-part MIME message, then no `Preamble` or `Epilogue` is permitted, and the single message part cannot have a `Header`. The data presented to the adapter for a single-part MIME message should have the following form:

```
<MIME-Message>
<Header>
...
</Header>
<Message-Part-Data>
This is my data
</Message-Part-Data>
</MIME-Message>
```

Notice that there are no `<MIME-Message-Part>...</MIME-Message-Part>` tags. The type tree `install_dir\examples\adapters\mime\mime.mtt` provided with the product can be used to create single-part data.

Header

The header can appear in the top-level message or the individual message parts. It is represented in the stream as follows:

```
<Header>
Content-Type: type; attr1="val1"; attr2="val2" ...
Content-Transfer-Encoding: base64 | quoted-printable
Encryption: SMIME(commands) | PGP(commands)
Content-ID: id
Content-Description: description
Extra-Header1: value1; attr1="val1"; attr2="val2" ...
Extra-Header2: value2; attr1="val1"; attr2="val2" ...
Boundary: OptionalTerminatingString
</Header>
```

The `<Header>` contains information about the content and the chosen encoding. The `Content-Type`, `Content-ID`, `Content-Description` and any additional header values, shown above as `Extra-Header1` and `Extra-Header2`, are copied without processing to the resultant MIME message.

Note that these can have any number of attributes. `Content-Transfer-Encoding` specifies an encoding scheme which is either Base64 or Quoted-Printable. The specified `Content-Transfer-Encoding` will be applied to the message data before any `Encryption` commands are applied to it.

The `Encryption` field instructs the MIME Adapter as to which adapter to invoke to perform data encryption. The encoding scheme might optionally be followed by parameters, (these are adapter commands that are passed directly to the adapter).

If the `Boundary` value is specified, it is added as an attribute of the `Content-Type` field in the resulting MIME message, and is used in the part delimiter of the multipart messages.

The adapter looks specifically for the following Content-Types:

- `application/pkcs7-mime` (encrypted or signed SMIME data)
- `multipart/signed` (a multipart message where the last part is a detached signature)
- `application/pkcs7-signature` (the message part is the detached signature)
- `application/pgp-encrypted` (PGP encrypted data)
- `application/pgp-signature` (PGP signed data)

It also looks for any Content-Type that begins with `multipart/` to determine if the resulting MIME message should have a multipart structure with boundary delimiters.

In the case that Content-Type is `application/pkcs7-mime`, the adapter checks the attributes of the Content-Type header field and looks for `smime-type=signed-data` or `smime-type=enveloped-data`. **Signed-data** indicates that the message has an encapsulated signature. **Enveloped-data** indicates that the message is encrypted and possibly signed. Otherwise, the Content-Type is not interpreted by the MIME Adapter.

Message Parts

Each part of the message is represented in the stream as follows:

```
<MIME-Message-Part>
<Header>
...
</Header>
<Message-Part-Data>
Size: 1234
(the data - can be binary or text)
OptionalTerminatingString
</Message-Part-Data>
</MIME-Message-Part>
```

The header is identical to the header used in the top-level message, but generally only uses the `Content-*` fields.

The data of the part is enclosed in the `<Message-Part-Data>` tags. This might begin with a size if the data is binary. The value of the size is given by a character integer value. The size is followed by a `CR/LF`. The data then follows. It can be terminated by a terminator that is specified in the header of the message part by the `Boundary` field. If this is not specified, then the terminator is `</Message-Part-Data>`, which is always present regardless of whether there is an additional terminator or not.

It is possible to nest message parts, which is required in contexts such as RosettaNet messages.

Using the type tree example

To access the adapter example files, navigate to `install_dir/examples/adapters`.

The data stream presented to the MIME Adapter to be encoded, or returned from the adapter when decoding MIME data, must comply to the type tree `mime.mtt` provided in the `examples` directory. The document element in this tree is the group `Message` which has the following components:

The `MessageHeader` group is an unordered collection of MIME header items. If the MIME message is a multi-part message then there will be one or more `MessagePart` groups. If the message is not multi-part then there will be no `MessagePart` groups, and the message data will be contained within the `MessageData Content` choice group.

A `MessagePart` consists of the following components:

The `Header` group is similar to the `MessageHeader` group but contains less components, since there are fewer relevant MIME header fields in an individual message part.

The `MessageData Content` is a choice group: the data contained within is either binary or text. If binary, the data is sized and the item `Sizeof` contains the size of the following binary item.

When the MIME Adapter decodes MIME data and returns it, the adapter fills in the `Sizeof` item with the correct size so that subsequent validation can determine the limits of the binary data. When using the `mime.mtt` type tree to build XML formatted input for the MIME Adapter, it is not necessary to map a value for the size, since the adapter will look for the `</Message-Part-Data>` delimiter to determine the end of the binary data.

The `NestedPart` group is used to build nested MIME data (such as is constructed by e-mail clients when messages are forwarded and the prior e-mail is attached).

The example maps in the `examples` directory show how this type tree can be used to build data to be encoded by the MIME Adapter and to decode MIME data.

MongoDB Adapter

Use the MongoDB adapter to create, read, update, and delete single or multiple JavaScript Object Notation (JSON) documents in a MongoDB database.

- [Type tree requirements](#)
To validate JSON documents fetched from a MongoDB collection, a map must use the MongoDB adapter and specify a JSON-based type tree on the input or output card.
- [Instance document formats](#)
A JSON instance document for a MongoDB collection can represent a single document in a collection or many documents in a collection. The MongoDB adapter supports both formats.
- [MongoDB adapter commands](#)
Use MongoDB adapter commands on input and output cards or GET and PUT functions to configure the adapter to create, read, update, and delete single or

multiple JSON documents in a MongoDB database.

Type tree requirements

To validate JSON documents fetched from a MongoDB collection, a map must use the MongoDB adapter and specify a JSON-based type tree on the input or output card.

To specify the type tree:

- Optimally, specify the file name of a native JSON document as the Type Tree on the input or output card. The native JSON parser in Design Studio uses the JSON document as the type tree during map compilation.
- Alternatively, you can use the JSON Importer in Design Studio to create a type tree (.mtt file) from a native JSON document, then specify the .mtt file as the Type Tree on the input or output card.

To create documents, you can use either:

- A JSON-based type tree.
- Any type that provides the entire JSON instance document.

MongoDB is a NoSQL database, so the documents in a MongoDB collection can have different fields and structures. Ensure that the JSON document you use as a type tree represents the documents in your collection.

Any document you insert into a MongoDB collection must be a JSON document.

Instance document formats

A JSON instance document for a MongoDB collection can represent a single document in a collection or many documents in a collection. The MongoDB adapter supports both formats.

Single document format

The format of an instance document (.json file) that represents a single document is similar to the following:

```
{  
    JSON-document-data  
}
```

For example:

```
{  
    Customer : Company X,  
    Location : Europe  
}
```

Multiple document format

It's common to have more than one document in a MongoDB collection. In this case, an instance document (.json file) includes more than one document in a JSON array. Each document in a JSON array is saved as separate document in the MongoDB collection. The format of the instance document is similar to the following:

```
[  
    {  
        JSON-document-data  
    },  
    {  
        JSON-document-data  
    }  
]
```

For example:

```
[  
    {  
        Customer : Company X,  
        Location : Europe  
    },  
    {  
        Customer : Company Y,  
        Location : North America  
    }  
]
```

Managing document formats

When the type tree of an input card represents single instance document, the **-SDF** command is required. The -SDF command indicates that the adapter is to send a non-array style, single JSON instance document to the map, even if the adapter fetches multiple documents. A single-document type tree cannot validate an array-style, multiple-document instance.

When the type tree of an output card represents single instance document, the -SDF command is required to ensure the adapter treats the instance as single document; otherwise, adapter errors occur when inserting documents into the MongoDB collection.

When you specify the -SDF command, the MongoDB adapter cannot transmit documents in array-style, multiple-document format.

By default, the MongoDB adapter processes instance documents as multiple-document arrays (multiple-document format). There is no corresponding command option.

When the type tree of an input card represents an array-style (multiple-document) instance document, the Native JSON parser can successfully process documents that are in either single-document format or multiple-document format. When the type tree of an output document represents an array-style instance document, the adapter can insert only documents that are in multiple-document format into a MongoDB collection.

MongoDB adapter commands

Use MongoDB adapter commands on input and output cards or GET and PUT functions to configure the adapter to create, read, update, and delete single or multiple JSON documents in a MongoDB database.

MongoDB adapter command alias

Use **MONGO** as the adapter command alias on input and output card overrides and in **GET** and **PUT** rules. For example:

Input source override execution command	-IAMONGO card_num
Output target override execution command	-OAMONGO card_num

Adapter commands

-HOST {hostname | MongoDB_URI}

-H {hostname | MongoDB_URI}

The host name or MongoDB URI (for example, `mongodb://localhost:27017/`) of the MongoDB server.

When you use the MongoDB URI, you can specify additional options for MongoDB client communication, such as enabling the client to use security based on certificates. Also, you can secure the user ID and password by using resource aliases for the **-USER** and **-PSWD** commands, and specify the `$user` and `$pswd` tokens on the URI. The user ID and password are dynamically resolved in the MongoDB URI during map execution.

This command is optional. If omitted, the default server is localhost.

-PORT port_num

-P port_num

The port number of the MongoDB server. This command is optional. If omitted, the default port number is 27017.

The **-PORT** command is ignored when you specify a MongoDB URI on the **-HOST** command.

-DATABASE db_name

-DB db_name

The name of the database on the MongoDB server.

-USER userID

-U userID

The user name or identifier that authenticates to the MongoDB server. Omit this keyword if user security is disabled on the server for connectivity.

-PASSWORD pwd

-PSWD pwd

The password of the user that authenticates to the MongoDB server. Omit this keyword if user security is disabled on the server for connectivity.

-COLLECTION collection_name

-C collection_name

The name of the MongoDB collection in the database to operate on.

-QUERY {"query_text" | file_URL}

-Q {"query_text" | file_URL}

The text of the JSON query that selects the documents to operate on, or the URL of a file that contains the query (for example, `file:///C:/myjsonquery.txt`). If the query contains spaces, enclose it in quotation marks. A relative URL is relative to the map directory.

-QTY

Specifies the number of documents that the adapter is to retrieve. In burst mode, the total number of documents that the adapter retrieves does not exceed the number specified by the **-QTY** command, although a single burst might return fewer documents. The **-QTY** command is optional. If you omit it, the default number of documents is 1.

-LSN

Specifies the amount of time, in seconds, that the adapter waits for a document to arrive. This command is optional. If you omit it, the adapter waits for an infinite amount of time. If a document does not arrive within the specified time frame:

- In Command Server mode, the adapter returns a warning.
- In Launcher mode, the Launcher continues to retry.

-NOW

Commits the transaction immediately instead of as defined by the Transaction Scope setting on the input or output card.

-SDF

Indicates that the JSON document is in single document format, rather than an array of documents. When you specify **-SDF**:

- A **GET** transaction returns only one document to the map, even when the adapter gets multiple documents.
- A **PUT** transaction writes only one document to the collection in the database.

-UPDATE

- Updates the documents that match the query with the data in the third argument of the **GET** function, then returns the documents to the map for further processing.

- Updates the documents that match the query with either the data in the output card or the data in the third argument of the **PUT** function, then adds the documents to the collection.

-DELETE

Deletes the documents that match the query from the collection.

-T [E | V] [+] *file_path*

The adapter trace level and full path to the adapter trace log.

-T

Log adapter informational messages.

-TE

Log only adapter errors during map execution.

-TV

Use verbose (debug) logging. The log file records all activity that occurs while the adapter is fetching or inserting documents.

+

Append the trace information to the existing log file. Omit this keyword to create a new log file.

MSMQ Adapter

You can use the MSMQ Adapter with a Command Server, Launcher, the Software Development Kit, or with a map in a map rule.

- [Overview](#)
- [MSMQ message content](#)
- [System and configuration requirements](#)
- [Command alias](#)
- [MSMQ commands](#)
- [Syntax summary](#)
- [MSMQ message header properties](#)
- [Troubleshooting](#)
- [Return codes and error messages](#)

Overview

The adapter for Microsoft Message Queue (MSMQ) servers integrates mapping technology with reliable data transactions provided by MSMQ servers. Business applications can reliably exchange data on distributed corporate networks. The resulting data conforms to the data format requirements of the target application.

For example:

- Use the Command Server to use MSMQ messages as input to a map and/or to build MSMQ messages as a result of data transformation rules within a map.
- Use the Launcher to execute systems of maps based upon the arrival of a message in an MSMQ server, or at the presence of specific message events or properties. Individual maps within the system then read the message content as input data.
- Use the Platform API to tightly integrate an application with source MSMQ messages or to create MSMQ messages.

MSMQ message content

The messages matching the criteria set by the correlation ID adapter command (**-CID**) or the Label adapter command (**-LABEL**), or the top-most messages on the queue are returned.

System and configuration requirements

In addition to any requirements in the release notes, the following are requirements to install and run the MSMQ Adapters:

The system executing maps must be a member of a configured MSMQ enterprise. The workstation upon which the MSMQ Adapters are installed must be an Intel or Intel-compatible platform using a supported Microsoft Windows operating system. See the system requirements.

Command alias

Adapter commands can be specified by using an execution command string on the command line or by creating a command file that contains adapter commands dictating the desired execution settings. For information about all of the options you can use with the execution commands for adapters or how to create a command file, see the *Execution Commands* documentation.

Use the Input Source Override - Message execution command (**-IM**) and the Output Target Override - Message execution command (**-OM**) with the appropriate MSMQ Adapter-specific alias. The execution command syntax is:

```
-IM[alias] card_num
-OM[alias] card_num
```

where **-IM** is the Input Source - Override execution command and **-OM** is the Output Target - Override execution command, **alias** is the adapter alias, and **card_num** is the number of the input or output card, respectively. The following table shows the adapter alias and execution commands.

Adapter	Alias	As Input	As Output
MSMQ	MSMQ	-IMMSMQcard_num	-OMMSMQcard_num

When using an adapter alias with the execution command, the MSMQ Adapter commands can be issued on the command line or in a command file. Use the adapter commands to specify adapter functions such as:

- specifying a particular message identifier
- allowing output data to be broken up into multiple messages
- retrieving a logical message from a source queue with a correlation identifier

For example, to override the adapter commands defined in output card 1, the command string for the adapter in the MSMQ environment might be:

```
-IMMSMQ1 '-QN .\topqueue -T'
```

This sample execution command string specifies a local queue named **topqueue** as the source for this card's data. The Trace command (**-T**) indicates that a trace file will be created to report adapter activity information, recording the events that occur while the adapter is retrieving this data.

- [GET > Source settings](#)
- [PUT > Target settings](#)

GET > Source settings

Use the Map Designer **GET** settings to configure options for input map cards using the MSMQ Adapters. Use the **GET > Source** setting to select the data source. For the **Source** setting, select MSMQ to use the MSMQ Adapter.

- [GET > Source > Command setting](#)
- [Source > Transaction > OnSuccess setting](#)
- [Source > Transaction > OnFailure Setting](#)
- [Source > Transaction > Scope setting](#)
- [Source > Transaction > Warnings setting](#)

GET > Source > Command setting

Use the **Command** setting to enter adapter commands. For command syntax, see [List of Commands](#).

Source > Transaction > OnSuccess setting

Use the **OnSuccess** setting with adapter sources to prevent deleting the source messages from the server from which the messages originate. The default value is **Keep**.

Value

Description

Keep

This keeps source messages on the server.

Delete

This deletes source messages following a successful map completion.

Source > Transaction > OnFailure Setting

Use the **OnFailure** setting with adapter sources to select the rollback or commit behavior if the map does not successfully complete. The default value is **Rollback**.

Value

Description

Rollback

If the map does not complete successfully, messages retrieved through the adapter are not deleted and the targets are not stored.

Commit

The adapter behaves as if the map was successful and the action specified by the **OnSuccess** setting (**Keep**) is taken.

Rollback is supported only when using a transactional queue.

Source > Transaction > Scope setting

Use the **Scope** setting to specify when to check for success (**OnSuccess**) or failure (**OnFailure**) at the completion of the processing of either a map, card, or burst. This is so that the rollback and retry actions can be performed as specified. The default value is **Map**.

Value

Description

Map	Check for success or failure at the completion of each map. If the map completes successfully, use the OnSuccess setting. If the map fails, use the OnFailure setting.
Burst	Check for success or failure at the completion of each burst. If the burst is successful, use the OnSuccess setting. If the burst fails, use the OnFailure setting.
Card	Check for success or failure at the completion of each card. If the card is successfully processed, use the OnSuccess setting. If the card fails, use the OnFailure setting.

Source > Transaction > Warnings setting

Use the **Warnings** setting to choose to fail the map or ignore warning conditions for the specific input map card. The default value is Ignore.

Value	Description
Ignore	Ignore warnings for this map card.
Fail	Fail the map upon receiving a warning for this map card.

PUT > Target settings

Use the Map Designer **PUT** settings to configure options for output map cards that use the MSMQ Adapter. Use the **PUT > Target** setting to select the data target. Select **MSMQ** to use the MSMQ Adapter.

- [PUT > Target > Command setting](#)
- [Target > Transaction > OnSuccess setting](#)
- [Target > Transaction > OnFailure setting](#)
- [Target > Transaction > Scope setting](#)
- [Target > Transaction > Warnings setting](#)

PUT > Target > Command setting

Use the **Command** setting to enter adapter commands. For command syntax, see [List of Commands](#).

Target > Transaction > OnSuccess setting

Use the **OnSuccess** setting with adapter targets to prevent a message from being created unnecessarily during the adapter process. The default value is Create.

Value	Description
Create	Upon successful completion of the burst, map, card, or rule determined by Scope settings, create the message.
CreateOnContent	Upon successful completion of the burst, map, card, or rule determined by Scope settings, create the message if the message body is not empty.

Target > Transaction > OnFailure setting

Use the **OnFailure** setting with adapter targets to select the rollback, which restore a previous version of the message, or commit behavior if the map does not complete successfully. The default value is Rollback.

Value	Description
Rollback	If the map does not complete successfully, the targets are not stored.
Commit	The adapter behaves as though the map was successful and the action specified by the OnSuccess setting (Create or CreateOnContent) is taken.

Target > Transaction > Scope setting

Use the **Scope** setting to specify when to check for success (**OnSuccess**) or failure (**OnFailure**) of a map, burst, or card in order to perform the rollback and retry options. The default value is Map.

Value	Description
Map	

Map

Check for success or failure at the completion of each map. If the map completes successfully, use the **OnSuccess** setting. If the map fails, use the **OnFailure** setting.

Burst

Check for success or failure at the completion of each burst. If the burst is successful, use the **OnSuccess** setting. If the burst fails, use the **OnFailure** setting.

Card

Check for success or failure at the completion of each card. If the card is processed successfully, use the **OnSuccess** setting. If the card fails, use the **OnFailure** setting.

Target > Transaction > Warnings setting

Use the **Warnings** setting to determine whether to fail the map or ignore warning conditions for the specific output map card. The default value is **Ignore**.

Value**Description****Ignore**

Ignore warnings for this map card.

Fail

Fail the map upon receiving a warning for this map card.

MSMQ commands

This section describes adapter commands used to configure and operate the MSMQ Adapters. When used with the Launcher, the MSMQ Adapters for sources or targets are configured using the Integration Flow Designer.

- [MSMQ Adapter commands](#)
- [Wildcard support](#)

MSMQ Adapter commands

The following table lists valid commands for the MSMQ Adapter, adapter command syntax, and if the adapter command is supported (✓) for use with data sources, data targets, or both.

Name	Syntax	Source	Target
Correlation ID (-CID) ¹	-CID <i>value</i>	✓	✓
Global Transaction Management (-GTX)	-GTX	✓	✓
Header (-HDR)	-HDR	✓	✓
Label (-LABEL)	-LABEL <i>message_label</i>	✓	✓
Listen (-LSN)	-LSN {0 S <i>wait_time_in_sec</i> }	✓	
Queue Name (-QN) ²	-QN <i>machine_name\queue_name</i> -or- -QN .\ <i>queue_name</i>	✓	✓
Quantity (-QTY)	-QTY { <i>value S</i> }	✓	
Trace (-T)	-T[E S] [<i>full_path</i>]	✓	✓
Transactional Queue (-TQ)	-TQ	✓	✓

¹The use of wildcards with this MSMQ Adapter command is supported. For more information about this support, see [Wildcard Support](#).

²For more information about specifying different kinds of queues, see [Queue Name \(-QN\)](#).

Wildcard support

The MSMQ Adapter supports the use of wildcards. Wildcards might be specified for either the Correlation ID adapter command (-CID) or the Label adapter command (-LABEL) on a single command line. The following rule for wildcards in the MSMQ Adapters applies:

An asterisk (*) represents a multi-character wildcard. The entire retrieved message is returned. If the wildcard is w*z and wxyz is returned, the wildcard * is expanded to xyz.

- [Correlation ID \(-CID\)](#)
- [Global Transaction Management \(-GTX\)](#)
- [Header \(-HDR\)](#)
- [Label \(-LABEL\)](#)
- [Listen \(-LSN\)](#)
- [Queue Name \(-QN\)](#)
- [Quantity \(-QTY\)](#)
- [Trace \(-T\)](#)
- [Transactional Queue \(-TQ\)](#)

Correlation ID (-CID)

Use the Correlation ID adapter command (-CID) to specify a particular correlation identifier (CID) for a source or target. Use this adapter command for a data source to retrieve messages from a queue with a specific correlation ID. You can also use it for a data target to assign a correlation ID to a message when placing it on a queue. To select a message with a specific correlation identifier, or to assign a specified value to a message for a data target, use the following syntax:

-CID *value*

Option

Description

value

Specify the application-defined correlation identifier. The value can be an alphanumeric string containing between 1 and 20 characters. For more information about the content and usage of MSMQ message properties, see the Microsoft MSMQ property definition PROPID_M_CORRELATIONID.

The MSMQ Adapters do not support Boolean operations on message properties other than AND. However, when a message to be mapped cannot be identified using the Correlation ID adapter command (-CID) and the Label adapter command (-LABEL) to specify the message identification properties PROPID_M_CORRELATIONID and PROPID_M_LABEL, additional message selection criteria can be performed using standard mapping techniques such as conditional mapping expressions, runtime functions, or functional maps.

When the Correlation ID adapter command (-CID) is specified on the command line of an output map card, the message is generated with the specified property.

Wildcards can be specified as the value for the correlation ID when running under the Launcher. See "[Wildcard Support](#)".

Global Transaction Management (-GTX)

Use the Global Transaction Management adapter command (-GTX) to indicate that the transactions for this card, whether input or output, should be processed as global transactions.

-GTX

For more information about global transaction management, see the *Global Transaction Management* documentation.

Header (-HDR)

Use the Header adapter command (-HDR) to receive or include MSMQ message properties with the body of the message. When the message stream includes data other than the message body, the additional data is referred to as the header. To include message properties other than the body of the message, use the header adapter command (-HDR).

-HDR

When the MSMQ Adapter is started without the Header adapter command (-HDR), the data consists only of the body of the message. A sample MSMQ type tree, named **msmq_in.mtt**, is provided in the **examples\adapters\msmq** folder. This type tree represents the content of the MSMQ message header properties. This type tree is configured to receive or set all properties and uses property names as identifiers that partition them into proper type groups.

When the MSMQ Adapter is started with the Header adapter command (-HDR) for a data source, the input to the map is automatically formatted as an array of records that includes all properties present in the messages being received, including the body.

When the MSMQ Adapter is started with the Header adapter command (-HDR) for a data target, the adapter searches for property identifiers in the data produced by the map and includes these properties in the MSMQ message output.

When the Header adapter command is specified, the body of the message is treated the same as any other property.

Usage of the Header command (-HDR) requires additional execution time and memory for the adapter to receive or set all of the message properties. Therefore, specifying the header command can affect performance. Performance depends upon the number of properties set on the received message.

Label (-LABEL)

Use the Label adapter command (-LABEL) to select a message using a specified message label value for a data source, or to create a message with a specified message label value for a data target. Use the following syntax:

-LABEL *message_label*

Option

Description

message_label

Specify the application-defined message label, that is represented in MSMQ with the property definition PROPID_M_LABEL. The value can be between 1 and 250 alphanumeric characters. If the value contains spaces it must be enclosed in double quotes.

When the Label adapter command (-LABEL) is used for a data source, it is a filter that selects messages from the queue based upon the message label properties. The MSMQ Adapters do not support Boolean operations on message properties other than AND. However, when a message to be mapped cannot be identified using the two

message identification properties, additional message selection criteria can be performed using standard mapping techniques such as conditional mapping expressions, runtime functions, or functional maps.

When the Label adapter command (-LABEL) is used for a data target, the message is generated with the specified filter property. Double quotation marks are not allowed in the LABEL value character string.

Wildcards might be specified for the value of the *message_label* when running under the Launcher. See "[Wildcard Support](#)".

Listen (-LSN)

Use the Listen adapter command (-LSN) for data sources to dictate the length of time (in seconds) that the MSMQ Adapters wait for one or more messages to be received. Map execution is suspended until the message is received or until the specified time lapses. The default value is S, meaning that the adapter waits indefinitely for a message to arrive in the queue.

```
-LSN {0|S|wait_time_in_sec}
```

Option**Description**

0

Do not wait at all. If there is no input available, the adapter does not wait for more messages.

S

This is an infinite wait time.

wait_time_in_sec

This is the number of seconds the adapter waits for a message

For example, to specify a wait time of 30 seconds, the syntax would be:

```
-LSN 30
```

Queue Name (-QN)

The Queue Name adapter command (-QN) is required for both data sources and data targets. Use the Queue Name adapter command (-QN) to identify the name of a specific MSMQ queue using the conventions for Microsoft MSMQ machine name and queue name.

```
-QN {. | machine_name } \queue_name
```

Option**Description**

.

This is a replacement for the local machine name.

machine_name

Specify a machine name.

queue_name

Specify a queue name.

In addition to the functionality described above, use this adapter command to support private queues and direct format names. Specify private queues using the following syntax:

```
-QN {. | machine_name } \PRIVATE$ \queue_name
```

where PRIVATE\$ specifies the usage of private queues. Private queues are registered on the local computer and not in the directory service.

- For MSMQ1.0, private queues are not registered in the MQIS SQL Server database.
- For MSMQ2.0, private queues are not registered in the Active Directory Services, which means that if MSMQ2.0 is used without Active Directory Services (Workgroup mode), private queues are the only supported queues.

Direct format names are supported, allowing specification of the queue name in the form.

If *queue_name* is specified using the direct format name and the queue is transactional, it is recommended that you specify the Transactional Queue (-TQ) adapter command. This command indicates to the adapter that this queue is transactional. If this command is not specified and the queue is transactional, the map might fail with the following error message:
The queue is not transactional

For public queues, use the following syntax:

```
-QN DIRECT=AddressSpecification\queue_name
```

For private queues, use the following syntax for a transactional queue:

```
-QN DIRECT=AddressSpecification\PRIVATE$ \queue_name -TQ
```

or the following syntax for a non-transactional queue:

```
-QN DIRECT=AddressSpecification\PRIVATE$ \queue_name
```

where AddressSpecification is one of the following:

SPX:MachineSPXNetworkAddress
(if SPX network protocol is used)

TCP:MachineIPNetworkAddress

(if TCP/IP network protocol is used)
An IP address can be IPv4 (for example, 1.2.3.4) or IPv6 (for example, a:b:c:d:0:1:2:3) format.

OS:MachineName

(where *MachineName* is the name of the machine recognized by the underlying operating system)

As indicated above, specify direct format names using **DIRECT=** preceding **AddressSpecification**.

Following below are examples of this syntax. The first example:

-QN DIRECT=SPX:00000012;00A0234F7500\Queue1 -TQ

specifies the transactional queue named **Queue1** on the machine with the SPX address **00000012;00A0234F7500**.

The next example:

-QN DIRECT=TCP:157.18.3.1\Queue2

specifies the queue named **Queue2** on the machine with an IP address of **157.18.3.1**. The adapter attempts to determine if this queue is transactional. If this effort is unsuccessful, the adapter assumes that this queue is not transactional because the **-TQ** adapter command was not specified.

The final example:

-QN OS:Jones\Queue3

specifies the queue named **Queue3** on the machine named **Jones** in the underlying operating system.

The transactional dead letter queue is specified as:

-QN machine_name;DEADXACT

or

-QN .;DEADXACT

for the local machine.

The non-transactional dead letter queue is specified as:

-QN machine_name ;DEADLETTER

or

-QN .;DEADLETTER

for the local machine.

Quantity (-QTY)

Use the Quantity adapter command (**-QTY**) to specify the number of messages to retrieve from the source queue. If the Quantity adapter command (**-QTY**) is not specified, the default value is 1.

-QTY {value|S}

Option

Description

S

This value returns all messages on the queue.

value

This is a positive integer representing the number of concurrent multiple messages to be retrieved.

For example, to specify a quantity of ten messages, the syntax would be:

-QTY 10

The Quantity adapter command (**-QTY**) defines the maximum number of messages across all bursts for a map.

When the Quantity adapter command (**-QTY**) is used, the message cursor is not returned to the head of the queue for other source cards in the same map using the identical queue.

The number of bursts in a single map execution can be controlled with the combination of values set in the Map Designer SourceRule...>FetchAs...>FetchUnit setting and the Quantity adapter command (**-QTY**).

When using the Quantity adapter command (**-QTY**) with the **S** option through either the Launcher or the Command Server, the Listen adapter command (**-LSN**) is also required with a value specified other than **S**.

Trace (-T)

Use the Trace adapter command (**-T**) to produce a trace file that contains information about connections to MSMQ, getting and putting messages on the queues, and MSMQ error codes.

The default filename is **msmqtrace.log** and it is created in the map directory unless otherwise specified. However, it is recommended that you specify that the trace file is created in a root directory, such as c:\ on Windows, because the adapter logs some events before the full path of an optional destination directory is known.

If the trace file does not already exist, it is created. If it already exists it is automatically appended.

-T[E|S] [full_path]

Option

Option	Description
E	Error mode. Produce a trace file containing only the adapter errors that occurred during map execution.
S	Summary mode. Use this option to reduce the size of the trace file. The summary trace file excludes polling information and function entries and exits-reporting only minimal information, such as the activity that occurs within a function when applicable.
full_path	Create a trace file with the specified name in the specified directory. By default, the directory is where the map is located and the file name is msmqtrace.log .

You can override the adapter command line trace options dynamically using the Management Console. See "Dynamic Adapter Tracing" in the *Launcher* documentation for detailed information.

Transactional Queue (-TQ)

Use the Transactional Queue adapter command (-TQ) to identify that a queue specified using the Queue Name (-QN) adapter command is transactional when the adapter cannot obtain this information internally from within the queue. If the adapter cannot obtain this information externally, as in when a remote private queue is accessed, it will search for specification of the -TQ adapter command to determine if the queue is transactional.

-TQ

When the -TQ adapter command is specified, the adapter will assume that the queue is transactional.

The MSMQ Adapter does not support transactional read from non-local remote queues, because it is not implemented by MSMQ. However, Microsoft provides a workaround for this feature which can be found at:

<http://msdn.microsoft.com/library/default.asp?URL=/library/backgrnd/html/msmqtips.htm>

Syntax summary

This documentation displays the syntax of the MSMQ Adapter commands for data sources and targets.

- [Data sources](#)
- [Data targets](#)
- [MSMQ maps](#)
- [MSMQ type trees](#)
- [Using the MSMQ type trees](#)

Data sources

The following is the syntax of the MSMQ Adapter commands used for data sources:

```
-QN machine_name\queue_name [-CID value]
[-LABEL value]
[-LSN {0|S} wait_time_in_sec]
[-QTY {value|S}]
[-HDR]
[-GTX]
[-T[E|S] [full_path]
[-TQ]]
```

Data targets

The following is the syntax of the MSMQ Adapter commands used for data targets:

```
-QN machine_name\queue_name [-CID value]
[-LABEL value]
[-HDR]
[-GTX]
[-T[E|S] [full_path]
[-TQ]]
```

MSMQ maps

The map source file (*install_dir/examples/adapters/msmq/msmq.mms*) contains seven maps that show how the MSMQ Adapter works.

Map1

The content of the **FileIn1.txt** source text file on the **TextFile** input card 1 maps to the message on the **.\queue1** MSMQ transactional queue (output card).

The **PUT->Target->Command** setting defined in the Map Designer for the **MSMQQueue** output card 1 is:

```
-QN .\queue1 -HDR -T
```

The Queue Name adapter command (-QN .\queue1) specifies that the data from the input card should be delivered as a message to the queue named **.\queue1**. The Header adapter command (-HDR) specifies inclusion of the message header properties other than the body of the message. These properties are LABEL (LABEL) and CORRELATION ID (CID). The Trace adapter command (-T) activates the adapter trace function to track function calls and to store them in a trace log file. The default log file name is **msmqtrace.log**.

Before you run the **Map1** map, be sure that the **.\queue1** transactional queue already exists or change the queue name in the **PUT->Target->Command** setting to some existing transactional queue. Purge the queue before you run the map.

The **MSMQQueue** output card 1, shown below, defines the message having the same content (message body) as the input file from the **TextFile** input card 1. The PROPID_M_CORRELATIONID message header property VT_CAB is defined as **CIDA**. The PROPID_M_LABEL message header property VT_LPSTR is defined as **LabelA**.

Run **Map1** and check the content of the **.\queue1** queue.

Results1

The queue now contains a message labeled **LabelA** with the following message body:

```
This sentence is a 46 bytes long message body.
```

Change Map1

Change the map rules for the **MSMQQueue** output card 1 for the PROPID_M_CORRELATIONID message header property VT_CAB component to CIDB and the PROPID_M_LABEL message header property VT_LPSTR component to **LabelB**. Run **Map1** again.

Results2

After you run **Map1** with the new map rules, the queue contains two messages. the first message with **LabelA** and **CIDA** and the new message with **LabelB** and **CIDB**.

Map2

Map2 maps a message from the **.\queue1** queue to both the **.\queue2** queue and a text file named **FileOut.txt**. **Map2** uses the two messages generated by **Map1**. These two messages are on the **.\queue1** queue. These messages have the PROPID_M_CORRELATIONID message header property VT_CAB = **CIDA** (first message) and **CIDB** (second message), and the PROPID_M_LABEL message header property VT_LPSTR = **LabelA** (first message) and **LabelB** (second message).

The GET>Source>Command setting for the **MSMQQueue1** input card 1 is:

```
-QN .\queue1 -LABEL LabelB -CID CIDB -HDR -T -LSN 5
```

The Queue Name adapter command (-QN .\queue1) specifies retrieval of messages on the queue named .\queue1. The Label adapter command (-LABEL LabelB) and the Correlation ID adapter command (-CID CIDB) specify retrieval of messages with the **LabelB** label and the **CIDB** correlation ID. The Header adapter command (-HDR) specifies retrieval of the message body and message header properties. The Trace adapter command (-T) enables tracing and tracks function calls and stores the trace information in the default file named **msmqtrace.log**. The Listen adapter command (-LSN 5) specifies a wait period of no more than five seconds for a message to arrive if that message is not already on the queue.

On the output side of the map are two cards. The first card specifies the **FileOut.txt** file. The second card specifies another MSMQ queue: .\queue2. The map specifies that all operations on the .\queue queue (input card) will belong to the transaction with a map scope (**OnFailure** = Rollback, **Scope** = Map) and that operations on the .\queue2 queue will not be in any transaction (**OnFailure** = Commit). This means that the .\queue2 queue can be a non-transactional queue.

Notice that the input card has an option (**OnSuccess** = Keep) that indicates that a copy of the message will remain on the source queue (.queue1).

The **MSMQQueue1** input card 1 has an **OnSuccess** setting of Keep, specifying that a copy of every message will remain on the .\queue1 source queue.

Run **Map2**.

Results1

Use the MSMQ Explorer to check the contents of .\queue2 queue. The message with the **LabelB** label is there. Both messages are still on the .\queue1 queue. In the **FileOut.txt** output file, notice that it contains the body of the received message.

Change Map2

Change the GET>Source>Command setting on the **MSMQQueue1** input card 1 to:

```
-QN .\queue1 -LABEL LabelA -HDR -T -LSN 5
```

Run **Map2** with this new GET>Source>Command setting.

Results2

The (**LabelA, CIDA**) message will be copied to the .\queue2 queue.

Map3

Map3 shows how to use the **PUT** function to place multiple messages on the queue. The **TextFile** input card 1 specifies a source text file named **FileIn2.txt** that contains the following structure:

```
This is Message 001  
This is Message 002  
This is Message 003  
This is Message 004  
...  
This is Message 099  
This is Message 100
```

Map3 uses these 100 text strings to create 100 messages on the queue named .\queue1 with labels entitled **Label001**, **Label002**, and so on, up to **Label100**.

The **MSMQQueue** output card 1 defines the **PUT>Target** setting as Sink, which means that there is no target. The Map Designer will execute the **PUT** function in the map rule of the **MSMQQueue** output card 1 for each occurrence of the **Body:TextFile** object. The Map Designer will call the MSMQ Adapter, which is specified as the first argument of the function "msmq". That means that this **PUT** function will execute 100 times-once for each message.

Non-printable characters are not displayed in the **Rule Bar**. They are represented in the Rule cell on the To window as a character.

The **File_In.MTT** type tree is specified for the **TextFile** input card as the data source. The type name is **File data**. The **Body** type is a component of **File** with a component range of S (some).

In the **TextFile** input card settings for **Map3**, the **GET>Source** setting is File. The **GET>Source>FilePath** setting is **FileIn2.txt**.

The first argument of the **PUT** function, "msmq", is the adapter alias that specifies the MSMQ Adapter.

The second argument of the **PUT** function is the adapter command plus the **RIGHT** function that returns a specified number of characters from a text expression beginning with the rightmost byte of a text item:

```
"-QN .\queue1 -T -LABEL Test001" + RIGHT(TEXT(Body:TextFile), 3)
```

The **RIGHT(TEXT(Body:TextFile), 3)** function takes the three right-most characters of the **Body** type on the input card named **TextFile**. For the first input string **This is Message 001**, the adapter command is:

```
-QN .\queue1 -T -LABEL Test001
```

For the second input string This is Message 002, the adapter command is:

```
-QN .\queue1 -T -LABEL Test002
```

And so on, concluding with the last message adapter command:

```
-QN .\queue1 -T -LABEL Test100
```

The third parameter of the `PUT` function specifies the content of the data message that is passed to the adapter. Because the Header adapter command (`-HDR`) is not specified, all data passed to the adapter should be treated as message bodies.

```
"<BODY>" + SYSTEM(13) + SYSTEM(10) + Body:TextFile + "</BODY>"  
+ SYSTEM(13) + SYSTEM(10)
```

The decimal value for a carriage return is 13. The decimal value for a line feed is 10. The carriage return and line feed are obtained using the `SYSTEM(13)` and `SYSTEM(10)` functions.

`<BODY><CR><LF>` is the literal initiator for the message body passed to the adapter and `</BODY><CR><LF>` is the literal terminator.

The `SYSTEM` function must be used because `<CR>` and `<LF>` are non-printable characters.

Before you run **Map3**, purge the `.\queue1` queue. Run **Map3**.

Results

The `.\queue1` queue will have 100 different messages.

Map4

Map4 uses burst mode to map multiple messages from one queue to another. Ten messages are transferred from the `.\queue1` queue to the `.\queue2` queue.

The `GET...Source...Transaction...OnSuccess` setting is `Delete`, specifying that the messages retrieved from the input queue will be deleted from that queue. The `SourceRule...FetchAs` setting is `Burst`, specifying retrieval of the messages in the burst units as specified in the `SourceRule...FetchUnit` setting. The `GET...Source...Command` setting is:

```
-QN .\queue1 -HDR -QTY 10 -LSN 3 -T
```

The Quantity adapter command (`-QTY 10`) specifies that ten messages should be retrieved from the `.\queue1` queue. The `FetchUnit` setting of 1 specifies that one message is retrieved per burst.

Before you run this map, `.\queue1` should contain at least 10 messages. You can run **Map3** to place 100 messages on it. These messages are needed to run **Map4**. Run **Map4**.

Results

Ten messages are transferred from the `.\queue1` queue to the `.\queue2` queue.

Map5

Map5 introduces some new features, including the ability to get more than one message per burst and using the `PUT` function to call adapter functions. **Map5** will attempt to map 105 messages from the `.\queue1` queue to the `.\queue2` queue. The `MSMQQueue` input card value for the `GET...Source` setting is `MSMQ`. The output card `Sink1` value for the `PUT...Target` setting is `Sink`, which is an empty output.

The Map Designer runs the `PUT` function on exit only for each appearance of the `MessageContainer` object on the input side, which is a component of the `ConcatenatedMessages` group type in the `Msmq_In.mtt` type tree.

The `Message` group type is a component of the `MessageContainer` group type. The `Message` group type contains one message with the literal message initiator value of `<MESSAGE><CR><LF>` and the literal message terminator value of `</MESSAGE><CR><LF>`. These initiators and terminators are for messages with more than one property, as opposed to the `<BODY><CR><LF>` initiators and terminators for messages with only body (content).

The `GET...Source...Command` setting for the `MSMQQueue` input card is:

```
-QN .\queue1 -HDR -QTY 105 -LSN 3 -T
```

The Quantity adapter command (`-QTY 105`) specifies retrieval of 105 messages from the `.\queue1` queue. The Listen adapter command (`-LSN 3`) specifies a wait period of not more than three seconds per burst. The Header adapter command (`-HDR`) specifies inclusion of all properties of the messages. The Trace adapter command (`-T`) specifies that function calls will be tracked in the `msmqtrace.log` file located in the map directory.

The map rule for the **Sink1** output card specifies the **PUT** function.

This map rule specifies the usage of the MSMQ Adapter. For each occurrence of the **MessageContainer** data object, extract the message label and message body from the input message and call the adapter function with the following adapter command:

```
-QN .\queue2 -T -LABEL label_constructed_from_input
```

Where *label_constructed_from_input* is the message label value constructed from the type values in the input card.

In the input card, the value of the **SourceRule**.>**FetchAs**.>**FetchUnit** setting is 10, specifying retrieval of ten messages per burst.

Before running **Map5**, purge the .\queue1 queue.

Results1

Attempt to run the map when the .\queue1 queue is empty. Because there are no messages on the .\queue1 queue, the adapter will wait for three seconds. After that, it will issue a warning. Because the input card **MSMQQueue** setting for the **Source**.>**Transaction**.>**Warnings** map setting is Fail, the warning will cause **Map5** to fail with the message **Source not available**. If you change the **Warnings** setting to Ignore, the map will run successfully.

Put messages on the queue

Run **Map3** to put 100 messages on the .\queue1 queue.

Run **Map5**.

Results2

Ten messages are retrieved from the .\queue1 queue ten times. These 100 messages are placed on the .\queue2 queue. An attempt will be made to retrieve five additional messages based upon the Quantity adapter command value (-QTY 105). Because there are no more new messages on the .\queue1 queue, the adapter will wait for three seconds (-LSN 3) and then it will give up. But this time, the warning is not issued. The map completes successfully, but only 100 messages are placed on the .\queue2 queue.

Map6

Map6 describes the use of response, administration, and dead letter queues. To run **Map6**, you must have three queues: **queue1**, **queue2**, and **queue3**. Note that **queue1** and **queue2** are transactional queues; **queue3** is non-transactional.

The **MSMQQueue** output card 1 defines placing a message on **queue1** having the same content (message body) as the input file from the **TextFile** input card 1. The PROPID_M_CORRELATIONID message header property VT_CAB is defined as **MyCID**. The PROPID_M_LABEL message header property VT_LPSTR is defined as **MyLabel**.

The output card uses the **Msmq_out_extended.mtt** type tree, which adds some message header properties and message header property variant types to the **Msmq_out.mtt** type tree used in previous map examples.

The following table describes properties for **Map6**:

Property

Specifies

PROPID_M_ACKNOWLEDGE

This is the type of acknowledgment messages that MSMQ posts in the administration queue when the message is sent:

MQMSG_ACKNOWLEDGMENT_NONE 0x00 MQMSG_ACKNOWLEDGMENT_POS_ARRIVAL 0x01 MQMSG_ACKNOWLEDGMENT_POS_RECEIVE 0x02
MQMSG_ACKNOWLEDGMENT_NEG_ARRIVAL 0x04 MQMSG_ACKNOWLEDGMENT_NEG_RECEIVE 0x08

PROPID_M_TIME_TO_REACH_QUEUE

This is the time limit, in seconds, for the message to reach the queue

PROPID_M_TIME_TO_BE_RECEIVED

This is the maximum length of time, in seconds, for a message to be received from the destination queue. This includes the time getting to the target queue and the time waiting in the queue before it is retrieved by an application.

PROPID_M_JOURNAL

This determines whether the message should be kept in a machine journal queue (on the originating machine), sent to a dead letter queue, or neither of the above.

PROPID_M_ADMIN_QUEUE

This is the queue used for MSMQ-generated acknowledgment messages.

PROPID_M_RESP_QUEUE

This is the queue to which application-generated response messages are returned.

PROPID_M_ACKNOWLEDGE is set to 8, representing the value MQMSG_ACKNOWLEDGMENT_NACK_RECEIVE. This means that notification is sent only when the message does not arrive at the **queue1** destination queue within the PROPID_M_TIME_TO_REACH_QUEUE-specified time of five seconds or that it arrives, but is not taken from the destination queue within the PROPID_M_TIME_TO_BE_RECEIVED-specified time of 50 seconds.

Notification messages are sent to **queue3**, which has been specified by PROPID_M_ADMIN_QUEUE as the administration queue. It is the user's responsibility to specify the queue to be used as the administration queue. The administration queue must be non-transactional.

The PROPID_M_JOURNAL property is set to 1—the value of the QMSG_DEADLETTER constant. This specifies that undelivered messages are to be placed on a dead-letter queue. MSMQ has the following two dead-letter queues:

- one for transactional messages (messages that are sent to a transactional queue) with a predefined name of **Xact Dead Letter**, and
- one for non-transactional messages (messages that are sent to a non-transactional queue) with a predefined name of **Dead Letter**.

Journal queues are used to track sent messages and to store report messages from MSMQ. Had PROPID_M_JOURNAL specified instead that the message be kept in a machine journal queue, MSMQ would have created a journal queue with the predefined name **Journal** in each machine added to the MSMQ enterprise and in each new queue.

The last property used in this type tree is PROPID_M_RESP_QUEUE. It is used to tell the receiving application to send a response message to the defined response queue (**queue2** in this example). The response queue can be either transactional or non-transactional.

Before you run the map, you must first create **queue1**, **queue2**, and **queue3**. Purge these queues to ensure they are clear of any old messages. You should also purge the **Xact Dead Letter** queue.

Run **Map6**.

Results

The message is placed on the **queue1** queue. If you go to the MSMQ Explorer quickly, you can see the **MyLabel** message on **queue1**. Right click on the message and select Properties. You will be able to see that **queue3** is the administration queue for this message and that **queue2** is the response queue.

After a few seconds, the message disappears from the queue. Because it was not received in 50 seconds, as specified in PROPID_M_TIME_TO_BE_RECEIVED, MSMQ will put the message onto the **Xact Dead Letter** queue. The **queue1** destination queue is transactional. If you right-click on this message in the **Xact Dead Letter** queue, the value of class property is Time to be received expired.

Because the administration queue has been specified, a copy of the **MyLabel** message will also be placed on the **queue3** administration queue.

Map7

Map7 explains how to use a map to read messages from dead letter queues. After **Map6** has been run, the **MyLabel** message has been placed on the **Xact Dead Letter** queue. **Map7** takes the message from this queue and stores its body to the **FileXact.txt** output file.

Similar to any other queue, dead letter queues are specified in adapter commands using the Queue Name adapter command (-QN). However, dead letter queues have a special naming convention. Each machine can have only one transactional dead letter queue and one non-transactional dead letter queue.

The transactional dead letter queue is specified as:

```
-QN machine_name;DEADXACT
```

or

```
-QN .;DEADXACT
```

for the local machine.

The non-transactional dead letter queue is specified as:

```
-QN machine_name;DEADLETTER
```

or

```
-QN .;DEADLETTER
```

for the local machine.

Because the **queue1** destination queue is transactional, the GET>Source>Command input card setting in **Map7** is:

```
-QN .;DEADXACT -HDR -T
```

Before you run **Map7**, you must first run **Map6**. **Map6** places the message on the dead letter queue that **Map7** is reading. Then run **Map7**.

The message from the **Xact Dead Letter** queue is mapped to the **FileXact.txt** file. Because the input card has the Source>Transaction>OnSuccess setting of Delete, the message will be removed from the queue after it has been received.

MSMQ type trees

Four MSMQ type trees are provided in the **examples\adapters\MSMQ** folder. These types describing different MSMQ message properties are provided so you can easily select the message types needed for input or output cards used in the Map Designer. Use a type tree appropriate for the data source. If the Header adapter command (-HDR) is not specified, the type tree representing the MSMQ message properties should not be used.

The **MSMQ_in.mtt** sample type tree should be used as a guide when creating new type trees to facilitate mapping of individual properties. This type tree is configured to receive or set all properties and it uses property names as identifiers that partition them into proper type groups. When setting or receiving individual message properties,

the type tree must define these properties exactly.

Using the MSMQ type trees

Depending upon how you want to map, either select one of the **Message** types as input or output or add a message content type as a **MessageData** component.

The type tree is arranged so you can integrate the definitions provided with any message data you want to define. The input card contains all message header properties. The output card contains only the message header properties you want. To optimize performance on the output card, select MSMQ_out.mtt and delete any unnecessary message header properties.

MSMQ message header properties

MSMQ message properties aid in identifying the message, routing the message, authenticating and signing the message, creating notifications, and tracing the message as it is being routed. MSMQ messages consist of message properties, each having its own name, type, value, and optional length.

Some MSMQ properties are of composite or aggregate type and thus have associated LEN (length) properties. Mapping of the LEN properties is not explicitly permitted. However, lengths are part of the record of the property to which the length belongs and are crucial to the mapping process.

An MSMQ property has a property ID that is an enumerated type representing the string of the property name. While MSMQ deals internally with the property IDs, property name strings are used to aid in mapping and tracing the mapping of properties. Each property has a variant type and a value.

- [MSMQ property variant type and values](#)
- [Message property definitions and values](#)

MSMQ property variant type and values

Each MSMQ property has a variant type and a value. There are five basic variant types:

- VT_CAB
 - VT_CLSID
 - VT_LPSTR
 - VT_UI1
 - VT_UI4
-
- [VT CAB](#)
 - [VT CLSID](#)
 - [VT LPSTR](#)
 - [VT UI1](#)
 - [VT UI4](#)

VT_CAB

This composite record type has a size field and a binary stream field. Except for PROPID_M_SECURITY_CONTEXT (cannot be received), PROPID_M_SENDERID, PROPID_M_MSGID and PROPID_M_SIGNATURE (cannot be set), all properties of this type can be used in mapping. MSMQ limits the size of PROPID_M_CORRELATIONID and PROPID_M_MSGID to 20 bytes. The adapter copies only the first 20 bytes in and out.

The following properties are in this group:

- PROPID_M_DEST_SYMM_KEY
- PROPID_M_SENDERID
- PROPID_M_BODY
- PROPID_M_MSGID (20 bytes fixed)
- PROPID_M_EXTENSION
- PROPID_M_SIGNATURE
- PROPID_M_CORRELATIONID (20 bytes fixed)
- PROPID_M_CORRELATIONID (20 bytes fixed)

VT_CLSID

This CLSID (GUID) record type is 16 bytes long. The adapter does not need a size field for this record because it is a fixed length field. It is critical that the data must be exactly 16 bytes long for proper input to MSMQ. The type tree should validate this.

The following properties are in this group:

- PROPID_M_CONNECTOR_TYPE
- PROPID_M_SRC_MACHINE_ID

VT_LPSTR

This is an ANSI string type. Properties of this type have an associated length property of type VT_UI4. The MSMQ Adapter performs conversions to UNICODE strings.

The MSMQ Adapter allows mapping of all properties of this type exclusive of PROPID_M_XACT_STATUS_QUEUE that cannot be set on an output card. The MSMQ Adapter expects the input data not to be null-terminated and depends upon the length record (four bytes). MSMQ limits the size of PROPID_M_LABEL to 250 characters and although the MSMQ Adapter does not place this limitation, the actual MSMQ property is set to the first 250 characters.

The following properties are in this group:

- PROPID_M_ADMIN_QUEUE
- PROPID_M_PROV_NAME
- PROPID_M_XACT_STATUS_QUEUE
- PROPID_M_DEST_QUEUE
- PROPID_M_RESP_QUEUE
- PROPID_M_LABEL (250 bytes max)

VT_UI1

This is an unsigned byte binary type. Properties of this type are assumed to be in their binary format when passed to and from the MSMQ Adapter. The proper type and conversion must take place. The adapter does not need a size field for this record because it is a fixed length field.

The following properties are in this group:

- PROPID_M_DELIVERY
- PROPID_M_ACKNOWLEDGE
- PROPID_M_TRACE
- PROPID_M_JOURNAL
- PROPID_M_PRIORITY

VT_UI4

This is an unsigned, four-byte binary type. Properties of this type are assumed to be in their binary format when passed to and from the MSMQ Adapter. The proper type conversion must take place.

The properties of this type that cannot be mapped are: PROPID_M_AUTH_LEVEL (cannot be received) and PROPID_M_SECURITY_CONTEXT (cannot be received). The adapter does not need a size field for this record because it is a fixed length field.

A number of time-stamping properties belong to this group. MSMQ time stamps are expressed in seconds since midnight of 01/01/1970 and the adapter returns data in this format. This release version includes runtime functions for conversion to and from this data format and a number of character and binary-based time formats. There are a few VT_UI2 properties that are returned as VT_UI4 (input card) and are property-casted to preserve the value.

When passing data on the output card, the user can create a new type with data that is two bytes long and the adapter correctly casts the data.

The following properties are in this group:

- PROPID_M_TIME_TO_BE_RECEIVED
- PROPID_M_AUTH_LEVEL
- PROPID_M_HASH_ALG
- PROPID_M_PROV_TYPE
- PROPID_M_APPSPECIFIC
- PROPID_M_TIME_TO_REACH_QUEUE
- PROPID_M_ENCRYPTION_ALG
- PROPID_M_PRIV_LEVEL
- PROPID_M_SECURITY_CONTEXT
- PROPID_M_BODY_TYPE

Message property definitions and values

The following general message properties can be set by the application. Length properties associated with another property are not included. The adapter converts normal strings to UNICODE when sending/receiving to/from MSMQ.

The following descriptions provide allowed values and, where appropriate, the hexadecimal values for the specific message property values. These values are present in the message header and are used when mapping message property data. This information is provided as a tool for mapping.

- [PROPID_M_ACKNOWLEDGE](#)
- [PROPID_M_ADMIN_QUEUE](#)
- [PROPID_M_APPSPECIFIC](#)
- [PROPID_M_BODY](#)
- [PROPID_M_BODY_TYPE](#)
- [PROPID_M_CONNECTOR_TYPE](#)
- [PROPID_M_CORRELATIONID](#)

- [PROPID_M_DELIVERY](#)
 - [PROPID_M_DEST_QUEUE](#)
 - [PROPID_M_EXTENSION](#)
 - [PROPID_M_JOURNAL](#)
 - [PROPID_M_LABEL](#)
 - [PROPID_M_PRIORITY](#)
 - [PROPID_M_RESP_QUEUE](#)
 - [PROPID_M_TIME_TO_BE_RECEIVED](#)
 - [PROPID_M_TIME_TO_REACH_QUEUE](#)
 - [PROPID_M_TRACE](#)
 - [PROPID_M_XACT_STATUS_QUEUE](#)
-

PROPID_M_ACKNOWLEDGE

This property specifies the type of acknowledgment messages that MSMQ posts in the administration queue when the message is sent.

Data format: Unsigned byte

Allowed Value	Hex Value
MQMSG_ACKNOWLEDGMENT_NONE	0x00
MQMSG_ACKNOWLEDGMENT_POS_ARRIVAL	0x01
MQMSG_ACKNOWLEDGMENT_POS_RECEIVE	0x02
MQMSG_ACKNOWLEDGMENT_NEG_ARRIVAL	0x04
MQMSG_ACKNOWLEDGMENT_NEG_RECEIVE	0x08

PROPID_M_ADMIN_QUEUE

This property specifies the queue used for MSMQ-generated acknowledgment messages.

Data format: Composite record with unsigned long integer size field, followed by zero-terminated UNICODE string up to 250 UNICODE characters long

Allowed values: Length of string in ULONG followed by string

PROPID_M_APPSPECIFIC

This property specifies an application specific index of values that can be used for sorting messages.

Data Format

Allowed Values

Unsigned long integer

Any application-specific index that fits in an unsigned long integer

PROPID_M_BODY

This property contains the body of the message and has PROPID_M_BODY_SIZE as an associated property.

Data Format

Allowed Values

Composite record with unsigned long integer size field, followed by variable-length byte stream of length given in size field

Length of byte stream in ULONG, followed by byte stream

PROPID_M_BODY_TYPE

This property indicates the type of body contained in the message.

Data format: Unsigned long integer

Allowed values:

- VT_EMPTY 0
- VT_NULL 1
- VT_I2 2
- VT_I4 3
- VT_R4 4
- VT_R8 5
- VT_CY 6
- VT_DATE 7

- VT_BSTR 8
- VT_DISPATCH 9
- VT_ERROR 10
- VT_BOOL 11
- VT_VARIANT 12
- VT_UNKNOWN 13
- VT_DECIMAL 14
- VT_I1 16
- VT_UI1 17
- VT_UI2 18
- VT_UI4 19
- VT_I8 20
- VT_UI8 21
- VT_INT 22
- VT_UINT 23
- VT_VOID 24
- VT_HRESULT 25
- VT_PTR 26
- VT_SAFEARRAY 27
- VT_CARRAY 28
- VT_USERDEFINED 29
- VT_LPSTR 30
- VT_LPWSTR 31
- VT_FILETIME 64
- VT_BLOB 65
- VT_STREAM 66
- VT_STORAGE 67
- VT_STREAMED_OBJECT 68
- VT_STORED_OBJECT 69
- VT_BLOB_OBJECT 70
- VT_CF 71
- VT_CLSID 72
- VT_VECTOR 0x1000
- VT_ARRAY 0x2000
- VT_BYREF 0x4000
- VT_RESERVED 0x8000
- VT_ILLEGAL 0xffff
- VT_ILLEGALMASKED 0xffff
- VT_TYPEMASK 0xffff

PROPID_M_CONNECTOR_TYPE

This property specifies the application connector type the message is using.

Data Format

Allowed Values

16-byte byte stream

16-byte byte stream

This must be exactly 16 bytes.

PROPID_M_CORRELATIONID

This property specifies the correlation identifier of the message.

Data Format

Allowed Values

Composite record with unsigned long integer size field, followed by variable-length byte stream of length given in size field up to 20 bytes

Length of byte stream in ULONG, followed by byte stream

PROPID_M_DELIVERY

This property specifies how the message is delivered.

Data Format	Allowed Values	
Unsigned byte	MQMSG_DELIVERY_EXPRESS	0
Unsigned byte	MQMSG_DELIVERY_RECOVERABLE	1

PROPID_M_DEST_QUEUE

This property specifies the target queue of the message and has PROPID_M_DEST_QUEUE_LEN as associated property.

Data Format

Allowed Values

Composite record with unsigned long integer size field, followed by zero-terminated UNICODE string up to 250 UNICODE characters
Length of string in ULONG, followed by string

PROPID_M_EXTENSION

This property provides a place to put additional information associated with a message and has PROPID_M_EXTENSION_LEN as associated property.

Data Format

Allowed Values

Composite record with unsigned long integer size field, followed by variable-length byte stream of length given in size field
Length of byte stream in ULONG, followed by byte stream

PROPID_M_JOURNAL

This property specifies if the message should be kept in a machine journal on the originating machine, sent to a dead letter queue, or no action should be taken.

Data Format	Keyword	Value
Unsigned byte	MQMSG_JOURNAL_NONE	0
Unsigned byte	MQMSG_DEADLETTER	1
Unsigned byte	MQMSG_JOURNAL	2

PROPID_M_LABEL

This property specifies a label of the message and has an associated PROPID_M_LABEL_LEN.

Data Format

Allowed Values

Composite record with an unsigned long integer size field, followed by zero-terminated UNICODE string up to 250 UNICODE characters
Length of string in ULONG, followed by string

PROPID_M_PRIORITY

This property specifies the message priority. A low number indicates low priority.

Data Format	Keyword	Values
Unsigned byte	MQ_MIN_PRIORITY	0 through 7
Unsigned byte	MQ_MAX_PRIORITY	0 through 7

PROPID_M_RESP_QUEUE

This property specifies the queue to which application generated response messages are returned. It has an associated PROPID_M_RESP_QUEUE_LEN property.

Data Format

Allowed Values

Composite record with unsigned long integer size field, followed by a zero-terminated UNICODE string up to 250 UNICODE characters
Length of string in ULONG, followed by string

PROPID_M_TIME_TO_BE_RECEIVED

This property specifies the total time, in seconds, that the message is allowed to live. This includes the time getting to the target queue and waiting in the queue before it is retrieved by an application.

Data Format

Allowed Values

Unsigned long integer
Time in seconds

PROPID_M_TIME_TO_REACH_QUEUE

This property specifies a time limit, in seconds, for the message to reach the queue.

Data Format

Allowed Values

Unsigned long integer
Time in seconds

PROPID_M_TRACE

This property specifies where report messages are sent when tracing a message.

Data Format	Keyword	Value
Unsigned byte	MQMSG_TRACE_NONE	0
Unsigned byte	MQMSG_SEND_ROUTE_TO_REPORT_QUEUE	1

PROPID_M_XACT_STATUS_QUEUE

This property identifies the transaction status queue on the source computer. This has an associated PROPID_M_XACT_STATUS_QUEUE_LEN property.

Data Format

Allowed Values

Composite record with unsigned long integer size field, followed by a zero-terminated UNICODE string up to 250 UNICODE characters
Length of string in ULONG, followed by string

Troubleshooting

For information about error codes and messages returned by the adapters, see [Return Codes and Error Messages](#).

Troubleshooting for the MSMQ Adapter includes the following:

- using the trace file generated with the Trace adapter command
- confirming your login permissions
- using transactional messages in a non-transactional queue
- [Trace log](#)
- [Error returned to engine \(-5\)](#)

Trace log

The Trace adapter command creates an internal trace file that records all of the input commands, called functions, found messages, and return values from all called functions. This data is recorded in the **msmqtrace.log** file located in the directory where the compiled map resides.

Error returned to engine (-5)

The following audit execution log file message

Error returned to engine: (-5) Could not open queue, MSMQ error MSMQerror_code

can be generated for different reasons:

- login permissions not established for you
Login permissions can be set at the server and corresponding queue object level. Whatever you have used as a login ID does not match the respective setting, disallowing your access to the queue.
The Launcher uses the `system` login ID as a default. You might need to change the Microsoft Windows control panel **Services** settings.
- transactional messages on non-transactional queues
You are trying to put or get a transactional message to or from a non-transactional queue.

If you are having trouble doing a `PUT` and the log file indicates that the properties are correctly set, make sure the property you are trying to set does not involve a resource that you do not have or that you are referencing incorrectly. For example, you might reference an encryption algorithm that is not supported on the other end or you might have a sender security certificate that must be validated against an external certificate authority that is not properly configured.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages might also be recorded as specified in the audit logs, trace files, execution summary files, and so forth.

- [Messages](#)

Messages

The following is a listing of all the codes and messages that can be returned as a result of using the MSMQ Adapter for sources or targets.

In addition to the following return codes, the MSMQ Adapter can return MSMQ error codes. Consult the MSMQ documentation for descriptions of these codes.

Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Return Code	Message
-1001	Trace file could not be accessed
-1002	Adapter command is incorrect
-1003	Failed to load and initialize MSMQ library
-1004	Queue could not be opened
-1005	Message could not be stored on the queue
-1006	Message could not be retrieved from the queue
-1007	Transaction could not be rolled back explicitly
-1008	Transaction could not be committed
-1009	Queue could not be closed
-1010	Invalid message format
-1011	Transaction monitor not supported
-1012	Problem occurred on the queue cursor
-1013	New transaction could not be started
-1014	Queue path could not be translated to the format name
-1015	Machine name could not be translated to the machine GUID
-1016	Transaction usage was required for a non-transactional queue

Microsoft SQL Server Adapter

This documentation discusses the Microsoft SQL Server Adapter. You can use the adapter with the Command Server, Launcher, Software Development Kit, or with a map in a map rule.

- [Overview](#)
- [System requirements](#)
- [Database columns and types](#)
- [Database Interface Designer settings](#)
- [Microsoft SQL Server Adapter commands](#)
- [Extensions for the Launcher](#)
- [Bulk copy example files](#)
- [Restrictions and limitations](#)
- [Return codes and error messages](#)

Overview

Use a Microsoft SQL Server Adapter for Windows to access and manipulate data contained in databases that are Microsoft SQL Server data sources. You can also install this adapter on additional systems for remote database connectivity.

System requirements

In addition to any requirements in the release notes, to install and run the Microsoft SQL Server database adapter on your Windows platform:

- Verify that you have installed Microsoft SQL Server or Server Client Utilities. For information about this, see your Microsoft SQL Server documentation.
- Set the following optional environment variables that can be used to satisfy the requirements for particular situations:
 - DTX_LOCALE_CHARSET
 - DTX_TEMPDB
 - DTX_SQLSVR_CONN_LIMIT
- [DTX_LOCALE_CHARSET](#)
- [DTX_TEMPDB](#)
- [DTX_SQLSVR_CONN_LIMIT](#)

DTX_LOCALE_CHARSET

Set the DTX_LOCALE_CHARSET environment variable to enable the usage of non-English characters in data. If not defined, the default character set of the locale is used. Generally, most western characters can be used if this environment variable is set to **ISO_1**, which is an alias for the **ISO88959-1** character set. For information about supported character sets, see your Microsoft SQL Server documentation.

DTX_TEMPDB

By default, the database adapter creates temporary stored procedures in the tempdb database. If you decide to use this default database, your database administrator should create a SQL script to be executed upon server startup, granting create and execute procedure permissions. If you decide to change this default database, you can set the DTX_TEMPDB environment variable to another database. For example, if you set it to mytmpdb, the database adapter will create temporary stored procedures in mytmpdb.

DTX_SQLSVR_CONN_LIMIT

By default, Microsoft SQL Server allows twenty-five simultaneous connections. If this is insufficient because of the need to simultaneously execute a large number of maps, the limit can be increased by defining the DTX_SQLSVR_CONN_LIMIT environment variable. For example, if you set it to 100 (DTX_SQLSVR_CONN_LIMIT=100), you would allow up to 100 connections.

Database columns and types

The Microsoft SQL Server Adapter is used with the Database Interface Designer to generate type trees for queries, tables, views, and stored procedures in a Microsoft SQL Server relational database management system (RDBMS). Item types are created in a type tree that represent the data types of the columns of a query, table, view, or stored procedure.

The Database Interface Designer gets information about columns by calling Microsoft SQL Server to describe the columns associated with a query, table, view, or stored procedure. Microsoft SQL Server returns the data type, length and other information to the Database Interface Designer. The Microsoft SQL Server data types are then mapped to types in a type tree.

- [Item type properties](#)
- [Date and time formats](#)

Item type properties

The following table lists the Microsoft SQL Server data types and the values of the item type properties to which they correspond when the type tree is generated.

Microsoft SQL Server Data Type	Interpret as	Item Subclass, Presentation	Length
BINARY	Binary	Text	*
CHAR	Character	Text	*
DATETIME	Character	Date & Time	23
DECIMAL(n) ¹	Character	Number, Integer	*
DECIMAL(n,m) ²	Character	Number, Decimal	*
FLOAT	Binary	Number, Float	8
IMAGE	Binary	Text	*
INT	Character	Number, Integer	11
MONEY	Character	Number, Decimal	17
NUMERIC(n) ¹	Character	Number, Integer	*
NUMERIC(n,m) ²	Character	Number, Decimal	*
REAL	Binary	Number, Float	4
SMALLDATETIME	Character	Date & Time	19
SMALLINT	Character	Number, Integer	6
SMALLMONEY	Character	Number, Decimal	17
TEXT	Character	Text	*
TIMESTAMP	Binary	Text	8
TINYINT	Character	Number, Integer	4
VARBINARY	Binary	Text	*
VARCHAR	Character	Text	*

¹ n ≥ 1

² n ≥ 1, m ≥ 0

* The DBMS dictates the length of this type.

Date and time formats

When using columns defined as **datetime** or **smalldatetime** in Microsoft SQL Server databases, the format for both input and output is:

datetime:

ccyy-mm-dd hh:mm:ss.fff

smalldatetime:

ccyy-mm-dd hh:mm:ss

where

cc	=	a two-year century
yy	=	a two-digit year
mm	=	a two-digit month
dd	=	a two-digit day
hh	=	a two-digit hour
mm	=	a two-digit minute
ss	=	a two-digit second
fff	=	fractional seconds

An example is 2001-08-27 00:00:00.000 which specifies August 27, 2001.

In the Generate Type Tree from dialog box, use the **Represent date/time columns as text items** check box to define whether to automatically format this information as Date & Time (which is with this check box disabled, the result of which is shown in the **Item Subclass, Presentation** column above) as a text string. When generated as a text string, it might be necessary to use either the **TEXTTODATE** or **TEXTTOTIME** function in a map rule to convert the text string to the date and time format required by the database. If you are generating new type trees, it is recommended that you disable this check box.

This **Represent date/time columns as text items** check box is modal. After it has been disabled, it will remain disabled for all subsequent type tree generations, regardless of source. Therefore, you must be careful in determining this setting.

Database Interface Designer settings

When you define a Microsoft SQL Server database in the Database Interface Designer, in addition to the common settings available for all the database adapters in the **Database** Definition window, you must enter the information specific to Microsoft SQL Server.

- [Database definition dialog](#)
- [Stored procedures native call syntax](#)

Database definition dialog

The Microsoft SQL Server Adapter-specific settings are described in the following table.

Setting			Description
Security			
	User ID		The user ID used to connect to the database
	Password		The authorization password to connect to the database
Data Source			
	Database Interface Designer		
		Server	The name of the Microsoft SQL Server that hosts the database to be accessed by the Database Interface Designer for design-time purposes
		Database	The name of the database to be accessed by the Database Interface Designer for design-time purposes
	Runtime		
		Server	The name of the Microsoft SQL Server that hosts the database to be accessed for runtime (map execution) purposes both from the Map Designer and a Command Server
		Database	The name of the database to be accessed for runtime (map execution) purposes both from the Map Designer and a Command Server

To specify a server, instance, and database combination (for example, to specify a Microsoft SQL Server 2005 database), enter *server_name\instance_name* in the Server field and *database_name* in the Database field.

Stored procedures native call syntax

A stored procedure can be accessed from within a map by specifying the native call syntax in the following:

- a query that is specified in an input card
- the first argument in a DBQUERY or DBLOOKUP function
This argument does not need to be a literal. The arguments to the stored procedure might be determined at map execution time.
- the SQL Statement adapter command (-STMT) in DBQUERY, DBLOOKUP, or GET functions

For information about using DBLOOKUP or DBQUERY, see database functions in the *Database Interface Designer* documentation. For information about using the syntax for device-independent calls to access return values and output adapter commands, see stored procedures in the *Database Interface Designer* documentation.

For example, a call to a stored procedure using Microsoft SQL Server in a DBLOOKUP might be:

```
DBLOOKUP      ("exec MyAddNameProc(' " + Name:Column + " ',-1)",
    "mydb.mdg",
    "MyDB")
```

String literals must be contained within single quotation marks. Adapter arguments must be separated by commas.

Microsoft SQL Server Adapter commands

This documentation describes the functions and usage of the Microsoft SQL Server Adapter commands and their options.

- [Adapter command summary](#)
- [Adapter commands for a source](#)
- [Adapter commands for a target](#)

Adapter command summary

The following is a summary of the adapter commands that can be used to specify data sources and targets. The applicability of many of the commands depends upon whether you are specifying a source or target, whether a database or query file (.mdq) is used, and the situations in which the usage of the command applies. Adapter commands can be used in GET,>Source,>Command or PUT,>Target,>Command settings in the Map Designer and Integration Flow Designer, using GET, PUT, DBLOOKUP, or DBQUERY function calls, or overriding a data source or target using execution commands in a RUN function or on the command line.

- [Adapter-specific command list](#)

Adapter-specific command list

The following sections describe those adapter commands that are Microsoft SQL Server-specific database parameters. For a complete listing of all adapter commands, see the *Resource Adapters* documentation.

- Database Adapter Type (-DBTYPE)
- Data Source Adapter Command (-SOURCE)
- Trigger Adapter Command (-TR or -TRIG)
- [Database Adapter Type \(-DBTYPE\)](#)
- [Data Source adapter command \(-SOURCE\)](#)
- [Trigger adapter command \(-TR or -TRIG\)](#)

Database Adapter Type (-DBTYPE)

Use the Database Adapter Type adapter command (-DBTYPE) to specify the database adapter type.

```
-DBTYPE SQLSVR
```

This command must be specified if the original card is not a database and no database is specified using the Database/Query adapter command (-MDQ) and the Database Name adapter command (-DBNAME).

Option	Description
SQLSVR	The database adapter type is Microsoft SQL Server.

Data Source adapter command (-SOURCE)

Use the Data Source adapter command (-SOURCE) to specify the Microsoft SQL Server data source.

```
-SOURCE server\\database
```

Option	Description
server\database	Specify the Microsoft SQL Server data source.

Trigger adapter command (-TR or -TRIG)

Use the Trigger adapter command (-TR or -TRIG) to specify the trigger string containing the options defined for a trigger specification.

-TRIG trigger_string

Option	Description
trigger_string	Specify the trigger string containing the options defined for a trigger specification.

Adapter commands for a source

This summary shows the syntax of the adapter commands that can be used when defining a data source using an **.mdq** file or without using one, including both the required and optional adapter commands in the following situations:

- using the **GET>Source>Command** setting in the Map Designer and Integration Flow Designer
- overriding a data source using the Input Source Override - Database execution command (-ID) using a **RUN** function or on the command line
- using a **DBLOOKUP**, **DBQUERY**, or **GET** function in map or component rules
- [GET>Source>Command setting](#)
- [-ID execution command](#)
- [DBLOOKUP or DBQUERY functions](#)
- [GET Function](#)

GET>Source>Command setting

Use the Map Designer or Integration Flow Designer to specify **Database** as the value for the **GET>Source** setting and enter the database adapter commands as desired for the **Command** setting.

With Database/Query File	Without Database/Query File
[-DBTYPE SQLSVR]	-DBTYPE SQLSVR
[-SOURCE server\database]	-SOURCE server\database
[-STMT SQL_statement]	-STMT SQL_statement
[-FILE [directory]]	[-FILE [directory]]
[-VAR name=value...]	[-VAR name=value...]
[-TRIG trigger_string]	[-TRIG trigger_string]
[-USER user_ID]	[-USER user_ID]
[-PASSWORD password]	[-PASSWORD password]
[-CSTMT [number]]	[-CSTMT [number]]
[-GTX]	[-GTX]
[-AUDIT[G][+] [full_path]]	[-AUDIT[G][+] [full_path]]
[[-TRACE]-TRACEERR[+][full_path]]	[[-TRACE]-TRACEERR[+][full_path]]

-ID execution command

Use the Input Source Override - Database execution command (-ID) to designate a database as the source or you can override one or more of the adapter command settings or database definitions in a **RUN** function or on the command line.

Adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

- [The source in the compiled map is a database](#)
- [The source in the compiled map is not a database](#)

The source in the compiled map is a database

With Database/Query File:

```
' [-MDQ mdq_file -DBNAME database_name]
 [-QUERY query_name|-STMT SQL_stmt]
 [-FILE [directory]]
 [-VAR name=value...]
```

```

[-TRIG trigger_string]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-GTX]
[-AUDIT[G] [+][full_path]]
[{-TRACE|-TRACEERR} [+][full_path]]'

```

Without Database/Query File:

```

'-DBTYPE SQLSVR
-SOURCE server\\database
-STM SQL statement
[-FILE [directory]]
[-VAR name=value...]
[-TRIG trigger_string]
[-USER user_ID]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-GTX]
[-AUDIT[G] [+][full_path]]
[{-TRACE|-TRACEERR} [+][full_path]]'

```

The source in the compiled map is not a database

With Database/Query File

```

'-MDQ mdq_file
-DBNAME database_name
-QUERY query_name|-STM SQL_stmt
[-FILE [directory]]
[-VAR name=value...]
[-TRIG trigger_string]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-GTX]
[-AUDIT[G] [+][full_path]]
[{-TRACE|-TRACEERR} [+][full_path]]'

```

Without Database/Query File

```

'-DBTYPE SQLSVR
-SOURCE server\\database
-STM SQL statement
[-FILE [directory]]
[-TRIG trigger_string]
[-USER user_ID]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-GTX]
[-AUDIT[G] [+][full_path]]
[{-TRACE|-TRACEERR} [+][full_path]]'

```

DBLOOKUP or DBQUERY functions

The DBLOOKUP and DBQUERY functions can be used in component rules in the Type Designer and map rules in the Map Designer when creating a map that can be used with a database.

With Database/Query File	Without Database/Query File
DBLOOKUP ("SQL_statement", "-MDQ mdq_file -DBNAME database_name [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-GTX] [-AUDIT[G][+][full_path]] [{-TRACE -TRACEERR}[+][full_path]]")	DBQUERY ("SQL_statement", "-DBTYPE SQLSVR -SOURCE server\\database [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-GTX] [-AUDIT[G][+][full_path]] [{-TRACE -TRACEERR}[+][full_path]]")

GET Function

The GET function returns the data from the source adapter.

With Database/Query File	Without Database/Query File
--------------------------	-----------------------------

With Database/Query File	Without Database/Query File
<pre>GET ("DB", "-MDQ mdq_file -DBNAME database_name -QUERY query_name -STMT SQL_stmt [-FILE [directory]] [-VAR name=value...] [-USER username] [-PASSWORD password] [-CCARD -CSTM [number]] [-GTX] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}[+] [full_path]]")</pre>	<pre>GET "DB", "-DBTYPE SQLSVR -SOURCE server\database -STMT SQL_stmt [-FILE [directory]] [-USER username] [-PASSWORD password] [-CCARD -CSTM [number]] [-GTX] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}[+] [full_path]]")</pre>

Adapter commands for a target

This summary shows the syntax of the adapter commands that can be used when defining a data target using an **.mdq** file or without using one, including both the required and optional adapter commands in the following situations:

- using the **PUT>Target>Command setting** in the Map Designer and Integration Flow Designer
- overriding a data source using the Output Source Override - Database execution command (**-OD**) using a **RUN** function or on the command line
- using the **PUT** function in map or component rules
- [**PUT>Target>Command setting**](#)
- [**-OD execution command**](#)
- [**PUT function**](#)

PUT> Target> Command setting

Use the Map Designer or the Integration Flow Designer to specify **Database** as the value for the **PUT>Target** setting and enter the adapter commands for the **Command** setting.

With Database/Query File	Without Database/Query File
<pre>[-DBTYPE SQLSVR] [-SOURCE server\database] [-PROC procedure_name -TABLE table_name] [-USER user_ID] [-PASSWORD password] [-CSTM [number]] [-DELETE] [-UPDATE [OFF ONLY]] [-BADDATA[+] full_path] [-GTX] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}[+] [full_path]]</pre>	<pre>-DBTYPE SQLSVR -SOURCE server\database -PROC procedure_name -TABLE table_name [-USER user_ID] [-PASSWORD password] [-CSTM [number]] [-DELETE] [-UPDATE [OFF ONLY]] [-BADDATA[+] full_path] [-GTX] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}[+] [full_path]]</pre>

-OD execution command

Use the Output Source Override - Database execution command (**-OD**) to designate a database as a target or you can override one or more of the adapter command settings or database definitions in a **RUN** function or on the command line.

The adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

- [**The target in the compiled map is a database**](#)
- [**The target in the compiled map is not a database**](#)

The target in the compiled map is a database

With Database/Query File

```
' [-MDQ mdq_file -DBNAME database_name]
[-PROC procedure_name|-TABLE table_name]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTM [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-GTX]
```

```
[-AUDIT[G] [+][full_path]

[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+][full_path]
[-GTX]
[-AUDIT[G] [+][full_path]
[{-TRACE|-TRACEERR} [+][full_path]]'
```

PUT function

Use the `PUT` function to pass data to the target adapter.

With Database/Query File	Without Database/Query File
<code>PUT ("DB", "-MDQ mdq_file -DBNAME database_name -PROC procedure_name -TABLE table_name [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [-BADDATA[+][full_path] [-GTX] [-AUDIT[G][+][full_path]] [{-TRACE -TRACEERR}[+][full_path]]")</code>	<code>PUT ("DB", "-DBTYPE SQLSVR -SOURCE server\\database -PROC procedure_name -TABLE table_name [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-DELETE] [-GTX] [-BADDATA[+][full_path] [-AUDIT[G][+][full_path] [{-TRACE -TRACEERR}[+][full_path]]")</code>

Extensions for the Launcher

Microsoft SQL Server database sources can be specified as input events for the Launcher. Insertions or updates to database tables can be the trigger mechanisms to execute a map.

If you are running the Launcher on Windows and want to use Microsoft SQL Server database sources as input events to execute a map, you will need to install the Microsoft SQL Server Extensions on your database host system.

- [Installing Microsoft SQL Server Extensions](#)

Installing Microsoft SQL Server Extensions

The Microsoft SQL Server Extensions are installed as one of the database components of the Database Interface Designer using the Design Studio installation program.

It is not necessary to install the Database Interface Designer or the IBM Transformation Extender Launcher on the same system hosting your Microsoft SQL Server database. The database adapter must be installed with the Database Interface Designer and also with the Launcher. The Microsoft SQL Server Extensions must be installed on the system hosting your Microsoft SQL Server database.

- [Adding extended stored procedures](#)

Adding extended stored procedures

To use the Microsoft SQL Server triggers, you must have your system administrator install and run the triggering installation script for Microsoft SQL Server: **m4sqlsvr.sql**. For more information about this procedure, see database triggers in the *Database Interface Designer* documentation.

Bulk copy example files

The bulk copy function transfers data between a table and an operation system file at high speeds. It is the most common way to load large amounts of data into a database table.

It is frequently used to transfer data between database vendors, spreadsheet applications and servers.

The example files are located in the following directory: *install_dir\examples\adapters\mssql*.

Restrictions and limitations

The Database Interface Designer and database adapter offer options and functions for accessing and manipulating data contained within a database. However, there is one restriction and limitation of a certain function when using the Microsoft SQL Server Adapter. This function is:

- **Bind Facility**
Using bind values in database functions is not supported.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages might also be recorded as specified in the audit logs, trace files, execution summary files, and so on.

For information about error codes and messages returned by database-specific adapters, see Return Codes and Error Messages> Database-specific Adapter Messages in the *Resource Adapters* documentation.

Various troubleshooting tools are available if you encounter problems while using the database adapters. For example, if you attempt to run a map that uses the adapter and encounter problems or do not receive the expected results, use the following adapter troubleshooting tools:

- adapter audit log (.log)
- adapter trace file (.mtr)

OData Adapter

The OData (Open Data Protocol) adapter provides support for performing read and write operations on data sources that expose OData interface. OData adapter is an ISO/IEC approved, OASIS standard that defines a set of best practices for building and consuming RESTful APIs.

OData adapter provides support for connecting to a compliant OData service, discovering entity sets exposed by the services and importing entity definitions in form of native JSON schemas. The adapter further supports fetching entities in managed mode, where the entity data complies with the imported schemas, as well as in raw mode where the OData service is accessed directly and the exchanged data is not constrained and validated by the adapter-provided schema. The adapter also supports inserting new entities into the specified entity set.

- [Authenticating connections](#)
The adapter supports Basic HTTP authentication, with the user provided username and password.
- [OData Adapter properties and commands](#)
- [GET function example](#)
- [PUT function example](#)

Authenticating connections

The adapter supports Basic HTTP authentication, with the user provided username and password.

OData adapter as a source

OData Adapter as a source supports:

- Filtering, projection, ordering and limiting of the fetched results
- Setting custom HTTP request headers
- Specifying data format

OData adapter as a target

ODATA adapter as a target supports:

- Inserting entities into the specified entity set
- Setting custom HTTP request headers
- Specifying data format

OData Adapter properties and commands

- **Root URL (-RU or -ROOTURL)**
Specifies the service root URL of the OData service. This is a mandatory property.
- **Authentication Type (-AT or -AUTHTYPE)**
Type of authentication to use for accessing the OData service. This is a mandatory property.
- **OData Version**
Specifies the version for OData adapter.
- **Username**
Specifies the username for the requests, when using Basic authentication method.
- **Password**
Specifies the password for the requests, when using Basic authentication method.
- **Entity Set**
Specifies the entity set in the service on which to perform the data operation. This is a mandatory property.
- **Headers**
Specifies custom request headers. This is an optional property.
- **Format**
Specifies the media type format of the data.
- **Filter**
Specifies the filter expression to apply when fetching the data.
- **Select**
Selects the required field. This is an optional property.
- **Top**
Specifies the limit for how many values to fetch. This is an optional property. The corresponding adapter command is -TOP.
- **Skip**
This property specifies the number of values to skip from the beginning. This is an optional property.
- **Order By**
Specifies an expression for determining what values are used to order the collection of entries. This is an optional property.
- **Read Mode**
Specifies the read mode of operation. Default is Managed. If Read Mode set to Managed, it generates schema directly.
- **Logging**
Specifies the level of logging to use for the log (trace) file produced by the adapter. The default is false.
- **Append Log**
Flag indicating what to do if the specified log file already exists.
- **Log File Path**
This is the location of the log file to which to write log messages.

Root URL (-RU or -ROOTURL)

Specifies the service root URL of the OData service. This is a mandatory property.

The corresponding adapter command is -RU (or -ROOTURL).

Authentication Type (-AT or -AUTHTYPE)

Type of authentication to use for accessing the OData service. This is a mandatory property.

There are two types of authentication:

- None: No authentication is performed.
- Basic: Basic HTTP authentication with username and password is performed.

The corresponding adapter command is -AT (or -AUTHTYPE).

OData Version

Specifies the version for OData adapter.

There are two versions for OData adapter: V4 and V2. The default is V4.

The corresponding adapter command is -OV.

Username

Specifies the username for the requests, when using Basic authentication method.

The corresponding adapter command is -U (or -USERNAME).

Password

Specifies the password for the requests, when using Basic authentication method.

The corresponding adapter command is -P (or -PASSWORD).

Entity Set

Specifies the entity set in the service on which to perform the data operation. This is a mandatory property.

The corresponding adapter command is -ES (or -ENTITYSET).

Headers

Specifies custom request headers. This is an optional property.

Each header is specified as name, value pair in the format name=value, and multiple headers are separated by a space character, for example: header1=value1 header2=value2 header3=value3. The corresponding adapter command is -H (or -HEADERS).

Format

Specifies the media type format of the data.

The corresponding adapter command is -FMT (or -FORMAT).

For additional information, see the OData website.

Filter

Specifies the filter expression to apply when fetching the data.

Filters the data as per your requirements. This is an optional property. The corresponding adapter command is -FIL (or -FILTER).

For more information, see the OData website.

Select

Selects the required field. This is an optional property.

Specifies the field selection expression for fetching the data. This is an optional property.

The corresponding adapter command is -SEL (or -SELECT).

Top

Specifies the limit for how many values to fetch. This is an optional property. The corresponding adapter command is -TOP.

For more information, see the OData website.

Skip

This property specifies the number of values to skip from the beginning. This is an optional property.

The corresponding adapter command is -SKP (or -SKIP).

For more information, see the OData website.

Order By

Specifies an expression for determining what values are used to order the collection of entries. This is an optional property.

The corresponding adapter command is -ORD (or -ORDERBY).

For more information, see the OData website.

Read Mode

Specifies the read mode of operation. Default is Managed. If Read Mode set to Managed, it generates schema directly.

In **Managed** mode, the imported JSON schema reflects the structure of the entities of the specified entity set. When fetching entities, only the properties captured in the schema are fetched and returned by the adapter.

In **Raw** mode, the imported schema contains just a plain text item. When fetching entities, the adapter returns the raw data returned by the service in unmodified form. To access individual properties and other pieces of information in the returned data, the plain text item would need to be manually replaced with a schema type that corresponds to the structure of the returned data.

Logging

Specifies the level of logging to use for the log (trace) file produced by the adapter. The default is false.

The value Information means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

Append Log

Flag indicating what to do if the specified log file already exists.

When set to true, the log messages are appended to the file. When set to false, the file is truncated, and the messages are written to the empty file. The default value is true.

Log File Path

This is the location of the log file to which to write log messages.

If not specified, the default log file name m4odata.mtr is used, and the file is stored to the directory in which the executed compiled map resides.

GET function example

In the following example, the GET map function is used to retrieve entities from the specified entity set, in managed mode, and with no authentication:

```
GET("ODATA", "-RU rootURL -AT none -RM managed -ES entitySetName")
```

PUT function example

In the following example, the PUT map function is used to insert a new entity (represented by the *entityPayload* data) to the specified entity set:

ODBC Adapter

You can use the Open DataBase Connectivity (ODBC) Adapter with a Command Server, Launcher, the Software Development Kit, or with a map in a map rule.

- [Overview](#)
- [System requirements](#)
- [Database columns and types](#)
- [Database Interface Designer settings](#)
- [ODBC Adapter commands](#)
- [Overriding column attributes](#)
- [Binding values in DBLOOKUP/DBQUERY](#)
- [Configuring DSN for Launcher startup](#)
- [Restrictions and limitations](#)
- [Return codes and error messages](#)

Overview

Use the ODBC Adapters to access and manipulate data contained in databases that are ODBC data sources. You can also install database adapters on additional systems for remote database connectivity.

This documentation discusses the requirements for installing and running the ODBC Adapters and provides the database-specific information required for using your specific adapters in your database host environment.

System requirements

For the latest information about how to install the drivers and configure your ODBC data sources, see IBM Transformation Extender product release notes and the ODBC documentation.

Database columns and types

The Database Interface Designer and **mtsmaker** with the Type Tree Maker generate type trees for queries, tables, views, and stored procedures in an ODBC-compliant RDBMS (Relational Database Management System). Item types are created in a type tree that represents the data types of the columns of a query, table, view, or stored procedure.

The Database Interface Designer and **mtsmaker** get information about columns by calling the ODBC driver for your RDBMS to describe the columns associated with a query, table, view, or stored procedure. The ODBC driver for the RDBMS has mapped the data types in each column to ODBC data types as appropriate. From the RDBMS, the ODBC Driver Manager returns the ODBC data type, length, and other information to the Database Interface Designer and **mtsmaker**. The ODBC data types are then mapped to types in a type tree. The Database Interface Designer and **mtsmaker** have no knowledge of the RDBMS-specific data types-only the ODBC data types.

- [Item type properties](#)
- [Date and time formats](#)

Item type properties

The following table lists the ODBC data types and the values of the item type properties to which they correspond when the type tree is generated.

ODBC Data Type	Interpret as	Item Subclass, Presentation	Length
SQL_VARCHAR	Character	Text	*
SQL_CHAR	Character	Text	*
SQL_DECIMAL	Character	Number, Decimal	*
SQL_NUMERIC	Character	Number, Decimal	*
SQL_SMALLINT	Character	Number, Integer	6
SQL_INTEGER	Character	Number, Integer	11
SQL_REAL	Binary	Number, Float	4
SQL_FLOAT	Binary	Number, Float	8
SQL_DOUBLE	Binary	Number, Float	8
SQL_LONGVARCHAR	Character	Text	*
SQL_BIT	Character	Number, Integer	*
SQL_TINYINT	Character	Number, Integer	4
SQL_BIGINT	Character	Number, Integer	20
SQL_BINARY	Binary	Text	*
SQL_VARBINARY	Binary	Text	*
SQL_LONGVARBINARY	Binary	Text	*

ODBC Data Type	Interpret as	Item Subclass, Presentation	Length
SQL_DATE	Character	Date & Time	*
SQL_TIME	Character	Date & Time	*
SQL_TIMESTAMP	Character	Date & Time	*
SQL_INTERVAL_HOUR	Character	Text	*
SQL_INTERVAL_MINUTE	Character	Text	*
SQL_INTERVAL_SECOND	Character	Text	*
SQL_INTERVAL_YEAR_TO_MONTH	Character	Text	*
SQL_INTERVAL_DAY_TO_HOUR	Character	Text	*
SQL_INTERVAL_DAY_TO_MINUTE	Character	Text	*
SQL_INTERVAL_DAY_TO_SECOND	Character	Text	*
SQL_INTERVAL_HOUR_TO_MINUTE	Character	Text	*
SQL_INTERVAL_HOUR_TO_SECOND	Character	Text	*
SQL_INTERVAL_MINUTE_TO_SECOND	Character	Text	*

* The DBMS dictates the length of this type.

Date and time formats

Precision can be specified on output. For example, a precision of 4 would change a date of format from ccyy-mm-dd to ccyy.

When using columns defined as dates and times in ODBC databases, the format for both input and output are:

date:

ccyy-mm-dd

time:

hh:mm:ss

timestamp:

ccyy-mm-dd hh:mm:ss[.ffff...]

If the group format is fixed, the field is padded to 26 with trailing spaces.

where

cc	=	a two-digit century
yy	=	a two-digit year
mm	=	a two-digit month
dd	=	a two-digit day
hh	=	a two-digit hour
mm	=	a two-digit minute
ss	=	a two-digit second
.ffff...	=	optional fractional seconds

An example is 2001-08-27 00:00:00 which specifies August 27, 2001.

In the Generate Type Tree from dialog, use the **Represent date/time columns as text items** check box to define whether to automatically format this information as Date & Time as a text string. When generated as a text string, it might be necessary to use either the TEXTTODATE or TEXTTOTIME function in a map rule to convert the text string to the date and time format required by the database. If you are generating new type trees, it is recommended that you disable this check box.

The **Represent date/time columns as text items** check box is modal. After it has been disabled, it will remain disabled for all subsequent type tree generations, regardless of source. Therefore, you must be careful in determining this setting.

Database Interface Designer settings

When you define an ODBC database in the Database Interface Designer, in addition to the common settings available for all of the database adapters in the Database Definition dialog, you need to enter the information specific to ODBC.

- [Database definition dialog](#)
- [Stored procedures native call syntax](#)

Database definition dialog

The ODBC Adapter-specific settings are described in the following table:

Setting	Description
Data Source	
Database Interface Designer	The data source you defined in your development PC that is used by the Database Interface Designer to access the database information for design-time purposes
Runtime	The data source you defined in your ODBC database host platform to be used for access to the database for runtime (map execution) purposes both from the Map Designer and a Command Server
Security	
User ID	The user ID used to connect to the database
Password	The authorization password to connect to the DB2® subsystem

Stored procedures native call syntax

A stored procedure can be accessed from within a map by specifying the native call syntax in the following:

- a query that is specified in an input card
- the first argument in a DBQUERY or DBLOOKUP function
This argument does not need to be a literal. The arguments to the stored procedure might be determined at map execution time.
- the SQL Statement adapter command (-SMT) in DBQUERY, DBLOOKUP, or GET functions

For information about using DBLOOKUP or DBQUERY, or about using the syntax for device-independent calls to access return values and output adapter commands, see the *Database Interface Designer* documentation.

For example, a call to a stored procedure using ODBC in a DBLOOKUP might be:

```
DBLOOKUP      ("{call MyAddNameProc('' + Name:Column + '' , -1)}",
                "mydb.mdq",
                "MyDB")
```

String literals must be contained within single quotation marks; adapter arguments must be separated by commas.

ODBC Adapter commands

- [Adapter command summary](#)
- [Adapter commands for a source](#)
- [Adapter commands for a target](#)

Adapter command summary

The following is a summary of the adapter commands that can be used to specify data sources and targets. The applicability of many of the commands depends upon whether you are specifying a source or target, whether a database or query file (.mdq) is used, and how the command is being used. Adapter commands can be used in GET->Source->Command or PUT->Target->Command settings in the Map Designer and Integration Flow Designer, using GET, PUT, DBLOOKUP, or DBQUERY function calls, or overriding a data source or target using execution commands in a RUN function or on the command line.

- [Adapter specific commands](#)

Adapter specific commands

This section lists and describes those adapter commands that are ODBC specific database parameters. For a complete listing of all database adapter commands, see the *Resource Adapters* documentation.

- [Database Adapter Type \(-DBTYPE\)](#)
- [Row Count \(-ROWCNT\)](#)
- [Data Source \(-SOURCE\)](#)
- [Database Adapter Type \(-DBTYPE\)](#)
- [Row Count \(-ROWCNT\)](#)
- [Data Source \(-SOURCE\)](#)

Database Adapter Type (-DBTYPE)

Use the Database Adapter Type adapter command (-DBTYPE) to specify the database adapter type.

-DBTYPE ODBC

Option	Description
ODBC	<p>The database adapter type is ODBC.</p> <p>This command must be specified if the original card is not a database and no database is specified using the Database/Query adapter command (-MDQ) and the Database Name adapter command (-DBNAME).</p>

Row Count (-ROWCNT)

Use the Row Count adapter command (-ROWCNT) to specify the number of rows to be retrieved per fetch.

-ROWCNT row_count

Option	Description
<i>row_count</i>	<p>This is the number of rows to be retrieved per fetch.</p> <p>The time to fetch is optimized in accordance with the increase in the number of rows to retrieve. Therefore, a significant performance improvement might be gained by retrieving as many rows as possible in a single fetch.</p> <p>The number of rows retrieved is limited only by the amount of memory installed on the querying PC.</p> <p>The default for the number of rows to be retrieved per fetch for the ODBC Adapter is one row.</p>

Data Source (-SOURCE)

Use the Data Source adapter command (-SOURCE) to specify the ODBC data source.

-SOURCE datasource

Option	Description
<i>datasource</i>	Specify the ODBC data source.

Adapter commands for a source

This summary shows the syntax of the adapter commands that can be used when defining a data source using an .mdq file or without using an .mdq file, including both the required and optional adapter commands in the following situations:

- using a GET>Source>Command setting in the Map Designer and Integration Flow Designer
- overriding a data source using the Input Source Override - Database execution command (-ID) using a RUN function or on the command line
- using a DBLOOKUP, DBQUERY, or GET function in map or component rules
- [GET> Source> Command setting](#)
- [-ID Execution command](#)
- [DBLOOKUP or DBQUERY functions](#)
- [GET function](#)

GET> Source> Command setting

Use the Map Designer or Integration Flow Designer to specify **Database** as the value for the GET>Source setting and enter the adapter commands for the **Command** setting.

With Database/Query File	Without Database/Query File
[-DBTYPE ODBC]	-DBTYPE ODBC
[-SOURCE <i>datasource</i>]	-SOURCE <i>datasource</i>
[-STMT <i>SQL_statement</i>]	-STMT <i>SQL_statement</i>
[-FILE [directory]]	[-FILE [directory]]
[-VAR <i>name=value...</i>]	[-VAR <i>name=value...</i>]
[-USER <i>user_ID</i>]	[-USER <i>user_ID</i>]
[-PASSWORD <i>password</i>]	[-PASSWORD <i>password</i>]
[-CSTMT [<i>number</i>]]	[-CSTMT [<i>number</i>]]
[-ROWCNT <i>row_count</i>]	[-ROWCNT <i>row_count</i>]
[-AUDIT[G][+] [<i>full_path</i>]]	[-AUDIT[G][+] [<i>full_path</i>]]
[-TRACE -TRACEERR [:] [<i>full_path</i>]]	[-TRACE -TRACEERR [:] [<i>full_path</i>]]

-ID Execution command

Use the Input Source Override - Database execution command (-ID) to designate a database as the source. Or, you can override one or more of the adapter command settings or database definitions in a RUN function or on the command line.

The following adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

- [The source in the compiled map is a database](#)
- [The source in the compiled map is not a database](#)

The source in the compiled map is a database

With Database/Query File

```
'[-MDQ mdq_file -DBNAME database_name]
[-QUERY query_name|-STMT SQL_stmt]
[-FILE [directory]]
[-VAR name=value...]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]
[(-TRACE|-TRACEERR)[+| [full_path]]]
```

Without Database/Query File

```
'-DBTYPE ODBC
-SOURCE datasource
-STM SQL_statement
[-FILE [directory]]
[-VAR name=value...]
[-USER user_ID]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]
[(-TRACE|-TRACEERR)[+| [full_path]]]
```

The source in the compiled map is not a database

With Database/Query File

```
'-MDQ mdq_file
-DBNAME database_name
-QUERY query_name|-STMT SQL_stmt
[-FILE [directory]]
[-VAR name=value...]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]
[(-TRACE|-TRACEERR)[+| [full_path]]]
```

Without Database/Query File

```
'-DBTYPE ODBC
-SOURCE datasource
-STM SQL_statement
[-FILE [directory]]
[-USER user_ID]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G] [+| [full_path]]
[(-TRACE|-TRACEERR)[+| [full_path]]]
```

DBLOOKUP or DBQUERY functions

The DBLOOKUP and DBQUERY functions can be used in component rules in the Type Designer and map rules in the Map Designer when creating a map that can be used with a database.

With Database/Query File	Without Database/Query File
--	---

With Database/Query File	Without Database/Query File
DBLOOKUP ("SQL_statement", "-MDQ mdq_file -DBNAME database_name [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-ROWCNT row_count] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}{+} [full_path]]")	DBQUERY ("SQL_statement", "-DBTYPE ODBC -SOURCE datasource [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-ROWCNT row_count] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}{+} [full_path]]")

GET function

The `GET` function returns the data from the source adapter.

With Database/Query File	Without Database/Query File
GET ("DB", "-MDQ mdq_file -DBNAME database_name -QUERY query_name -STMT SQL_stmt [-FILE [directory]] [-VAR name=value...] [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-ROWCNT row_count] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}{+} [full_path]]")	GET "DB", "-DBTYPE ODBC -SOURCE datasource -STMT SQL_stmt [-FILE [directory]] [-USER username] [-PASSWORD password] [-ROWCNT row_count] [-CCARD -CSTMT [number]] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}{+} [full_path]]")

Adapter commands for a target

This summary shows the syntax of the adapter commands that can be used when defining a data target using an `.mdq` file or without using an `.mdq` file, including both the required and optional adapter commands in the following situations:

- using a `PUT>Target>Command` setting in the Map Designer and Integration Flow Designer
- overriding a data source using the Output Source Override - Database execution override (`-OD`) using a `RUN` function or on the command line
- using the `PUT` function in map or component rules
- [PUT> Target> Command setting](#)
- [-OD execution command](#)
- [PUT function](#)

PUT> Target> Command setting

Use the Map Designer or the Integration Flow Designer to specify **Database** as the value for the `PUT>Target` setting and enter the adapter commands for the **Command** setting.

With Database/Query File	Without Database/Query File
[-DBTYPE ODBC] [-SOURCE datasource] [-PROC procedure_name -TABLE table_name] [-USER user_ID] [-PASSWORD password] [-CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [-BADDATA[+] full_path] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}{+} [full_path]]	-DBTYPE ODBC -SOURCE datasource -PROC procedure_name -TABLE table_name [-USER user_ID] [-PASSWORD password] [-CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [-BADDATA[+] full_path] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}{+} [full_path]]

-OD execution command

Use the Output Source Override - Database execution command (`-OD`) to designate a database as a target or you can override one or more of the adapter command settings or database definitions in a `RUN` function or on the command line.

The following adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

- [The target in the compiled map is a database](#)

- [The target in the compiled map is not a database](#)

The target in the compiled map is a database

With Database/Query File

```
'[-MDQ mdq_file -DBNAME database_name]
[-PROC procedure_name|-TABLE table_name]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]]'
```

Without Database/Query File

```
'-DBTYPE ODBC
-SOURCE datasource
-PROC procedure_name|-TABLE table_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]]'
```

The target in the compiled map is not a database

With Database/Query File

```
'-MDQ mdq_file
-DBNAME database_name
-PROC procedure_name|-TABLE table_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]]'
```

Without Database/Query File

```
'-DBTYPE ODBC
-SOURCE datasource
-PROC procedure_name|-TABLE table_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]]'
```

PUT function

Use the `PUT` function to pass data to the target adapter.

With Database/Query File	Without Database/Query File
<pre>PUT ("DB", "-MDQ mdq_file -DBNAME database_name -PROC procedure_name -TABLE table_name [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [-BADDATA[+] full_path] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}[+] [full_path]]")</pre>	<pre>PUT ("DB", "-DBTYPE ODBC -SOURCE datasource -PROC procedure_name -TABLE table_name [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [-BADDATA[+] full_path] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}[+] [full_path]]")</pre>

Overriding column attributes

When using the Database Interface Designer to generate a type tree for a query, table, view, or stored procedure, you might want to specify how columns are to be interpreted, rather than relying upon the interpretation of a particular database driver.

These column overrides are saved in the **.mdq** file. When generating a type tree with the ODBC Adapter and enabling the **Override Column Definitions** check box in the Generate Type Tree from dialog for a query, table, view, or stored procedure, the Column Datatype Specification dialog appears. Any overrides you specify in these dialogs are saved when the **.mdq** file is saved.

The generated type tree with overrides is represented in the Navigator with an icon having black spheres.

If a tree is regenerated at a later date for the same query, table, view, or stored procedure within a database, you are prompted to confirm whether the previously defined overrides should be applied to the new tree.

The following steps and dialogs show how to define column override attributes for a table or view. However, the steps and dialogs for a stored procedure are very similar and should follow the same process.

- [Defining column attribute overrides](#)

Defining column attribute overrides

The following procedure describes how to define column attribute overrides for a:

- table or stored procedure
- [To define column definition overrides for a query](#)

To define column attribute overrides for a table or stored procedure

1. In the Database Interface Designer, open the **.mdq** file.
2. In the Navigator, select the database containing the table for which you want to generate a type tree with column attribute overrides.
3. From the Database menu, select either Generate Tree From **> Table** or Generate Tree From **> Procedure**, depending upon the one you are generating. Either the **Generate Type Tree from Tables** or Generate Type Tree from Procedures dialog appears, depending upon your selection. An example of the Generate Type Tree from Tables dialog follows. For more information about the type tree generation dialogs, see the *Database Interface Designer* documentation.
4. Select one or more tables, views, or procedures for which you want to generate a type tree.
5. Enter a name for the type tree file (**.mtt**)
or
6. Enable one of the **Type options** to specify how you want the newly generated types to be saved.
7. From the **Row group format** list, enable **Delimited** or **Fixed**.
8. Accept the default values for the **Group options** fields (**Delimiter**, **Terminator**, and **Release**) or change them.
9. To specify how columns are to be interpreted, select the **Override column definitions** check box.
10. Click **Generate**.
The Column Datatype Specification dialog appears.
11. From the **Tables/Views** list, select the table or view containing the column or columns for which you want to specify an override.
12. From the **Columns** list, select the column for which you want to specify an override.
13. Specify the **Subclass**, **Interpret as**, **Presentation**, and **Length** values for the selected column. For more information about setting these attributes, see the *Type Designer* documentation. In most cases, the specified length should not be shorter than the default length because this might result in data truncation errors.
14. Repeat Steps 11-13 for each column for which you want to specify an override.
15. When finished, click **OK**.

To define column definition overrides for a query

1. In the Database Interface Designer, open the **.mdq** file.
2. In the Navigator, select the query for which you want to generate a type tree.
3. From the **Queries** menu, choose **Generate Tree**.
The Generate Type Tree from Query dialog appears, an example of which follows. For details on the type tree generation dialog, see the *Database Interface Designer* documentation.
4. Enter a name for the type tree file (**.mtt**)
or
5. To specify the way you want to save the newly generated types, enable one of the **Type options** check boxes.
6. From the **Row group format** list, enable either **Delimited** or **Fixed**.
7. Accept the default values for the **Group options** fields (**Delimiter**, **Terminator**, and **Release**) or change them.
8. To specify how columns are to be interpreted, select the **Override column definitions** check box.
9. Click **OK**.
The Column Datatype Specification dialog appears.
10. From the **Columns** list, select the column for which you want to specify an override.
11. Specify the **Subclass**, **Interpret as**, **Presentation**, and **Length** values for the selected column as desired. For more information about setting these attributes, see the *Type Designer* documentation. In most cases, the specified length should not be shorter than the default length because this might result in data truncation errors.
12. Repeat Steps 10-11 for each column for which you want to specify an override.
13. Click **OK**.

Binding values in DBLOOKUP/DBQUERY

When using a `DBLOOKUP` or `DBQUERY` function, use the Bind facility to submit similarly constructed SQL statements to the database server so that the statements are syntactically identical. By binding a value to a placeholder in the SQL statement, the actual syntax of the statement can be made static, which might improve performance. For more information about using bind values in database functions, see the *Database Interface Designer* documentation.

- [Limitation when using ODBC](#)
- [Specifying the data type](#)

Limitation when using ODBC

When binding values using ODBC, a limitation exists because ODBC cannot determine the data type of the column to which the value is being bound at the time the SQL statement is executed. Therefore, the data type of the value being passed must be explicitly specified. Because of this ODBC limitation, the ODBC Adapter determines the data type of the value according to the following rule:

If the value contains only numeric characters or numeric characters with a decimal point, the value is assumed to be numeric. Otherwise, the value is assumed to be text.

This rule provides the expected results in most cases. However, there might be some situations in which the rule might not apply and it might be necessary to specify the exact data type. For example, if the value is a text field consisting solely of numeric characters, the value is incorrectly interpreted as numeric unless correctly specified.

Specifying the data type

To override the default behavior and to explicitly specify the data type, a data type indicator must precede the bind value. The syntax for this is:

```
:bind([T|N|D], value)
```

The following table lists the data type indicators and the relationship between each data type indicator and the ODBC data types.

Data Type Indicator	ODBC data type
T or TEXT	SQL_CHAR
N or NUM or NUMBER	SQL_NUMERIC
D or DATE	SQL_DATETIME

For information about item formats and interpretation, see [Item Type Properties](#).

As an example of specifying a data type, to bind a date value to a statement, you must specify that the value be of data type DATETIME. The SQL statement would be entered as:

```
DBLOOKUP("select Age from Person where DateOfBirth=:bind([DATE] , " +
          DateItem:Row + ")",
          "DB.mdg",
          "MyDB")
```

If the `[DATE]` data type indicator is not specified, the trace file from the adapter displays the following error message:

```
Message: [Microsoft][ODBC Microsoft Access 97 Driver]
        Data type mismatch in criteria expression.
```

Configuring DSN for Launcher startup

This information also applies to establishing a Windows-based data source name for the Informix® adapter. For information about how to configure a DSN for UNIX, see your UNIX documentation.

Using ODBC, data sources are configured in the **ODBC Data Source Administrator** applet in the **Control Panel** as system sources (**System DSN**) that are visible to all users and NT services on the system, or to user sources (**User DSN**) that are visible only to you, the current user.

For Windows operating systems, access this applet by selecting Administrative Tools in the **Control Panel**, then **Data Sources (ODBC)**.

Based upon each data source configuration, the data source is allowed access only if the logon account is correctly specified. A system data source can be accessed only when using a system account logon, which is the default. A user data source can be accessed only when using a user account logon that must be specified.

When using the Launcher and access to ODBC data sources is required, the Launcher must be started from the **Services** applet with the correct logon, either system or user account, that allows access to the data sources required by the Launcher during runtime.

For example, if a data source is defined as a system source in the **System Data Sources** list on the **System DSN** tab, the Launcher must be started using the **System Account** logon, which is the default.

However, if your ODBC data sources are defined as user data sources and are listed in the **User Data Sources** list on the User DSN tab of the **ODBC Data Source Administrator** applet, you must change the Launcher **Startup** options so that the logon is specified for the user account. This allows the Launcher to have access to the data sources associated with the user account that are required during Launcher runtime.

The following steps are based on the Windows operating system.

To change Launcher Startup Options:

1. From the Start menu, select **Settings > Control Panel**.
2. Select **Administrative Tools**.
3. Open the **Services** applet.
The Services dialog appears.
4. In the **Name** column, double-click IBM Transformation Extender Launcher.
The IBM Transformation Extender Launcher Properties dialog appears.
5. Click the **Log On** tab.
The Log On page appears.
6. Enable **This account** and click **Browse** to select the user account under which the DSN was created.
7. Enter values for the selected user account in the **Password** and **Confirm password** fields. The Launcher will use these values to log on to the system and access the user data sources.
8. Click **OK**.

For more information, see the *Launcher* documentation.

Restrictions and limitations

The Database Interface Designer and database adapters offer options and functions for accessing and manipulating data contained within a database. However, there is one restriction for this adapter: database triggers are not supported. You cannot use a data source as an input event trigger for the Launcher.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages might also be recorded as specified in the audit logs, trace files, execution summary files, and so on.

For information about error codes and messages returned by database-specific adapters, see the *Resource Adapters* documentation.

Various troubleshooting tools are available in case you encounter problems while using the database adapters. For example, if you attempt to run a map that uses the adapter and encounter problems or do not receive the expected results, use the following adapter troubleshooting tools:

- adapter audit log (.log)
- adapter trace file (.mtr)

OLE DB Adapter overview

Use the OLE DB Adapter to access and manipulate data contained in databases that are OLE DB data links. You can install database adapters on additional systems for remote database connectivity.

This documentation discusses the requirements for running the OLE DB Adapter and provides the database-specific information required for using your specific adapters in your database host environment.

- [System requirements](#)
- [Creating a universal data location file](#)
- [Database columns and types](#)
- [Database interface designer settings](#)
- [OLE DB Adapter commands](#)
- [Restrictions and limitations](#)
- [Return codes and error messages](#)

System requirements

Currently, there are three supported OLE DB providers to be used with the OLE DB Adapter:

- Microsoft OLE DB Provider for SQL Server
- Microsoft OLE DB Provider for Oracle
- Microsoft Jet OLE DB Provider (for Access)

Verify that you have installed one of the above listed OLE DB providers and have configured your OLE DB data links. The data link populates a Universal Data Connection (**.udl**) file that you can create. For more information about how to configure and manage these data links, see the OLE DB documentation included with your OLE DB providers.

Creating a universal data location file

Before you can access data from OLE DB, you must provide specific connection information such as:

- the type of data to be accessed
- the server upon which the data resides
- the database in which the data is stored

For example, to connect to an Oracle database, you must specify the Microsoft OLE DB provider for Oracle and provide a server name.

A connection string is a string version of this connection information that you can save and reuse in your applications. You can build this string in the Data Link Properties dialog and associated tabbed pages. Using this interface, you can save this connection string as a data link in the **.udl** file.

An alternative to using the Microsoft Data Link menu option as described in the following procedure, because some operating systems might not have this option, is to create a **.txt** file and change the file extension to **.udl**.

- [Creating a .udl file](#)

Creating a .udl file

The following procedure outlines how to create the **.udl** file necessary to use the OLE DB Adapter.

1. In Explorer, either create a new directory or select an existing directory in which to create a data link.
2. Highlight the directory. From the File menu, select New>Microsoft Data Link.
A file with the **.udl** extension is created.
3. Name the file and double-click it.
The Data Link Properties dialog appears.
4. On the Provider tab, select the OLE DB provider for your platform from the **OLE DB Providers** list.
5. Click Next.
The Connections tab appears.
6. Enter or select from the list the name of the data source.
7. Enter appropriate values in the **User name** and **Password** fields that will be used only to test the connection, not at runtime.
8. In the **Select initial catalog to use** field, enter the database to be used.
9. Click Test Connection. If successful, you can go to the Database Interface Designer Database Definition dialog.

Now you are ready to use this **.udl** file for the **Data Link** settings in the Database Definition dialog.

Database columns and types

The Database Interface Designer and **mtsmaker** with the Type Tree Maker generate type trees for queries, tables, views, and stored procedures in an OLE DB-compliant RDBMS (Relational Database Management System). Item types are created in a type tree that represent the data types of the columns of a query, table, view, or stored procedure.

The Database Interface Designer and **mtsmaker** get information about columns by calling the OLE DB Adapter that calls the OLE DB provider for your RDBMS to describe the columns associated with a query, table, view, or stored procedure. The OLE DB provider for the RDBMS has mapped the data types in each column to OLE DB data types as appropriate. From the RDBMS, the OLE DB Adapter returns the OLE DB data type, length, and other information to the Database Interface Designer and **mtsmaker**. The OLE DB data types are then mapped to types in a type tree. The Database Interface Designer and **mtsmaker** have no knowledge of the RDBMS-specific data types, only the OLE DB data types.

- [Item type properties](#)
- [Date and time formats](#)

Item type properties

The following table lists the OLE DB data types and the values of the item type properties to which they correspond when the type tree is generated.

OLE DB Data Type	Interpret as	Item Subclass, Presentation	Length
DBTYPE_UI1	Character	Number, Integer	3
DBTYPE_UI2	Character	Number, Integer	5
DBTYPE_UI4	Character	Number, Integer	10
DBTYPE_UI8	Character	Number, Integer	20
DBTYPE_I1	Character	Number, Integer	4
DBTYPE_I2	Character	Number, Integer	6
DBTYPE_I4	Character	Number, Integer	11
DBTYPE_I8	Character	Number, Integer	20
DBTYPE_R4	Binary	Number, Float	4
DBTYPE_R8	Binary	Number, Float	8
DBTYPE_CY	Character	Number, Decimal	*

OLE DB Data Type	Interpret as	Item Subclass, Presentation	Length
DBTYPE_NUMERIC	Character	Number, Decimal	*
DBTYPE_BOOL	Character	Text (ASCII)	1
DBTYPE_STR	Character	Text (ASCII)	*
DBTYPE_WSTR	Character	Text (UNICODE)	*
DBTYPE_BYTES	Binary	Text (Byte stream)	*
DBTYPE_DBDATE	Character	Date & Time	10
DBTYPE_DBTIME	Character	Date & Time	8
DBTYPE_DBTIMESTAMP	Character	Date & Time	19-26

* The DBMS dictates the length of this type.

Date and time formats

When using columns defined as dates and times in OLE DB databases, the format for both input and output is:

date

yyyy-mm-dd

time:

hh:mi:ss

timestamp:

yyyy-mm-dd hh:mi:ss [.fff...]

If the group format is fixed, the field is padded to 26 with trailing spaces.

where

yyyy	=	a four-digit year
mm	=	a two-digit month
dd	=	a two-digit day
hh	=	a two-digit hour
mi	=	a two-digit minute
ss	=	a two-digit second
.fff...	=	an optional fractional second

An example is 2001-08-27 00:00:00 which specifies August 27, 2001.

In the Generate Type Tree from dialog, use the **Represent date/time columns as text items** check box to define whether to automatically format this informations as Date and Time, which is with this check box disabled, as shown in the **Item Subclass, Presentation** column above, as a text string. When generated as a text string, it might be necessary to use either the TEXTTODATE or TEXTTOTIME function in a map rule to convert the text string to the date and time format required by the database. If you are generating new type trees, it is recommended that you disable this check box.

The **Represent date/time columns as text items** check box is modal. After it has been disabled, it will remain disabled for all subsequent type tree generations, regardless of source. Therefore, you must be careful in determining this setting.

Database interface designer settings

When you define an OLE DB database in the Database Interface Designer, in addition to the common settings available for all of the database adapters in the Database Definition dialog, you must enter the information specific to OLE DB.

- [Database Designer dialog](#)
- [Stored procedures native call syntax](#)

Database Designer dialog

The OLE DB Adapter-specific settings are described in the following table:

Setting		Description
Data Link		
	Database Interface Designer	Location of the Universal Data Location (.udl) file on your OLE DB development PC that is used to access the database information for design-time purposes

Setting		Description
	Runtime	Location of the Universal Data Location (.udl) file defined in your OLE DB database host platform to be used to access the database for runtime (map execution) purposes both from the Map Designer and either a Command Server or a Launcher.
Security		
	User ID	The user ID to connect to the database.
	Password	The authorization password to connect to the database.

Stored procedures native call syntax

A stored procedure can be accessed from within a map by specifying the native call syntax in the following:

- a query that is specified in an input card
- the first argument in a `DBQUERY` or `DBLOOKUP` function
This argument does not need to be a literal. The arguments to the stored procedure might be determined at map execution time.
- the SQL Statement adapter command (`-STMT`) in `DBQUERY`, `DBLOOKUP`, or `GET` functions

For information about using `DBLOOKUP` or `DBQUERY`, see the *Database Interface Designer* documentation. For information about using the syntax for device-independent calls to access return values and output adapter commands, see the *Database Interface Designer* documentation. Also see that documentation for information about calling stored procedures with object type parameters.

For example, a call to a stored procedure using OLE DB in a `DBLOOKUP` might be:

```
DBLOOKUP      ("{call MyAddNameProc('' + Name:Column + '',-1)}",
    "mydb.mdq",
    "MyDB")
```

String literals must be contained within single quotation marks; adapter arguments must be separated by commas.

OLE DB Adapter commands

This documentation describes the functions and usage of the OLE DB Adapter commands and their options.

- [Adapter command summary](#)
- [Adapter commands for a source](#)
- [Adapter commands for a target](#)

Adapter command summary

The following is a summary of the adapter commands that can be used to specify data sources and targets. The commands you use depends upon if you are specifying a source or target, if a database or query file (.mdq) is used, and the situations in which you are using the command. Adapter commands can be used in `GET`, `Source`, `Command` or `PUT`, `Target`, `Command` settings in the Map Designer and Integration Flow Designer, using `GET`, `PUT`, `DBLOOKUP`, or `DBQUERY` function calls, or overriding a data source or target using execution commands in a `RUN` function or on the command line.

- [Adapter specific commands](#)
- [Database Adapter Type \(-DBTYPE\)](#)
- [Row Count \(-ROWCNT\)](#)
- [Data Source \(-SOURCE\)](#)

Adapter specific commands

These adapter commands are OLE DB specific database parameters. For a complete listing of all database adapter commands, see the *Resource Adapters* documentation.

- [Database Adapter Type \(-DBTYPE\)](#)
- [Row Count \(-ROWCNT\)](#)
- [Data Source \(-SOURCE\)](#)

Database Adapter Type (-DBTYPE)

Use the Database Adapter Type adapter command (`-DBTYPE`) to specify the database adapter type.

-DBTYPE OLEDB

Option

Description

OLEDB

The database adapter type is OLE DB.

This command must be specified if the original card is not a database and no database is specified using the Database/Query adapter command (-MDQ) and the Database Name adapter command (-DBNAME).

Row Count (-ROWCNT)

Use the Row Count adapter command (-ROWCNT) to specify the number of rows to be retrieved per fetch.

-ROWCNT row_count

Option

Description

row_count

This is the number of rows to be retrieved per fetch.

The time to fetch is optimized in accordance with the increase in the number of rows to retrieve. Therefore, a significant performance improvement might be gained by retrieving as many rows as possible in a single fetch. The number of rows retrieved is only limited by the amount of memory installed on the querying PC.

The default for the number of rows to be retrieved per fetch for the OLE DB Adapter is one row.

Data Source (-SOURCE)

Use the Data Source adapter command (-SOURCE) to specify the OLE DB data link.

-SOURCE datalink

Option

Description

datalink

Specify the OLE DB data link.

Adapter commands for a source

This summary shows the syntax of the adapter commands that can be used when defining a data source using an .mdq file or without using an .mdq file, including both the required and optional adapter commands in the following situations:

- using a GET>Source>Command setting in the Map Designer and Integration Flow Designer
- overriding a data source using the Input Source Override - Database execution command (-ID) using a RUN function or on the command line
- using a DBLOOKUP, DBQUERY, or GET function in map or component rules
- [GET> Source> Command setting](#)
- [-ID Execution command](#)
- [DBLOOKUP or DBQUERY functions](#)
- [GET function](#)

GET> Source> Command setting

Use the Map Designer or Integration Flow Designer to specify **Database** as the value for the GET>Source setting and enter the adapter commands for the **Command** setting.

With Database/Query File	Without Database/Query File
[-DBTYPE OLEDB]	-DBTYPE OLEDB
[-SOURCE <i>datalink</i>]	-SOURCE <i>datalink</i>
[-STMT <i>SQL_statement</i>]	-STMT <i>SQL_statement</i>
[-FILE [directory]]	[-FILE [directory]]
[-VAR <i>name=value...</i>]	[-VAR <i>name=value...</i>]
[-USER <i>user_ID</i>]	[-USER <i>user_ID</i>]
[-PASSWORD <i>password</i>]	[-PASSWORD <i>password</i>]
[-CSTMT [<i>number</i>]]	[-CSTMT [<i>number</i>]]
[-ROWCNT <i>row_count</i>]	[-ROWCNT <i>row_count</i>]
[-AUDIT[G][+] [<i>full_path</i>]]	[-AUDIT[G][+] [<i>full_path</i>]]
[[-TRACE]-TRACEERR[+] [<i>full_path</i>]]	[[-TRACE]-TRACEERR[+] [<i>full_path</i>]]

-ID Execution command

Use the Input Source Override - Database execution command (-ID) to designate a database as the source. Or, use it to override one or more of the adapter command settings or database definitions in a RUN function or on the command line.

The following adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

- [The source in the compiled map is a database](#)
- [The source in the compiled map is not a database](#)

The source in the compiled map is a database

With Database/Query File

```
'[-MDQ mdq_file -DBNAME database_name]
[-QUERY query_name|-STMT SQL_stmt]
[-FILE [directory]]
[-VAR name=value...]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+][full_path]]'
```

Without Database/Query File

```
'-DBTYPE OLEDB
-SOURCE datalink
-STMT SQL_statement
[-FILE [directory]]
[-VAR name=value...]
[-USER user_ID]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+][full_path]]'
```

The source in the compiled map is not a database

With Database/Query File

```
'-MDQ mdq_file
-DBNAME database_name
-QUERY query_name|-STMT SQL_stmt
[-FILE [directory]]
[-VAR name=value...]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+][full_path]]'
```

Without Database/Query File

```
'-DBTYPE OLEDB
-SOURCE datalink
-STMT SQL_statement
[-FILE [directory]]
[-USER user_ID]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+][full_path]]'
```

DBLOOKUP or DBQUERY functions

The DBLOOKUP and DBQUERY functions can be used in component rules in the Type Designer and map rules in the Map Designer when creating a map that can be used with a database.

With Database/Query File	Without Database/Query File
DBLOOKUP ("SQL_statement", "-MDQ mdq_file -DBNAME database_name [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-ROWCNT row_count] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}[+][full_path]])"	DBQUERY ("SQL_statement", "-DBTYPE OLEDB -SOURCE datalink [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-ROWCNT row_count] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}[+][full_path]])"

GET function

The `GET` function returns the data from the source adapter.

With Database/Query File	Without Database/Query File
<code>GET ("DB", "-MDQ mdq_file -DBNAME database_name -QUERY query_name -STMT SQL_stmt [-FILE [directory]] [-VAR name=value...] [-USER username] [-PASSWORD password] [-CCARD -CSTMN [number]] [-ROWCNT row_count] [-AUDIT[G][+] [full_path]] [{-TRACE}-TRACEERR][+] [full_path]]")</code>	<code>GET "DB", "-DBTYPE OLEDB -SOURCE datalink -STMT SQL_stmt [-FILE [directory]] [-USER username] [-PASSWORD password] [-ROWCNT row_count] [-CCARD -CSTMN [number]] [-AUDIT[G][+] [full_path]] [{-TRACE}-TRACEERR][+] [full_path]]")</code>

Adapter commands for a target

This summary shows the syntax of the adapter commands that can be used when defining a data target either using or not using an `.mdq` file, including both the required and optional adapter commands in the following situations:

- using the `PUT>Target>Command setting` in the Map Designer and Integration Flow Designer
- overriding a data source using the Output Source Override - Database execution command (`-OD`) using a `RUN` function or on the command line
- using the `PUT` function in map or component rules
- [PUT>Target>Command setting](#)
- [-OD Execution command](#)
- [PUT function](#)

PUT> Target> Command setting

Use the Map Designer or the Integration Flow Designer to specify **Database** as the value for the `PUT>Target` setting and enter the adapter commands for the **Command** setting.

With Database/Query File	Without Database/Query File
<code>[-DBTYPE OLEDB] [-SOURCE datalink] [-PROC procedure_name -TABLE table_name] [-USER user_ID] [-PASSWORD password] [-CSTMN [number]] [-DELETE] [-UPDATE [OFF ONLY]] [-BADDATA[+] full_path] [-AUDIT[G][+] [full_path]] [{-TRACE}-TRACEERR][+] [full_path]]</code>	<code>-DBTYPE OLEDB -SOURCE datalink -PROC procedure_name -TABLE table_name [-USER user_ID] [-PASSWORD password] [-CSTMN [number]] [-DELETE] [-BADDATA[+] full_path] [-AUDIT[G][+] [full_path]] [{-TRACE}-TRACEERR][+] [full_path]]</code>

-OD Execution command

Use the Output Source Override - Database execution command (`-OD`) to designate a database as a target. You can also use it to override one or more of the adapter command settings or database definitions in a `RUN` function or on the command line.

The following adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

- [The target in the compiled map is a database](#)
- [The target in the compiled map is not a database](#)

The target in the compiled map is a database

With Database/Query File

```
' [-MDQ mdq_file -DBNAME database_name]  
[-PROC procedure_name|-TABLE table_name]  
[-USER username]  
[-PASSWORD password]
```

```

[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]]'

```

Without Database/Query File

```

'-DBTYPE OLEDB
-SOURCE datalink
-PROC procedure_name|-TABLE table_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]]'

```

The target in the compiled map is not a database

With Database/Query File

```

'-MDQ mdq_file
-DBNAME database_name
-PROC procedure_name|-TABLE table_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]]'

```

Without Database/Query File

```

'-DBTYPE OLEDB
-SOURCE datalink
-PROC procedure_name|-TABLE table_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-BADDATA[+] full_path]
[-AUDIT[G][+] [full_path]]
[{-TRACE|-TRACEERR}[+] [full_path]]'

```

PUT function

Use the **PUT** function to pass data to the target adapter.

With Database/Query File	Without Database/Query File
<pre> PUT ("DB", "-MDQ mdq_file -DBNAME database_name -PROC procedure_name -TABLE table_name [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-DELETE] [-UPDATE [OFF ONLY]] [-BADDATA[+] full_path] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}[+] [full_path]]") </pre>	<pre> PUT ("DB", "-DBTYPE OLEDB -SOURCE datalink -PROC procedure_name -TABLE table_name [-USER username] [-PASSWORD password] [-CCARD -CSTMT [number]] [-DELETE] [-BADDATA[+] full_path] [-AUDIT[G][+] [full_path]] [{-TRACE -TRACEERR}[+] [full_path]]") </pre>

Restrictions and limitations

The Database Interface Designer and adapters offer tremendous options and functions for accessing and manipulating data contained within a database. However, there are some restrictions and limitations of certain functions when using the adapters for OLE DB. These functions are:

- **Database Triggers**
Using a data source as an input event trigger for the Launcher is not supported.
- **Bind Facility**
Using bind values in database functions is not supported.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages might also be recorded as specified in the audit logs, trace files, execution summary files, and so on.

For information about error codes and messages returned by database-specific adapters, see [Return Codes and Error Messages > Database-specific Adapter Messages](#) in the *Resource Adapters* documentation.

Troubleshooting tools are available in case you encounter problems while using the database adapters. For example, if you attempt to run a map that uses the adapter and encounter problems or do not receive the expected results, use the following adapter troubleshooting tools:

- adapter audit log (**.log**)
- adapter trace file (**.mtr**)

OpenPGP Adapter overview

Use the OpenPGP Adapter to exchange information with the GnuPG application. The OpenPGP Adapter creates so called *pipes* to perform the Inter Process Communication (IPC) between the process that uses the adapter, for example, Command Server and the GnuPG process.

The OpenPGP Adapter is based on the Gnu implementation of the OpenPGP Adapter standard, called GnuPG. The adapter uses native operating system calls to start the GnuPG application, and then it uses pipes to exchange information with it.

- [Pipes](#)
- [System requirements](#)
- [Command alias](#)
- [OpenPGP Adapter commands](#)
- [Syntax summary](#)

Pipes

The OpenPGP Adapter uses the following pipes:

- **Status pipe** to obtain status information from GnuPG about the operation that is being performed. For example, status messages that describe steps in the encryption procedure.
- **Command pipe** to specify information during the GnuPG execution that is normally provided through the standard input, either a shell or prompt. This pipe is used to provide the user password when GnuPG needs it, for example, when signing a message. See [User Password \(-PW\)](#) to see how a password is provided to GnuPG from a map.
- **Standard input pipe** to provide GnuPG with the data on which the operation is performed, for example, plain text for encryption.
- **Standard output pipe** to read processed data, for example, cipher text that represents the encrypted data.

System requirements

The minimum requirements and installation instructions for the OpenPGP Adapter are detailed in the release notes. It is assumed that a Command Server has already been installed on the computer where the adapter is to be installed for runtime purposes.

Command alias

Adapter commands can be specified by using a command string on the command line or creating a command file that contains adapter commands. The execution command syntax is:

```
-IM[alias] card_num  
-OM[alias] card_num
```

where **-IM** is the Input Source Override execution command and **-OM** is the Output Target Override execution command, *alias* is the adapter alias, and *card_num* is the number of the input or output card. The following table shows the adapter alias and its execution command.

Adapter	Alias	As Input	As Output
OpenPGP Adapter	OPGP	-IMOPGP <i>card_num</i>	-OMOPGP <i>card_num</i>

OpenPGP Adapter commands

This documentation describes the functions and use of the OpenPGP Adapter commands and their options.

- [List of commands](#)

List of commands

The following table lists valid commands for the OpenPGP Adapter, the command syntax, and if the command is supported (✓) for use with data sources, targets, or both.

Command	Syntax	Source	Target
Action (-ACTION)	-ACTION <i>action</i>	✓	✓
Additional Command (-ADDCMD)	-ADDCMD <i>additional_command(s)</i>	✓	✓
Comment (-COMMENT)	-COMMENT <i>comment</i>	✓	✓
Compression Algorithm (-COMALG)	-COMALG <i>algorithm_id</i>	✓	✓
Decode (-DECODE)	-DECODE	✓	✓
Encode (-ENCODE)	-ENCODE	✓	✓
Encryption Algorithm (-ENCALG)	-ENCALG <i>algorithm_id</i>	✓	✓
Encryption Type (-ENCTYPE)	-ENCTYPE <i>type</i>	✓	✓
Message Digest (-DIGEST)	-DIGEST	✓	✓
Message File Name (-FILE)	-FILE <i>filename</i>	✓	✓
Message Recipient (-R)	-R <i>recipient</i>	✓	✓
Signature Type (-SIGTYPE)	-SIGTYPE <i>type</i>	✓	✓
Signing Algorithm (-SIGALG)	-SIGALG <i>algorithm_id</i>	✓	✓
Trace (-T)	-T[+][<i>file_name</i>]	✓	✓
User Login (-U)	-U <i>user</i>	✓	✓
User Password (-PW)	-PW <i>password</i>	✓	✓

- [Action \(-ACTION\)](#)
- [Additional Command \(-ADDCMD\)](#)
- [Comment \(-COMMENT\)](#)
- [Compression Algorithm \(-COMALG\)](#)
- [Decode \(-DECODE\)](#)
- [Encode \(-ENCODE\)](#)
- [Encryption Algorithm \(-ENCALG\)](#)
- [Encryption Type \(-ENCTYPE\)](#)
- [Message Digest \(-DIGEST\)](#)
- [Message File Name \(-FILE\)](#)
- [Message Recipient \(-R\)](#)

- [Signing Algorithm \(-SIGALG\)](#)
- [Trace \(-T\)](#)
- [User Login \(-U\)](#)
- [User Password \(-PW\)](#)

Action (-ACTION)

Use the Action adapter command (-ACTION) to specify what action needs to be performed by the adapter.

-ACTION *action*

The following table lists the *action* values and their meaning:

Action	Meaning
SIGN	Only sign the message and return the signed data. The -PW adapter command must be specified along with this action to specify the password used to access the signer's private key. The -USER adapter command might be used to specify the signer other than the default user.
ENCRYPT	Only encrypt the message and return the encrypted data. The -R adapter command must be used along with this action to specify the user for which the message is being encrypted.
SIGNANDENCRYPT	Sign and encrypt the message and return the signed and encrypted data.
VERIFY	Only verify the signed message. No data is returned.
DECRYPT	Only decrypt the encrypted message and return the original data. If the message is signed, the signature is verified as well. This is the default action.
VERIFYANDDECRYPT	Same as DECRYPT. The signature is automatically verified if it is present in the encrypted message.

Additional Command (-ADDCMD)

Use the Additional Command adapter command (-ADDCMD) to specify additional options in the command line that is passed to the **GnuPG** executable.

These options are added to the options specified by the OpenPGP Adapter in the adapter command. See the GnuPG documentation to learn about the various command line options that can be used with the GnuPG.

If the Trace adapter command (-T) is specified, the adapter will trace the complete command line that was passed to GnuPG.

```
-ADDCMD " additional_command(s) "
```

For example:

```
-ADDCMD " --armor --version -verbose "
```

- --armor creates ASCII armored output
 - --version displays the GnuPG version in the output message. By default, the version is not displayed.
 - --verbose generates some extra information about the progress of the performed action, which can later be looked at in the trace file.
- Use extreme caution with the -ADDCMD adapter command. Make sure that the GnuPG command options specified through -ADDCMD are not in conflict with the commands that the adapter uses. Do not use the -ADDCMD adapter command to specify options that can be specified through other adapter commands. For example, the -ACTION SIGN adapter command should be used for signing documents, and not -ADDCMD "--sign". The former format instructs the adapter to communicate with GnuPG in the signing mode, while the later one only tells the adapter to append additional commands to the initial GnuPG command line.

Also, note that the --comment GnuPG command option should not be specified through the -ADDCMD adapter command. The OpenPGP Adapter provides the -COMMENT adapter command that can be used for this purpose.

Comment (-COMMENT)

Use the Comment adapter command (-COMMENT) to specify the comment that appears in the encrypted or signed message's header. This adapter command corresponds to the --comment GnuPG command option.

```
-COMMENT " comment "
```

For example:

```
-COMMENT " Message signed with GnuPG "
```

When the -COMMENT adapter command is not present; the comment is omitted from the generated message.

When the comment value contains no white spaces, quotes can be omitted. However, note that on UNIX systems, the adapter does not support comments with white spaces. Replace the white spaces with other characters, for example, the underscore character '_', before passing it to the adapter.

Compression Algorithm (-COMALG)

Use the Compression Algorithm adapter command (-COMALG) to specify the compression algorithm used to compress the message.

It corresponds to the --compress-algo NAME GnuPG command option.

```
-COMALG algorithm_id
```

The following table lists the allowed values for the *algorithm_id* and the corresponding algorithms:

Algorithm_id	Algorithm
1	ZLIB compression (RFC1951)
2	RFC1950 compression (default)

Decode (-DECODE)

The -DECODE adapter command is a special command that is used in the adapter chaining process.

The -DECODE special command should be used *only* when chaining the adapter with another adapter, for example, the E-mail adapter. The -DECODE adapter command has no arguments.

```
-DECODE
```

Encode (-ENCODE)

The -ENCODE adapter command is a special command that is used in the adapter chaining process.

The -ENCODE special command should be used *only* when chaining the adapter with another adapter, for example, the E-mail adapter. The -ENCODE adapter command has no arguments.

```
-ENCODE
```

Encryption Algorithm (-ENCALG)

Use the Encryption Algorithm adapter command (-ENCALG) to specify the cipher algorithm used in the message encryption process.

-ENCALG *algorithm_id*

The following table lists the allowed values for the *algorithm_id* and the corresponding algorithms:

Algorithm_id	Algorithm
3DES	Triple DES Block Cipher
CAST5	CAST5 128-bit block cipher
BLOWFISH	Blowfish block cipher
RIJNDAEL	AES (Rijndael) block cipher 128 bit key
RIJNDAEL192	AES (Rijndael) block cipher 192 bit key
RIJNDAEL256	AES (Rijndael) block cipher 256 bit key
TWOFISH	Twofish 128 bit block cipher

The -ENCALG adapter command is meaningful only if the following conditions are met:

- -ENCODE adapter command is used
- -ACTION ENCRYPT or -ACTION SIGNANDENCRYPT adapter command is used

Encryption Type (-ENCTYPE)

Use the Encryption Type adapter command (-ENCTYPE) to specify the type of the encryption.

-ENCTYPE *type*

The allowed values for *type* are listed in the following table:

Type	Meaning
PUBLICKEY	Use public-key cipher for the message encryption. This is the default.
SYMMETRIC	Use only symmetric cipher for the message encryption.

Message Digest (-DIGEST)

Use the Message Digest adapter command (-DIGEST) to calculate the message digest for the specified data. The MD5 and SHA1 message digests can be calculated. The syntax is:

-DIGEST

This is an optional command.

The following table illustrates the usage of the -DIGEST adapter command depending on if the -ACTION and -SIGALG commands are specified:

	-SIGALG <i>algorithm_id</i>	-SIGALG not specified
-ACTION VERIFY_AND_DECRYPT or DECRYPT	The message is first verified (and/or decrypted), and the message digest is calculated for the original data using the algorithm specified with <i>algorithm_id</i> .	The message is first verified (and/or decrypted) and the message digest is calculated for the original data using SHA1 algorithm.
-ACTION not specified	The message digest is calculated directly for the input data using the <i>algorithm_id</i> algorithm.	The message digest is calculated directly for the input data using SHA1 algorithm.
-ACTION VERIFY or SIGN or ENCRYPT or SIGN_AND_ENCRYPT	invalid usage	invalid usage

The -ACTION VERIFY command is not supported because it does not return any data. If no data is returned, there is no information on which to calculate the message digest.

To verify the signature in a signed message and calculate the message digest for the originally signed data, -ACTION VERIFY_AND_DECRYPT or -ACTION DECRYPT should be used in combination with the -DIGEST command.

Message File Name (-FILE)

Use the Message File Name adapter command (**-FILE**) to specify the file used by the adapter on input or output depending on the map design scenario.

-FILE filename

Where *filename* is the full path to the file that contains the message data.

The message data will be plain or cipher text, depending on the action that is to be performed.

The actual interpretation of the value depends on the scenario in which the adapter is being used.

Depending on the context in which the adapter is being used, the **-FILE** adapter command will be treated differently. The possible scenarios are:

- [Input Card](#) (source adapter type is OpenPGP Adapter)
- [Output Card](#) (target adapter type is OpenPGP Adapter)
- [GET Map Function](#)
- [PUT Map Function](#)
- [Input card](#)
- [Output card](#)
- [GET Map function](#)
- [PUT map function](#)

Input card

When the source adapter type is OpenPGP Adapter the **-FILE** adapter command is required. The adapter performs the action specified in the **-ACTION** adapter command on the data from the specified file. The processed data is returned to the execution engine.

Output card

When the target adapter type is OpenPGP Adapter the **-FILE** adapter command is required. The adapter performs the action specified in the **-ACTION** adapter command on the data that it receives from the execution engine. The processed data is stored to the specified file. The **-ENCODE** and **-DECODE** adapter commands should not be specified in these cases.

GET Map function

If the **GET** function has three parameters, the adapter performs the action specified in the **-ACTION** adapter command on the data in the third parameter of the **GET** function. In this case, the **-FILE** adapter command might be omitted. If specified, it will be ignored by the adapter.

If the input data is not provided to the adapter from the execution engine, then the **-FILE** command must be specified. In that case, the adapter performs the action specified in the **-ACTION** adapter command on the data from the specified file.

In both cases, the processed data is returned to the execution engine.

PUT map function

The adapter performs the action specified in the **-ACTION** adapter command on the data in the third parameter of the **PUT** function.

If the adapter is not participating in adapter chaining, when its output is used as input to another adapter, the **-FILE** adapter command is required.

If adapter chaining is taking place, or **-ENCODE** or **-DECODE** is explicitly specified in the adapter command, the adapter ignores the **-FILE** adapter command and returns the processed data back to the execution engine to be passed as input to another adapter in the chain.

Message Recipient (-R)

Use the Message Recipient adapter command (**-R**) to specify the recipient of the message. The message is then encrypted for this particular recipient.

-R recipient

Where *recipient* corresponds to the local GnuPG user.

This command is required when the input message needs to be encrypted. The adapter encrypts the input message for the specified recipient.

Signature Type (-SIGTYPE)

Use the Signature Type adapter command (**-SIGTYPE**) to specify the type of the signature.

-SIGTYPE type

The allowed values for the *type* are listed in the following table:

Type	Meaning
NORMAL	Sign the data with the regular OpenPGP Adapter signature.
CLEAR	Sign the data with the clear text signature.
DETACHED	Creates a detached signature.

Signing Algorithm (-SIGALG)

Use the Signing Algorithm adapter command (-SIGALG) to specify the digest algorithm used for hashing when signing a message. It corresponds to the **--digest-algo NAME** option for the GnuPG executable.

-SIGALG algorithm_id

The following table lists the allowed values for the *algorithm_id* and the corresponding algorithms:

Algorithm_id	Algorithm
SHA1	Secure Hash Algorithm version 1.
MD5	Rivest's Message Digest.
RIPEMD160	160 bit output Message Digest.

The -SIGALG adapter command can always be specified, but its value will only be used when a message needs to be signed. This happens when the following condition is met:

- -ACTION SIGN or -ACTION SIGNANDENCRYPT adapter command is used

Trace (-T)

Use the Trace adapter command (-T) to produce a diagnostics file that contains detailed information about OpenPGP Adapter activity.

The default filename is **m4opgp.mtr** and it is created in the map directory unless otherwise specified.

-T[E] [+] [file_name]

Option

Description
E Produce a trace file containing only the adapter errors that occurred during map execution.
+ Append trace information to the existing trace file.
file_name Creates a trace file with the specified name in the specified directory.

You can override the adapter command line trace options dynamically using the Management Console. See "Dynamic Adapter Tracing" in the Launcher documentation for more information.

User Login (-U)

Use the User Login adapter command (-U) to specify the local user which needs to perform the action specified in -ACTION adapter command.

This adapter command corresponds to the **--local-user gpg** option.

-U user

Where *user* is the local GnuPG user.

User Password (-PW)

Use the User Password adapter command (-PW) to specify the password, also called passphrase, of the user whose private key needs to be accessed.

A password is required when signing or decrypting a message. It is also required when encrypting a message with a symmetric cipher (-ENCTYPE SYMMETRIC).

In these scenarios, the `-PW` adapter command is required. The `-PW` adapter command value is passed to the GnuPG executable through the *command pipe*. See ["Pipes"](#) for more information.

`-PW password`

Where *password* is the password of the local user specified in the `-U` adapter command, or the default user, if `-U` is not specified.

Syntax summary

This documentation discusses the OpenPGP Adapter syntax summary and how it is used.

- [Data sources and targets](#)
 - [Example 1](#)
 - [Example 2](#)
-

Data sources and targets

The following is the command syntax of the OpenPGP Adapter commands used for data sources and targets:

```
[-ACTION action] [-ADDCMD " additional_command(s) "]  
[-COMMENT " comment "] [-COMALG algorithm_id]  
[-DECODE]  
[-DIGEST] [-ENCODE]  
[-ENCALG algorithm_id]  
[-ENCTYPE type]  
[-FILE filename] (*)  
[-R recipient] (*)  
[-SIGTYPE type]  
[-SIGALG algorithm_id]  
[-T[E] [+]] [filename]  
[-U user]  
[-PW password] (*)
```

(*) This command is not optional in certain scenarios. See the description of the specific command to see when it is required.

Example 1

For the GET Source setting in an input card, select OpenPGP Adapter. In the **GET > Source > Command** field, enter:

```
-U foo -ACTION ENCRYPT -R foo -ADDCMD "-armor" -FILE input.txt -T
```

The adapter will:

- read the file **input.txt**
- encrypt it for the **foo** GnuPG user
- return the ASCII armored encrypted message back
- trace the activity in the default trace file **m4opgp.mtr** in the map directory

The encrypted message can then be passed to some target, for example, E-mail, in an output card.

Example 2

In a **PUT** map function call enter:

```
=PUT("OPGP", " -U foo -ACTION ENCRYPT -FILE out. t -R fee -  
ADDCMD "--armor\"", "Message to encrypt")
```

This map function call will:

- encrypt the *Message to encrypt* string for the *fee* GnuPG user, using *fee*'s public key. The message will be encrypted on behalf of the user *foo*.
- generate encrypted data that will be ASCII armored and stored to file **out.txt**.

Oracle Adapter overview

Use the Oracle Adapter to access and manipulate data contained in Oracle databases. The Database Interface Designer along with the database adapters for Windows are part of the Design Studio installation. You can also install database adapters on additional systems for remote database connectivity.

There are requirements for running the Oracle Adapter and other database-specific information required for using specific adapters in your database host environment.

You can use the adapter with a Command Server, a Launcher, the Software Development Kit, or with a map in a map rule.

- [System requirements](#)
- [Database columns and types](#)
- [Database Interface Designer settings](#)
- [Oracle client result cache support](#)

The Oracle adapter supports the Oracle client result cache. The Oracle client result cache stores the results of an Oracle database SQL **SELECT** query in memory on the Oracle client. Subsequent identical SQL queries can retrieve data from the cached query results in memory rather than through I/O to the Oracle database, reducing the number of Oracle server round trips and query executions.

- [Oracle Adapter commands](#)
- [Bulk copy example files](#)
- [Restrictions and limitations](#)
- [Return codes and error messages](#)

System requirements

See the [system requirements](#) for details. In addition to these requirements, to install and run the Oracle adapter:

- You must be currently running the appropriate version of Oracle on the machine upon which you are going to install this adapter. See also the [release notes](#).
- Verify that the Oracle environment variables, for example, ORACLE_HOME, are defined. For information about how to do the verification, see your Oracle documentation.
- When running on UNIX, the Oracle client creates a process whenever a connection is made to Oracle. If any of these processes terminates, defunct processes remain in the process list. Although not required, because these do not cause problems nor do they consume resources, you can prevent this occurrence by adding the following line to the sqlnet.ora file in the \$ORACLE_HOME/network/admin path:

```
bequeath_detach=YES
```

The effect of this line is to create these same connection processes as detached orphans, thus eliminating the possibility of them becoming defunct.

- Set the shared library path environment variable for UNIX.

After installing the adapters on a UNIX system and running the environment variable setup program (**setup**), add the *install_dir* directory to your shared library path environment variable if it is not already there. The following instructions assume that your *install_dir* installation directory is defined in the **DTX_HOME_DIR** environment variable.

If you change your path or library path after you run the **setup** program, you must run the **setup** program again.

Note: These instructions assume that your UNIX environment is the Korn (ksh) shell.

- For HP-UX:

```
SHLIB_PATH=$DTX_HOME_DIR/lib:$ORACLE_HOME/lib:$SHLIB_PATH
export SHLIB_PATH
```

- For Solaris:

```
LD_LIBRARY_PATH=$DTX_HOME_DIR/lib:$ORACLE_HOME/
lib:$LD_LIBRARY_PATH export LD_LIBRARY_PATH
```

- For IBM® RS/6000® AIX®:

```
LIBPATH=$DTX_HOME_DIR/lib:$ORACLE_HOME/lib:$LIBPATH
export LIBPATH
```

Database columns and types

The Database Interface Designer and **mtsmaker** with the Type Tree Maker generate type trees for queries, tables, views, and stored procedures in an Oracle-compliant DBMS (Database Management System). Item types will be created in a type tree that represent the data types of the columns of a query, table, view, or stored procedure.

The Database Interface Designer and **mtsmaker** get information about columns by calling Oracle to describe the columns associated with a query, table, view, or stored procedure. Oracle returns the data type, length, and other information to the Database Interface Designer and **mtsmaker**. The Database Interface Designer and **mtsmaker** then map the Oracle data types to item types in a type tree.

Note: Type trees for messages can be generated only using the Database Interface Designer. For more information, see the Database Interface Designer documentation.

- [Item type properties](#)
- [Date and time format](#)
- [XML type](#)
- [URIType](#)

Item type properties

The following table lists the Oracle data types and the values of the item type properties to which they correspond in a generated type tree. The DBMS dictates the length of each type except for the DATE type. The DATE type length is 19.

Oracle Data Type	Interpret as	Item Subclass, Presentation
VARCHAR2	Character	Text
NVARCHAR2	Character	Text
INTEGER	Character	Number, Integer

Oracle Data Type	Interpret as	Item Subclass, Presentation
NUMBER Precision = 0 Scale = 0	Character	Number, Decimal
NUMBER Precision > 0 Scale = 0	Character	Number, Integer
NUMBER Precision > 0 Scale > 0	Character	Number, Decimal
FLOAT	Character	Number, Decimal
LONG	Character	Text
DATE	Character	Date & Time
RAW	Binary	Text
LONG RAW	Binary	Text
CHAR	Character	Text
NCHAR	Character	Text
BLOB	Binary	Text
CLOB	Character	Text
BFILE	Binary	Text
NCLOB	Character	Text
TIMESTAMP(f)	Character	
TIMESTAMP(f) WITH TIME ZONE	Character	Text
TIMESTAMP(f) WITH LOCAL TIME ZONE	Character	
INTERVAL DAY(d) TO SECOND(f)	Character	Text
INTERVAL YEAR(y) TO MONTH	Character	Text
XMLType	Character	Text
URIType	Character	Text

*

The BLOB and NCLOB data types are not supported as parameters for stored procedures. The Oracle Adapter supports object types. These are alternatively referred to as abstract data types (ADT). The object type is a composite type that includes data types such as number, date, varchar, and so on. Object types can include nested object types.

When generating Oracle type trees that contain ADTs, you must manually edit the tree to make the ADT group required. This will prevent atomic null violations.

Date and time format

The Oracle date and time format for both input and output is:

`ccyy-mm-dd hh24:mm:ss [.6-6]`

If the group format is fixed, the field is padded to 19 with trailing spaces.

Formats

Format	Description
cc	two-digit century
yy	two-digit year
mm	two-digit month
dd	two-digit day
hh	two-digit hour
mi	two-digit minute
ss	two-digit second
.fff...	optional fractional seconds
ffffff	six-digit fraction of a second
hh24	two-digit hour using a 24-hour day

An example is 2001-08-27 23:00:00, which specifies August 27, 2001 at 11:00 PM.

For the **DATE** column type, there are never fractional seconds; hence, the width of the field is always 19. For the **TIMESTAMP** and **TIMESTAMP WITH LOCAL TIME** columns, the precision of the fractional seconds is determined by the column definition.

In the Generate Type Tree from dialog, use the Represent date/time columns as text items check box to define whether to automatically format this information as Date & Time (which is with this check box disabled, the result of which is shown in the Item Subclass, Presentation column) as a text string. When generated as a text string, it might be necessary to use either the **TEXTTODATE** or **TEXTTOTIME** function in a map rule to convert the text string to the date and time format required by the database. If you are generating new type trees, it is recommended that you disable this check box.

This Represent date/time columns as text items check box is modal. After it has been disabled, it will remain disabled for all subsequent type tree generations, regardless of source. Therefore, you must be careful in determining this setting.

XML type

XMLEType is supported and can still be used to a limited degree. It is possible to query **XMLEType** columns as well as inserting data into them.

To query from an **XMLEType** column, the `getClobVal` method of the **XMLEType** object must be used.

Consider the table created by this statement:

```
CREATE TABLE MY_XML (myCol sys.xmletype)
```

The following query can be executed to get the XML data:

```
SELECT t.myCol.getClobVal() FROM MY_XML t
```

To insert into the table, you must use the `createXML` method. It is not possible to do this by creating a type tree for the table and using this tree in an output card. Instead, the `INSERT` statement should be executed through a `DBLOOKUP`.

The following is an example of the syntax of the SQL:

```
INSERT INTO MY_XML VALUES (sys.xmletype.createXML
(`<XMLDocument>cat</XMLDocument>'))
```

Oracle parses the XML document when it is inserted. Therefore, the above statement will fail if the XML is invalid.

URIType

URIType provides a means to store a URI in the database, rather than the document referenced by the URI. In the same way that the methods of the **XMLEType** object can be used to insert or create XML document objects, methods of **URIType** objects can be used to insert or query URIs.

Consider the table created by this statement:

```
CREATE TABLE uri_tab (url sys.uritype)
```

The following query can be executed to get the document referenced by the URI:

```
SELECT e.url.getLOB() FROM uri_tab e
```

To insert into the table, you must use the `createHTTPURI` or `createDBURI` method. It is not possible to do this by creating a type tree for the table and using this tree in an output card. Instead, the `INSERT` statement must be executed through a `DBLOOKUP`.

The following is an example of the syntax:

```
INSERT INTO uri_tab VALUES (sys.httpuritype.createHttpuri
('http://www.oracle.com'))
```

or

```
INSERT INTO uri_tab VALUES (sys.dburitype.createDBuri
('/SCOTT/ EMPLOYEE/ROW[ENAME="Jack"]'))
```

Database Interface Designer settings

When you define an Oracle database in the Database Interface Designer, in addition to the common settings available for all the database adapters in the Database Definition dialog, you need to enter the information specific for Oracle.

- [Database definitions](#)
- [Specifying connect strings](#)
- [Stored procedures native call syntax](#)

Database definitions

The Oracle Adapter-specific settings in the Database Interface Designer are described in the following table.

Setting		Description
Connect String		

Setting		Description
	Database Interface Designer	The connect string used to connect to the Oracle database that is accessed by the Database Interface Designer for design-time purposes
	Runtime	The connect string used to connect to the Oracle database to be accessed for runtime (map execution) purposes both from the Map Designer and either a Command Server or a Launcher
Security		
	User ID	The user ID used to connect to the database
	Password	The authorization password to connect to the database

Specifying connect strings

If an SQL*Net host connection string is specified, the connection is established through SQL*Net. If no connection string is specified, a direct connection is established to the database identified by the current ORACLE_SID environment setting.

For example, specifying

```
UserID
  Scott
Connect String
    remote_db
```

results in connecting with the connection string `Scott@remote_db`.

Note: A connection string is always required when connecting to a remote database. For more information about the syntax of the connection string, see your Oracle documentation.

Stored procedures native call syntax

A stored procedure can be accessed from within a map by specifying the native call syntax in:

- A query that is specified in an input card.
- The first argument in a DBQUERY or DBLOOKUP function.
This argument does not need to be a literal. The arguments to the stored procedure might be determined at map execution time.
- The SQL Statement adapter command (-STMT) in DBQUERY, DBLOOKUP, or GET functions.

For information about using DBLOOKUP or DBQUERY, or for information about using the syntax for device-independent calls to access return values and output adapter commands, see the Database Interface Designer documentation. In addition, you will find information about calling stored procedures with object type parameters.

For example, a call to a stored procedure using Oracle in a DBLOOKUP might be:

```
DBLOOKUP ("begin MyAddNameProc('"+ Name:Column +" ',-1);end;"  
"mydb.mdq",  
"MyDB")
```

Note: String literals must be contained within single quotation marks; adapter arguments must be separated by commas.

Oracle client result cache support

The Oracle adapter supports the Oracle client result cache. The Oracle client result cache stores the results of an Oracle database SQL **SELECT** query in memory on the Oracle client. Subsequent identical SQL queries can retrieve data from the cached query results in memory rather than through I/O to the Oracle database, reducing the number of Oracle server round trips and query executions.

Maps that make identical SQL **SELECT** queries to an Oracle database can potentially improve performance by using the adapter cache (**-CACHE**) option. The queries must be for simple data types in a read-only or read-mostly database.

- [SQL SELECT query requirements](#)
SELECT queries must be syntactically identical to retrieve results from the Oracle client result cache and to reuse database connections. Use bind variables to create syntactically identical **SELECT** queries.
- [Tuning Oracle adapter database connections](#)
The Oracle adapter **-CACHE** option defines a unique database connection for each **SELECT** statement. This connection is reserved solely for cache-based queries and is re-used only if another **SELECT** query matches identically. Therefore, the total number of Oracle connections that an existing map requires to run can increase when you add the **-CACHE** option to the adapter command.
- [Enabling the Oracle adapter to use the Oracle client result cache](#)
Enable the client result cache on the Oracle server, and configure the Oracle adapter command and the SQL **SELECT** query to use the cache.

SQL SELECT query requirements

SELECT queries must be syntactically identical to retrieve results from the Oracle client result cache and to reuse database connections. Use bind variables to create syntactically identical **SELECT** queries.

Related information

- [Using bind values in database functions](#)
-

Tuning Oracle adapter database connections

The Oracle adapter **-CACHE** option defines a unique database connection for each **SELECT** statement. This connection is reserved solely for cache-based queries and is re-used only if another **SELECT** query matches identically. Therefore, the total number of Oracle connections that an existing map requires to run can increase when you add the **-CACHE** option to the adapter command.

For example, a map that doesn't use the **-CACHE** option uses one database connection for three unique **SELECT** queries. When you add the **-CACHE** option to each **SELECT** statement, the map requires a database connection for each unique **SELECT** statement (a total of three connections). Two instances of this map that run in parallel require six database connections (instead of two connections without the **-CACHE** option).

Opening a database connection adds to the total time to complete the query, but keeping a connection open consumes memory on the server. You need to tune the number of open database connections to maximize connection reuse and minimize the number of open but unused connections.

You can use the `/runtime/Connection Manager/DB` path of the config.yaml configuration file to limit the number of idle database connections. The `/runtime/Connection Manager/DB/sLim` path limits the number of idle database connections, but that limit can be exceeded during peak load. The optimal number of database connections is affected by the number of connections that each map requires and the number of running instances of each map.

To count the number of connections that a map requires, enable the **-AUDIT** adapter command with the global option (**-AG**) on the first database operation in the map. The **-AG** command audits all subsequent database operations in the map.

The audit log includes the following information about a map database query:

Attribute	Description
Connections	A list of unique values. Each unique value represents a connection.
Time	The total elapsed time for the database adapter to process and execute the query.
Database	The portion of the total time for the Oracle driver to return a query result set.

After a query runs and the result is cached, the total elapsed time of subsequent identical queries is reduced, whether the queries are in the same map or in other maps.

Related information

- [-AUDIT adapter command](#)
-

Enabling the Oracle adapter to use the Oracle client result cache

Enable the client result cache on the Oracle server, and configure the Oracle adapter command and the SQL **SELECT** query to use the cache.

Procedure

- On the Oracle server, set the `CLIENT_RESULT_CACHE_SIZE` initialization parameter and restart the database. For example:

```
alter system set client_result_cache_size=4M scope=spfile
```

See your Oracle documentation for details and for other Oracle server initialization parameters.

- Add the **-CACHE** option to the Oracle adapter command line on the input card or on the **GET**, **DBLookup**, or **DBQuery** functions.
- Add the SQL `RESULT_CACHE` hint to the **SELECT** query. Ensure that there are no spaces between the asterisk (*) character and the and plus (+) character in the hint. For example:

```
=GET("DB","-CACHE -STMT ""SELECT /*+ RESULT_CACHE */ name FROM employee WHERE id=:bind('12')"" -DBTYPE ORACLE -CONNECT ORA -U u1 -P p1")
```

Oracle Adapter commands

This topic describes the functions and usage of the Oracle Adapter commands and their options.

- [Database triggers using Oracle](#)

Adapter properties and commands

This topic describes the functions and usage of the Oracle Adapter commands and their options.

Adapter command summary

Use the adapter commands when specifying data sources and targets. The applicability of many of the commands depends upon whether you are specifying a source or target, whether a database/query file (.mdq) is used, and the situations in which the command applies.

Adapter commands can be used in GET->Source->Command or PUT->Target->Command settings in the Map Designer and Integration Flow Designer, using GET, PUT, DBLOOKUP, or DBQUERY function calls, or overriding a data source or target using execution commands in a RUN function or on the command line.

The following adapter commands are Oracle-specific database parameters.

Connect string

Specifies the host connect string. The corresponding adapter command is **-CONNECT**.

-CONNECT *connect_string*

connect_string: Specify the host connect string. If an SQL*Net host connection string is specified, the connection is established through SQL*Net. If none is specified, a direct connection is established to the database identified by the ORACLE_SID environment setting.

Database adapter type

This property specifies the database adapter type. The corresponding adapter command is **-DBTYPE**.

This command must be specified if the original card is not a database and no database is specified using the Database/Query adapter command (-MDQ) and the Database Name adapter command (-DBNAME).

-DBTYPE ORACLE

ORACLE: The database adapter type is Oracle.

Client result cache

Enables the Oracle adapter to retrieve the results of a **SELECT** query from the Oracle client result cache. The corresponding adapter command is **-CACHE**.

Trigger

Specifies the trigger string containing the options defined for a trigger specification. The corresponding adapter command is **-TR** (or **-TRIG**). This command is used to specify the trigger string for the trigger specification.

-TRIG *trigger_string*

trigger_string: Specify the trigger string containing the options defined for a trigger specification.

Row count

Specifies the number of rows to be retrieved per fetch. The corresponding adapter command is **-ROWCNT**.

-ROWCNT *row_count*

row_count: Specify the number of rows to be retrieved per fetch.

The time to fetch is optimized in accordance with the increase in the number of rows to retrieve. Therefore, a significant performance improvement may be gained by retrieving as many rows as possible in a single fetch.

The number of rows retrieved is limited only by the amount of memory installed on the querying computer.

The Oracle Adapter default for the number of rows to be retrieved per fetch is based upon an allocation of 64K buffer. A calculation is then performed to indicate the number of rows that can be held in the buffer.

-INSERTALL

Enables multiple rows of data to be inserted into an Oracle table at once. The corresponding adapter command is **-IA** (or **-INSERTALL**).

By batching a user-specified number of rows, execution times can be improved, when network latency exists between the Oracle adapter and the Oracle server. This option uses the Oracle **INSERT ALL** database statement, which allows multiple inserts with one database command, reducing network roundtrips during the output card processing of multiple input records.

The **-INSERTALL** command can be specified on output cards and works only on tables containing supported Oracle built-in data types. Custom types like Abstract Data Types (ADTs) will force the adapter to use one database insert operation at a time. This limitation applies when using the Default On NULL Oracle capability, as activated by the **-DON** command.

The **-INSERTALL** database statement constructed by the Oracle adapter can be viewed in the log file.

By default, a batch of ten inserts is used. However, this number can be overridden on the command line, depending on the network configuration and deployment requirements. The ideal number for performance will vary based on the network setup. The performance of various values can be compared using the audit option on the command line

Adapter commands for a source

This summary shows the syntax of the adapter commands that can be used when defining a data source using an .mdq file or without using one, including both the required and optional adapter commands in the following situations:

- Using the GET->Source->Command setting in the Map Designer and Integration Flow Designer.
 - Overriding a data source using the Input Source Override - Database execution command (-ID) using a RUN function or on the command line.
 - Using a DBLOOKUP, DBQUERY, or GET function in map or component rules.
 - [GET > Source > Command setting](#)
 - [Database execution command: input source override \(-ID\)](#)
 - [DBLOOKUP and DBQUERY functions](#)
 - [GET function](#)
-

GET > Source > Command setting

In an input card, when you specify Database as the value for the GET->Source setting, the Command field is displayed where you can enter adapter commands.

Database command options when there is a database/query file:

```
[-DBTYPE ORACLE]
[-CACHE]
[-CONNECT connect_string]
[-STMT SQL_statement]
[-FILE [directory]]
[-VAR name=value...]
[-TRIG trigger_string]
[-USER user_ID]
[-PASSWORD password]
[-CSTMT [number]]
[-ROWCNT row_count]
[-CACHE]
[-GTX]
[-AUDIT[G] [+]
 [full_path]]
[{-TRACE|-TRACEERR} [+]
 [full_path]]
```

Database command options when there is not a database/query file:

```
-DBTYPE ORACLE
[-CACHE]
-STMT SQL_statement
[-CONNECT connect_string]
[-FILE [directory]]
[-VAR name=value...]
[-TRIG trigger_string]
[-USER user_ID]
[-PASSWORD password]
[-CSTMT [number]]
[-ROWCNT row_count]
[-CACHE]
[-GTX]
[-AUDIT[G] [+]
 [full_path]]
[{-TRACE|-TRACEERR} [+]
 [full_path]]
```

Database execution command: input source override (-ID)

Use the Input Source Override - Database execution command (-ID) to designate a database as the source or you can override one or more of the adapter command settings or database definitions in a RUN function or on the command line.

The adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

Scenario: compiled map source is a database

Database/query file (.mdq):

```
'[-MDQ mdq_file
-DBNAME database_name]
[-CACHE]
[-QUERY query_name]-STMT SQL_stmt]
[-FILE [directory]]
[-VAR name=value...]
[-TRIG trigger_string]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-ROWCNT row_count]
[-GTX]
[-AUDIT[G] [+]
 [full_path]]
[{-TRACE|-TRACEERR} [+]
 [full_path]]'
```

No database/query file (.mdq):

```
'-DBTYPE ORACLE
[-CACHE]
```

```

-STMT SQL_statement
[-CONNECT connect_string]
[-FILE [directory]]
[-VAR name=value..]
[-TRIG trigger_string]
[-USER user_ID]
[-PASSWORD password]
[-CCARD|-CSTM [number]]
[-ROWCNT row_count]
[-GTX]
[-AUDIT[G] [+|] [full_path]]
[{-TRACE|-TRACEERR} [+|] [full_path]]'

```

Scenario: compiled map source is not a database

Database/query file (.mdq):

```

'[-MDQ mdq_file
-DBNAME database_name
[-CACHE]
[-QUERY query_name|-STMT SQL_stmt]
[-FILE [directory]]
[-VAR name=value..]
[-TRIG trigger_string]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTM [number]]
[-ROWCNT row_count]
[-GTX]
[-AUDIT[G] [+|] [full_path]]
[{-TRACE|-TRACEERR} [+|] [full_path]]'

```

No database/query file (.mdq):

```

'-DBTYPE ORACLE
[-CACHE]
-STMT SQL_statement
[-CONNECT connect_string]
[-FILE [directory]]
[-TRIG trigger_string]
[-USER user_ID]
[-PASSWORD password]
[-CCARD|-CSTM [number]]
[-ROWCNT row_count]
[-GTX]
[-AUDIT[G] [+|] [full_path]]
[{-TRACE|-TRACEERR} [+|] [full_path]]'

```

DBLOOKUP and DBQUERY functions

The DBLOOKUP and DBQUERY functions can be used in component rules in the Type Designer and map rules in the Map Designer when creating a map that can be used with a database.

Using DBLOOKUP with a database/query file

```

DBLOOKUP ("SQL_statement",
"-MDQ mdq_file
-DBNAME database_name
[-CACHE]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTM [number]]
[-ROWCNT row_count]
[-GTX]
[-AUDIT[G] [+|] [full_path]]
[{-TRACE|-TRACEERR} [+|] [full_path]]")

```

Using DBQUERY without a database/query file

```

DBQUERY ("SQL_statement",
"-DBTYPE ORACLE
[-CACHE]
[-CONNECT connect_string]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTM [number]]
[-ROWCNT row_count]
[-GTX]
[-AUDIT[G] [+|] [full_path]]
[{-TRACE|-TRACEERR} [+|] [full_path]]")

```

GET function

The GET function returns the data from the source adapter.

Using GET with a database/query file

```
GET ("DB",
"-MDQ mdq_file
-DBNAME database_name
[-CACHE]
{QUERY query_name|-STMT SQL_stmt}
[-FILE [directory]]
[-VAR name=value...]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTM [number]]
[-ROWCNT row_count]
[-GTX]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]])
```

Using GET without a database/query file

```
GET "DB",
"-DBTYPE ORACLE
[-CACHE]
-STM SQL_stmt
[-CONNECT connect_string]
[-FILE [directory]]
[-USER username]
[-PASSWORD password]
[-ROWCNT row_count]
[-CCARD|-CSTM [number]]
[-GTX]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]])
```

Adapter commands for a target

This summary shows the syntax of the adapter commands that can be used when defining a data target using an .mdq file or without using one, including both the required and optional adapter commands in the following situations:

- Using the PUT > Target > Command setting in the Map Designer and Integration Flow Designer.
 - Overriding a data source using the Output Source Override - Database execution command (-OD) using a RUN function or on the command line
 - Using the PUT function in map or component rules.
- [PUT > Target > Command setting](#)
 - [PUT function](#)
 - [Database execution command: output source override \(-OD\)](#)

PUT > Target > Command setting

In an output card, when you specify Database as the value for the PUT > Target setting, the Command field is displayed so that you can enter adapter commands.

Database command options when there is a database/query file

```
[-DBTYPE ORACLE]
[-CONNECT connect_string]
[-PROC procedure_name|-TABLE table_name]
[-USER user_ID]
[-PASSWORD password]
[-CSTM [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-GTX]
[-BADDATA[+| full_path]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]])
```

Database command options when there is no database/query file

```
-DBTYPE ORACLE
-PROC procedure_name|-TABLE table_name
[-CONNECT connect_string]
[-USER user_ID]
[-PASSWORD password]
[-CSTM [number]]
[-DELETE]
[-GTX]
[-BADDATA[+| full_path]
[-AUDIT[G] [+| [full_path]]
[{-TRACE|-TRACEERR} [+| [full_path]]])
```

PUT function

Use the PUT function to pass data to the target adapter.

Using PUT with a database/query file

```
PUT ("DB",
"-MDQ mdq_file
-DBNAME database_name
-PROC procedure_name| -TABLE table_name
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-GTX]
[-BADDATA[+] full_path]
[-AUDIT[G] [+][ full_path]]
[{-TRACE|-TRACEERR} [+][ full_path]]")
```

Using PUT without a database/query file

```
PUT "DB",
"-DBTYPE ORACLE
-PROC procedure_name| -TABLE table_name
[-CONNECT connect_string]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-GTX]
[-BADDATA[+] full_path]
[-AUDIT[G] [+][ full_path]]
[{-TRACE|-TRACEERR} [+][ full_path]]")
```

Database execution command: output source override (-OD)

Use the Output Source Override - Database execution command (-OD) to designate a database as a target or you can override one or more of the adapter command settings or database definitions in a RUN function or on the command line.

The adapter commands are shown using a single quotation mark, which is the Windows syntax. For non-Windows platforms, use two single quotation marks followed by one single quotation mark and end with one single quotation mark followed by two single quotation marks.

Scenario: compiled map target is a database

Database/query file (.mdq):

```
' [-MDQ mdq_file -DBNAME database_name]
[-PROC procedure_name| -TABLE table_name]
[-USER username]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-GTX]
[-BADDATA[+] full_path]
[-AUDIT[G] [+][ full_path]]
[{-TRACE|-TRACEERR} [+][ full_path]]'
```

No database/query file (.mdq):

```
'-DBTYPE ORACLE
-PROC procedure_name| -TABLE table_name
[-CONNECT connect_string]
[-USER user_ID]
[-PASSWORD password]
[-CCARD|-CSTMT [number]]
[-DELETE]
[-UPDATE [OFF|ONLY]]
[-GTX]
[-BADDATA[+] full_path]
[-AUDIT[G] [+][ full_path]]
[{-TRACE|-TRACEERR} [+][ full_path]]'
```

Scenario: compiled map target is not a database

Database/query file (.mdq):

```
'-MDQ mdq_file
-DBNAME database_name
-PROC procedure_name| -TABLE table_name
[-USER username]
```

```
[-PASSWORD password]  
[-CCARD|-CSTMT [number]]  
[-DELETE]  
[-UPDATE [OFF|ONLY]]  
[-GTX]  
[-BADDATA[+] full_path]  
[-AUDIT[G] [+]] [full_path]]  
[{-TRACE|-TRACEERR} [+]] [full_path]]'
```

No database/query file (.mdq):

```
'-DBTYPE ORACLE  
-PROC procedure_name| -TABLE table_name  
[-CONNECT connect_string]  
[-USER user_ID]  
[-PASSWORD password]  
[-CCARD|-CSTMT [number]]  
[-DELETE]  
[-UPDATE [OFF|ONLY]]  
[-GTX]  
[-BADDATA[+] full_path]  
[-AUDIT[G] [+]] [full_path]]  
[{-TRACE|-TRACEERR} [+]] [full_path]]'
```

Database triggers using Oracle

When using Oracle, the triggering installation scripts must be installed and run by your system administrator. For more information about these scripts, see the topic about database triggers in the Database Interface Designer documentation.

Bulk copy example files

The bulk copy function transfers data between a table and an operation system file at high speeds. It is the most common way to load large amounts of data into a database table.

It is frequently used to transfer data between database vendors, spreadsheet applications and servers.

The example for this adapter is located at *install_dir\examples\adapters\oracle*.

Restrictions and limitations

The Database Interface Designer and database adapters offer options and functions for accessing and manipulating data contained within a database.

There are no restrictions or limitations when using the Oracle Adapter. However, the BLOB and NCLOB data types are not supported as parameters for stored procedures.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages can also be recorded as specified in the audit logs, trace files, execution summary files, and so forth.

For information about error codes and messages returned by database-specific adapters, see the Resource Adapters documentation.

Various troubleshooting tools are available in case you encounter problems while using the database adapters. For example, if you attempt to run a map that uses the adapter and encounter problems or do not receive the expected results, use the following adapter troubleshooting tools:

- adapter audit log (.log)
- adapter trace file (.mtr)

Oracle AQ Adapter overview

The Oracle Advanced Queuing (AQ) Adapter handles the enqueueing (posting of messages) and dequeuing (removal of messages) to or from a queue based upon what has been specified using the adapter commands such as the receipt of a message or messages with specific characteristics defined

- [Oracle AQ message content](#)
- [System requirements](#)
- [Command alias](#)
- [Oracle AQ Adapter commands](#)
- [Syntax summary](#)
- [Data format](#)
- [Trace log](#)
- [Return codes and error messages](#)

Oracle AQ message content

The Oracle AQ is a first-in-first-out (FIFO) queue. Oracle AQ has the ability to support messages of two data types:

- Raw
- Object types

These are alternatively referred to as abstract data types (ADT). The object type is a composite type that includes Oracle data types such as number, date, varchar, and so on. Object types can include nested object types.

Types allowed in a message on a queue are controlled by the queue table to which the queue belongs. A queue table also controls the consumer type (single or multiple), default exception queue, message grouping, and default sorting option on dequeuing for all queues created within the queue table.

Individual queues control default delay for creation and message expiration date for all messages within the queue. A subscriber list can be configured for multi-consumer queues at the queue level. A subscriber can be another queue or an application identified by its agent name.

Queues can be propagated through an administrative interface. Subscription lists can be dynamically set and altered through the administrative interface as well.

When an individual message is enqueued, a specific recipient list that overrides subscription list setup for the queue can be specified, along with message grouping, correlation ID, and delay or expiration time for the message. Enqueuing also controls the priority and the relative position of the enqueued message. When a message is enqueued, Oracle assigns it a system-wide global ID (the Message ID) that is returned to the application.

Dequeuing specifications can include the relative position, correlation ID, and wait period of the message being dequeued. For multi-consumer queues, only a consumer whose name is on the recipient list can dequeue a message. Messages that are not dequeued before their expiration time are automatically moved into the exception queue. The adapters do not support the positioning of messages relative to a message ID.

System requirements

The minimum system requirements and operating system requirements for the Oracle AQ Adapter are detailed in the release notes. In addition to these requirements, the following are additional requirements to install and run the Oracle AQ Adapter:

- To install and run the Oracle AQ Adapter, the Oracle Enterprise Edition version and the Oracle AQ Adapter must be installed on the machine hosting the Command Server.
- When running on a UNIX system, the Oracle client creates a process whenever a connection is made to Oracle. If any of these processes terminates, defunct processes will remain in the process list. Although not required (because these do not cause problems nor do they consume resources), you can prevent this occurrence by adding the following line to the **sqlnet.ora** file in the **\$ORACLE_HOME/network/admin** path:

```
bequeath_detach=YES
```

The effect of this line will be to create these same connection processes as detached orphans, thus eliminating the possibility of them becoming defunct.

Command alias

Adapter commands can be specified by using an execution command string on the command line or by creating a command file that contains adapter commands dictating the desired execution settings. For information about all of the options you can use with the execution commands for adapters or how to create a command file, see the *Execution Commands* documentation.

Use the Input Source Override - Message execution command (**-IM**) and the Output Target Override - Message execution command (**-OM**) with the appropriate Oracle AQ Adapter-specific alias. The execution command syntax is:

```
-IM[ alias ] card_num  
-OM[ alias ] card_num
```

where **-IM** is the Input Source - Override execution command and **-OM** is the Output Target - Override execution command, *alias* is the adapter alias, and *card_num* is the number of the input or output card, respectively. The following table shows the adapter alias and execution commands.

Adapter	Alias	As Input	As Output
Oracle AQ	AQ	-IMAQcard_num	-OMAQcard_num

When using an adapter alias with the execution command, the Oracle AQ Adapter commands can be issued on the command line or in a command file. Use the adapter commands to specify adapter functions such as:

- Setting a priority level of a message.
- Identifying subscribers and recipients when using multi-consumer queues.
- Retrieving a logical message from a source queue with a correlation identifier.

For example, to override the adapter commands defined in output card 1, the command string for the adapter in an Oracle AQ environment might be:

```
-OMAQ1 '-Q DEV.ITQUE -C 4aq -US wb -PW y4i6 -EQ ERR.ITQUE -T'
```

This example execution command string defines the Oracle AQ Adapter as the data target. The required Queue Name adapter command (**-Q DEV.ITQUE**) specifies a queue named **DEV.ITQUE**. The required connect string **4aq** is specified using the Connect String adapter command (**-C 4aq**). The user ID **wb** is specified using the required User ID adapter command (**-US wb**). The password **y4i6** is specified using the required Password adapter command (**-PW y4i6**). The Exception Queue adapter command (**-EQ ERR.ITQUE**) specifies an exception queue **ERR.ITQUE**, in which the message is moved if it is not successfully processed. The Trace adapter command (**-T**) indicates that a trace file will be created to report adapter activity information, recording the events that occur while the adapter is retrieving this data.

Note: If the parameter of an adapter command used on the command line is a negative number, the value must be enclosed in double quotation marks so that it cannot be mistaken for another adapter command. For example, enter **-P "-1"** for a priority level of negative one.

- [GET > Source settings](#)
- [PUT > Target settings](#)

GET > Source settings

Use the Map Designer **GET** settings to configure options for input map cards that use the Oracle AQ Adapter. For the **GET > Source setting**, select OracleAQ to use the Oracle AQ Adapter.

- [GET > Source > Command setting](#)
- [Source > Transaction > OnSuccess setting](#)
- [Source > Transaction > OnFailure setting](#)
- [Source > Transaction > Scope setting](#)
- [Source > Transaction > Warnings setting](#)

GET > Source > Command setting

Use the **Command** setting to enter adapter commands. For the syntax of the commands, see ["Commands"](#).

Source > Transaction > OnSuccess setting

Use the **OnSuccess** setting with adapter sources to prevent deletion of the source message(s) from the server from which the messages originate. The default value is **Keep**.

Value	Description
Keep	Keep source messages on the server.
Delete	Delete source messages following a successful map completion.

Source > Transaction > OnFailure setting

Use the **OnFailure** setting with adapter sources to select the rollback (restore a previous version of the message) or commit behavior if the map does not complete successfully. The default value is **Rollback**.

Value	Description
Rollback	If the map does not successfully complete, sources retrieved through the adapter are not deleted nor are the targets stored.
Commit	The adapter behaves as if the map was successful, and the action (Keep or Delete) specified by the OnSuccess setting is taken.

Source > Transaction > Scope setting

Use the **Scope** setting to specify when to check for success (**OnSuccess**) or failure (**OnFailure**) of a map, card, or burst. This is so that the rollback and retry options can be performed as specified. The default value is **Map**.

Value	Description
Map	Check for success or failure at the completion of each map. If the map completes successfully, use the OnSuccess setting. If the map fails, use the OnFailure setting.
Burst	Check for success or failure at the completion of each burst. If the burst is successful, use the OnSuccess setting. If the burst fails, use the OnFailure setting.
Card	Check for success or failure at the completion of each card. If the card is processed successfully, use the OnSuccess setting. If the card fails, use the OnFailure setting.

Source > Transaction > Warnings setting

Use the **Warnings** setting to determine whether to fail the map or ignore warning conditions for the specific input map card. The default value is **Ignore**.

Value	Description
Ignore	

Ignore Ignore warnings for this map card.

Fail

Fail the map upon receiving a warning for this map card.

PUT > Target settings

Use the Map Designer **PUT** settings to configure options for output map cards that use the Oracle AQ Adapter. Use the **PUT > Target** setting to select the data target. Select OracleAQ to use the Oracle AQ Adapter.

- [PUT > Target > Command setting](#)
 - [Target > Transaction > OnSuccess setting](#)
 - [Target > Transaction > OnFailure setting](#)
 - [Target > Transaction > Scope setting](#)
 - [Target > Transaction > Warnings setting](#)
-

PUT > Target > Command setting

Use the **Command** setting to enter adapter commands. For the syntax of the commands, see "[Commands](#)".

Target > Transaction > OnSuccess setting

Use the **OnSuccess** setting with adapter targets to prevent a message from being unnecessarily created during any processes. The default value is Create.

Value

Description

Create

Upon successful completion of the burst, map, card, or rule (determined by the **Scope** settings), create the message.

CreateOnContent

Upon successful completion of the burst, map, card, or rule (determined by the **Scope** settings), create the message only if it is not an empty message.

Target > Transaction > OnFailure setting

Use the **OnFailure** setting with adapter targets to select the rollback or commit behavior if the map does not complete successfully. The default value is Rollback.

Value

Description

Rollback

If the map does not complete successfully, the target is not stored.

Commit

The adapter behaves as though the map was successful and the action (**Create** or **CreateOnContent**) specified by the **OnSuccess** setting is taken.

Target > Transaction > Scope setting

Use the **Scope** setting to specify when to check for success (**OnSuccess**) or failure (**OnFailure**) of a map, burst, or card so that the rollback and retry options can be performed as specified. The default value is Map.

Value

Description

Map

Check for success or failure at the completion of each map. If the map completes successfully, use the **OnSuccess** setting. If the map fails, use the **OnFailure** setting.

Burst

Check for success or failure at the completion of each burst. If the burst is successful, use the **OnSuccess** setting. If the burst fails, use the **OnFailure** setting.

Card

Check for success or failure at the completion of each card. If the card is processed successfully, use the **OnSuccess** setting. If the card fails, use the **OnFailure** setting.

Target > Transaction > Warnings setting

Use the **Warnings** setting to determine whether to fail the map or ignore warning conditions for the specific output map card. The default value is Ignore.

Value

Description

Ignore

Ignore warnings for this map card.

Fail

Fail the map upon receiving a warning for this map card.

Oracle AQ Adapter commands

When used with the Launcher, an Oracle AQ Adapter for a source or a target is configured using the Integration Flow Designer.

The adapter commands allow for connection to Oracle and control of the following Oracle AQ attributes:

- Consumer/producer agent names
- Queue names
- Message correlation IDs
- Message expiration and delay times
- Exception queues
- Wait periods on dequeuing
- Message's recipient list
- Message priority
- [List of commands](#)

List of commands

The following table lists valid commands for the MSMQ adapter, the adapter command syntax, and whether the adapter command is supported (✓) for use with data sources, data targets, or both.

Command	Syntax	Source	Target
Connect String (-C)	-C connect_string	✓	✓
Correlation ID (-CID)	-CID value	✓	✓
Database Name (-DBNAME)	-DBNAME database_name	✓	✓
Database/Query File (-MDQ)	-MDQ mdq_file	✓	✓
Delay (-D)	-D wait_time_in_sec		✓
Exception Queue (-EQ)	-EQ except_queue_name		✓
Expiration (-E)	-E exp_time_in_sec		✓
Global Transaction Management (-GTX) (Oracle, Oracle AQ, Microsoft SQL Server only)	-GTX	✓	✓
Header (-HDR)	-HDR	✓	
Immediate (-I)	-I	✓	✓
IP address (-IP)	-IP	✓	
Listen (-LSN)	-LSN {0 S wait_time_in_sec}	✓	
No Data (-NODATA)	-NODATA	✓	
Password (-PW)	-PW {password@[filename]}	✓	✓
PORT number (-PORT)	-PORT	✓	
Priority (-P)	-P level_number		✓
Quantity (-QTY)	-QTY {value S}	✓	
Queue Name (-Q)	-Q queue_name	✓	✓
Recipient (-R)	-R name name,name... @full_path or -R name	✓	✓
Sender (-S)	-S sender_name		✓
Trace (-T)	-T[E][+]{[path level]} [level path]}	✓	✓
User ID (-US)	-US user_ID	✓	✓

Connect string (-C)

Use the Connect String adapter command (-C) to specify the connection string service name or Oracle service.

-C connect_string

Option

Description

connect_string

This is the connection string service name or Oracle service.

The Connect String adapter command (-C) is required for data sources and data targets.

Correlation ID (-CID)

Use the Correlation ID adapter command (-CID) to specify a particular correlation identifier (CID) for a source or target. For a data source, use this command to retrieve messages from a queue with a specific correlation ID. For a data target, use this command to assign a correlation ID to a message when placing it on a queue.

-CID value

Option

Description

value

This is the correlation identifier used for a source or target.

A correlation identifier is an alphanumeric string up to 128 characters in length.

The * wildcard character can be specified as a data source and is mapped to the Oracle wildcard character %. For more information about wildcard notation, see the *Launcher* documentation.

Database name (-DBNAME)

Use the Database Name adapter command (-DBNAME) to specify the name of a database defined in the database/query file (.mdq) that is specified using the Database/Query File adapter command (-MDQ). The Database Name adapter command can be used for a source or target or in a GET or PUT function.

-DBNAME database_name

The *database_name* you supply is case-sensitive.

Database/query file (-MDQ)

Use the Database/Query File adapter command (-MDQ) to specify the name of the database/query file (.mdq) that contains the database definition for the database to be used (as specified using the -DBNAME adapter command). This Database/Query File adapter command can be used for a source or target or in a GET or PUT function.

-MDQ mdq_file

When this adapter command is used, the .mdq file must be available at map run time. Also, if the database/query file is not in the same directory as the compiled map file, the full path name is required.

Note: Using the combination of the Database Name adapter command (-DBNAME) and the Database/Query File adapter command (-MDQ) provides the same information as the combination of the Connect String adapter command (-C), the User Name adapter command (-US), and the Password adapter command (-PW). If both sets of commands exist in the command line, the -C, -US, and -PW combination takes precedence.

Delay (-D)

Note: The Delay adapter command (-D) requires that the queue manager be started.

Use the Delay adapter command (-D) to specify the delay of the enqueued message for data targets.

By default, when a message is enqueued, it is immediately available for dequeuing. Use the Delay adapter command (-D) for data targets to specify a length of time to wait (in seconds) after which a message is available for dequeuing.

-D wait_time_in_sec

Option

Description

wait_time_in_sec

This is the length of time to wait (in seconds), after which a message is available for dequeuing.

Exception queue (-EQ)

Use the Exception Queue adapter command (-EQ) for data targets to specify an exception queue to which a message is moved if it is not processed successfully.

-EQ except_queue_name

Option

Description

except_queue_name

This is the exception queue to which a message is moved if it is not processed successfully.

Messages are moved to the exception queue when either of the following occurs:

- The number of unsuccessful consumer dequeue attempts exceeds the permitted limit.
- The message has reached the expiration time set by the Expiration adapter command (-E).

Expiration (-E)

Note: The Expiration adapter command (-E) requires that the queue manager be started.

Use the Expiration adapter command (-E) for data targets to specify the length of time (in seconds) that a message is available on the queue before it expires. If the message is not dequeued within the specified time, the message expires and is moved to the exception queue.

-E exp_time_in_sec

Option

Description

exp_time_in_sec

This is the length of time (in seconds) that a message is available on the queue before it expires.

If the Delay adapter command (-D) is used to specify a delay time, the expiration time begins after the delay time has lapsed. For example, if a delay time of two seconds is specified with a five-second expiration time, the message expires in seven seconds and is moved to the exception queue.

Global transaction management (-GTX)

Use the Global Transaction adapter command (-GTX) to indicate that the operations on a card (whether input or output) should be processed within a global transaction.

-GTX

For more information about global transaction management, see the Global Transaction Management documentation.

Header (-HDR)

Use the Header adapter command (-HDR) for data sources to specify inclusion of header information with the actual message.

-HDR

For data targets, the Header adapter command (-HDR) is not necessary. The adapter detects the presence of a header in the target data. The header data overrides any values specified for the corresponding elements with adapter commands.

The following header elements are used to return message attributes for data sources or to specify message attributes for data targets.

Attribute	For a Data Source	For a Data Target
Priority	This returns the priority with which the message was enqueued.	This specifies the message priority and overrides the Priority adapter command (-P).
Delay	This returns the delay with which the message was enqueued.	This specifies the message delay and overrides the Delay adapter command (-D).
Expiration	This returns the expiration with which the message was enqueued.	This specifies the message expiration and overrides the Expiration adapter command (-E).
Correlation	This returns the correlation ID of the received message.	This specifies the message correlation ID and overrides the Correlation ID adapter command (-CID).
Exception Queue	This value is always NONE.	This specifies the message exception queue and overrides the Exception Queue adapter command (-EQ).
Sender	This value is always NONE.	This specifies the sender of the message and overrides the Sender adapter command (-S).
Enqueue Time	This returns the time at which the message was enqueued. The format is: <i>YYYY-MM-DD HH24:MI:SS</i>	On output, this value is ignored.
Recipients	This value is always NONE.	This specifies the comma-separated list of recipients of the message and overrides the Recipient adapter command (-R).

The format of header information is contained within an XML tag <Header> as follows:

```
<Header>
<Priority>... </Priority>
```

```
<Delay>... </Delay>
<Expiration>... </Expiration>
<Correlation>... </Correlation>
<ExceptionQueue>... </ExceptionQueue>
<Sender>... </Sender>
<EnqueueTime> ... </EnqueueTime>
<Recipients>... </Recipients>
</Header>
```

Immediate (-I)

Use the Immediate adapter command (`-I`) for data sources and data targets to dictate immediate enqueueing or dequeuing of the message.

`-I`

When the Immediate adapter command (`-I`) is specified, a message is acted upon immediately (enqueued or dequeued). The default behavior is to wait for successful map completion and current transaction completion.

When the Immediate adapter command (`-I`) is specified, it is not possible to roll back based upon the success status of the map.

IP address (-IP)

Use the IP address adapter command (`-IP`) to specify the IP address of the network interface to listen for incoming notifications from subscriptions to which the adapter is subscribed.

`-IP`

This adapter command is applicable only when using the adapter under the Launcher and when the adapter is configured as a watch for the events. By default, the adapter listens on all the available network interfaces. In addition to the `-IP` adapter command, another way to explicitly specify the IP address is by using the `WTX_AQ_SUBSCRIBER_IP` environment variable for the Launcher process.

When a value is specified through both the adapter command and the environment variable, the adapter command value takes precedence.

Listen (-LSN)

Use the Listen adapter command (`-LSN`) for data sources to indicate the length of time (in seconds) that the Oracle AQ Adapters wait for a message to be received.

`-LSN {0|S|wait_time_in_sec}`

Option

Description

0

Do not wait at all. If there is no input available, the adapter does not wait for more messages.

S

This is an infinite wait time.

`wait_time_in_sec`

This is the number of seconds that the adapter waits for a message.

For example, to specify the wait time of 45 seconds, the syntax would be:

`-LSN 45`

Map execution is suspended until the message(s) is/are received or until the specified time lapses, at which time a warning message is returned. The warning `No messages were found` is returned if there are no messages. The warning `Fetch unit not reached` is displayed if fewer messages were found than specified with the `FetchUnit` setting in the Map Designer.

No data (-NODATA)

Use the No Data adapter command (`-NODATA`) to return only the message header from the queue but not return its data. This is an alternative to the `-HDR` option.

`-NODATA`

Note that the `OnSuccess` setting is ignored if this option is specified, since it is not possible to delete a message if this option is specified.

Password (-PW)

Use the required Password adapter command (`-PW`) to specify the user authorization for connection to Oracle.

`-PW {password} @filename`

Option

Description

password

This is the string that specifies the user authorization.

@filename

This is the name of the file containing the password. No spaces are allowed in the filename.

The `password` option corresponds to the user specified by the User ID adapter command (`-US`). The password can be specified directly or from a file. Using the `filename` method provides greater password security.

For example, to specify a password of `007`, the syntax would be:

```
-pw 007
```

To specify the password contained in the `jbond` file, the syntax would be:

```
-pw @jbond
```

With regard to the format of the password in the password file, the password must be specified in the first line of this file and can contain both leading and trailing white space characters that are removed during processing. Each line is truncated to 128 characters.

The Password adapter command (`-PW`) is required for both data sources and data targets.

PORT number (-PORT)

Use `-PORT` number adapter command to specify the port number of the network interface to listen for incoming notifications from subscriptions to which the adapter is subscribed.

`-PORT`

This adapter command is applicable only when using the adapter under the Launcher and when the adapter is configured as a watch for the events. By default, the adapter listens on a random port dynamically assigned by Oracle AQ. In addition to the `-PORT` adapter command, another way to explicitly specify the port number is by using the `WTX_AQ_SUBSCRIBER_PORT` environment variable for the Launcher process.

When a value is specified through both the adapter command and the environment variable, the adapter command value takes precedence.

Priority (-P)

Use the Priority adapter command (`-P`) to set the priority level of a message for data targets.

```
-P level_number
```

Option

Description

level_number

The priority can be any number including negative numbers. The lower the number is, the higher is its priority.

When messages with the same priority are placed on a queue, the message enqueued earlier is dequeued first. However, when messages have different priorities, the message assigned the highest priority (lowest number) is dequeued first, regardless of when it was enqueued.

Quantity (-QTY)

Use the Quantity adapter command (`-QTY`) to specify the number of messages to retrieve from the source queue. If the Quantity adapter command (`-QTY`) is not specified, the default value is `1`.

```
-QTY {value|S}
```

Option

Description

S

This returns all messages on the queue.

value

This is a positive integer representing the total number of messages to be retrieved.

For example, to specify a quantity of ten messages, the syntax would be:

```
-QTY 10
```

The Quantity adapter command (`-QTY`) defines the maximum number of messages across all bursts for a map.

When the Quantity adapter command (`-QTY`) is used, the message cursor is not returned to the head of the queue for other source cards in the same map that use the same queue. The number of bursts in a single map invocation can be controlled using the combination of values set in the Map Designer SourceRule `> FetchAs > FetchUnit` setting and the Quantity adapter command (`-QTY`).

When using the Quantity adapter command (`-QTY`) with the `S` option through either the Launcher or the Command Server, the Listen adapter command (`-LSN`) is also required with a value specified other than `S`.

Queue name (-Q)

Use the Queue Name adapter command (-Q) to specify the name of the queue for data sources and data targets.

-Q queue_name

Option

Description

queue_name

This is the name of the queue for data sources and data targets.

The Queue Name adapter command (-Q) is required for data sources and data targets.

The queue specified with the Queue Name adapter command (-Q) cannot be an exception queue.

Recipient (-R)

Use the Recipient adapter command (-R) for data sources and data targets to identify the subscribers and recipients when multi-consumer queues are used.

-R {name|name,name,...|@full_path}

or

-R name

Option

Description

name

For a data source, specify the name of one recipient. Only messages sent to this specified recipient are received.

name, name, ...

For a data target only, specify a list of subscribers delimited with commas (no spaces).

@full_path

For a data target only, specify the full path and file name of a file that contains a list of recipients with each recipient's name appearing on a separate line.

For a data target, specify the name of a single recipient or multiple recipients. The file name must be specified using a full path or a relative path to the directory that contains the map file and must be preceded by the "at" sign (@). For example:

-R @c:\inventory\bikes\tricycles.txt

or

-R @/customer/western/stetson.lst

Regarding the format of the map file, each recipient name should be on a separate line in the file. There can be leading and trailing white space characters that are removed during processing. Each line is truncated to 128 characters.

Sender (-S)

Use the Sender adapter command (-S) for data targets only. This identifies the original sender of a message.

-S sender_name

Trace (-T)

Use the Trace adapter command (-T) to produce a log file with the default name **m4aq.log** in the map execution directory. The Trace adapter command (-T) is used with data sources or data targets to enable adapter tracing.

-T[E] [+| [path] [level]

Option	Description						
E	Produce a trace file containing only the adapter errors that occurred during map execution.						
+	This appends the current trace file to an existing trace file. Without the +, the existing trace is deleted and the new trace is written to an empty file.						
path	This is the relative or full path name of the trace file location. If no name is specified, the default file name is m4aq.log .						
level	This indicates the level of information provided in the trace file. The lower the number, the more basic the information. As level numbers increase, additional information is provided in the trace file. (See the available values below.) If no value is specified, the default is 0. <table border="1"><thead><tr><th>Level</th><th>Description</th></tr></thead><tbody><tr><td>0 or 1</td><td>Provides recorded detailed information about the adapter activity such as messages retrieved, SQL statements executed, errors returned (if any), and so on.</td></tr><tr><td>2 or higher</td><td>In addition to the information provided for a 0 level trace, this level provides information about processing individual object fields.</td></tr></tbody></table>	Level	Description	0 or 1	Provides recorded detailed information about the adapter activity such as messages retrieved, SQL statements executed, errors returned (if any), and so on.	2 or higher	In addition to the information provided for a 0 level trace, this level provides information about processing individual object fields.
Level	Description						
0 or 1	Provides recorded detailed information about the adapter activity such as messages retrieved, SQL statements executed, errors returned (if any), and so on.						
2 or higher	In addition to the information provided for a 0 level trace, this level provides information about processing individual object fields.						

The trace file contains information about internal adapter states.

User ID (-US)

Use the User ID adapter command (`-US`) to specify the user ID for connection to Oracle.

`-US user_ID`

Option

Description

`user_ID`

This is the user name for connection to Oracle.

The User ID adapter command (`-US`) is required for data sources and data targets.

Syntax summary

This topic displays the syntax of the Oracle AQ Adapter commands for data sources and targets.

- [Data sources](#)
 - [Data targets](#)
 - [Oracle AQ Adapter example files](#)
-

Data sources

The following is the syntax of the Oracle AQ Adapter commands used for data sources:

```
-Q queue_name -C connect_string -US user_ID -PW {password|@filename}
[-GTX]
[-NODATA]
[-MDQ [mdq_file]]
[-DBNAME [database_name]]
[-I]
[-HDR]
[-CID value]
[-LSN {0|S|wait_time_in_sec}]
[-QTY {value|S}]
[-R name]
[-S]
[-T[E] [+]] [path] [level]]
```

Data targets

The following is the syntax of the Oracle AQ Adapter commands used for data targets:

```
-Q queue_name -C connect_string -US user_ID -PW {password|@filename}
[-GTX]
[-MDQ [mdq_file]]
[-DBNAME [database_name]]
[-I]
[-P level_number]
[-D wait_time_in_sec]
[-EQ except_queue_name]
[-E exp_time_in_sec]
[-CID value]
[-R {name|name,name,...|@full_path}]
[-S]
[-T[E] [+]] [path] [level]]
```

Oracle AQ Adapter example files

To access the adapter example files, navigate to `install_dir/examples/adapters/aq`.

An Oracle AQ type tree is provided. The **simple.mtt** type tree is suitable for receiving and sending simple messages.

- [Connection sharing and transactions](#)
-

Connection sharing and transactions

The Oracle AQ Adapters share connections among multiple Oracle AQ cards based upon the user name, password, service name, rollback option and thread of execution. This is done to improve the performance of the interface.

Data format

The Oracle AQ Adapter formats message data as infix delimited, using a vertical bar (|) as the delimiter. Groups (ADT types) are denoted with a left bracket as the initiator ([:]) and a right bracket as the terminator (:]) to facilitate detection of null groups. (A null group indicates that the entire ADT is null, not just individual members within the group.)

Only the nested ADTs are initiated or terminated; the top ADT group is not.

Because a vertical bar (|), left bracket ([), and right bracket (]) are special characters, when these characters are present in any message, they are released with an exclamation point (!) release character. This process should be transparent to the user.

Note: If an ADT type queue is used, one consisting of only simple types (no nested ADTs), the data itself must not contain any left bracket ([) or right bracket (]) special characters (the adapter releases them, but the type tree will not recognize them).

Using the Database Interface Designer with the Oracle adapters, you can create a type tree to reflect the message types and data format expected by the Oracle AQ Adapter.

Trace log

Use the Trace adapter command (-T) to create a trace file that reports adapter activity information, recording the events that occur while the adapter is retrieving and sending data. The trace command produces a log file with the default name **m4aq.log** file in the map execution directory.

The trace file contains information about connections to the Oracle AQ messaging system, message sizes, error messages, and adapter error messages.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages might also be recorded as specified in the audit logs, trace files, execution summary files, and so on.

- [Oracle AQ Adapter messages](#)

Oracle AQ Adapter messages

The following is a listing of all the codes and messages that can be returned as a result of using the Oracle AQ Adapter for sources or targets.

In addition to the following return codes and messages, the Oracle AQ Adapter can return Oracle AQ error codes. Consult the documentation from Oracle Corporation about the AQ messaging system for descriptions of these codes.

Note: Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Table 1. Oracle AQ Adapter error codes and messages

Return Code	Message
-1001	Invalid command line option
-1002	Missing command line argument
-1003	Invalid command line argument
-1004	Command line processing failed
-1005	Invalid queue name
-1101	Unsupported data type
-1102	Invalid release character position

PDF Adapter

The PDF Adapter works with Acrobat forms and templates to generate a PDF document or extract data from all or part of an input PDF document.

In Design Studio, use the PDF importer (File > Import > PDF) to generate a native XML schema type tree and an associated name-lookup file from the Acrobat form (AcroForm) of a PDF document. The name-lookup file is required to generate formatted PDF output. The name-lookup file maps each type in the schema to the corresponding AcroForm field name, as follows:

TX_type_name=AcroForm_field_name

You can use the native XML schema type tree for mapping, but do not edit the names in the schema. To change schema field names, edit the AcroForm and import the native schema (.xsd) type tree from the PDF document again. On output, the PDF Adapter can generate a formatted PDF file from an Acrobat form, or Acroform template. Without a template, the adapter can create a PDF file that contains unformatted text.

- [System requirements](#)

See the [release notes](#) for the PDF Adapter requirements.

- [PDF Adapter commands](#)

System requirements

See the [release notes](#) for the PDF Adapter requirements.

PDF Adapter commands

- [**Command aliases**](#)
The PDF Adapter works with Acrobat forms and templates to generate a PDF document or extract data from all or part of an input PDF document.
- [**Transaction scope and document persistence in memory**](#)
When a document is added using the -ADOC command, the PDF Adapter stores the document in memory. Documents stored in memory are identified by a document identifier that is either provided by the user, or generated by the PDF Adapter. The document persists in memory as specified by the transaction scope in the card settings.
- [**The data_from_map option**](#)
Some of the PDF Adapter action commands that follow include the *data_from_map* option. The *data_from_map* option represents the data that is passed as the third parameter of a **GET** function. It is not a parameter on the adapter command line.
- [**Add document \(-ADOC\) command**](#)
The **-ADOC** command adds a file on the local file system, or a remote file, accessible through **http** protocol, on the file system as a document in memory and returns the document ID to the map. Alternatively, the **-ADOC** command can add dynamic data from a map as a document in memory and return the document ID to the map.
- [**Remove document \(-RDOC\) command**](#)
The **-RDOC** command removes a document from memory. By default, documents are removed from memory when a map, or card, processing completes. Transaction scope card setting determines the document persistence in memory. Use this command if too many intermediate documents accumulate in memory during map processing.
- [**Replace document \(-UDOC\) command**](#)
The **-UDOC** command replaces an existing document in memory with a new one and returns the new document ID.
- [**Get document data \(-GDOC\) command**](#)
The **-GDOC** command returns data from a document in memory.
- [**Filename \(-URL\) command**](#)
- [**Schema \(-SCHEMA\) command**](#)
- [**Page \(-PAGE\) command**](#)
- [**PDF Template \(-TEMPLATE\) command**](#)
- [**Name lookup file \(-NAMES\) command**](#)
- [**Append data \(-APPEND\) command**](#)
- [**PDF transformation \(-PDF\) command**](#)
The **-PDF** command allows the map to transform map data in XML format to PDF data using the **GET** map rule. **PUT** receives map data in XML format and transforms it to formatted PDF data. This command allows the same with **GET**, so that it can return PDF data back to the map, by performing in-memory transformation. The XML format data must conform to the PDF importer generated, native XML schema type tree, for the corresponding PDF document

Command aliases

The PDF Adapter works with Acrobat forms and templates to generate a PDF document or extract data from all or part of an input PDF document.

Use **PDF** as the adapter command alias on input and output card overrides and in **GET** and **PUT** rules. For example:

Input source override execution command	-IAPDF card_num
Output target override execution command	-OAPDF card_num

Inbound adapter examples

Command line:

```
-U JohnDoe1040.pdf -S f1040.xsd
```

GET rule:

```
=PARSE(GET("PDF", "-S f1040.xsd", BlobIn))
```

Command line for reading pages:

```
-U txredbook.pdf -PAGE 22-23  
-U txredbook.pdf -PAGE 22
```

Outbound adapter commands

Command line with template:

```
-U My1040.pdf -N f1040.names -P f1040.pdf
```

PUT rule:

```
=PUT("PDF", "-U My1040.pdf -N f1040.names -P f1040.pdf -T", Input)
```

Transaction scope and document persistence in memory

When a document is added using the -ADOC command, the PDF Adapter stores the document in memory. Documents stored in memory are identified by a document identifier that is either provided by the user, or generated by the PDF Adapter. The document persists in memory as specified by the transaction scope in the card settings.

- When the transaction scope is MAP, the document is accessible in memory to later map rules in the same map. The document is removed from memory when the map completes processing.
- When the transaction scope is CARD, the document is accessible in memory to later map rules on the same card. The document is removed from memory when the card completes processing, and is not accessible to map rules in later cards.

The *data_from_map* option

Some of the PDF Adapter action commands that follow include the *data_from_map* option. The *data_from_map* option represents the data that is passed as the third parameter of a **GET** function. It is not a parameter on the adapter command line.

If both **-URL** and *data_from_map* options are provided, then *data_from_map* has precedence over the **-URL** option.

Add document (-ADOC) command

The **-ADOC** command adds a file on the local file system, or a remote file, accessible through **http** protocol, on the file system as a document in memory and returns the document ID to the map. Alternatively, the **-ADOC** command can add dynamic data from a map as a document in memory and return the document ID to the map.

-ADOC command syntax

-URL

Adds a single file, specified by a local file URL (**file:///**), or a remote file URL (**http://**), as a document in memory and returns a document ID to the map. The **-URL** keyword is optional, but you must specify either the **-URL**, or the *data_from_map* option on the **-ADOC** command. **doc_ID** is an optional parameter. If specified, the **-ADOC** command associates the user-specified identifier for the document in memory and returns the same. If not specified, the **-ADOC** command generates a unique document identifier for the document in memory and returns the same.

data_from_map

Adds dynamic data from a map as a document in memory and returns the document ID to the map. The *data_from_map* is optional, but you must specify either the **-URL**, or the *data_from_map* option in the **-ADOC** command.

Examples

The following example adds the `parsewds.txt` file as a document in memory and returns the document ID to the map:

```
=GET("PDF", "-URL file:///C:\parsewds.txt -ADOC")
```

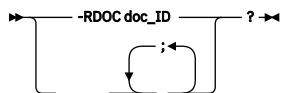

The following example adds the `Hello World!!` text string as a document in memory and returns **mydocid** to the map:

```
=GET("PDF", "-ADOC mydocid", "Hello World!!")
```

Remove document (-RDOC) command

The **-RDOC** command removes a document from memory. By default, documents are removed from memory when a map, or card, processing completes. Transaction scope card setting determines the document persistence in memory. Use this command if too many intermediate documents accumulate in memory during map processing.

-RDOC command line syntax

doc_ID

doc_ID indicates the document identifier of a document to be deleted from memory, if needed.

Replace document (-UDOC) command

The **-UDOC** command replaces an existing document in memory with a new one and returns the new document ID.

-UDOC command syntax

-URL

Specifies the local file URL (**file:///**), or remote file URL (**http://**) of the document that is to replace the document in memory. Either the **-URL** or the *data_from_map* option is required.

data_from_map

Replaces the document in memory with dynamic data from a map. Either the *data_from_map* or the -URL option is required.

Get document data (-GDOC) command

The **-GDOC** command returns data from a document in memory.

-GDOC command syntax

►► -GDOC doc_ID ►►

Filename (-URL) command

-U *filename.pdf*

-URL *filename.pdf*

The -URL command specifies a URL to a local file on the file system (**file:///**), a remote file on a host server (**http://**), or a document in memory (**memory://**). If you do not specify either a local or remote file URL, the adapter treats the PDF document file path as relative to the map directory. Use this command for data sources and data targets.

The -URL command is optional for **GET** rules, but the command is required on input cards. For example, a map can pass PDF Acroform data as a blob to the PDF Adapter, and the adapter can extract data from the blob in XML format.

The -URL command is required on output cards and **PUT** rules.

Schema (-SCHEMA) command

-S *schema.xsd*

-SCHEMA *schema.xsd*

Use this command for data sources and data targets.

On input cards and **GET** rules, the -SCHEMA command specifies the name of the XML schema file that the **GET** transaction is to return with the PDF data. You must specify either -SCHEMA or -PAGE on input cards and **GET** rules. The -SCHEMA and -PAGE command are mutually exclusive.

On output cards and **PUT** rules, the -SCHEMA command specifies the XML schema used to parse XML data when generating a PDF document. The -SCHEMA command is optional on output cards and **PUT** rules. If you omit both the -SCHEMA and -TEMPLATE commands, the adapter creates a PDF document of unformatted text.

Page (-PAGE) command

-PAGE { *nn* | *nn-nn* }

Specifies a page or a range of pages to read from a PDF document and send to the map as a text blob. Use this command on data sources. This command is optional. You must specify either -SCHEMA or -PAGE on input cards and **GET** rules. The -SCHEMA and -PAGE command are mutually exclusive.

PDF Template (-TEMPLATE) command

-P *template_name.pdf*

-TEMPLATE *template_name.pdf*

The PDF template to use to generate a PDF document. Use this command for data targets. This command is optional. If you omit both the -SCHEMA and -TEMPLATE commands, the adapter creates a PDF document containing unformatted text.

Name lookup file (-NAMES) command

-N *filename.names*

-NAMES *filename.names*

The name-lookup file created by importing a PDF document. The .names file maps the AcroForm field names to the types in the schema. Use this command for data targets. This command is required on output cards and **PUT** rules to create a formatted PDF document. If you omit the -NAMES command, the generated PDF document contains unformatted text.

Append data (-APPEND) command

-APPEND

Appends data to the specified PDF document. Use this command for data targets. This command is optional.

PDF transformation (-PDF) command

The **-PDF** command allows the map to transform map data in XML format to PDF data using the **GET** map rule. **PUT** receives map data in XML format and transforms it to formatted PDF data. This command allows the same with **GET**, so that it can return PDF data back to the map, by performing in-memory transformation. The XML format data must conform to the PDF importer generated, native XML schema type tree, for the corresponding PDF document

This command is useful in environments where file system access is restricted to the users, and PDF transformations must be performed in memory and then the transformed output to be returned to the map for further processing. A stream of PDF data is passed to the map with GET:

```
=GET("PDF","-PDF -NAMES memory://<names-document-id> -TEMPLATE memory://<template-document-id>",<xml-map-data>)
```

A template must be added to memory, if it is not a remote file, using the **-ADOC** command when performing in-memory transformation of XML formatted data to PDF formatted data. The **-ADOC** command returns a user specified document ID, or system ID for the template.

Note: The document in memory is referenced as: **memory://**

This three step process is shown here:

- **template-document-id=GET("PDF","-ADOC",<template-file-data-as-stream>)** or **=GET("PDF","-ADOC <my-template-documentid>",<template-file-data-as-stream>)**
- **names-document-id=GET("PDF","-ADOC",<names-file-data-as-stream>)** or **=GET("PDF","-ADOC <my-names-documentid>",<names-file-data-as-stream>)**
- **pdf-data-out=GET("PDF","-PDF -NAMES memory://<names-document-id> -TEMPLATE memory://<template-document-id>",<xml-map-data>)**

If you have to specify **-SCHEMA** (or **-S**), then you can do the same for the schema files.

Store output document in memory

Without the **-PDF** command, instead of streaming to a map, output operation can keep the output document in memory until it is fetched with **-GDOC** option. This is a two step process:

- **=PUT("PDF","-URL memory://<my-output-doc-id> -NAMES memory://<names-document-id> -TEMPLATE memory://<template-document-id>",<xml-map-data>)** or the adapter command line can be used with the output card.
- **pdf-data-out=GET("PDF","-GDOC <my-output-doc-id>")**

Default File URL

It is required to specify **memory://** for memory documents, **http://** for remote documents, or **file:///** for local file system documents using the **-URL (-U)**, **-NAMES (-N)**, **-SCHEMA (-S)** and **-TEMPLATE (-P)** commands.

Reference XML data

-URL memory://<xml-data-document-id> can be specified. XML data is in memory and can be referenced instead of passing map data as a third parameter of GET. The third parameter has precedence over the **-URL** option.

RabbitMQ Adapter

This documentation describes the RabbitMQ Adapter.

- [**Overview**](#)
The RabbitMQ adapter provides access to RabbitMQ message broker exchanges and queues.
- [**Introduction**](#)
The RabbitMQ adapter is used in maps and flows to send messages to the specified exchange or to receive messages from the specified queue.
- [**Prerequisites**](#)
- [**Authenticating connections**](#)
The RabbitMQ adapter supports username and password-based authentication to establish the connections to the RabbitMQ broker. The username and password credentials need to be specified in the User and Password properties in the connection definition for the adapter. The provided credentials are mandatory to authenticate AMQP connections established on the Port property and HTTP connections established on the Management Port property.
- [**Adapter properties and commands**](#)
This section lists the properties and commands supported by the adapter.
- [**Design Time Operations**](#)
- [**Examples**](#)

Overview

The RabbitMQ adapter provides access to RabbitMQ message broker exchanges and queues.

Introduction

The RabbitMQ adapter is used in maps and flows to send messages to the specified exchange or to receive messages from the specified queue.

The following features are supported by the RabbitMQ adapter:

- Testing of configured connections.
- Listing of available queues and exchanges.
- Generating schemas.
- Receiving messages from the specified queue with the support for multiple receiving guarantee modes.
- Sending messages to the specified exchange using the specified routing key with the support for multiple delivery guarantee modes.
- Accessing the message payload and metadata in individual messages including native message headers.
- Using TLS for secure connections.

Prerequisites

It is recommended that the RabbitMQ broker is up to date with the latest available patches. For more information about officially supported RabbitMQ releases and the latest available patches, see <https://www.rabbitmq.com/versions.html>.

The RabbitMQ client library utilized by the adapter to connect to the RabbitMQ broker is included with the adapter library and does not need to be installed separately in the adapter's runtime environment.

Configure the network connectivity from the adapter's runtime environment to the broker. The value of the Host property in the connection definition for the adapter must be either of the following options:

- DNS-resolvable host name.
- IP address of the broker.

For the adapter to establish an AMQP connection and a HTTP connection with the broker, the port numbers in Port and Management Port properties in the connection definition for the adapter must be active and accessible on the broker from the adapter's runtime environment.

Authenticating connections

The RabbitMQ adapter supports username and password-based authentication to establish the connections to the RabbitMQ broker. The username and password credentials need to be specified in the User and Password properties in the connection definition for the adapter. The provided credentials are mandatory to authenticate AMQP connections established on the Port property and HTTP connections established on the Management Port property.

In addition to the authentication of the user based on the username and password credentials, the adapter supports certificate-based authentication with the RabbitMQ broker by utilizing TLS-secured AMQP and HTTP connections.

- The adapter can be configured to request the RabbitMQ broker to provide a certificate that the adapter validates using the truststore information specified in the Truststore Location and Truststore Password properties.
- The Verify Hostname property can be set to instruct the adapter to verify, if the host name specified in the connection is also listed in the certificate presented by the broker. The adapter can also be configured to present its certificate using the keystore information specified in the Keystore Location, Keystore Password, and Key Password properties when the broker is configured to request clients to provide their certificate when connecting to it. The Key Password is applicable when the private key in the keystore is protected by a password different from the keystore password.
- [RabbitMQ adapter as a source](#)
- [RabbitMQ adapter as a target](#)

RabbitMQ adapter as a source

The RabbitMQ adapter as a source:

- Can be used as a data source for input card in maps, and a source node in flows. In this capacity, the adapter connects to the broker and receive messages from the queue specified in the Queue Name property.
- Can be configured to act as a watch for the source nodes in flows. In this capacity, the adapter is utilized from the listener service and registers itself with the RabbitMQ broker to notify the messages arriving on the queue specified in the Queue Name property. The adapter captures the messages and reports them as events which in turn are used to trigger instances of the flow in which the watch is defined. When an instance of the flow runs, the input node in the flow on which the watch is defined operates on the data collected from the event that triggered the flow instance without a need to connect to the broker again.
- Receives messages from the specified queue with support of multiple Receiving Guarantee Mode. In the simplest cases, the adapter can be configured to read messages with automatic acknowledgment which removes messages from the queue immediately and with automatic negative acknowledgment which always restores messages on the queue. The adapter can also be configured to acknowledge messages positively or negatively to the broker and to receive messages under AMQP transactions and commit or roll back the transactions based on the reported execution status in the map or flow.
- Provides support for accessing payloads and message properties in the received messages including custom message headers which all can be used in the transformation logic defined for the map or flow. When providing message properties along with the payload data, the adapter reports them together in form of JSON documents. The adapter supports encoding binary message payloads as base64 or hex-digit pairs encoded values in JSON documents that cannot be represented as text.

RabbitMQ adapter as a target

The RabbitMQ adapter as a target:

- Can be used as data target for output card in maps, and a target node in flows. In this capacity, the adapter connects to the broker and sends messages to the exchange specified in the Exchange Name property using the routing key specified in the Routing Key property.
- Sends messages to the specified exchange using the specified routing key with the support of multiple Delivery Guarantee Mode. In the simplest cases, the adapter can be configured to send messages in "fire-and-forget" mode in which case it does not receive or expect to receive any confirmation from the broker. The adapter

can also be configured to request confirmation on successful delivery from the broker and act on the confirmation status and to send messages under AMQP transactions and commit or roll back the transactions based on the reported execution status in the map or flow.

- Provides support for setting payloads and message properties for the produced messages which can be provided manually or derived by the transformation logic defined for the map or flow. When providing message properties along with the payload data, the adapter reports them together in form of JSON documents. The adapter supports encoding binary message payloads as base64 or hex-digit pairs encoded values in JSON documents that cannot be represented as text.

Adapter properties and commands

This section lists the properties and commands supported by the adapter.

Host

Specifies the host name where the RabbitMQ broker is installed and running. This is a valid DNS name of the host or its IP address. This is a mandatory property. The corresponding adapter command is `-H host` (or `-HOST host`).

Port

Specifies the port on which the RabbitMQ broker is listening for connections from clients such as the RabbitMQ adapter and communicating with them using the AMQP protocol. Messages are consumed and produced on the connection established on this port. The default value is 5672. If TLS Connections property is set to value AMQP or AMQP/HTTP, the adapter establishes secure AMQP connection to the broker. The port number must match the port on which RabbitMQ accepts secure AMQP connections. Default port is 5671. The corresponding adapter command is `-P port` (or `-PORT port`).

Management Port

Specifies the port on which the RabbitMQ broker is accepting API calls over HTTP for performing management operations. The adapter connects to this port on the broker to obtain the lists of available exchanges and queues to display in the web UI. The default value is 15672. If TLS Connections property is set to value HTTP or AMQP/HTTP, the adapter establishes secure HTTP (HTTPS) connection to the broker. The port number must match the port on which RabbitMQ accepts secure HTTP connections. Default port is 15671. The corresponding adapter command is `-MP port` (or `-MANAGEMENTPORT port`).

User

Specifies the username to use for authentication when connecting to the message broker. This is a mandatory property. The corresponding adapter command is `-USR username` (or `-USERNAME username`).

Password

Specifies the password value to use for authentication when connecting to the message broker. The corresponding adapter command is `-PWD password` (or `-PASSWORD password`).

Virtual Host

Specifies the virtual host for the connection defined in the broker. The user must be authorized to access that virtual host. The default value is `/`, which is the default virtual host defined in the broker. The corresponding adapter command is `-VH vhost` (or `-VIRTUALHOST vhost`).

Connection Name

Specifies the optional name to use for identifying the connection. The broker includes this value in the broker log messages which makes it easier to locate log messages that apply to the connection established by the adapter. The corresponding adapter command is `-CN name` (or `-CONNECTIONNAME name`).

TLS Connection

Specifies the types of connections to utilize TLS for security. The corresponding adapter command is `-TLSC connections` (or `-TLS CONNECTIONS connections`). The following values are supported:

- **None**: TLS is never used. This is the default value. The corresponding adapter command value is `none`.
- **AMQP**: TLS for AMQP connections only. AMQP connections are used for producing and consuming messages. The corresponding adapter command value is `amqp`.
- **HTTP**: TLS for HTTP connections only. HTTP connections are used for listing available queues and exchanges in the web UI. The corresponding adapter command value is `http`.
- **AMQP/HTTP**: TLS for both AMQP and HTTP connections. The corresponding adapter command value is `amqp_http`.

Truststore Location

Specifies the path to the truststore in PKCS#12 or JKS format that the adapter uses to validate the broker certificate when TLS is enabled. The truststore must contain the chain of certificates up to the CA certificate that is used to sign the broker certificate. The corresponding adapter command is `-TSL path` (or `-TRUSTSTORELOCATION path`).

Truststore Password

Specifies the password for the adapter to use to access the specified truststore when TLS is enabled. The corresponding adapter command is `-TSP password` (or `-TRUSTSTOREPASSWORD password`).

Verify Hostname

Verifies the hostname specified for the connection is listed in the certificate presented by the broker when TLS is enabled. If it is not listed in the certificate, the connection fails. The corresponding adapter command is `-VH` (or `-VERIFYHOSTNAME`).

Keystore Location

Specifies the path to the keystore in PKCS#12 or JKS format that the adapter uses to retrieve the private key and certificate with the public key. Which is required, if the broker is configured to request clients to provide a certificate for TLS connections (mutual TLS). The corresponding adapter command is `-KSL path` (or `-KEYSTORELOCATION path`).

Keystore Password

Specifies the password for the adapter to access the specified keystore when TLS is enabled and mutual TLS is configured. The corresponding adapter command is `-KSP password` (or `-KEYSTOREPASSWORD password`).

Key Password

Specifies the password for the adapter to access the private key in the specified keystore when TLS is enabled and mutual TLS is configured. The password is required, if the private key is secured with a password different from the keystore password. The corresponding adapter command is `-KP password` (or `-KEYPASSWORD password`).

Queue Name

Specifies the name of the queue from which to consume messages. Click the Fetch button when configuring this property in the web UI to show the available queue and select a queue from the list. You can enter in the name of the queue manually. The corresponding adapter command is `-Q name` (or `-QUEUE name`).

Exchange Name

Specifies the name of the exchange to produce the messages. Click the Fetch button when configuring this property in the web UI to show the available exchanges and select an exchange from the list. You can type in the name of the exchange manually. The corresponding adapter command is `-E name` (or `-EXCHANGE name`).

Routing Key

Specifies the routing key for the broker to use along with the exchange name to determine the queue or queues to which the produced messages should be routed and stored. The corresponding adapter command is `-RK key` (or `-ROUTINGKEY key`).

Receiving Guarantee Mode

Specifies the guarantee mode to request when consuming messages from the queue. The corresponding adapter command is `-RGM mode` (or `-RECEIVINGGUARANTEEMODE mode`). The following values are supported:

- **Transactions (AMQP TX):** The adapter consumes messages under an AMQP (TX) transaction. If the adapter is requested to commit the transaction in the map or flow, it positively acknowledges the messages consumed under the transaction and commits the AMQP transaction after which the broker removes the messages from the queue. If the adapter is requested to roll back the transaction in the map or flow, it rolls back the AMQP transaction which results in the messages remaining on the queue. This is the default option. The corresponding adapter command value is `tx`.
- **Acknowledgments Only:** The adapter consumes messages outside of an AMQP (TX) transaction. If the adapter is requested to commit the transaction defined in the map or flow context, it positively acknowledges the messages consumed under the transaction and the broker removes them from the queue. If the adapter is requested to roll back the transaction in the map or flow, it negatively acknowledges (nacks) the messages consumed under the transaction with redelivery enabled which results in the messages remaining on the queue. The corresponding adapter command value is `acknowledgments_only`.
- **Read Only:** When a message is consumed by an adapter with redelivery enabled, the adapter negatively acknowledges the message regardless of whether it is requested to commit or rollback the transaction, so the message always remains on the queue. The corresponding adapter command value is `read_only`.
- **None:** The adapter consumes messages in auto-acknowledge mode. This means that the messages are permanently removed from the queue after consumed by the adapter regardless of whether the adapter is subsequently requested to commit or rollback the transaction in the map or flow context. The corresponding adapter command value is `none`.

Delivery Guarantee Mode

Specifies the guarantee mode to request when producing messages to the exchange. The corresponding adapter command is `-DGM mode` (or `-DELIVERYGUARANTEEMODE mode`). The following values are supported:

- **Transactions (AMQP TX):** The adapter produces messages to the exchange under an AMQP (TX) transaction. If the adapter is requested to commit the transaction in the map or flow context, it commits the AMQP transaction after which the broker stores the messages. If the adapter is requested to roll back the transaction in the map or flow context, it rolls back the AMQP transaction which results in the messages not being stored on the queue(s). Note that for the true transactional behavior to be enforced all the messages need to be routed to the same queue, it means the exchange and the routing key used for producing the messages must result in all messages in the transaction being routed and stored on the same queue. This is the default option. The corresponding adapter command value is `tx`.
- **Publisher Confirms:** The adapter requests the broker to send confirmations about successful acceptance of each message. If the adapter is subsequently requested to commit the transaction in the map or flow context, it checks if all the messages in the transaction were positively acknowledged (acked) by the broker (and waits for any pending confirmations if necessary) and performs no further action. If any messages were negatively acknowledged (nacked) by the broker, the adapter logs them, if the logging is enabled and throws an exception to indicate the problem. The messages that were already positively acknowledged by the broker are stored on the broker and those that were negatively acknowledged are not. The corresponding adapter command value is `publisher_confirms`.
- **None:** This is a 'fire and forget' mode. The adapter publishes messages and does not perform any further checking to verify if the messages were successfully accepted and stored by the broker. The corresponding adapter command value is `none`.

Mandatory Routing

Specifies the mandatory routing for the messages for the specified exchange name and routing key. When this property is enabled and a message not routed to its destination, the broker returns the messages to the adapter asynchronously and the adapter is notified about this throws an exception and causes the map or flow to fail.

When this property is enabled and Delivery Guarantee Mode is set to Transactions (AMQP TX), the adapter is notified about non-routable messages during the execution of the AMQP commit call. If that happens, the commit will complete successfully and the messages that were successfully routed will be committed but the adapter will still throw exception to indicate that some messages could not be routed and were returned by the broker.

When this property is enabled and Delivery Guarantee Mode is set to Publisher Confirms, the adapter is be notified about non-routable messages prior to being notified with positive or negative confirmation for each message. Since the adapter always waits for the confirmations from the broker in this mode, it will be timely notified of any non-routable and returned messages and will throw an exception. By default, this property is enabled.

If an alternate exchange is defined for the exchange to which the messages are published and the message could not be routed to the original exchange, it will be re-routed by the broker to the alternate exchange and will not be considered as non-routable. If this property is enabled, the broker will not return the message to the adapter as the message will be considered successfully routed. Returned messages are always logged by the adapter in the adapter log when logging is enabled. The corresponding adapter command is `-MR` (or `-MANDATORYROUTING`).

Consumer Tag

Specifies the consumer tag for the consumer. Tag to assign to the consumer created by the adapter for consuming messages from the broker to serve as events for triggering flow instances. Therefore, this property only applies to the consumer the adapter creates when used in a source node in a flow for that a watch is enabled. When the value is not specified for this property, the broker automatically generates a consumer tag value for the consumer. The corresponding adapter command is `-CTAG tag` (or `-CONSUMERTAG tag`).

Message Header

Specifies the JSON schema version that represents messages. The default value `None` means that message metadata will not be processed, only the message payload. The adapter does not do any JSON processing in this case and the entire data passed to and from the adapter represents the message payload binary data. The corresponding adapter command value is `0`. The value `Version 1` indicates the message JSON structure version 1, which is covered in detail in the Generating Schema section. The corresponding adapter command value is `1`. The corresponding adapter command is `-HDR version` (or `-HEADER version`).

Charset

Specifies the character set to use for conversion between the raw bytes exchanged with the adapter framework and the Java strings required for the message header JSON fields. By default, the charset encoding from the current system locale is used. The corresponding adapter command is `-CS charset` (or `-CHARSET charset`).

Message Header Element

Specifies the message header fields. Comma-separated list of message header fields to include in the generated JSON schema and in the generated JSON representation of messages when consuming messages. Any extra whitespaces around the values are not ignored and are considered parts of those values. The property applies only when the Message Header property is set to a value other than `None`. The corresponding adapter command is `-MHE list` (or `-MESSAGEHEADERELEMENTS list`).

For example, if this property is set to the value `app_id,priority,message_id,user_id`, the JSON representation of the message will be:

```
{
    "app_id": "",
    "priority": 0,
    "message_id": "",
    "user_id": ""
}
```

It is important to note that the order of fields in the property value matches the order of elements in the generated JSON. Also, the payload element must be set among the property's fields to be included in JSON.

Native Headers

Specifies the native message headers. Comma-separated list of native message headers to include in the headers element in the generated JSON schema and in the generated JSON representation of messages when consuming messages. The native headers are required to be captured. They are required to be captured when the Message Header Elements property is not set, in that case all message header elements are automatically included and when it is set to a comma-separated list of values which includes the headers values. It is important to note that any extra whitespaces around the values in the list are not ignored and are considered parts of those values. The corresponding adapter command is -NH *list* (or -NATIVEHEADERS *list*).

For example, if generating a schema and the property Message Header Elements is set to value message_id,headers,payload, and the Native Header Fields is set to value title,size, as part of the schema generation process the adapter retrieves message from the queue that contains title header of string type and size header of numeric integer type then the generated JSON schema will be:

```
{
    "message_id": "",
    "headers": [
        "title": "",
        "size": 0
    ],
    "payload": ""
}
```

Native Headers Element Type

Specifies the type to use when generating schema and consuming messages. You can define the type of the headers element in the JSON messages representation. When producing messages, the adapter automatically detects the type used in the JSON data provided to it. The corresponding adapter command is -NHET *type* (or -NATIVEHEADERSELEMENTTYPE *type*). The supported values are:

- Object:** The headers element is a JSON object. This is the default value. The corresponding adapter command value is object.
- Array:** The headers element is a JSON array. The corresponding adapter command value is array.

When the headers element is of array type, it is a JSON array with an arbitrary number of JSON objects that contains the key and value elements. In most cases, string types are appropriate when all headers for the message can be represented by the same atomic type:

```
"headers": [
    {
        "key": "header1_name",
        "value": "header1_value"
    }
]
```

When the headers element is of object type, it is a JSON object with the number of elements that matches the number of headers in the message and where each of those elements has name and value that match the corresponding header's key and value. It is appropriate to use when the headers for the message have different types, such as a string, integer, floating-point decimal number, Boolean, and list of string values:

```
"headers": {
    "header1_name": "header1_value",
    "header2_name": 10,
    "header3_name": 10.05,
    "header4_name": true,
    "header5_name": [
        "header5_element1_value"
    ]
}
```

Message Payload Encoding

Specifies the encoding of the value of the payload element in the JSON message representation. The corresponding adapter command is -MPE *encoding* (or -MESSAGEPAYLOADENCODING *encoding*). The supported values are:

- Text:** The value is a string representation of the message payload. It assumes that the message payload is text encoded using the current system locale encoding or the encoding specified in the Charset property. The corresponding adapter command value is text.
- JSON:** The value is in JSON format. This can be an atomic JSON value, a JSON object, or a JSON array. It assumes that the message payload is JSON text encoded using the current system locale encoding or the encoding specified in the Charset property. The corresponding adapter command value is json.
- Hex Pairs:** The value is a string consisting of consecutive hex-digit pairs, where each pair corresponds to a single byte in the message payload's binary content. The corresponding adapter command value is hex_pairs.
- Base64:** The value is a string that represents base64 encoded message payload's binary content. The corresponding adapter command value is base64.

Application Id

Specifies the application identifier message property value to set for the produced messages. The value can also be set on a per-message basis using the app_id element in the JSON message structure. When both values are specified, the app_id JSON element value takes preference. The corresponding adapter command is -AID *id* (or -APPLICATIONID *id*).

Content Type

Specifies the content type message property value to set for the produced messages, for example gzip. The value can also be set on a per-message basis using the content_type element in the JSON message structure. When both values are specified, the content_type JSON element value takes preference. The corresponding adapter command is -CTYPE *type* (or -CONTENTTYPE *type*).

Content Encoding

Specifies the content encoding message property value to set for the produced messages, for example text/plain or application/json. The value can also be set on a per-message basis using the content_encoding element in the JSON message structure. When both values are specified, the content_encoding JSON element value takes preference. The corresponding adapter command is -CENC *encoding* (or -CONTENTENCODING *encoding*).

Correlation Id

Specifies the correlation identifier message property value to set for the produced messages. The value can also be set on a per-message basis using the correlation_id element in the JSON message structure. When both values are specified, the correlation_id JSON element value takes preference. The corresponding adapter command is -CID *id* (or -CORRELATIONID *id*).

Delivery Mode

Specifies the mode of delivery to set for the produced messages. The value can also be set on a per-message basis using the delivery_mode element in the JSON message structure. When both values are specified, the delivery_mode JSON element value takes preference. The corresponding adapter command is -DM *mode* (or -DELIVERYMODE *mode*). The following values are supported for this property:

- **Transient:** For instructing the broker to store messages in memory. This is the default value. The corresponding adapter command value is transient.
- **Persistent:** For instructing the broker to persist messages on disk. The corresponding adapter command value is permanent.

Reply To

Specifies the name of the response queue to set for the produced messages. The value can also be set on a per-message basis using the reply_to element in the JSON message structure. When both values are specified, the reply_to JSON element value takes preference. The corresponding adapter command is -RTO *name* (or -REPLYTO *name*).

Expiration

Specifies the message expiration duration in milliseconds to set for the produced messages. The value can also be set on a per-message basis using the expiration element in the JSON message structure. When both values are specified, the expiration JSON element value takes preference. The corresponding adapter command is -EXP *duration* (or -EXPIRATION *duration*).

Message Id

Specifies the message identifier message property value to set for the produced messages. The value can also be set on a per-message basis using the message_id element in the JSON message structure. When both values are specified, the message_id JSON element value takes preference. The corresponding adapter command is -MID *id* (or -MESSAGEID *id*).

Priority

Specifies the priority to set for the produced messages. The value can also be set on a per-message basis using the priority element in the JSON message structure. When both values are specified, the priority JSON element value takes preference. The corresponding adapter command is -PRI *priority* (or -PRIORITY *priority*).

Timestamp

Specifies the timestamp message property value to set for the produced messages. It is a string value in the yyyy-MM-dd HH:mm:ss format representing a timestamp with a second precision and using the timezone from the current system locale. The value can also be set on a per-message basis using the timestamp element in the JSON message structure. When both values are specified, the timestamp JSON element value takes preference. The corresponding adapter command is -TS *timestamp* (or -TIMESTAMP *timestamp*).

Type

Specifies the user defined message type to set for the produced messages. The value can also be set on a per-message basis using the type element in the JSON message structure. When both values are specified, the type JSON element value takes preference. The corresponding adapter command is -TYP *type* (or -TYPE *type*).

User Id

Specifies the user identifier message property value to set for the produced messages. When set, RabbitMQ verifies that it matches the user id associated with the current connection. The value can also be set on a per-message basis using the user_id element in the JSON message structure. When both values are specified, the user_id JSON element value takes preference. The corresponding adapter command is -UID *id* (or -USERID *id*).

Limit

Specifies the total number of messages to consume. The default value is 1. The special value S indicates all available messages. When the adapter is utilized as a listener for a flow node with a watch this property does not affects. In that case, the adapter waits indefinitely for a new message to arrive for as long as it is in the running state. The corresponding adapter command is -QTY *limit*.

Timeout

Specifies the time duration (in seconds) to wait for before retrieving the message. The default value is S. This is a special value that indicates unlimited (infinite) wait. The value 0 means no wait. When the adapter is utilized as a listener for a flow node with a watch this property does not affects. In that case, the adapter waits indefinitely for a new message to arrive for as long as it is in the running state. The corresponding adapter command is -LSN *timeout*.

Logging

Specifies the level of logging to use for the log (trace) file produced by the adapter.

The value Information means log informational messages, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

The corresponding adapter command is:

-T[V|E][+] [*log_file*]

-T -> Log adapter informational messages.

-TE -> Log only adapter errors.

-TV -> Use verbose (debug) logging. The log file records all activity that occurs while the adapter is producing or consuming messages.

+ -> Appends the trace information to the existing log file. Omit this argument to create a new log file.

log_file -> Specifies the location of the log file to which to write log messages. If not specified, the default log file name m4rabbitmq.mtr is used and the file is stored to the directory in which the executed compiled map resides.

Append Log

Flag indicating what to do if the specified log file already exists. When set to true, the log messages are appended to the file. When set to false, the file is truncated, and the messages are written to the empty file. The default value is true.

Log File Path

Specifies the location of the log file to which to write log messages. If not specified, the default log file name m4rabbitmq.mtr is used and the file is stored to the directory in which the executed compiled map resides.

Design Time Operations

The following functions are performed by the adapter in the web UI to assist with the design process when designing maps or flows that utilize the RabbitMQ adapter:

- Testing connection.
- Listing the available queues and exchanges.
- Generating schema.

- **Testing Connections**

When defining a RabbitMQ connection in the web UI, the Test option is provided to verify the connections settings by attempting to connect to the RabbitMQ broker specified in the connection definition.

- **Listing queues and exchanges**

When defining properties for a RabbitMQ action, card, or node in the UI, the values for the Queue Name and Exchange Name properties can be entered manually or the Fetch option can be selected to retrieve the list of available queues and exchanges in the broker and then a value selected from the list. To retrieve the list, the adapter establishes HTTP connection to the broker using the settings from the connection definition associated with that action, card, or node.

- **Generating Schema**

When defining schema for a RabbitMQ action, card or node in the UI, an existing schema in the project can be selected or a new schema can be generated and automatically selected. When generating the schema, if the Message Header property is set to value None, adapter generates a simple classic schema with a single item to represent the message payload as raw binary data.

Testing Connections

When defining a RabbitMQ connection in the web UI, the Test option is provided to verify the connections settings by attempting to connect to the RabbitMQ broker specified in the connection definition.

For implementing the Test function, the adapter tries to establish AMQP connection to the RabbitMQ host at the port specified in the Port property. The user credentials and the TLS settings if enabled for the AMQP connection are utilized when establishing the connection and are therefore verified by the test operation.

The Management Port property is not used when performing the test operation from the UI, so the ability to establish HTTP connection to the broker is not verified by the test operation. The testing of HTTP connection is performed indirectly from the UI by listing the available queues and exchanges in the UI page on which the action, card, or node properties for the adapter are defined. Since those operations are performed using management API calls to the broker that require HTTP connection to the broker performing them will result in testing the Management Port property along with the credentials and TLS settings, if those have been enabled for the HTTP connections.

Listing queues and exchanges

When defining properties for a RabbitMQ action, card, or node in the UI, the values for the Queue Name and Exchange Name properties can be entered manually or the Fetch option can be selected to retrieve the list of available queues and exchanges in the broker and then a value selected from the list. To retrieve the list, the adapter establishes HTTP connection to the broker using the settings from the connection definition associated with that action, card, or node.

Generating Schema

When defining schema for a RabbitMQ action, card or node in the UI, an existing schema in the project can be selected or a new schema can be generated and automatically selected. When generating the schema, if the Message Header property is set to value None, adapter generates a simple classic schema with a single item to represent the message payload as raw binary data.

If the Message Header property is set to Version 1, the adapter generates JSON schema to represent the message metadata and payload.

The following example shows default Version 1 message JSON structure:

```
{  
    "version": 0,  
    "delivery_tag": 0,  
    "redelivered": true,  
    "exchange": "",  
    "routing_key": "",  
    "consumer_tag": "",  
    "app_id": "",  
    "content_type": "",  
    "content_encoding": "",  
    "correlation_id": "",  
    "delivery_mode": 0,  
    "reply_to": "",  
    "expiration": "",  
    "headers": {},  
    "message_id": "",  
    "priority": 0,  
    "timestamp": "",  
    "type": "",  
    "user_id": "",  
    "payload": ""  
}
```

By default, the adapter includes all the fields in the generated JSON schema. A reduced set of fields to include in the schema can be specified using the Message Header Elements property. When the property is set the adapter includes only the elements specified in the comma-separated list of values set in the property. Refer to the

Message Header Elements property description for more information.

The JSON type of the headers element can be array or object. When generating schema and consuming messages the selection for the type to use in the JSON generated by the adapter is made using the Native Headers Element Type property. For more information, see the Native Headers Element Type property description.

The JSON type of the payload element is string by default and captures the message payload in text format. It can also be any other JSON type if the message payload is JSON and the adapter is configured to capture the JSON structure. When generating schema and consuming messages the selection for the JSON type to use in the JSON generated by the adapter is made using the Message Payload Format property. For more information, see the Message Payload Format property description.

When generating schema, the adapter in certain cases needs to establish AMQP connection and retrieve a message from the specified queue, so that it can inspect the structure of the message and generate correct schema. In those cases, the adapter expects at least one message to be available on the queue. It proceeds to consume that message and then negatively acknowledges it so that it is restored on the queue. Note that this results in the message technically being redelivered and will result in the broker setting the redelivered property on the message to true.

The following conditions are required for connecting to the broker and retrieving a message from the queue when generating a schema:

- The Message Header is set to a value other than None. If set to None, the adapter generates a simple fixed schema with a single item to represent the message payload.
- Schema generation is initiated while configuring a source action, card, or node. The Queue Name property must be set in that case. When configuring a target action, card or node, the default simple schema or JSON schema with all elements is generated depending on the Message Header value.
- One or both of the following applies:
 - The JSON message structure is requested to have the headers element.
 - The Message Payload Format property is set to the value JSON. It is important to note that the headers element is implicitly requested when the Message Header Elements property is not set, in that case it is automatically included. It is explicitly requested when the Message Header Element property is set to a list of values including headers.

The following table provides a brief description about individual JSON elements in the JSON message structure.

Element	JSON type	Description
version	number	Version. Set the value 1 for the header version 1 .
delivery_tag	number	Delivery tag, applicable when consuming messages.
redelivered	boolean	Redelivered flag, applicable when consuming messages.
exchange	string	Exchange name, applicable when consuming messages.
routing_key	string	Routing key, applicable when consuming messages.
consumer_tag	string	Consumer tag, applicable when consuming messages with a flow listener.
app_id	string	Application id. Custom value assigned by the user.
content_type	string	Message content type, such as gzip .
content_encoding	string	Message content encoding, such as text/plain .
correlation_id	string	Correlation id. Custom value assigned by the user.
delivery_mode	number	Delivery mode. Value 1 for transient, Delivery mode. Value 2 for persistent.
reply_to	string	Queue name for response messages.
expiration	string	Message expiration. To set string representation of a number representing expiration time in milliseconds.
headers	object or array	Native headers associated with the message. The type is controlled using the Native Headers Element Type property.
message_id	string	Message id. Custom value assigned by the user.
priority	integer	Message priority as assigned by the user.
timestamp	string	Message timestamp in yyyy-MM-dd HH:mm:ss format, in the current system locale's time zone.
type	string	Message type. Custom value assigned by the user.
user_id	string	User id. When set, checking is performed to ensure it matches the user id of the current connection.
payload	string or JSON	Message payload. The type is controlled by using the Message Payload Encoding property.

Examples

- [Example of the GET map function](#)
- [Example of the PUT map function](#)

Example of the GET map function

In the following example, assume that the adapter is used in a GET function:

- When the adapter is used to retrieve all messages from a RabbitMQ queue `queue1` on the RabbitMQ broker running on the same host on which the map runs. Messages are acknowledged as part of committing the source transaction. Logging is enabled, with verbose level and default log file `m4rabbitmq.mtr` created in the map directory:

```
GET("RABBITMQ", "-H localhost -P 5672 -Q queue1 -RGM tx -QTY S -LSN 0 -TV")
```

Example of the PUT map function

In the following example, assume that the adapter is used in a PUT function:

- When the adapter is used to write a message to an exchange with the specified routing key on the RabbitMQ broker running on the same host on which the map runs. In this case, the built-in `amq.direct` exchange is used with the routing key `queue1` configured in the broker to route the message to the queue with the same name. The

input_data represents the message produced for the exchange, and this is a reference to a type from another card in the map. The log file rabbitmq.log is created in the directory in which the map runs, it is created in append mode, and only messages of the error severity are logged:

```
PUT("RABBITMQ", "-H localhost -P 5672 -E amq.direct -RK queue1 -TE+ rabbitmq.log", input_data)
```

Redis Adapter

This documentation describes the Redis Adapter.

- [Overview](#)
The Redis adapter provides access to Redis servers.

Overview

The Redis adapter provides access to Redis servers.

Introduction

The Redis adapter supports all the data structures supported by Redis, and many operations for the data structures.

It can be used to set values in Redis data structures, get values from Redis and to subscribe to channels when acting as a listener for flow execution.

The supported versions of the Redis server are 3.0.1 and later.

Redis adapter as a source

The adapter can be specified as a data source for input cards in maps, and for source nodes in flows. All Redis commands are non-blocking except for SUBSCRIBE, PSUBSCRIBE, BLPOP, and BRPOP. For these commands, a time out can be specified.

The adapter can also be configured to act as a watch for the source nodes in flows. This is supported for **SUBSCRIBE**, **PSUBSCRIBE**, **BLPOP**, and **BRPOP** commands. The adapter is utilized from the listener service and executes the selected command. Once data is available on the channel, or in the list (If **BLPOP** or **BRPOP** are called) the adapter captures the messages and reports them as events which in turn are used to trigger instances of the flow in which the watch is defined. When an instance of the flow runs, the input node in the flow on which the watch is defined operates on the data collected from the event that triggered that flow instance, without a need to connect to the broker again.

For commands that return structured data, such as hashes, sets, and sorted sets, the data can either be returned in delimited form, or as JSON. This is determined by the setting of the JSON property.

Some commands both require data and return data. There are several ways to call such commands:

Invoke the adapter from an input card or source node and pass the request data in the Data property.

- Invoke the adapter from a request node in a flow.
- Invoke the adapter from a GET map function, providing the request data as the third argument.

Redis adapter as a target

The adapter can be specified as a data target for output cards in maps and for target nodes in flows.

Supported Redis adapter

The following commands are supported by the adapter. Any command can be invoked in any context because data can either be provided in the card data, or via the Data property.

Primitive commands

- **GET**
- **SET [EX=expireTime | NX]**
- **APPEND**
- **DEL**
- **EXISTS**
- **INCR**
- **INCRBY**
- **DECR**
- **DECRBY**

List commands

- **LPOP**
- **RPOP**
- **BLPOP**
- **BRPOP**
- **LPUSH**
- **RPUSH**

Set commands

- **SADD**
- **SMEMBERS**

Sorted set commands

- **ZADD [XX|NX]**
- **ZCARD**
- **ZCOUNT**
- **ZRANGE [BYScore | REV | WITHSCORES]**
- **ZREM**
- **ZRANK [WITHSCORE]**
- **ZREVRANK [WITHSCORE]**
- **ZSCORE**

Hash commands

- **HSET**
- **HGET**
- **HMGET**
- **HGETALL**
- **HEXISTS**
- **HDEL**
- **HSETNX**
- **HKEYS**
- **HINCRBY**

Channel (Pub/Sub) commands

- **SUBSCRIBE channel(s)**
- **PSUBSCRIBE pattern(s)**

- **PUBLISH** channel data

Adapter properties and commands

This section provides the detailed description of the adapter properties for defining connections, actions, and cards.

Host

Specifies the host name or TCP/IP address of the Redis server. This is a mandatory property. The corresponding adapter command is **-H name** (or **-HOST name**).

Port

Specifies the Redis sever port. The default value is 6379. The corresponding adapter command is **-P number** (or **-PORT number**).

Password

Specifies the password for connection to the server if required. The corresponding adapter command is **-PWD password** (or **-PASSWORD password**).

Database ID

Specifies the ID of the database to connect to, if required by the Redis server. The corresponding adapter command is **-DID id** (or **-DATABASE id**).

Enable SSL

User can enable this property if the server requires an SSL/TLS connection. The corresponding adapter command is **-S** (or **-SSL**).

Certificate Authority Key File

Specifies the file containing the authority key certificate, if used. The corresponding adapter command is **-CAF filename** (or **-CAFILE filename**).

Private Key File

Specifies the location of the private key file to use when mutual TLS is enabled. The corresponding adapter command is **-KF filepath** (or **-KEYFILE filepath**).

Public Key Certificate File

Specifies the file containing the public key certificate when mutual TLS is enabled. The corresponding adapter command is **-KF filepath** (or **-CERTFILE filepath**).

Server Name Indicator

Specifies the DNS hostname for server name indication. The corresponding adapter command is **-SNI**.

Verify Hostname

Instructs the adapter to verify the hostname value in the server certificate presented by the Redis server during the SSL/TLS handshake. The corresponding adapter command is **-V** (or **-VERIFY**).

Command

Specifies the command to execute. The corresponding adapter command is **-C command** (or **-CMD command**).

Key

Specifies the Redis key. This is required for all commands except **SUBSCRIBE**, **PSUBSCRIBE**, and **PUBLISH**. The corresponding adapter command is **-K key** (or **-KEY key**).

Channel

Specifies the name of the channel for pub/sub operations. The corresponding adapter command is **-CH name** (or **-CHANNEL name**).

Data

Specifies the data. The corresponding adapter command is **-D data** (or **-DATA data**).

When providing data to the adapter, it can be passed to the input terminals of a target or request node, or to the output card of a map. Alternatively, it can be passed via the Data property. This is convenient if calling a command that requires request data, such as **HMGET** or sorted set commands. For more information, see the Data Formats section.

JSON

If this option is enabled, the data sent to, or received from Redis is sent as JSON data. The corresponding adapter command is **-J** (or **-JSON**).

Options

Specifies the options to modify the behavior of certain commands. Multiple options should be separated with a | character. The corresponding adapter command is **-O** (or **-OPTIONS**).

The supported options are as follows:

Command	Option	Description
SET	EX=expiration	Expiration time in seconds.
SET	NX	Set if the key does not already exist.
ZADD	XX	Only update elements that already exist.
ZADD	NX	Only add new elements.
ZRANGE	BYSCORE	Start and stop are scores rather than index.
ZRANGE	REV	Reverse the order of the results.
ZRANGE	WITHSCORES	Return the scores with the elements.
ZRANK	WITHSCORES	Return the score with the rank.
ZREVRANGE	WITHSCORES	Return the score with the rank.

Charset

Specifies the character set of the data. Default value is UTF-8.

The character set of any string data. This is used when converting from strings to bytes to send to Redis, or when creating a string from bytes in Redis. If not specified, the default system encoding is used. The corresponding adapter command is **-CS charset** (or **-CHARSET charset**).

Timeout

The blocking time in seconds for **BLPOP**, **BRPOP**, **SUBSCRIBE**, and **PSUBSCRIBE** operations. If set to 0, the operation will block until an object is available. The corresponding adapter command is **-TO timeout** (or **-TIMEOUT timeout**).

Logging

This property specifies the level of logging to use for the log (trace) file produced by the adapter. The default is Off. The value Information means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

The corresponding adapter command is:

-T [E|V] [+] [file_path]

-T -> Log adapter informational messages.

-TE -> Log only adapter errors.

-TV -> Use verbose (debug) logging. The log file records all activity that occurs while the adapter is producing or consuming messages.

+ -> Appends the trace information to the existing log file. Omit this argument to create a new log file.

file_path -> The m4redis.mtr log file in the map directory.

Data Formats

For primitive operations, the data is passed as strings with no formatting. Data passed to operations is sent in database-delimited format (| delimiter, \n terminator, ! release). If the JSON option is enabled, then data is instead passed and returned as JSON objects/arrays. This table lists what is required for inputs and outputs for each command. For input data, lists should be specified terminating each entry with \n terminator. If multiple values are required, delimit the values with | or \n characters.

Command	In	Out	JSON
GET	-	Bytes	-
SET	Bytes	-	-
APPEND	Bytes	-	-
DEL	-	-	-
EXISTS	-	true or false	-
INCR	-	Integer	-
INCRBY	Integer	Integer	-
DECR	-	Integer	-
DECRBY	Integer	Integer	-
LPOP	-	Bytes	-
RPOP	-	Bytes	-
BLPOP	-	Bytes	-
BRPOP	-	Bytes	-
LPUSH	Bytes	-	-
RPUSH	Bytes	-	-
SADD	Bytes	-	-
SMEMBERS	-	List of members	Out
HSET	List of field/values	-	In
HSETNX	List of field/values	-	In
HGET	Key	Value	-
HMGET	List of fields		In/Out
HMGETALL	-	List of field/values	Out
HEXISTS	Key	true or false	-
HDEL	Key	-	
HKEYS	-	List of Keys	Out
HINCRBY	Field/Integer	Integer	In
ZADD	List of member/scores	-	In
ZCARD	-	Integer	-
ZCOUNT	Min/Max	Integer	In
ZRANGE	Start/Stop	List of members	In/Out
ZRANGE with scores	Start/Stop	List of member/scores	In/Out
ZREM	List of members	-	In
ZRANK	Member	Integer	
ZRANK with score	Member	Rank/Score	Out
ZREVRANK	Member	Integer	-
ZREVRANK with score	Member	Rank/Score	Out
ZSCORE	Member	Score	-
PUBLISH	Bytes	-	-
SUBSCRIBE	-	Bytes	-
PSUBSCRIBE	-	Bytes	-

Schemas can be generated from the Map Designer when the Redis adapter is used in an input or output card. It generates the appropriate schema based on:

- Whether the adapter is used in an input or output card.
- The selected command.
- Whether the JSON option is enabled.

Examples

Examples of the GET map function

In the following example, assume that the adapter is used in a GET function.

This command will execute the **ZRANGE** command for key "sortedset:1", specifying the start as 2 and stop as 5 (via the **-DATA** command). The **-OPTIONS** commands instructs the adapter to return the scores together with the elements, and to reverse the order of the data.

```
GET("REDIS", "-H redis-host -P 6379 -CMD ZRANGE -KEY sortedset:1 -DATA 2|5 -OPTIONS withscores|rev")
```

Examples of the PUT map function

In the following example, assume that the adapter is used in a PUT function.

This command will set the key "mykey" to the value provided as the 3rd parameter of the PUT function.

```
PUT("REDIS", "-H redis-host -P 6379 -CMD SET -KEY mykey", "This is my data!")
```

ServiceNow Adapter

The ServiceNow adapter provides support for accessing ServiceNow REST API resources.

The ServiceNow adapter provides access to the following ServiceNow REST APIs:

- Table API
- Aggregate API

- [Introduction](#)

The ServiceNow adapter is used to perform data integration with ServiceNow by invoking ServiceNow APIs to perform read and write operations on the tables used to store data for those resources. For more information about ServiceNow REST API, refer to the ServiceNow documentation.

- [Adapter Properties and Commands](#)

This section lists the properties supported by the adapter.

- [Examples](#)

This chapter provides GET and PUT examples.

Introduction

The ServiceNow adapter is used to perform data integration with ServiceNow by invoking ServiceNow APIs to perform read and write operations on the tables used to store data for those resources. For more information about ServiceNow REST API, refer to the ServiceNow documentation.

- [Authentication Connections](#)

Authentication Connections

The adapter supports the following authentication methods:

- Basic authentication. The user provides username and password values and the adapter automatically provides them to ServiceNow to perform the authentication. ServiceNow adapter supports Basic authentication by default.
- OAuth 2.0 authentication. It requires to provide access token as captured outside of the application. However, when the token expires, the following actions for the adapter to take can be configured using the Access Token Expiry Action property:
 - Report Error
 - Refresh Token
 - Request New Token Using Username and Password
 - Request New Token Using Client Credentials.

ServiceNow adapter as a source

ServiceNow adapter as a source:

- Retrieves the record(s).
- Computes aggregates.

ServiceNow adapter as a target

ServiceNow adapter as a target:

- Creates the record(s).
- Update the record(s).
- Deletes the record(s).

Adapter Properties and Commands

This section lists the properties supported by the adapter.

- **[Instance Name](#)**
- **[Authentication](#)**
Specifies the authentication methods to authorize the user access to the ServiceNow REST APIs/endpoints.
- **[Username](#)**
Specifies the username for the connection.
- **[Password](#)**
Specifies the password for the connection.
- **[Access Token](#)**
Specifies an access token to access the ServiceNow REST APIs using OAuth 2.0 Authentication.
- **[Access Token Expiry Action](#)**
Specifies the action to be taken by the adapter, if the provided access token is reported expired or invalid.
- **[Consumer Key](#)**
- **[Consumer Secret](#)**
Specifies the consumer secret value to use when performing Request New Token expiry action.
- **[Refresh Token](#)**
Specifies the refresh token to perform Refresh Token expiry action.
- **[Security Token](#)**
Specifies the security token value to perform the Request New Token expiry action.
- **[Token Storage File](#)**
Specifies the location of the file in the local file system in which to store the access token retrieved after performing Refresh Token or Request New Token expiry action.
- **[Encryption Key](#)**
Specifies the key to use for encrypting the access token with AES-256 encryption method when saving the token in the token storage file.
- **[Version](#)**
Specifies the service version of ServiceNow Table API.
- **[Endpoint](#)**
Specifies the endpoint entry in the configuration. This is a mandatory property. The corresponding adapter command is -E *value* (or -ENDPOINT *value*).
- **[Table Name](#)**
Specifies the ServiceNow table name to be acted upon when action Get Record, Insert Record, Update Record or Delete Record is selected.
- **[System Id](#)**
- **[Query Parameter](#)**
Specifies the parameters those would be passed to endpoint while invoking the ServiceNow REST API calls. The corresponding adapter command is -P (or -PROPERTIES). Query parameters should be specified in as a whitespace separated list of *param=value* pairs.
- **[Logging](#)**
This property specifies the level of logging to use for the log (trace) file produced by the adapter.
- **[Log File Path](#)**

Instance Name

Specifies a ServiceNow instance allocated to the user. Users can access an instance via web browser using each instance's unique URL such as <https://instancename.service-now.com>. This is a mandatory property. The corresponding adapter command is -INAME *instance* (or -INSTANCENAME *instance*).

Authentication

Specifies the authentication methods to authorize the user access to the ServiceNow REST APIs/endpoints.

The corresponding adapter command is -A *value* or -AUTH *value*. The following two authentication methods are supported:

- Basic - Authentication with username and password. The corresponding adapter command *value* is basic.
- OAuth 2.0 - Authentication with access token obtained through OAuth 2.0 workflow. The corresponding adapter command *value* is oauth2.

Username

Specifies the username for the connection.

The corresponding adapter command is -UN *username* (or -USERNAME *username*).

Password

Specifies the password for the connection.

The corresponding adapter command is -PWD *password* (or -PASSWORD *password*).

Access Token

Specifies an access token to access the ServiceNow REST APIs using OAuth 2.0 Authentication.

Refer to the ServiceNow documentation for information on how to configure OAuth 2.0 authentication and generate initial access token.. It can be generated by REST API tools, such as Postman. This is a mandatory property. The corresponding adapter command is -AT *token* (or -ACCESSTOKEN *token*).

Access Token Expiry Action

Specifies the action to be taken by the adapter, if the provided access token is reported expired or invalid.

The corresponding adapter command is -ATEA *value* (or -ACCESSTOKENEXPIRYACTION *value*). The following actions are supported:

- Report Error. The corresponding adapter command value is report_error.
 - Refresh Token. The corresponding adapter command value is refresh_token.
 - Request New Token Using Username and Password. The corresponding adapter command value is password.
 - Request New Token Using Client Credentials. The corresponding adapter command value is client_credentials.
-

Consumer Key

Specifies the consumer key value to use when performing Refresh Token or Request New Token expiry action. The corresponding adapter command is -CK *key* (or -CONSUMERKEY *key*).

Consumer Secret

Specifies the consumer secret value to use when performing Request New Token expiry action.

It is enabled when the user sets up an application under the Connected Apps in ServiceNow. This is a mandatory property. The corresponding adapter command is -CS secret (or -CONSUMERSECRET *secret*).

Refresh Token

Specifies the refresh token to perform Refresh Token expiry action.

It needs to be captured outside the adapter application to enable the adapter to refresh the access token without any user interaction. The corresponding adapter command is -RT *token* (or -REFRESHTOKEN *token*).

Security Token

Specifies the security token value to perform the Request New Token expiry action.

If it is present, it will be appended to the password in case of OAuth 2.0 authentication. The corresponding adapter command is -ST *token* (or -SECURITYTOKEN *token*) command.

Token Storage File

Specifies the location of the file in the local file system in which to store the access token retrieved after performing Refresh Token or Request New Token expiry action.

This is a mandatory property. The corresponding adapter command is -TF *filepath* (or -TOKENFILE *filepath*).

Encryption Key

Specifies the key to use for encrypting the access token with AES-256 encryption method when saving the token in the token storage file.

This is a mandatory property. The corresponding adapter command is -EK *key* (or -ENCRYPTIONKEY *key*).

Version

Specifies the service version of ServiceNow Table API.

All available service versions can be fetched during configuration of the adapter in the web UI. The corresponding adapter command is -V *version* (or -VERSION *version*).

Endpoint

Specifies the endpoint entry in the configuration. This is a mandatory property. The corresponding adapter command is **-E value** (or **-ENDPOINT value**).

Actions available in ServiceNow adapter are as follows:

- Table API
 - Retrieve records from a table. The corresponding adapter command *value* is `getTableRecords`.
 - Retrieve a record. The corresponding adapter command *value* is `getRecord`.
 - Insert a record in specified table. The corresponding adapter command *value* is `insertRecord`.
 - Update a specified record in the table. The corresponding adapter command *value* is `updateRecord`.
 - Delete a specified record. The corresponding adapter command *value* is `deleteRecord`.
- Aggregate API
 - Compute Aggregate. The corresponding adapter command *value* is `computeAggregate`.

Table Name

Specifies the ServiceNow table name to be acted upon when action Get Record, Insert Record, Update Record or Delete Record is selected.

This is a mandatory property. The corresponding adapter command is **-TN name** (or **-TABLENAME name**).

System Id

Specifies the system id of the record to fetch, update or delete. The corresponding adapter command is **-SID id** (or **-SYSID id**).

Query Parameter

Specifies the parameters those would be passed to endpoint while invoking the ServiceNow REST API calls. The corresponding adapter command is **-P** (or **-PROPERTIES**). Query parameters should be specified in as a whitespace separated list of *param=value* pairs.

For valid endpoint parameters of Table API and Aggregate API, refer to the ServiceNow documentation.

Logging

This property specifies the level of logging to use for the log (trace) file produced by the adapter.

The default is Off. The value Information means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

The corresponding adapter command is **-T [E|V] [+]** [file_path]

-T -> Log adapter informational messages.

-TE -> Log only adapter errors.

-TV -> Use verbose (debug) logging. The log file records all activity that occurs while the adapter is producing or consuming messages.

+ -> Appends the trace information to the existing log file. Omit this argument to create a new log file.

file_path -> The full path to the adapter trace log. If you omit this keyword, the adapter creates the m4svcnnow.mtr log file in the map directory.

Log File Path

Specifies the location of the log file to which to write log messages. If not specified, the default log file name m4svcnnow.mtr is used, and the file is stored to the directory in which the executed compiled map resides.

Examples

This chapter provides GET and PUT examples.

- [GET examples](#)
- [PUT examples](#)

GET examples

GET function example for fetching records from a table API

```
GET("SVCNOW", "-E getTableRecords -A basic -UN username -PWD password -INAME https://dev1instance.service-now.com/ -TN problem -V v1")
```

GET function example for fetching records from an aggregate API

```
GET("SVCNOW", "-E computeAggregate -A basic -UN username -PWD password -INAME https:// dev1instance.service-now.com/ -TN problem -P sysparm_avg_fields=problem_state")
```

PUT examples

PUT function example

```
PUT("SVCNOW", "-E insertRecord -A basic -UN username -PWD password -INAME https://dev1instance.service-now.com/ -TN problem", inputdatarequest)
```

The *inputdatarequest* must be in JSON request format.

REST Adapter

REST adapter provides the ability to invoke REST operations with JSON requests constructed in the map, and to produce JSON responses from REST operations for further processing in the map, that way adding support for integration with REST services from the maps. It supports the following key functions:

- HTTP and HTTPS protocol schemes.
- GET, POST, PUT, DELETE, PATCH and HEAD methods.
- Basic and OAuth 2.0 authentication modes.
- Custom request headers.
- Multipart data.
- [Authenticating connections](#)
- [REST Adapter properties and commands](#)
This section provides details about the properties and corresponding adapter commands.
- [SSL/TLS support in REST adapter](#)
The SSL/TLS provides stricter security for HTTPS connections involving very selected parties.
- [Pagination support in REST adapter](#)
- [Examples](#)
- [OAuth 2.0 authentication examples](#)
In case the access token provided in this authentication scheme expires, access token expiry action can be taken using below options:
- [Proxy server support](#)
This documentation describes the Proxy server support.

Authenticating connections

The adapter supports the following authentication methods:

- Basic authentication. The user provides username and password values and the adapter automatically assembles them into appropriate authorization header.
- OAuth 2.0 authentication. The user provides access token obtained through OAuth 2.0. The username and password can still be used to automatically refresh the access token.

REST Adapter as a source:

REST adapter as a source performs the specified GET or HEAD operation and returns the response.

REST Adapter as a target:

REST adapter as a target submits requests to the specified POST, PUT, PATCH or DELETE operation, as applicable.

REST Adapter properties and commands

This section provides details about the properties and corresponding adapter commands.

- [Configuration mode](#)
- [URL](#)
- [Method](#)
- [Headers](#)
- [Script Path](#)

- **Endpoint**
Specifies the endpoint entry in the configuration. This property is enabled only in Configuration Script and Configuration Package modes and is currently reserved for internal use only.
- **Package Id**
Specifies the identifier string for the deployment package. This property is enabled only in Configuration Package mode and is currently reserved for internal use only.
- **Authentication**
Specifies the authentication method to use for the REST calls. The corresponding adapter command is -A (or -AUTH).
- **Access Token**
- **Access Token Expiry Action**
Specifies the action to be taken by Rest Adapter if the access token provided is either expired or invalid.
- **Access Token URL**
- **Consumer Key**
- **Consumer Secret**
- **Refresh Token**
- **Security Token**
- **Token Storage File**
Specifies the location of the file in the local file system in which to store the access token retrieved after performing Refresh Token or Request New Token expiry action.
- **Encryption Key**
Specifies the key to use for encrypting the access token with AES-256 encryption method when saving the token in the token storage file.
- **Logging**
- **Append Log**
- **Log File Path**
Name of the log file to which to write log messages. If not specified, the default log file name m4rest.mtr is used, and the file is stored to the directory in which the executed compiled map resides.

Configuration mode

Specifies the mode of work for the adapter. The default value is Generic, and when selected, the URL, Method and Headers properties are enabled and used to define which URL to connect to, which method to perform on the resource specified in the URL and which request headers (if any) to set on the request. The values Configuration Script and Configuration Package are used for implementing custom adapter extensions and are currently reserved for internal use only.

URL

Specifies the URL of the resource (endpoint). The URL can include query parameters. The corresponding adapter command is -U (or -URL).

Method

Specifies the method to perform on the resource. The corresponding adapter command is -M (or -METHOD). The supported values are:

- GET (Adapter command value: get)
- Head (Adapter command value: head)
- PUT (Adapter command value: put)
- GET (Adapter command value: get)
- POST (Adapter command value: post)
- PATCH (Adapter command value: patch)
- DELETE (Adapter command value: delete)

Headers

Specifies one or more HTTP request headers. This is an optional property. It can be specified by command with spaces separated key value pairs. For example:
header1=value1 header2=value2.

To specify REST Adapter Header values that contain a space character, see [technote](#).

Script Path

Provides the script path. This property is available, when you set Configuration Mode to Configuration Script and is currently reserved for internal use only. This is a mandatory property.

Endpoint

Specifies the endpoint entry in the configuration. This property is enabled only in Configuration Script and Configuration Package modes and is currently reserved for internal use only.

Actions available in REST adapter as follows:

- Get Record (Adapter command value: getRecord)
 - Insert Record (Only Target Mode) (Adapter command value: createRecord)
 - Update Record (Only Target Mode) (Adapter command value: updateRecord)
 - Delete Record (Only Target Mode) (Adapter command value: deleteRecord)
 - Execute Query (Adapter command value: query)
 - Execute QueryAll (Adapter command value: queryAll)
 - Query Performance (Adapter command value: queryPerformance)
 - Search String (Adapter command value: searchString)
-

Package Id

Specifies the identifier string for the deployment package. This property is enabled only in Configuration Package mode and is currently reserved for internal use only.

Authentication

Specifies the authentication method to use for the REST calls. The corresponding adapter command is -A (or -AUTH).

There are three methods as follows

- Authentication is not performed. The adapter command value is None.
 - Authentication with username and password. The adapter command value is Basic.
 - Authentication with access token obtained through OAuth 2.0 workflow. The adapter command value is OAuth 2.0.
-

Access Token

Specifies the access token string to use with OAuth2.0 authentication method. The corresponding adapter command is -AT (or -ACCESSTOKEN).

Access Token Expiry Action

Specifies the action to be taken by Rest Adapter if the access token provided is either expired or invalid.

The default value is Report Error. The following values are supported:

- Report Error (Adapter command value: reportError).
- Refresh Token (Adapter command value: refresh_token).
- Request New Token (Adapter command value: password).

This is a mandatory property. The corresponding adapter command is -ATEA or (-ACCESSTOKENEXPIRYACTION).

Access Token URL

Specifies the URL of the authentication server for providing access tokens. This property is enabled when Refresh Token and Request New Token expiry action is selected. The corresponding adapter command is -TURL (or -TOKENURL).

Consumer Key

Specifies the consumer key value to use when performing Refresh Token or Request New Token expiry action. The corresponding adapter command is -CK (or -CONSUMERKEY).

Consumer Secret

Specifies the consumer secret value to use when performing Request New Token expiry action. The corresponding adapter command is -CS (or -CONSUMERSECRET).

Refresh Token

Specifies the refresh token to provide when performing Refresh Token expiry action. The corresponding adapter command is -RT (or -REFRESHTOKEN).

Security Token

Specifies the security token value to perform when performing Request New Token expiry action. The corresponding adapter command is -ST (or -SECURITYTOKEN).

Token Storage File

Specifies the location of the file in the local file system in which to store the access token retrieved after performing Refresh Token or Request New Token expiry action.

The corresponding adapter command is -TF (or -TOKENFILE).

Encryption Key

Specifies the key to use for encrypting the access token with AES-256 encryption method when saving the token in the token storage file.

The corresponding adapter command is -EK (or -ENCRYPTIONKEY).

Logging

Specifies the level of logging to use for the log (trace) file produced by the adapter. The default is off. The value info means log informational and error messages, the value error means log error messages only, and the value verbose means log debug and trace level messages along with the informational and error messages.

Append Log

Flag indicating what to do if the specified log file already exists. The default value is true. When set to true, the log messages are appended to the file. When set to false, the file is truncated, and the messages are written to the empty file.

Log File Path

Name of the log file to which to write log messages. If not specified, the default log file name m4rest.mtr is used, and the file is stored to the directory in which the executed compiled map resides.

SSL/TLS support in REST adapter

The SSL/TLS provides stricter security for HTTPS connections involving very selected parties.

The REST adapter/node provides a way to refer an SSL certificate that will identify them.

The SSL handshake will not work if server and client certificates are not a match. By doing so, no credential is sent over the Internet, just encrypted data that will be decrypted correctly only if the certificates match.

- **Authenticate Server**

The Authenticate Server property is used to authenticate to the server.

- **Truststore file full path**

The Truststore file full path property indicates the full path for truststore file for SSL handshake.

- **Truststore Password**

The Truststore Password property specifies the password for truststore.

- **Authenticate Client**

The Authenticate Client property is used for client certificate validation.

- **Keystore file path**

The Keystore file path property is used to specify the keystore file full path.

- **Keystore Password**

The Keystore Password property specifies the password for keystore.

- **Key Password**

- **Verify host name**

Authenticate Server

The Authenticate Server property is used to authenticate to the server.

The Authenticate Server property is applicable only when the protocol specified is HTTPS. This notifies the adapter that client server certificate validation will take place during the SSL handshake.

The corresponding command for this property is -AS (or -AUTHSERVER).

Truststore file full path

The Truststore file full path property indicates the full path for truststore file for SSL handshake.

This property is applicable only when the protocol used is **HTTPS** and Authenticate Server property is specified.

The default path for Truststore file full path property is JAVA_HOME/lib/security/cacerts

The corresponding command for this property is -TSL [file_path] (or -TRUSTSTORELOCATION [file_path]).

Truststore Password

The Truststore Password property specifies the password for truststore.

This property is applicable only when the protocol used is **HTTPS** and Authenticate Server property is specified.

The default password for Truststore Password property is changeit.

The corresponding command for this property is -TSP [pwd] (or -TRUSTSTOREPASSWORD [pwd]).

Authenticate Client

The Authenticate Client property is used for client certificate validation.

The Authenticate Client property is applicable only when the protocol used is **HTTPS**. This property notifies the adapter that client certificate validation will take place during SSL handshake.

The corresponding command for this property is -AC (or -AUTHCLIENT).

Keystore file path

The Keystore file path property is used to specify the keystore file full path.

This property is applicable only when the protocol used is **HTTPS** and Authenticate Client property is specified.

The default path for Keystore file path property is JAVA_HOME/lib/security/cacerts

The corresponding command for this property is -KSL [file_path] (or -KEYSTORELOCATION [file_path]).

Keystore Password

The Keystore Password property specifies the password for keystore.

This property is applicable only when the protocol used is **HTTPS** and Authenticate Client property is specified.

The default password for Keystore Password property is changeit.

The corresponding command for this property is -KSP [pwd] (or -KEYSTOREPASSWORD [pwd]).

Key Password

The Key Password property specifies the password for key.

This property is applicable only when the protocol used is **HTTPS** and Authenticate Client property is specified and ensure that the Key Password is different from the Keystore Password.

The default password for Key Password property is changeit.

The corresponding command for this property is -KP [pwd] (or -KEYPASSWORD [pwd]).

Verify host name

The Verify host name property is used to instruct the adapter to verify the hostname value in the server certificate presented by the REST endpoint server during the SSL handshake.

The property is applicable only when the protocol used is **HTTPS** and Authenticate Client property is specified.

The corresponding command for this property is -VH (or -VERIFYHOSTNAME).

Pagination support in REST adapter

Pagination turns big archives of data into smaller, more digestible pieces.

Many REST APIs provide a way to retrieve data using multiple calls and a pagination mechanism to get additional pages of data with each call to the API.

Pagination support in REST Adapter in the context of a burst mode of operation is where each call returns data that is provided to the map or flow which then processes the data and returns to the source for more data to get the next burst.

- **Pagination Type**

The there are four patterns that are commonly used for implementing pagination in REST APIs and they can be specified using the Pagination Type property.

- **Records per Call**

The Records per Call property specifies the number of records to fetch per call.

- **Limit**

The Limit property specifies the total number of records to return across all calls.

- **First Offset**

The First Offset property specifies the offset value to provide in the first call.

- **Number of Records Location**

The Number of Records Location property specifies the location in response as where to find the total number of records.

- **Number of Records Path**

The Number of Records Path property specifies the header name or the path where the total number of records are found.

- **First Page**

The First Page property specifies the page value to provide in the first call.

- **Number of Pages Location**

The Number of Pages Location property specifies the response location where the total number of pages are found.

- **Number of Pages Path**

The Number of Pages Path property specifies the header name or the path where the total number of pages are found.

- **Next Page Link Location**

The Next Page Link Location property specifies the name of the header or the path in the body for the field containing an URL for the next page. The URL may be absolute or relative.

- **Next Page Link Path**

The Next Page Link Path property specifies the header name or path where the URL for the next page is found.

- **Base URL**

The Base URL property specifies the URL to which all relative links for next pagination call would be appended.

- **Next Page Token Location**

The Next Page Token Location property specifies the name of the header or the path in the body for the field containing the token for the next page.

- **Next Page Token Path**

The Next Page Token Path property specifies the header name or path where the token for the next page is found.

- **Pagination Token Location**

The Pagination Token Location property specifies the location where the pagination token for subsequent calls would be configured.

- **Pagination Token Name**

The Pagination Token Name property specifies the name of the pagination token to be passed in the next subsequent calls.

- **Header and Parameter Special Values**

Pagination Type

There are four patterns that are commonly used for implementing pagination in REST APIs and they can be specified using the Pagination Type property.

The four patterns are as follows:

- Offset (offset)

- Page (page)

- Next Page Link (link)

- Next Page Token (token)

The corresponding command for this property is -PT [none | offset | page | link | token | USEENDPOINTDEF] (or -PAGINATIONTYPE [none | offset | page | link | token | USEENDPOINTDEF]).

Note: The **USEENDPOINTDEF** type would only be specified when the configuration mode is not a generic mode.

Records per Call

The Records per Call property specifies the number of records to fetch per call.

The corresponding command for this property is -RPC [num] (or -RECORDSPERCALL [num]).

Limit

The Limit property specifies the total number of records to return across all calls.

This property is applicable only when the Pagination Type is set to Offset.

The corresponding command for this property is -L [num] (or -LIMIT [num]).

First Offset

The First Offset property specifies the offset value to provide in the first call.

This property is applicable only when the Pagination Type is set to Offset.

The corresponding command for this property is -FO [num] (or -FIRSTOFFSET [num]).

Number of Records Location

The Number of Records Location property specifies the location in response as where to find the total number of records.

This property is applicable only when the Pagination Type is set to Offset.

The corresponding command for this property is -NRL [headers|body] (or -NUMRECORDSLOCATION [headers|body]).

Number of Records Path

The Number of Records Path property specifies the header name or the path where the total number of records are found.

This property is applicable only when the Pagination Type is set to Offset.

The corresponding command for this property is -NRP [path|name] (or -NUMRECORDPATH [path|name]).

First Page

The First Page property specifies the page value to provide in the first call.

This property is applicable only when the Pagination Type is set to Page.

The corresponding command for this property is -FP [num] (or -FIRSTPAGE [num]).

Number of Pages Location

The Number of Pages Location property specifies the response location where the total number of pages are found.

This property is applicable only when the Pagination Type is set to Page.

The corresponding command for this property is -NPL [headers|body] (or -NUMOFPAGESLOCATION [headers|body]).

Number of Pages Path

The Number of Pages Path property specifies the header name or the path where the total number of pages are found.

This property is applicable only when the Pagination Type is set to Page.

The corresponding command for this property is -NPP [path|name] (or -NUMOFPAGESPATH [path|name]).

Next Page Link Location

The Next Page Link Location property specifies the name of the header or the path in the body for the field containing an URL for the next page. The URL may be absolute or relative.

This property is applicable only when the Pagination Type is set to Next Page Link.

The corresponding command for this property is -NLL [headers|body] (or -NEXTLINKLOCATION [headers|body]).

Next Page Link Path

The Next Page Link Path property specifies the header name or path where the URL for the next page is found.

This property is applicable only when the Pagination Type is set to Next Page Link.

The corresponding command for this property is -NLP [path|name] (or -NEXTLINKPATH [path|name]).

Base URL

The Base URL property specifies the URL to which all relative links for next pagination call would be appended.

This property is applicable only when the Pagination Type is set to Next Page Link.

The corresponding command for this property is -BURL [URL] (or -BASEURL [URL]).

Next Page Token Location

The Next Page Token Location property specifies the name of the header or the path in the body for the field containing the token for the next page.

This property is applicable only when the Pagination Type is set to Next Page Token.

The corresponding command for this property is -NTL [headers|body] (or -NEXTTOKENLOCATION [headers|body]).

Next Page Token Path

The Next Page Token Path property specifies the header name or path where the token for the next page is found.

This property is applicable only when the Pagination Type is set to Next Page Token.

The corresponding command for this property is -NTP [path|name] (or -NEXTTOKENPATH [path|name]).

Pagination Token Location

The Pagination Token Location property specifies the location where the pagination token for subsequent calls would be configured.

This property is applicable only when the Pagination Type is set to Next Page Token.

The corresponding command for this property is -PTL [headers|query] (or -PAGINATIONTOKENLOCATION [headers|query]).

Pagination Token Name

The Pagination Token Name property specifies the name of the pagination token to be passed in the next subsequent calls.

This property is applicable only when the Pagination Type is set to Next Page Token.

The corresponding command for this property is -PTN [token_name] (or -PAGINATIONTOKENNAME [token_name]).

Header and Parameter Special Values

In paginated API calls the pagination parameters are provided either as query parameters, or (less commonly) as header values. Since these values change with each call to the API, these can be specified in the query parameter or header tables.

This is provided by special properties that have the syntax {{...}}. These special values are as follows:

- {{record_count}}
Specifies the value of records per call property.

For example: The {{record_count}} value provides a mechanism by which the Records per Call property can be easily changed or passed as a flow variable, without changing the value in the parameter or header definition.

- {{offset}}
Specifies the next offset value. On each call this will be incremented by the value of the Records per Call property.
 - {{page}}
Specifies the next page number. On each call this will be incremented.
 - {{pagination_token}}
Specifies the pagination token from the prior call. On the first call, the query parameter or header will not be set. On subsequent calls, it will be set to the value of the pagination token from the previous call.
-

Examples

- [No Authentication Examples](#)
 - [Basic Authentication examples](#)
-

No Authentication Examples

GET Example:

```
GET("REST", "-U restURL -M get -A none -H \"header1=value1 header2=value2\"")
```

PUT Example:

```
PUT("REST ", "-U restURL -M put -A none -H \"header1=value1 header2=value2\"")
```

Basic Authentication examples

GET Example:

```
GET("REST", "-U restURL -M get -A BASIC -UN username -PWD password -H \"header1=value1 header2=value2\"")
```

PUT Example:

```
PUT("REST ", "-U restURL -M put -A BASIC -UN username -PWD password -H \"header1=value1 header2=value2\"")
```

OAuth 2.0 authentication examples

In case the access token provided in this authentication scheme expires, access token expiry action can be taken using below options:

In case the access token provided in this authentication scheme expires, access token expiry action can be taken using below options:

REPORT ERROR

GET Example:

```
GET("REST", " -U restURL -M get -A OAUTH2 -ATEA reportError -AT accToken -H \"header1=value1 header2=value2\"")
```

PUT Example:

```
PUT("REST ", " -U restURL -M put -A OAUTH2 -ATEA reportError -AT accToken -H \"header1=value1 header2=value2\"")
```

REFRESH TOKEN

GET Example:

```
GET("REST", " -U restURL -M get -A OAUTH2 -ATEA refresh_token -TURL tokenURL -CK consumerKey -AT accToken -RT refreshToken -TF filepath -EK eKey -H \"header1=value1 header2=value2\"")
```

PUT Example:

```
PUT("REST ", " -U restURL -M put -A OAUTH2 -ATEA refresh_token -TURL tokenURL -CK consumerKey -AT accToken -RT refreshToken -TF filepath -EK eKey -H \"header1=value1 header2=value2\"")
```

REQUEST NEW TOKEN

GET Example:

```
GET("REST", " -U restURL -M get -A OAUTH2 -ATEA password -UN username -PWD password -TURL tokenURL -CK consumerKey -CS consumerSecret -AT accToken -ST secToken -RT refreshToken -TF filepath -EK eKey -H \"header1=value1 header2=value2\"")
```

PUT Example:

```
PUT("REST ", " -U restURL -M put -A OAUTH2 -ATEA password -UN username -PWD password -TURL tokenURL -CK consumerKey -CS consumerSecret -AT accToken -ST secToken -RT refreshToken -TF filepath -EK eKey -H \"header1=value1 header2=value2\"")
```

Proxy server support

This documentation describes the Proxy server support.

- [Proxy server support in REST Adapter](#)

The Services and REST Adapter provide the option to configure a proxy server URL. A proxy server serves as an intermediary between the client and the server. It receives REST requests from IBM Sterling Transformation Extender and acts on behalf of IBM Sterling Transformation Extender when connecting to the end server. The Proxy server is utilized when access to the destination server is restricted, and connection must be made exclusively through a proxy server.

- [Troubleshooting of proxy server](#)

Proxy server support in REST Adapter

The Services and REST Adapter provide the option to configure a proxy server URL. A proxy server serves as an intermediary between the client and the server. It receives REST requests from IBM Sterling Transformation Extender and acts on behalf of IBM Sterling Transformation Extender when connecting to the end server. The Proxy server is utilized when access to the destination server is restricted, and connection must be made exclusively through a proxy server.

- [Proxy configuration using environment variables](#)

This documentation describes proxy configuration using environment variables.

- [Proxy configuration using flow variables](#)

This documentation describes proxy configuration using flow variables.

- [Proxy configuration using properties](#)

This documentation describes proxy configuration using properties.

- [Proxy configuration using the command line](#)

This documentation describes proxy configuration using the command line.

Proxy configuration using environment variables

This documentation describes proxy configuration using environment variables.

HTTP_PROXY

To establish connections to any HTTP URLs through the REST adapter, you can set the `HTTP_PROXY` environment variable on the machine where IBM Sterling Transformation Extender is installed. This configuration allows the proxy server URL provided to be utilized for establishing connections.

Example: `HTTP_PROXY=http://proxy-server-ip:port`

HTTPS_PROXY

To establish connections to HTTPS URLs through the REST adapter, you can configure the `HTTPS_PROXY` environment variable on the machine where IBM Sterling Transformation Extender is installed. By setting this variable, the provided proxy server URL will be utilized for making connections to any HTTPS URLs.

Example: `HTTPS_PROXY=http://proxy-server-ip:port`

NO_PROXY

To bypass the proxy server for specific URLs in the machine where IBM Sterling Transformation Extender is installed, you can set the `NO_PROXY` environment variable. This variable should be configured with a comma-separated list of URLs that do not need to be passed through the proxy server URL specified in `HTTP_PROXY` or `HTTPS_PROXY`.

Example: `NO_PROXY=localhost,some-domain.com`

Note: For adding these flow variables in the docker installation, one must edit `setenv.sh` file in hip-server and hip-rest containers.

Proxy configuration using flow variables

This documentation describes proxy configuration using flow variables.

proxy_url

When deploying and running flows, you have the option to configure the "`proxy_url`" flow variable for both HTTPS and HTTP URL connections using the REST Adapter.

Proxy configuration using properties

This documentation describes proxy configuration using properties.

Proxy URL

You can configure the Proxy URL property in Service Builder and REST Adapter.

Proxy configuration using the command line

This documentation describes proxy configuration using the command line.

-PURL

In the command line mode of the REST Adapter, you can utilize the "**-PURL**" command to configure the proxy server URL.

Example: -PURL<https://proxy-server-ip:3128>

Troubleshooting of proxy server

To verify the proxy configuration checks, follow these steps:

- Check if the Proxy server URL can be accessed from the machine where IBM Sterling Transformation Extender is installed. Use the Telnet command to access the proxy server.
For example: `telnet <proxy-server-ip> <proxy-server-port>`
- If you are unable to access your port, ensure that it is enabled if you are behind a firewall.
- If your proxy server IP is not accessible, make sure to include the DNS entry of the proxy server details in the hosts file where IBM Sterling Transformation Extender is installed.
- If the REST API requests are not being passed through the proxy server, ensure that there is an entry for the end resource URLs in your host's file on the proxy server.

Salesforce Adapter

Salesforce Adapter provides support for accessing Salesforce service over REST API interface.

Using Salesforce Adapter, you can:

- Retrieve a record of a Salesforce object, such as Account, User, or custom object.
- Perform a query or search.
- Update or delete records.

Introduction

Salesforce Adapter is used to connect to REST APIs provided by Salesforce for easy integration and development without writing REST APIs frameworks in the application. Salesforce Adapter is an easy way to create and update underlying data model and standard objects.

- [Authenticating connections](#)
- [Properties and commands](#)
This chapter provides a detailed description of the adapter properties.
- [Examples](#)

Authenticating connections

OAuth 2.0 authentication. The user provides access token obtained through OAuth 2.0 workflow. The username and password can still be used to automatically refresh the access token. Before making REST API calls through Salesforce adapter, you must authenticate the application user using OAuth 2.0. Refer to Salesforce product documentation.

Salesforce adapter as a source:

The Salesforce adapter as a source is used to:

- Get a record.
- Execute a Query
- Check the query performance.
- Search a String.

Salesforce adapter as a target:

The Salesforce adapter as a target is used to:

- Insert a record.
- Update a record.
- Delete a record.
- [Salesforce adapter as source](#)

- [Salesforce adapter as a target](#)
-

Salesforce adapter as source

Salesforce adapter as a target

Properties and commands

This chapter provides a detailed description of the adapter properties.

- **Instance URL**
Specifies a server instance of organization. User can view their instance URL when they open their Salesforce Org screen. This is a mandatory property. The corresponding adapter command is -IURL (or -INSTANCEURL).
 - **Access token**
Specifies an access token to access the Salesforce REST APIs using OAuth 2.0 Authentication. Refer to [Generate an Initial Access Token](#) to generate initial access token.
 - **Version**
 - **Endpoint**
Specifies the endpoint entry in the configuration. This is a mandatory property. The corresponding adapter command is -E (or -ENDPOINT).
 - **Access Token Expiry Action**
This property specifies the action to be taken by Salesforce Adapter if the access token provided is either expired or invalid.
 - **Consumer key**
Specifies the consumer key value to use when performing Refresh Token or Request New Token expiry action.
 - **Consumer secret**
Specifies the consumer secret value to use when performing Request New Token expiry action. It is enabled when the user sets up an application under the Connected Apps in Salesforce.
 - **Refresh token**
Specifies the refresh token to provide when performing Refresh Token expiry action.
 - **Security Token**
Specifies the security token value to perform when performing Request New Token expiry action.
 - **Token Storage File**
Specifies the location of the file in the local file system in which to store the access token retrieved after performing Refresh Token or Request New Token expiry action.
 - **Encryption key**
Specifies the key to use for encrypting the access token with AES-256 encryption method when saving the token in the token storage file.
 - **Object Name**
This property specifies the object name to be acted upon when action Get Record, Insert Record, Update Record or Delete Record is selected.
 - **Id**
Specifies the record ID that is used for fetching, updating or deleting any record.
 - **SOQL Query**
SOQL Query is enabled, when you select the Execute Query, Execute QueryAll, or Query Performance action.
 - **Search string**
Specifies the search parameter that is used for simplified searching in Salesforce data instead of a SOQL clause.
 - **Logging**
Specifies the level of logging to use for the log (trace) file produced by the adapter.
 - **Append Log**
The Append Log is a flag that indicates what to do if the specified log file already exists.
 - **Log File Path**
Name of the log file to which to write log messages.
-

Instance URL

Specifies a server instance of organization. User can view their instance URL when they open their Salesforce Org screen. This is a mandatory property. The corresponding adapter command is -IURL (or -INSTANCEURL).

Access token

Specifies an access token to access the Salesforce REST APIs using OAuth 2.0 Authentication. Refer to [Generate an Initial Access Token](#) to generate initial access token.

After setting up the application under Connected Apps in Salesforce, you need the access token. It can be generated REST API tools, such as Postman. This is a mandatory property. The corresponding adapter command is -AT or (-ACCESTOKEN)

Version

Specifies the service version of Salesforce REST API which you want to connect to your Salesforce Org. All available service versions can be fetched in the UI listing. This is a mandatory property. The corresponding adapter command is -SV (or -SERVICEVERSION).

Endpoint

Specifies the endpoint entry in the configuration. This is a mandatory property. The corresponding adapter command is -E (or -ENDPOINT).

Actions available in Salesforce adapter as follows:

- Get Record (Adapter command value: getRecord).
 - Insert Record (Only Target Mode) (Adapter command value: createRecord).
 - Update Record (Only Target Mode) (Adapter command value: updateRecord).
 - Delete Record (Only Target Mode) (Adapter command value: deleteRecord).
 - Execute Query (Adapter command value: query).
 - Execute QueryAll (Adapter command value: queryAll).
 - Query Performance (Adapter command value: queryPerformance).
 - Search String (Adapter command value: searchString).
-

Access Token Expiry Action

This property specifies the action to be taken by Salesforce Adapter if the access token provided is either expired or invalid.

The default value is Report Error. The following values are supported:

- Report Error (Adapter command value: reportError).
- Refresh Token (Adapter command value: refresh_token).
- Request New Token (Adapter command value: password).

This is a mandatory property. The corresponding adapter command is -ATEA or (-ACCESSTOKENEXPIRYACTION).

Consumer key

Specifies the consumer key value to use when performing Refresh Token or Request New Token expiry action.

This is a mandatory property. The corresponding adapter command is -CK (or -CONSUMERKEY).

Consumer secret

Specifies the consumer secret value to use when performing Request New Token expiry action. It is enabled when the user sets up an application under the Connected Apps in Salesforce.

This is a mandatory property. The corresponding adapter command is -CS (or -CONSUMERSECRET).

Refresh token

Specifies the refresh token to provide when performing Refresh Token expiry action.

The corresponding adapter command is -RT (or -REFRESHTOKEN).

Security Token

Specifies the security token value to perform when performing Request New Token expiry action.

The corresponding adapter command is -ST or -SECURITYTOKEN command.

Token Storage File

Specifies the location of the file in the local file system in which to store the access token retrieved after performing Refresh Token or Request New Token expiry action.

This is a mandatory property. The corresponding adapter command is -TF (or -TOKENFILE).

Encryption key

Specifies the key to use for encrypting the access token with AES-256 encryption method when saving the token in the token storage file.

This is a mandatory property. The corresponding adapter command is -EK (or -ENCRYPTIONKEY).

Object Name

This property specifies the object name to be acted upon when action Get Record, Insert Record, Update Record or Delete Record is selected.

The default value is Get Record. This is a mandatory property. The corresponding adapter command is -SON (or -SOBJECTNAME).

Id

Specifies the record ID that is used for fetching, updating or deleting any record.

This is a mandatory property. The corresponding adapter command is -SOID (or -SOBJECTID).

SOQL Query

SOQL Query is enabled, when you select the Execute Query, Execute QueryAll, or Query Performance action.

Make sure that it contains valid SOQL query string. This is a mandatory property. The corresponding adapter command Is -SOQL (or -SOQLQUERY).

Refer to Salesforce Object Query Language (SOQL) for valid SOQL syntax.

Search string

Specifies the search parameter that is used for simplified searching in Salesforce data instead of a SOQL clause.

The corresponding adapter command -SS (or -SEARCHSTRING).

Logging

Specifies the level of logging to use for the log (trace) file produced by the adapter.

The default is off. The value info means log informational and error messages, the value error means log error messages only, and the value verbose means log debug and trace level messages along with the informational and error messages.

Append Log

The Append Log is a flag that indicates what to do if the specified log file already exists.

The default value is true. When set to true, the log messages are appended to the file. When set to false, the file is truncated, and the messages are written to the empty file.

Log File Path

Name of the log file to which to write log messages.

If not specified, the default log file name m4sforce.trc is used, and the file is stored to the directory in which the executed compiled map resides.

Examples

- [GET map function](#)
- [PUT map function](#)

GET map function

Access token expiry action (-ATEA) is set to reportError, the adapter will throw 401 – Unauthorized error, if token is invalid or expired.

```
GET("SFORCE", " -E getRecord -ATEA reportError -AT access_token -IURL https://resourceful-hawk-wrhtdc-dev-ed.my.salesforce.com -SV 46.0 -SON Account")
```

To refresh the access token when it expires, set ATEA to 'refresh_token' (Refresh Token). -RT is provided with refresh token captured outside HIP/ITX along with consumer key:

```
GET("SFORCE", " -E getRecord -ATEA refresh_token -CK consumerKey -AT accessToken -RT refreshToken -TF filepath -EK ekey -IURL https://resourceful-hawk-wrhtdc-dev-ed.my.salesforce.com -SV 46.0 -SON Account")
```

To get new token, if it expires, ATEA is set to 'password' (Request New Token) along with username, password, consumer key and consumer secret. Optionally security token, if provided by Salesforce:

```
GET("SFORCE", " -E getRecord -ATEA password -UN username -PWD pwd -CK consumerKey -CS consumersecret -AT accessToken -ST secToken -RT refreshToken -TF filepath -EK ekey -IURL https://resourceful-hawk-wrhtdc-dev-ed.my.salesforce.com -SV 46.0 -SON Account")
```

PUT map function

```
PUT("SFORCE ", " -E createRecord -ATEA reportError -AT accessToken -IURL https://resourceful-hawk-wrhtdc-dev-ed.my.salesforce.com -SV 45.0 -SON Account ",  
inputdata)
```

Secure File Transfer Protocol (SFTP) Adapter

Overview

With the Secure File Transfer Protocol (SFTP) adapter, you can send and fetch files securely to and from an SFTP server. When you use the SFTP adapter as a source, you can read data from a file as well as fetch a list of files present in any directory on an SFTP server location. When you use the SFTP adapter as a target, you can send data to a specified file on the SFTP server. You can either:

- Create a new file.
- Overwrite an existing file.
- Append data to an existing file.

If you have configured the adapter to overwrite a file or append data to a file that does not exist—but if the directory structure in the file path is valid—the file is automatically created. If the directory structure in the specified file path does not exist, the write operation fails unless you have configured the adapter to create a new directory in case the specified file path does not exist. In that case, the adapter automatically creates the missing directories.

Introduction

The SFTP is a protocol for secure file data transfer over computer networks. The SFTP adapter conforms to this protocol and can be configured to act as an SFTP client to transfer and access file data to and from SFTP servers.

Command alias

Specify adapter commands by using a command string on the command line or by creating a command file that contains adapter commands. The command syntax is:

```
-IA[alias]card_num
```

```
-OA[alias]card_num
```

In the command syntax, -IA is the Input Source Override execution command and -OA is the Output Target Override execution command, *alias* is the adapter alias, and *card_num* is the number of the map card. The SFTP adapter alias and corresponding execution commands are listed in the following table.

Adapter	Alias	As Input	As Output
SFTP	SFTP	-IASFTP	-OASFTP

Authenticating connections

The Secure File Transfer Protocol (SFTP) is a protocol for secure file data transfer over computer networks. The SFTP adapter conforms to this protocol and can be configured to act as an SFTP client to transfer and access file data to and from SFTP servers.

The SFTP adapter offers the following two methods to authenticate a user to connect to an SFTP server:

- Password-based – You need to provide the correct password.
- Keypair-based – You need to enter the private key file path, public key file path, keypair name, and passphrase.

You can select any one of the two authentication methods as the preferred one. The adapter first attempts the preferred authentication method. If that attempt is not successful, the adapter then tries for the other method to authenticate.

Note: For Keypair-based authentication method, only the private-key file path is required. The public-key file path, keypair name, and passphrase are optional. Username is required for both the authentication methods.

After successfully connecting to an SFTP server, you can send and receive files to and from the server.

SFTP adapter as a source

SFTP adapter as a source supports:

- File list – Use this mode to fetch all the files from any directory on an SFTP server location.
- File data – Use this mode to fetch the content of a specified file from an SFTP server location.

SFTP adapter as a target

SFTP adapter as a target supports:

- Create – Use this mode to create a new file in the SFTP server location and write data to it, or report an error if the file already exists.
- Overwrite – Use this mode to overwrite a file with any new data if the file already exists; or otherwise to create a file and write data to it—if the specified file does not exist.
- Append – Use this mode to append any new data to an existing file on the SFTP server location, or otherwise to create a new file and write data to it—if no file of the specified name exists.

Note: When you fetch a file, the file is left on the server or removed based on the value specified in the File Success Action property.

Adapter properties and commands

This section lists the properties supported by the adapter.

Host

Specifies the host name or IP address of the SFTP server. This is a mandatory property. The corresponding adapter command is `-HOSTname` (or `-HOSTNAMEname`).

Port

Specifies the port on which the SFTP server is listening for incoming connections. The default value is 22. The corresponding adapter command is `-PORT number` (or `-PORTNUMBER number`).

Preferred authentication

Specifies the authentication method to try first when establishing a connection. The supported values are Password and Public Key. The default value is Password. The corresponding adapter command is `-PA method` (or `-PREFERREDAUTHENTICATION method`) where the `method` is one of password or public key.

User

Specifies the username for the connection. This is a mandatory property. The corresponding adapter command is `-USR name` (or `-USERNAME name`).

Password

Specifies the password value to use when performing password-based authentication. The corresponding adapter command is `-PWD value` (or `-PASSWORD value`).

Known hosts file path

Specifies the location of the known hosts file. The value is optional, and when specified results in enforcing strict host name checking against the specified file when establishing connections. If not specified, it results in omitting strict host name-checking. The corresponding adapter command is `-KHFP path` (or `-KNOWNHOSTSFILEPATH path`).

Key pair name

Specifies the name of the keypair to use when performing keypair based authentication. The value is optional and when not specified the name identifying the key pair is derived from the private key file name. The corresponding adapter command is `-KPN name` (or `-KEYPAIRNAME name`).

Private key file path

Specifies the location of the private key file to use when performing keypair based authentication. The corresponding adapter command is `-PRKFP path` (or `-PRIVATEKEYFILEPATH path`).

Passphrase

Specifies the passphrase is used to access the key data when performing keypair based authentication. The value is optional, and when not specified, it is assumed that the key is not passphrase protected. The corresponding adapter command is `-PSP value` (or `-PASSPHRASE value`).

Connection timeout

Specifies the amount of time, in seconds, to wait for the server to respond when establishing a connection, before considering the connection attempt unsuccessful. The default value is 30. The value 0 indicates no timeout. The corresponding adapter command is `-CT duration` (or `-CONNECTIONTIMEOUT duration`).

Retry connection count

Specifies the number of times to retry establishing a connection to the server before giving up and reporting the error. The default value is 0, which indicates no retries. This setting is not applicable when performing Test connection operation in the design UI, and the value 0 is automatically enforced in that case. The corresponding adapter command is `-RCC count` (or `-RETRYCONNECTIONCOUNTcount`).

Retry connection interval

Specifies the amount of time, in seconds, to wait between successive connection retries. The default value is 60. This setting is applicable only when the Retry Connection Count is set to a value greater than 0.

The corresponding adapter command is `-RCI duration` (or `-RETRYCONNECTIONINTERVAL duration`).

Path

Specifies the path of the directory or file to access on the SFTP server. Forward slash (/) character is used as a file separator. If the specified path value starts with a forward slash, it is treated as an absolute path; otherwise, it is treated as a path relative to the current default directory for the connection. The corresponding adapter command is `-P path` or `(-PATH path)`.

Create directory

Specifies the setting which when enabled results in the automatic creation of all missing directories in the specified directory path. When not enabled, the adapter reports an error if the specified directory structure does not exist on the SFTP server. The setting is applicable only when the adapter is used as a target. The corresponding adapter command is `-CD` (or `-CREATEDIRECTORY`).

Read mode

This property specifies the mode in which to use the adapter as a source. The File Data mode is used to read the content of the file specified in the Path setting. The File List mode is used to retrieve the list of absolute paths of the files located in the directory specified in the Path setting. The default value is File Data. The corresponding adapter command is -RM *mode* (or -READMODE *mode*), where *mode* is one of file_data or file_list.

Write mode

Specifies the mode in which to use the adapter as a source. The File Data mode is used to read the content of the file specified in the Path setting. The File List mode is used to retrieve the list of absolute paths of the files located in the directory specified in the Path setting. The default value is File Data. The corresponding adapter command is -WM *mode* (or -WRITEMODE *mode*), where *mode* is one of create, overwrite or append.

File Success Action

Specifies the success action to be taken by the adapter on the file as what to do with it after the successful run of a transaction. The default value is Keep.

The corresponding adapter command is -FILESUCCESSACTION (or -FSA). The following actions are supported:

- Keep: Keeps the file at the source after the successful run of a transaction. The corresponding adapter command value is keep.
- Delete Always: Deletes the file at the source in case of successful run of a transaction. The corresponding adapter command value is delete_always.
- Delete If Empty: Deletes the file at the source in case of a successful run. Checks, if the file is empty or not. If the file is empty, it is deleted, otherwise it is left in place. The corresponding adapter command value is delete_if_empty.

Failure Action

Specifies the failure action to be taken by the adapter on the file as where to place it after the failure run of a map. The default value is Commit.

The following actions are supported:

- Commit: This option will commit the transaction in case of transaction failure.
- Rollback: This option will rollback the transaction in case of transaction failure.

The following list shows the outcomes for different combinations of File Success Action and Failure Action property values:

- keep + commit = keep
- delete always + commit = delete
- delete if empty + commit (when file has data) = keep
- delete if empty + commit (when file does not have data) = delete
- keep + rollback = keep
- delete + rollback = keep
- delete if empty + rollback (when file has data) = keep
- delete if empty + rollback (when file does not have data) = keep

Logging

This property specifies the level of logging to use for the log (trace) file produced by the adapter. The default is Off. The value Information means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

The corresponding adapter command is:

-T [E|V] [+] [file_path]

-T -> Log adapter informational messages.

-TE -> Log only adapter errors.

-TV -> Use verbose (debug) logging. The log file records all activity that occurs while the adapter is producing or consuming messages.

+ -> Appends the trace information to the existing log file. Omit this argument to create a new log file.

file_path -> The full path to the adapter trace log. If you omit this keyword, the adapter creates the m4sftp.mtr log file in the map directory.

Append log

Flag indicating what to do if the specified log file already exists. When set to true, the log messages are appended to the file. When set to false, the file is truncated, and the messages are written to the empty file. The default value is true.

Log file path

Specifies the location of the log file to which to write log messages. If not specified, the default log file name m4sftp.mtr is used, and the file is stored to the directory in which the executed compiled map resides.

Convert Data

Specifies to convert data to parsed form. If enabled, support for converting CSV, Avro, Excel, Parquet and JSON documents into sets of data records in the CSV format. This means that the data produced by the converters can be loaded directly into relational databases.

Data Format

Specifies the data format. This is a mandatory property. Select one of the following as per the data format type. This property field is applicable when Convert Data property toggle is enabled.

- CSV
- Excel
- Avro
- Parquet
- JSON

Header

If enabled, specifies whether the CSV data contains a header row.

Quote

Specifies the quote character. Default value is ".

Delimiter

Specifies the field delimiter character. Default value is ,.

- Escape**
Specifies the escape character.
- Separator**
Specifies the row separator characters. Default value is \r\n.
- Character Set**
Specifies the character set of the data. Default value is UTF-8.
- Limit**
Specifies the maximum number of records to return.
- Sample Size**
Specifies the number of records to analyze when determining the data structure. Default value is 100.
- Worksheet Index**
Specifies the index of the worksheet. The index of the first worksheet is 1 (default).
- Select Source Tables**
Select which arrays of objects in the AVRO data you wish to map to tables in the target.
- Find Array**
If enabled, specifies that the output will iterate on the first array found in the JSON document.
- Array Path**
Specifies the path of the JSON array within the document. Omit if the document is an array. For example, "/resources".

Examples

Examples of the GET map function

In the following example, assume that the adapter is used in a GET function.

- When the adapter is used to fetch file content:

```
GET("SFTP", "-USR testUser -HOST host1 -PORT 22 -PA Password -PWD pwd1 -P /myDirectory/MyFile.txt -RM file_data -TV
/tmp/logfile.log")
```

- When the adapter is used to fetch file list:

```
GET("SFTP", "-USR testUser -HOST host1 -PORT 22 -PA Password -PWD pwd1 -P /myDirectory/ -RM file_list -TV
/tmp/logfile.log")
```

- When the adapter is used to File Success Action:

```
GET("SFTP", "-USR testUser -HOST host1 -PORT 22 -PA Password -PWD pwd1 -P /myDirectory/MyFile.txt -RM file_data -FSA keep
-TV/tmp/logfile.log")
```

Examples of the PUT map function

In the following example, assume that the adapter is used in a PUT function.

- When the adapter is used to create a new file, if the file is not present:

```
PUT ("SFTP", "-USR testUser -HOST host1 -PORT 22 -PA Password -PWD pwd1 -P /myDirectory/MyFile.txt -WM create -TV
/tmp/logfile.log", in_data_type)
```

- When the adapter is used to overwrite an existing file:

```
PUT ("SFTP", "-USR testUser -HOST host1 -PORT 22 -PA Password -PWD pwd1 -P /myDirectory/MyFile.txt -WM overwrite -TV
/tmp/logfile.log", in_data_type)
```

- When the adapter is used to append data to an existing file:

```
PUT ("SFTP", "-USR testUser -HOST host1 -PORT 22 -PA Password -PWD pwd1 -P /myDirectory/MyFile.txt -WM append -TV
/tmp/logfile.log", in_data_type)
```

- When the adapter is requested to automatically create missing directories:

```
PUT ("SFTP", "-USR testUser -HOST host1 -PORT 22 -PA Password -PWD pwd1 -P /myDirectory/MyFile.txt -WM create -CD -TV
/tmp/logfile.log", in_data_type)
```

Example of RUN() function in a map rule

- Here is an example of using RUN() function in a map rule to run a map map1 and override its output card 1 to use SFTP adapter:

```
=RUN("map1", "-OASFTP1 '-HOST server1 -PORT 10022 -USR user1 -PWD password1 -PATH /tmp/test.txt -WM overwrite -TV'")
```

- Here is the same example, but this time using command server from command line on Linux to run the map map1.lnx and perform the same override:

```
dtxcmdsv map1.lnx "-OASFTP1 '-HOST server1 -PORT 10022 -USR user1 -PWD password1 -PATH /tmp/test.txt -WM overwrite -TV'"
```

SNMP Adapter overview

The SNMP Adapter is used to create and send custom-defined traps to an SNMP manager. A *trap* is a message indicating that an event has occurred on the host running the network resource.

The generic term *SNMP manager* is used in this documentation when referencing SNMP-enabled network management software.

A typical use scenario is a data-sensitive trigger or a particular condition that occurs during a map execution. For example, using conditional logic and the `PUT` function in a map, a trap is sent when a datum exceeds a specified value.

The SNMP Adapter can be used only in an output card or `PUT` function (data target). For example,

```
=IF (Price:InputStream > 1000000,  
PUT ("SNMP", "-T", "Threshold exceeded (" +  
TEXT(Price:InputStream) + ")"), NONE)
```

A trap community must be defined in the `dtx.acl` file that specifies which IP address or domains are to receive trap notifications. The trap community identifies the community and hosts that can receive the traps. You can specify an IP address that is in IPv4 (for example, 1.2.3.4) or IPv6 (for example, a:b:c:d:0:1:2:3) format.

IPv4 format example:

```
trap = { trap-community = mycommunity  
hosts = 192.168.100.1,147.137.16.1
```

IPv6 format example:

```
trap = { trap-community = mycommunity  
hosts = 1080:0:0:0:8:700:200C:417A, 1081:0:0:0:8:800:200C:418B
```

- [System requirements](#)
- [Command alias](#)
- [SNMP Adapter commands](#)
- [Return codes and error messages](#)

System requirements

The minimum system requirements and operating system requirements for the SNMP Adapter are detailed in the release notes.

Command alias

Adapter commands can be specified by using a command string on the command line or creating a command file that contains adapter commands. The execution command syntax is:

```
-IA[alias] card_num  
-OA[alias] card_num
```

where `-IA` is the Input Source Override execution command and `-OA` is the Output Target Override execution command, `alias` is the adapter alias, and `card_num` is the number of the input or output card. The following table shows the adapter alias and its execution command.

Adapter	Alias	As Input	As Output
SNMP	SNMP	<code>-IASNMP</code> <i>card_num</i>	<code>-OASNMP</code> <i>card_num</i>

SNMP Adapter commands

This documentation describes the functions and use of the SNMP Adapter commands and their options.

- [List of commands](#)

- [Example files](#)

List of commands

The following table lists valid commands for the SNMP Adapter, the command syntax, and if the command is supported (✓) for use with data sources, targets, or a combination.

Commands can be specified on the adapter's command line or through adapter properties. The commands are not case sensitive but each value is case sensitive.

Command	Syntax	Source	Target
Context name (-CONTEXTNAME or -N)	<code>-CONTEXTNAME</code> <i>context_name</i>		✓
Port (-PORT or -P)	<code>-PORT</code> <i>port_number</i>		✓
Security level (-SECURITYLEVEL or -L)	<code>-SECURITYLEVEL</code> 0 1 3		✓
Trace (-TRACE or -T)	<code>-T[E][+]</code> [<i>full_path</i>]		✓
User (-USER or -U)	<code>-USER</code> <i>user_name</i>		✓

Command	Syntax	Source	Target
Version (-VERSION or -V)	-VERSION 1 2 3		✓
XML (-XML)	-XML		✓

Context name (-CONTEXTNAME or -N)

Use the context name (-CONTEXTNAME or -N) adapter command to specify the name of the SNMPv3 context that is authorized.

Option	Description
<code>context_name</code>	The context name specified in the dtx.uacl file.

Port (-PORT or -P)

Use the Port adapter command (-PORT) to specify the port number to receive trap notifications. The SNMP manager installed on the machine that is connected to that port will receive trap notifications.

Option	Description
<code>port_number</code>	The port number to receive trap notifications. The default port number is 162 .

Security level (-SECURITYLEVEL or -L)

Use the security level (-SECURITYLEVEL or -L) adapter command to set the level of security for communication in the SNMPv3 network, as specified in the **dtx.uacl** file.

Option	Description
<code>security_level</code>	One of the following values:
0	No authentication and no privacy (noAuthNoPriv).
1	Authentication and no privacy (authNoPriv).
3	Authentication and privacy (authPriv).

Trace (-TRACE or -T)

Use the Trace adapter command (-TRACE or -T) to produce a diagnostics file that contains detailed information about SNMP Adapter activity.

The default filename is **m4snmp.mtr** and it is created in the map directory unless otherwise specified.

-T [E] [+] [*full_path*]

Option	Description
<code>E</code>	Produce a trace file containing only the adapter errors that occurred during map execution.
<code>+</code>	Append trace information to the existing trace file.
<code>full_path</code>	Creates a trace file with the specified name in the specified directory.

You can override the adapter command line trace options dynamically using the Management Console. See "Dynamic Adapter Tracing" in the Launcher documentation for detailed information.

User (-USER or -U)

Use the user (-USER or -U) adapter command to specify the name of the SNMPv3 user that is authorized.

Option	Description
<code>user_name</code>	The user name specified in the dtx.uacl file.

Version (-VERSION or -V)

Use the version (-VERSION or -V) adapter command to specify the version of the SNMP network protocol.

Option

Description

version

One of the following values:

- 1 SNMPv1. This is the default version.
- 2 SNMPv2c
- 3 SNMPv3

XML (-XML)

Use the XML adapter command (-XML) to specify that the data being sent to the SNMP Adapter is in XML format.

The default message format is plain text.

The format of the XML message is as follows:

```
<Message>
<String><! [CDATA[ string data ]]></String>
<Integer>integer value</Integer>
<Binary>base64 encoded binary data</Binary>
<Priority>integer value [0-6]</Priority>
</Message>
```

This format allows for binary data and an integer variable to be sent in the trap message. This enables an error code to be sent in addition to the data, and any other kind of data that the permitting binary data allows. If the XML format is not used, then only the text variable is sent in the trap.

A single MIB variable, the string or binary value, is limited to 64K due to a limitation in the SNMP protocol.

Example

For the PUT Target setting in an output card, select SNMP. In the **PUT > Target > Command** field, enter:

```
PUT ("SNMP", "-T+ output.txt -XML -
PORT 162", PACKAGE(TrapInfo))
```

This command specifies the following:

- Appends trace information to **output.txt**.
- Receives input from type tree in XML format.
- Sends traps to SNMP managers connected to port **162**.
- Sends the output from an output card named **TrapInfo**.

Example files

An example program is provided in the *install_dir\examples\adapters\sntp* directory. This example demonstrates how to send SNMP traps using the SNMP Adapter.

Return codes and error messages

Return codes and error messages are returned when the particular activity completes. Return codes and error messages might also be recorded as specified in the audit logs, trace files, and execution summary files.

- [SNMP Adapter messages](#)

SNMP Adapter messages

The following lists all the codes and messages that can be returned as a result of using the SNMP Adapter for sources or targets.

Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Return Code	Message
-------------	---------

Return Code	Message
0	Success
999	MPIRC_E_SNMP_EXCEPTION
998	MPIRC_E_SNMP_TOO_MANY_COMMANDS_EXCEPTION
997	MPIRC_E_SNMP_MISSING_CMDLINEARG_EXCEPTION
996	MPIRC_E_SNMP_INVALID_PORT_EXCEPTION

SOAP (WSDL) Adapter

SOAP defines the XML-based message format that applications use to communicate and inter-operate with each other over the Web.

The heterogeneous environment of the Web demands that applications support a common data encoding protocol and message format.

SOAP is a standard for encoding messages in XML that invoke functions in other applications running on any hardware platform regardless of different operating systems or programming languages. It is analogous to Remote Procedure Calls (RPC) used in many technologies such as Distributed Component Object Model (DCOM), but eliminates some of the complexities of using these interfaces.

The SOAP (WSDL) Adapter supports the SOAP 1.1 protocol as defined by <http://www.w3.org/TR/SOAP/>.

Use the SOAP (WSDL) Adapter to help to create SOAP request messages and to interpret response messages. The SOAP (WSDL) Adapter does not handle the delivery of messages and should be used with a transport adapter, such as HTTP, to deliver the request and receive the response message.

When you send a SOAP-based HTTP request, the default encoding of the content of the HTTP request is ISO-8859-1. The SOAP adapter requires a UTF-8 encoded response from the HTTP server, but the request can be in any Western or UTF-8 encoded format. See the description of the **-TYPE** command in the HTTP adapter documentation for details about how to specify the encoding.

The adapter has the following capabilities:

- Adds SOAP envelopes if they are not provided
- Parses the response message to extract scalar data elements
- Removes envelope and simplifies the form of SOAP responses to aid mapping of the response data
- Understands fault codes and interprets them as map failures

The SOAP (WSDL) Adapter does not provide a listener. The transport adapter provides this functionality.

- [System requirements](#)
- [Command alias](#)
- [SOAP Adapter commands](#)
- [Syntax summary](#)
- [Using the adapter](#)
- [Return codes and error messages](#)

System requirements

The minimum system requirements and operating system requirements for the SOAP (WSDL) Adapter are detailed in the release notes.

Command alias

Adapter commands can be specified by using a command string on the command line or by creating a command file that contains adapter commands. The execution command syntax is:

```
-IA[alias] card_num
-OA[alias] card_num
```

where **-IA** is the Input Source Override execution command and **-OA** is the Output Target Override execution command, **alias** is the adapter alias, and **card_num** is the number of the input or output card. The following table shows the adapter alias and its execution command.

Adapter	Alias	As Input	As Output
SOAP	SOAP	-IASOAPcard_num	-OASOAPcard_num

SOAP Adapter commands

This documentation describes the functions and use of the SOAP (WSDL) Adapter commands and their options.

- [List of commands](#)

List of commands

The following table lists valid commands for the SOAP (WSDL) Adapter, the command syntax, and whether the command is supported (✓) for use with data sources, targets, or any other combination.

Commands can be specified on the adapter's command line or through adapter properties. Note that the commands are not case sensitive but that each value is case sensitive.

Command	Syntax	Source	Target
Decode (-DECODE)	-DECODE	✓	
Encode (-ENCODE)	-ENCODE		✓
Header (-HDR)	-HDR	✓	
Raw (-RAW)	-RAW	✓	
Return (-RETURN)	-RETURN element	✓	
SOAPAction (-SA)	-SA soap_action		✓
Trace (-T)	-T[E][NX][+] [filename]	✓	✓
Transport (-TRANSPORT)	-TRANSPORT 'adapter_name (adapter_command_line)'	✓	✓

- [Decode \(-DECODE\)](#)
- [Encode \(-ENCODE\)](#)
- [Header \(-HDR\)](#)
- [Raw \(-RAW\)](#)
- [Return \(-RETURN\)](#)
- [SOAPAction \(-SA\)](#)
- [Trace \(-T\)](#)
- [Transport \(-TRANSPORT\)](#)

Decode (-DECODE)

Use the Decode adapter command (-DECODE) to instruct the adapter to decode the SOAP message, which involves stripping the envelope and SOAP envelope header, and handling SOAP faults.

-DECODE

For example, to decode a message received over HTTP:

```
GET ("SOAP", "-DECODE -TRANSPORT 'HTTP (-URL http:/myurl/)'" )
```

The -DECODE option is optional since it is implied by the invocation of the SOAP (WSDL) Adapter in an input card or GET function.

For more information on encoding and decoding data, see *Encoding and Decoding Data* in the Resource Adapters documentation.

Encode (-ENCODE)

Use the Encode adapter command (-ENCODE) to instruct the adapter to encode the SOAP message, which involves adding a SOAP envelope if none is provided.

-ENCODE

For example, to encode a SOAP message before transporting over HTTP:

```
PUT ("SOAP", "-ENCODE -TRANSPORT 'HTTP (-URL http:/myurl/)'  
SoapRequest )
```

The -ENCODE option is optional since it is implied by the invocation of the SOAP (WSDL) Adapter in an output card or PUT function.

For more information on encoding and decoding data, see *Encoding and Decoding Data* in the Resource Adapters documentation.

Header (-HDR)

Use the Header adapter command (-HDR) to specify that the SOAP envelope header be returned. This is an optional command. The default is to not return the SOAP header.

-HDR

See [Source Options Behavior](#) for more information on the behavior of the SOAP (WSDL) Adapter and its combinations of available options.

Raw (-RAW)

Use the Raw adapter command (-RAW) to specify that the response message be returned unmodified, except the SOAP envelope header is removed.

-RAW

If the **-RAW** command is specified, the only processing of the response data is:

The SOAP envelope header is stripped out. To keep the header specify **-HDR**.

Fault codes are interpreted

For example, using the **-RAW** command results in the data being returned as follows (intact, but without SOAP envelope header):

```
<?xml version="1.0" encoding="UTF-8" standalone="no" ?>
- <SOAP-ENV:Envelope SOAP-
  ENV:encodingStyle=http://schemas.xmlsoap.org/soap/encoding/
  xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">
- <SOAP-ENV:Body>
- <SOAPSSDK1:AddResponse
  xmlns:SOAPSSDK1="http://tempuri.org/message/">
  <Result>290</Result>
</SOAPSSDK1:AddResponse>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

If the **-RAW** command is not specified, then the following is returned:

- The body of the request without the enclosing **<Body>...</Body>** tags
- Any namespace prefixes are removed
- Any attributes are removed

For example, the message shown above is returned as follows:

```
- <AddResponse>
  <Result>290</Result>
</AddResponse>
```

See [Source Options Behavior](#) for more information on the behavior of the SOAP (WSDL) Adapter and its combinations of available options.

Return (-RETURN)

Use the Return adapter command (**-RETURN**) to return a single scalar value from the response message. In many cases, a map only has interest in a single value. This option simplifies mapping in these types of cases. This command can only be used if the value of the element is a scalar value.

This command is incompatible with the **-HDR** command.

This is an optional command. The default is a null reply.

-RETURN element

Option

Description
element

Specify the path and the element to be returned using XPath syntax.

XPath is a language for addressing parts of an XML document. For more information on the XPath language, go to www.w3.org/TR/xpath.

For example, to specify /cat/dog as the XML element to be returned:

-RETURN /cat/dog

See [Source Options Behavior](#) for more information on the behavior of the SOAP (WSDL) Adapter and its combinations of available options.

- [Return option and XPath](#)

Return option and XPath

The element to return is specified using an XPath subject to the following limitations:

- The element to return must be a scalar type. That is, it cannot be an array or contain another element.
- Only fully qualified paths are accepted, for example:
/Message/StockQuote/Price
- Attributes of elements can be specified using the standard XPath '@' notation, for example:
/Message/StockQuote/@currency

While the SOAP standard does not forbid the use of attributes, it recommends not using them.

No other XPath syntax is supported

The limitations in the previous examples are taken into consideration in the following sample message:

```

<Message>
  <StockQuote>
    <Symbol>XYZ</Symbol>
    <Price currency="dollar">20</Price>
  </StockQuote>
</Message>

```

The names of the elements in the path correspond to the name in the returned data. Therefore, if the `-RAW` command is used, the names correspond to the element names in the raw response message. In this case, the elements are often qualified by namespace prefixes.

Consider the following example return message:

```

<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/">
<SOAP-ENV:Body SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<NS1:BabelFishResponse xmlns:NS1="urn:BorlandBabelIntf-IBorlandBabel">
<return xsi:type="xsd:string">Freeend</return>
</NS1:BabelFishResponse>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>

```

If we want to return only the `<return>` element, the following command(s) should be used:

```

-Raw -Return /SOAP-ENV:Envelope/SOAP-ENV:Body/
NS1:BabelFishResponse/return

```

Or, if the `-RAW` command is not specified:

```

-Return /BabelFishResponse/return

```

SOAPAction (-SA)

When the transport is HTTP, many Web services require the `SOAPAction` field to be added to the HTTP header of a SOAP request. Use the `SOAPAction` adapter command (`-SA`) to indicate to the server the intent of the request.

Use one of the following values:

- `NULL` (`-SA` with no argument), means that there is no indication of the intent
- `Empty string` (`-SA ""`), means that the intent of the request is provided by the HTTP request URI or Uniform Resource Identifier (no value is specified between the single quotes)
- `URI` (`-SA 'http://www.me.com/'`), where the intent is provided by the URI

The presence and content of the `SOAPAction` header field can be used by servers to appropriately filter SOAP request messages.

This is an optional command. The default is no `SOAPAction`.

```

-SA soap_action

```

Option

Description
<code>soap_action</code>

Specify the intent of the request for the SOAP message.

When using the HTTP adapter as the transport, the HTTP adapter command `-HDR+/-URL` must be used to instruct the HTTP adapter to add the specified `SOAPAction` to the HTTP header.

For example, to specify `urn:BorlandBabelIntf-IBorlandBabel#BabelFish` as the `SOAPAction`:

```

GET("SOAP", "-SA 'urn:BorlandBabelIntf-
IBorlandBabel#BabelFish' -TRANSPORT 'http(-HDR+ -HDR+ -URL
http://ww6.borland.com/webservices/BorlandBabel/
BorlandBabel.exe/soap/IBorlandBabel -T)'", requestData)

```

If the WSDL Importer is used to create the schemas for the SOAP request messages, the value that should be assigned to the `SOAP action` command can be found in the description of the corresponding operation.

See the Schema Importers documentation for more information on the WSDL Importer.

Trace (-T)

Use the `Trace` adapter command (`-TRACE` or `-T`) to produce a diagnostics file that contains detailed information about SOAP (WSDL) Adapter SOAP (WSDL) Adapter activity.

The default filename is `m4soap.mtr` and the file is created in the map directory unless otherwise specified.

```

-T[E] [NX] [+]
[filename]

```

Option	Description
E	Produce a trace file containing only the adapter errors that occurred during map execution.
NX	Excludes information about XML data from the trace file.
+	Append trace information to the existing trace file.
<i>filename</i>	Creates a trace file with the specified name in the specified directory.

You can override the adapter command line trace options dynamically using the Management Console.

Transport (-TRANSPORT)

Use the Transport adapter command (-TRANSPORT) to specify which transport adapter to use and the command line for the transport adapter.

The syntax of the command must include the single quotes and parentheses as shown below.

```
-TRANSPORT 'adapter_name (adapter_command_line)'
```

Option	Description
<i>adapter_name</i>	Specify which transport adapter to use.
<i>adapter_command_line</i>	Specify the command line for the transport adapter. You must enclose this option within parentheses () .

For example, to specify the HTTP adapter as the transport adapter, and to send the SOAP request to the http://localhost/WebService/test URL, enter the following command:

```
-TRANSPORT 'http (-URL http://localhost/WebService/test -T)'
```

Syntax summary

This documentation discusses the SOAP syntax summary and how it is used.

- [Data sources](#)
 - [Data targets](#)
 - [Source options behavior](#)
-

Data sources

The following is the command syntax for the SOAP (WSDL) Adapter commands used for data sources:

```
-TRANSPORT 'adapter_name (adapter_command_line)'
[-DECODE]
[-RAW]
[-HDR]
[-RETURN element]
[-T[E] [NX] [+]] [filename]
```

- [Example](#)
-

Example

For the GET Source setting in an input card, select SOAP. In the **GET > Source > Command** field, enter:

```
-T -RAW -TRANSPORT 'http (-URL http://www.myws.com/DoWS)'
```

This command specifies that the SOAP message:

- Received data from the HTTP URL <http://www.myws.com/DoWS> using the HTTP adapter (-TRANSPORT)
 - Returned data in full (-RAW)
 - Adapter trace is enabled (-T) and a diagnostics file is produced
-

Data targets

The following is the command syntax for the SOAP adapter commands used for data targets:

```
-TRANSPORT 'adapter_name (adapter_command_line)'  
[-ENCODE]  
[-SA soap_action]  
[-T[E] [NX] [+]] [filename]
```

- [Example](#)
-

Example

For the PUT Target setting in an output card, select SOAP. In the PUT>Target>Command field, enter:

```
-SA " -T -TRANSPORT 'http (-URL http://www.myws.com/DoWS)'
```

This command specifies that the SOAP message:

- Sent data over HTTP to the URL <http://www.myws.com/DoWS> using the HTTP adapter (-TRANSPORT)
 - SOAPAction is provided by the HTTP request URL (SA ")
 - Adapter trace is enabled (-T) and a diagnostics file is produced
-

Source options behavior

The following table defines the behavior of the SOAP (WSDL) Adapter based upon combinations of available options.

Commands	Behavior
No formatting commands	Only the contents of the body of the message are returned (this is the default). No attributes are returned and namespace prefixes are removed.
-RAW alone	If a header is in the message's envelope, it is removed, but the envelope and body are returned intact.
-HDR alone	Equivalent to -RAW and -HDR , since an envelope is required to ensure the well-formedness of the XML document. For more information on XML document standards go to www.w3.org/TR/1998/REC-xml-19980210 .
-RAW and -HDR	The SOAP request is returned in its entirety.
-RETURN XPath	Only the single scalar value is returned. See Return Option and XPath for more information.

Using the adapter

Use the SOAP (WSDL) Adapter to either invoke a Web service by sending a request message and processing the response, or in the implementation of a Web service.

Note that two adapters are used in communicating between the map and the Web service:

- The SOAP (WSDL) Adapter
- A transport adapter, such as an HTTP adapter

There are two primary usage scenarios for the SOAP (WSDL) Adapter:

- As a consumer of Web services
 - As a provider of Web services
 - [Consumer scenario](#)
 - [Provider scenario](#)
 - [Example files](#)
-

Consumer scenario

A common scenario is the flow of a request from a map, through SOAP and HTTP adapters to the Web Service, and the flow of the response back to the map from the Web Service.

The adapter is designed to be called in a GET map function call. The third parameter of the GET is the request message. For example:

```
Response = GET("SOAP", "-HDR -TRANSPORT 'HTTP(-URL http://  
www.stuff.com -T)'", PACKAGE(Request))
```

Adapter Action Sequence

The following describes the sequence of actions that occur in the consumer scenario.

- The request message is first passed to the SOAP (WSDL) Adapter.

- The request message might or might not have a SOAP envelope. If the envelope is not provided, the adapter adds it.
- The request message might or might not have a SOAP envelope header. The adapter does nothing with the header. If it is not provided in the request, then no header is sent.
- The adapter specified in the **-TRANSPORT** command is invoked to issue the request and receive a reply. Typically, this is the HTTP adapter that will then send an HTTP request and return the HTTP response.
- The SOAP (WSDL) Adapter is invoked a second time to process the reply.
- The adapter looks in the body to see if there is a Fault tag. If there is, the SOAP (WSDL) Adapter returns an error message that is comprised of the faultstring and the faultcode.
- The SOAP envelope is removed unless the **-RAW** command is specified.
- If the adapter is called with the **-HDR** command, and there is a SOAP envelope header, the header data will be returned.
- If the adapter is called with the **-RETURN** command, then all XML tags are removed and only the specified datum from the response message is returned. If the response message returns more than one datum, then the whole XML response message is returned with a warning code. This command is mutually exclusive with the **-HDR** command.

Provider scenario

The following descriptions explain using the SOAP (WSDL) Adapter with the HTTP adapter.

- [Response](#)

Response

The HTTP Adapter is invoked to send the response message.

Example files

The `install_dir\examples\web_services` directory contains sample files to be used with Web Services components, including the WSDL Importer, SOAP and HTTP adapters, to implement Web services strategies.

See `readme.txt` located in the example directory for more information about the examples.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages might also be recorded as specified in the audit logs, trace files and execution summary files.

- [Messages](#)

Messages

The following is a listing of all the codes and messages that can be returned as a result of using the SOAP (WSDL) Adapter for sources or targets.

Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Return Code	Message
-2001	General internal adapter error
-2002	Invalid command line option
-2003	Missing argument in command line option
-2004	Missing command line option
-2005	Invalid argument in command line option
-2006	FC A fault code has been generated.
-2007	Xpath data not found
-2008	Xpath duplicate data found
-2009	Stream error
-2010	

Socket Adapter overview

The Socket Adapter provides a means of passing data to and from IBM Transformation Extender through standard TCP/IP sockets. The adapter provides a listener interface that enables maps to be triggered upon arrival of data on a socket and therefore enables remote applications to pass data to IBM Transformation Extender without the need for additional middleware software.

The Socket Adapter is implemented as a dynamic-link library (DLL) on Windows platforms (**m4sock.dll**) and as a shared object on UNIX platforms (**m4sock.sl** or **m4sock.so**). It is assumed that message formats are binary.

The Socket Adapter supports the following:

- Conversations
- Client or Server mode

The adapter provides these functions:

- Gets one or more messages from a socket for input to IBM Transformation Extender
- Puts a message to a socket as output from IBM Transformation Extender
- Listens for messages and triggers maps to run as messages arrive

For the adapter commands that can be used with this adapter, see the list of adapter-specific commands.

- [System requirements](#)
- [How the adapter works](#)
- [Command alias](#)
- [Socket Adapter commands](#)
- [Syntax summary](#)
- [Troubleshooting](#)

System requirements

The minimum system requirements and operating system requirements for the Socket Adapter are detailed in the release notes. It is assumed that a Command Server has already been installed on the computer where the adapter is to be installed for runtime purposes.

How the adapter works

Because communication over sockets is through streams or bytes, the adapter needs some protocol to be able to distinguish where one message begins and another one ends.

To meet this need, the adapter provides the following options:

- Fixed size messages (**-FIXED**), where the length of each message is a known, fixed value.
- Sized messages (**-SIZED** or **-ISIZED**), where each message is preceded by a value representing the size of that message.
- File message (**-EOF**), where the shut down of the socket defines the message.
- Delimited messages (**-EOM**), where one or more specified characters indicate the end of the message.
- [Client or server mode](#)
- [Conversation support](#)

Client or server mode

The adapter operates either as the client or server of the socket connection. Server mode is only applicable to an input event. If the **mode** flag is not specified, the default is **client**.

In client mode, the listener or input card will connect to the specified remote socket.

In server mode, the listener creates the socket and waits for client connections to attach and send data. On the arrival of a message, a thread is spawned to read the message and process it.

Generally, if multiple cards in a map connect to the same port having the same **-HOST** and **-PORT** or **-SERVICE** then the same socket connection should be used in each card.

Conversation support

When a message is received on a socket connection for an input card or **GET** function, if an output card or **PUT** function in the same map specifies the same host and port number, the connection will be reused for the output card. A response message will be sent to the client that sent the request message.

The communication adapter supports conversations in several scenarios, including:

- **Input is an event** - Listener detects message, **GET** retrieves it, and an output card sends a response to the same socket.
- **Input is not an event - GET** retrieves message and an output card sends a response to the same socket.
- **=GET()** mapping function is used. The third parameter is data to send to a socket, the resulting message is returned from the **GET**. In this case, the same protocol must be used both for the write and the read.

When using the communication adapter in server mode (**-MODE server**), the conversation between client and server can be controlled by a variety of parameters. The most important of these is the Client Connection (**-CCON**) command, which determines how the conversation is ended.

The default value for **-CCON** is exclusive (**excl**), which means that the connection with a client is used exclusively by an instance of a map.

This can be with the Number of Event Messages command (**-NEM**) to initiate a conversational map instance. The **-NEM** command determines how many messages need to be received to start an instance of a map. If this map instance is run in burst mode, each burst might process one or more additional message from the client, and send one or more response back to the client. In this scenario, the map instance is ended when the client disconnects from the socket.

If **-CCON** is set to shared (**shared**) then a single client connection might be used by multiple map instances concurrently. In this scenario, the **-NEM** command cannot be used. The number of messages processed by a single map instance is determined by the Quantity (**-QTY**) and Listen (**-LSN**) commands. The listener receives the number of messages specified by these parameters and these messages are processed by a map instance, which can send one or more response messages to the client.

If the client continues to send messages while one map instance is running, another map instance might be started. Both map instances will use the same client connection. It is the responsibility of the client to associate the request messages with any responses that might be sent from these maps. That using the **-CCON (shared)** command does not preclude multiple clients connecting to the socket.

Command alias

Specify adapter commands by using a command string on the command line or by creating a command file that contains adapter commands. The command syntax is:

```
-IA[alias]card_num
-OA[alias]card_num
```

In the command syntax, **-IA** is the Input Source Override execution command and **-OA** is the Output Target Override execution command, *alias* is the adapter alias, and *card_num* is the number of the map card. The adapter alias and corresponding execution commands are listed below.

Adapter	Alias	As Input	As Output
Socket Adapter	SOCKET	-IASOCKET <i>card_num</i>	-OASOCKET <i>card_num</i>

Socket Adapter commands

This section of the documentation describes the functions and use of the Socket Adapter commands and their options.

- [List of commands](#)

List of commands

Socket Adapter protocol options specify how data is delimited during the transfer process. The following table lists the valid commands for the Socket Adapter, the command syntax, and if the command is supported (✓) for use with data sources, targets, or both.

The following commands can be specified on the adapter's command line or through adapter properties. The commands are not case sensitive, but each value is case sensitive. For ease of use, most commands have a short form and a long form.

Command	Syntax	Source	Target
Client Connection (-CCON)	-CCON excl shared	✓	
Data Header (-DHDR)	-DHDR 0x<hex terminator> -DHDR <i>terminator</i> -DHDR "terminator"	✓	
End Of File (-EOF)	-EOF	✓	✓
End Of Message (-EOM)	-EOM 0x<hex terminator> -EOM <i>terminator</i> -EOM "terminator"	✓	✓
Fixed (-FIXED)	-FIXED <i>size</i>	✓	✓
Host (-H or -HOST)	-HOST name or address	✓	✓
Inclusive Sized (-ISIZED)	-ISIZED	✓	✓
Listen (-LSN)	-LSN <i>seconds</i>	✓	
Mode (-M or -MODE)	-MODE server client	✓	
Number of Event Messages (-NEM)	-NEM <i>number</i>	✓	
Port (-P or -PORT)	-PORT <i>port number</i>	✓	✓
Quantity (-QTY)	-QTY <i>number</i>	✓	
Service (-S or -SERVICE)	-SERVICE <i>service name</i>	✓	✓
Sized (-SIZED)	-SIZED	✓	✓
Trace (-T or -TRACE)	-T[E V][+] [<i>file</i>]	✓	✓
Window Size (-WNDSIZE)	-WNDSIZE <i>size</i>		✓

-

Client Connection (-CCON)

The Client Connection adapter command determines if client connections are associated exclusively with a specific map instance, or might be shared between map instances.

`-CCON excl | shared`

Option	Description
<code>excl</code>	The client connection is exclusive to a particular map instance. This is the default client connection mode. Once a client has connected to the adapter that is running in server mode, that connection is associated with the map instance until the client disconnects. The map can involve a conversation with the client, where multiple requests are received from the client, and multiple responses returned. This option should be used in an environment where the client connects to the socket, engages in a conversation, and then disconnects.
<code>shared</code>	The client connection can be shared by multiple map instances. When used in collaboration with the <code>-QTY</code> and <code>-LSN</code> commands, the adapter can be configured to run a map once a number of messages have been received, as specified by the <code>-QTY</code> command, or when a listening time has elapsed, as specified by the <code>-LSN</code> command. This option should be used in an environment where the client connects to the socket, and then remains connected, feeding a continual stream of messages to the Launcher.

See "[Conversation Support](#)" for more information on using this command.

This command option can only be used in input cards, input events to the Launcher, that have a mode of server (`-MODE server`).

Data header (-DHDR)

The data header adapter command (`-DHDR`) discards the message header, which is terminated by the specified terminator.

`-DHDR 0x<hex terminator>`
`-DHDR terminator`
`-DHDR "terminator"`

Option	Description
<code>0x<hex terminator></code>	Hexadecimal value.
<code>terminator</code>	Character string.
<code>"terminator"</code>	Comma-delimited character string.

The "terminator" can contain white space and if the string itself contains quotation marks then you must double them. For example, "This is ""the terminator"".

End Of File (-EOF)

The End Of File (`-EOF`) adapter command defines a single message.

The adapter uses this command when communicating with other programs that invoke and detect calls to the **shutdown** function as defined by the Socket Application Programming Interface (API). The **shutdown** function disables any further send or receive operations on a socket connection. It is used to mark the end of one message.

On a data retrieval (**GET** or input card) operation, the adapter detects the End Of File marker after your program calls the **shutdown** function on the write end of the socket. All data that is received before the End Of File marker defines the single message that is used during map processing.

On a data routing (**PUT** or output card) operation, the adapter sends the End Of File marker to your program by calling the **shutdown** function on the write end of the socket. All data that is sent before the End Of File marker defines the single message that is used by your program.

When you use the End Of File command in a three-parameter **GET** rule, the following results occur. One message is first sent to the client. The message contains all of the data that is referenced by the third parameter. After one message is received from the client, the adapter then closes the socket connection.

When you use the End Of File command in a two-parameter **GET** rule or in an input card, you can also use it in a **PUT** rule or in an output card of the same map. The converse is true as well. When you use the End Of File command in a two-parameter **PUT** rule or in an output card, you can also use it in a **GET** rule or in an input card of the same map. After one data retrieval operation and one data routing operation that both use the End Of File command completes processing, your program can close the socket connection.

Because the End Of File command defines only one message for each **GET** and **PUT** operation, you cannot specify burst mode or the Quantity (**-QTY**) adapter command in the command line.

With the End Of File command used on the command line of an input card for a Launcher watch event, the map is triggered when the Socket Adapter receives one input message from any client or server connection. The adapter sends a reply to that same client or server connection by using the End Of File command on a data routing (**PUT**) operation or an output card. Like the three-parameter **GET** function, the triggered map receives one message and sends one message.

For a Launcher watch event, however, the triggered map can divide the one reply message into multiple data routing operations. For instance, you can design the output cards for modularized processing in the following way. Specify one output card to send the header portion of the message. Specify a second output card to send the body portion. You must specify the host name and port number in the command line on both output cards. You must also specify the End Of File command, but only on the second output card. The first output card causes the Socket Adapter to send the first portion of the message, which is the header. After the map invokes the second output card and the Socket Adapter detects the End Of File command, the adapter sends the last portion of the message, which is the body. It then calls the **shutdown** function to mark the end of the message. Whenever you use the Socket Adapter in this way, remember to use only the End Of File command on the last output card.

End Of Message (-EOM)

The End Of Message (-EOM) command indicates that a specific terminator marks the end of a message. This terminator must not appear in the message data. If this option is specified on output, the terminator characters are appended to the message data. If this option is specified on input, the data is parsed to find the terminator.

```
-EOM 0x<hex terminator>
-EOM terminator
-EOM "terminator"
```

Option

Description
0x<hex terminator>
Hexadecimal value.
terminator
Character string.
"terminator"
Comma-delimited character string.

Fixed (-FIXED)

The fixed command (-FIXED) specifies that the data is a fixed size (n bytes) specified in bytes. This many bytes will be read from or written to the socket.

```
-FIXED size
```

Option

Description
size

Specify that the data is a fixed size (n bytes) and that this many bytes will be read from or written to the socket.

Host (-H or -HOST)

Use the Host (-H or -HOST) command to specify the host name or TCP/IP address of the remote host. If the -HOST command is omitted then the name of the local machine is used.

```
-HOST name or address
```

Option

Description
name or address

The host name or TCP/IP address. For example, use *host_name* or use 192.168.1.120 for the IPv4 version of the IP address, or 1080:0:0:0:8:800:200C:417A, using the IPv6 version of the IP address.

Inclusive sized (-ISIZED)

The inclusive sized (-ISIZED) command is a variant of the -SIZED message type. Using the -SIZED message type, the first four bytes of a message represent the size of the message that follows. Using the -ISIZED message type, the first four bytes of data represent the size of the message that follows, but includes the first four bytes in the total length. Therefore, if the first four bytes of data indicate that the message size is 14 bytes, the message is complete after 10 more bytes.

Listen (-LSN)

Use the listen command (-LSN) to specify a time in seconds to wait for messages to arrive. If not specified, the adapter waits for an infinite amount of time.

The command -LSN 0 means do not wait at all. If no message is immediately available, the adapter returns a warning indicating that no messages were found.

-LSN seconds

Option

Description

seconds

The number of seconds to wait for messages to arrive.

Mode (-M or -MODE)

The mode command (-M or -MODE) sets the connection mode to either **server** or **client**.

-MODE server|client

Option

Description

server

The adapter waits for remote clients to connect and send messages that will trigger the map.

This option is valid only in input cards when the Launcher runs the map.

client

The adapter connects to the remote server and reads messages.

Number of event messages (-NEM)

Used only in Launcher scenarios, this command specifies the number of messages that will trigger maps to launch. The specified number of messages are read into memory and will be available when the map is run.

-NEM number

Option

Description

number

The number of messages that will trigger maps to run.

Port (-P or -PORT)

Use the Port command (-P or -PORT) to specify the TCP/IP port number. When the adapter is used in **server** mode, the port number specifies the port to which remote clients can connect. In **client** mode, the port number is the port on the remote host to which the adapter connects.

-PORT port number

Option

Description

port number

The TCP/IP port number.

Quantity (-QTY)

Use the Quantity command (-QTY) to capture the number of messages to be retrieved by the adapter. If you are running in burst mode, each burst might return less than -QTY messages, but the total number of messages returned by the adapter will not exceed the value specified by the -QTY command. If not specified, the default quantity is **1**.

-QTY number

Option

Description

number

The number of messages to be retrieved by the adapter.

Service (-S or -SERVICE)

Mutually exclusive of the port command (-PORT), use the service command (-S or -SERVICE) to specify the service name that is used to map a TCP/IP port number. The service command and the port command are interchangeable and cannot be used at the same time.

-SERVICE *service name*

Option

Description

service name

The service name that is used to map a TCP/IP port number.

Sized (-SIZED)

The Sized command (-SIZED) specifies that data be sized. The first four bytes of the message represent the size of the message that follows.

Trace (-T or -TRACE)

Use the Trace adapter command (-T or -TRACE) to produce a diagnostics file that contains detailed information about Socket Adapter activity.

The default filename is m4sockt.log and it is created in the map directory unless otherwise specified.

-T [E|V] [+] [*file*]

Option

Description

E

Produce a trace file containing only the adapter errors that occurred during map execution.

V

Verbose mode. Record in the log file all activity occurring while the adapter is retrieving data. The maximum size of the log file is 256 bytes. If you need to trace more or less bytes, set the TX_SOCKET_MAX_BYTES_IN_TRACE_MESSAGE environment variable.

+

Appends trace information to the existing log file; otherwise, the log file is recreated.

file

The log filename.

If a filename contains spaces or other special characters it must be enclosed in quotation marks. Example: "test-file.txt".

You can override the adapter command line trace options dynamically using the Management Console. See "Dynamic Adapter Tracing" in the *Launcher* documentation for detailed information.

Window Size (-WNDSIZE)

The Window Size command (-WNDSIZE) specifies the size in bytes of the buffer in which the End Of Message (EOM) is searched. If not specified, it defaults to 10,000 bytes.

This option is used only if -EOM is specified.

-WNDSIZE *size*

Option

Description

size

Specify the size in bytes of the buffer in which the End Of Message (EOM) is searched.

Syntax summary

This section of the documentation discusses the communication adapter syntax summary and how it is used.

- [Data sources](#)
- [Data targets](#)
- [Examples](#)

Data sources

The following is the command syntax of the communication adapter commands used for data sources:

```
[-CCON {excl|shared}]
[-DHDR 0x<hex terminator>|terminator|"terminator"]
[-HOST name or address]
[-LSN seconds]
[-MODE {server|client}]
[-NEM number]
[-PORT port number]
[-QTY number]
[-SERVICE service name]
[-SIZED|-ISIZED|-FIXED size|-EOF|
-EOM [0x<hex terminator>|terminator|"terminator"]]
[-T[E|V][+] [file]]
```

Data targets

The following is the command syntax of the communication adapter commands used for data targets:

```
[-HOST <name or address>]
[-PORT <port number>]
[-SERVICE <service name>]
[-SIZED|-ISIZED|-FIXED size|-EOF|
-EOM [0x<hex terminator>|terminator|"terminator"]]
[-T[E|V][+] [file]]
[-WNDSIZE size]
```

Examples

The following command example means connect on localhost on port 7352, read three sized messages, and generate a default trace file.

```
-PORT 7352 -SIZED -QTY 3 -TRACE
```

The following command example means start listening on host 192.168.75.32 and port 7352 for one EOM type message for 10000 seconds and generate a default trace file. The map is triggered after the adapter receives one message.

```
-HOST 192.168.75.32 -PORT 7352 -MODE SERVER -NEM 1-EOM "end" -
-QTY S -LSN 10000 -T
```

Troubleshooting

For information about return codes and error messages returned by the adapters, see "Return Codes and Error Messages" in the Resource Adapters documentation.

Standards Processing Engine Adapter

The Standards Processing Engine (SPE) adapter connects IBM Sterling Transformation Extender with Standards Processing Engine (SPE). Specify the SPE adapter on a IBM Sterling Transformation Extender map rule to run the map on SPE and to invoke the enveloping, de-enveloping, and transformation capabilities of a Pack solution.

Read the details about SPE and the associated Pack solutions in the Standards Processing Engine documentation.

- **[System requirements](#)**

The Standards Processing Engine (SPE) adapter function requires the installation of Standards Processing Engine and a solution Pack.

- **[SPE adapter commands and data harness functions](#)**

Standards Processing Engine (SPE) adapter commands fall into two categories: data harness functions and adapter action commands.

System requirements

The Standards Processing Engine (SPE) adapter function requires the installation of Standards Processing Engine and a solution Pack.

See the [IBM Sterling Transformation Extender system requirements](#) for details about the minimum system requirements of the SPE adapter. See the [Standards Processing Engine system requirements](#) for the minimum system requirements of SPE and the associated Pack solution.

SPE adapter commands and data harness functions

Standards Processing Engine (SPE) adapter commands fall into two categories: data harness functions and adapter action commands.

Data harness functions read and write to the underlying SPE database through a data harness, and are valid only when a map is running under SPE.

Adapter action commands are valid in maps that are running on IBM Sterling Transformation Extender Launcher, Command Server, or the TX Programming Interface. The commands:

- Start the SPE envelope and de-envelope functions
 - Run a map on SPE
 - Operate on documents in memory that pass data between IBM Sterling Transformation Extender and SPE
 - Data harness functions**
A IBM Sterling Transformation Extender map can read and write to the Standards Processing Engine (SPE) database through commands that invoke the SPE data harness. Data harness functions are appropriate only in maps that are running under SPE.
 - Data harness function syntax**
The Standards Processing Engine (SPE) adapter supports data harness functions that operate on SPE correlations, process data, code lists, delimiters, and the transaction register. You can use data harness functions only in IBM Sterling Transformation Extender maps that run under SPE.
 - SPE adapter action command overview**
This table summarizes the adapter action commands, syntax, and whether you can use the command with data sources, data targets, or both. You can specify the commands on the adapter command line or through map rules.
-

Data harness functions

A IBM Sterling Transformation Extender map can read and write to the Standards Processing Engine (SPE) database through commands that invoke the SPE data harness. Data harness functions are appropriate only in maps that are running under SPE.

You invoke the data harness functions by configuring either:

- The PUT and GET rules in a map
- An input card or output card command line that specifies the SPE adapter

By using the SPE adapter, maps can read SPE data on input cards and from GET rules, and write to SPE data from output cards and PUT rules. To execute the harness function as soon as the PUT rule is processed, use the -NOW argument. The -NOW argument executes the function even if the map fails.

When the PUT rule does not include the -NOW argument, the function executes when the map completes.

When the map runs successfully, the output from the adapter is associated with an SPE document for use by normal stream adapters.

Data harness function syntax

The Standards Processing Engine (SPE) adapter supports data harness functions that operate on SPE correlations, process data, code lists, delimiters, and the transaction register. You can use data harness functions only in IBM Sterling Transformation Extender maps that run under SPE.

Command Description

`getBinaryDocument`

Retrieves the specified binary document. This command is valid in a GET function.

`getEnvelope`

Retrieves the specified field from an envelope. This command is valid in a GET function.

`setCorrelation`

Updates the Standards Processing Engine correlation table with the specified name/value pair for the document or business process. This command is valid in a PUT function.

`getProcessData`

Retrieves process data from the XML document object model (DOM) specified by the XPath. *Process data* is intermediate data that accumulates in an XML document during document processing. You can use process data to determine the next step in document processing, such as which map to launch based on the result of parsing a document. This command is valid in a GET function.

`setProcessData`

Stores process data from the current field into the XML DOM that is specified by the XPath. *Process data* is intermediate data that accumulates in an XML document during document processing. You can use process data to determine the next step in document processing, such as which map to launch based on the result of parsing a document. This command is valid in a PUT function.

`getCodeListItemBySenderCode`

Retrieves a trading-partner code-list entry from SPE by sender code. A *trading partner code list* consists of one or many pairs of code values containing a sender code and a receiver code. Code pairs in code lists identify items in transactions between two or more trading partners. This command is valid in a GET function.

`getCodeListItemByReceiverCode`

Retrieves a trading-partner code list from SPE by receiver code. A trading partner code list consists of one or many pairs of code values containing a sender code and a receiver code. Code pairs in code lists identify items in transactions between two or more trading partners. This command is valid in a GET function.

`getTransactionRegister`

Compares the fields that you loaded into the Transaction Register with the input data, returns a code, and clears the Transaction Register. This command is valid in a GET function.

Code Meaning

0

Success; no duplicate data found.

1

Failure; duplicate data found.

8

No updates performed to this transaction register yet. Cannot perform a select before an update. The Transaction Register is empty. You must invoke **setTransactionRegister** to load the Transaction Register before you can invoke **getTransactionRegister**.

The following example:

```
PUT("SPE", "-t+ -c setTransactionRegister -k 1", "Reg 1")
GET("SPE", "-t+ -c getTransactionRegister")
GET("SPE", "-t+ -c getTransactionRegister")
```

1. Loads Transaction Register field 1 with the literal value Reg 1.
2. Compares the input document data to the content of the Transaction Register and returns 0 or 1.
3. Attempts to invoke **getTransactionRegister** again without loading the Transaction Register, resulting in return code 8.

The following example loads Transaction Register field 3 with the contents of the specified input data field:

```
PUT("SPE", "-t+ -c setTransactionRegister -k 3", PONumber Field:In1)
```

setTransactionRegister

Loads the specified Transaction Register field with the specified data. You can load up to six fields of data into memory for the Transaction Register. This command is valid in a PUT function.

After you run the **setTransactionRegister** command, you can run the **getTransactionRegister** command to check for duplicate input data.

getDelimiter

Gets a delimiter from an SPE document envelope. This command is valid in a GET function.

validateCodeWords

Validates a series of code words defined by a delimited string. This command takes the code words to validate from the `data_from_map` option instead of the **-KEY** argument. This command is valid in a **GET** function.

This example **PUT** rule uses the SPE adapter to create an element under process data that is called "getmap". The **-NOW** option creates the key even if the map fails:

```
=PUT("SPE", "-t+ -c setProcessData -k getmap -now", "data")
```

This example **GET** rule uses the SPE adapter to read the value of a key called "getmap" from the process data:

```
=GET rule " + VALID( GET("SPE", "-t+ -c getProcessData -k getmap") )
```

This example of a SPE adapter command line on a card creates a correlation that is called "adapter" when the card completes. The correlation includes all of the data that was built on the card:

```
-c setCorrelation -k adapter -t+
```

The SPE adapter supports the harness functions with the following command line arguments:

Table 1. SPE adapter command line arguments

Command Long Form	Command Short Form	Description
-COMMAND	-C	Command
-KEY	-K	Key
-CODE	-D	Sender/Receiver Code
-TABLE	-B	Code table name
-NOW	-N	Executes the harness function as soon as the PUT rule is processed, even if the map fails
-T	-T	Adapter trace (overwrite)
-T+	-T+	Adapter trace (append)
-TE	-TE	Adapter trace error (overwrite)
-TE+	-TE+	Adapter trace error (append)
-TV	-TV	Adapter trace verbatim (overwrite)
-TV+	-TV+	Adapter trace verbatim (append)

The default trace file name is M4spe.mtr.

This table describes the data harness functions and key values that you can use on the SPE adapter:

Table 2. SPE adapter data harness functions and key values

Command	Key
getBinaryDocument	The name of the document to retrieve.
setCorrelation	The name of the correlation to update.
getProcessData	The XPATH to select.
setProcessData	The XPATH to update.
getCodeListItemBySenderCode	The sender value for the code-list entry to retrieve. The command requires a sender code, code list table name, and column.
getCodeListItemByReceiverCode	The receiver value for the code-list entry to retrieve. The command requires a receiver code, code list table name, and column.
getEnvelope	The envelope field name.
getTransactionRegister	There are no keys for this command.
setTransactionRegister	Each entry is a number between 1 and 6 that indicates the field to update.
getDelimiter	An array of numbers that indicates the fields to select. The list is defined in <i>Table 4</i> .
validateCodeWords	This command takes the code words to validate from the <code>data_from_map</code> option instead of from the -KEY argument.

The following table lists the sender and receiver keys and values to use with the **getCodeListItemBySenderCode** and **getCodeListItemByReceiverCode** functions. You define the column names for the code list. The keys refer to the position of the column, not to a specific column name. This pattern continues for as many text columns as you have in the table.

Table 3. Sender and receiver keys
and values

Key	Value
COL_SENDER	0
COL_RECEIVER	1
COL_DESC	2
First_text_column	3
Second_text_column	4
Third_text_column	5
Fourth_text_column	6
Fifth_text_column	7
Sixth_text_column	8
Seventh_text_column	9
Eighth_text_column	10
Ninth_text_column	11

The following table lists the keys and values to use with the **getDelimiter** function.

Table 4. Delimiter keys and values

Key	Value
SEGMENT_TERMINATOR	0
TAG_DELIMITER	1
ELEMENT_DELIMITER	2
SUB_ELEMENT_DELIMITER	3
REPEATING_ELEMENT_DELIMITER	4
RELEASE_CHAR	5
DECIMAL_SEPARATOR	6

The following table lists the keys and values to use with the **setTransactionRegister** function.

Table 5. Transaction Register keys and values

Key	Value
COL_TEXT1	0
COL_TEXT2	1
COL_TEXT3	2
COL_TEXT4	3
COL_TEXT5	4
COL_TEXT6	5

SPE adapter action command overview

This table summarizes the adapter action commands, syntax, and whether you can use the command with data sources, data targets, or both. You can specify the commands on the adapter command line or through map rules.

The commands are not case-sensitive, but the command values are case-sensitive. Choices are separated by the OR symbol | . Optional parameters are enclosed in brackets [].

The topics that follow include the short forms of the commands and keywords, and provide the command syntax in railroad track format.

Table 1. SPE adapter command summary

Command	Syntax	Use with Data Source (GET)	Use with Data Target (PUT)
-ADOC	-URL file_URL -BATCH file_URL[file_URL] -ADOC [data_from_map]	Yes	No
-GDOC	-DOCID doc_ID -GDOC	Yes	No
-RDOC	{-DOCID doc_ID -BATCH {doc_ID [;doc_ID]}} -RDOC	Yes	Yes
-UDOC	-DOCID doc_ID [-URL file_URL] -UDOC [data_from_map]	Yes	No
-ENVELOPE	-DBURL {db_URL db_cfg_file} [-DBUSER user_name] [-DBPSWD password] -DBDRIVER driver_name [-DBSCHEMA schema_name] {-URL file_URL -DOCID doc_ID -BATCH {doc_ID [;doc_ID file_URL [;file_URL]}} -SENDER sender_ID -RECEIVER receiver_ID -ALIAS acceptor_lookup_alias [-EDISTANDARD edi_standard] [-SENDERQUAL sender_qualifier] [-RECEIVERQUAL receiver_qualifier] [-DEFERRED -GETDEFERRED -INTERCHANGE interchange_ID]] -ENVELOPE [-KEEP] [-ALLDOCS] [data_from_map]	Yes	No
-DEENVELOPE	-DBURL {db_URL db_cfg_file} [-DBUSER user_name] [-DBPSWD password] -DBDRIVER driver_name [-DBSCHEMA schema_name] {-URL file_URL -DOCID doc_ID -BATCH {doc_ID [;doc_ID file_URL [;file_URL]}} -DEENVELOPE [-KEEP] [-ALLDOCS] [data_from_map]	Yes	No
-TRANSFORM	-DBURL {db_URL db_cfg_file} [-DBUSER user_name] [-DBPSWD password] -DBDRIVER driver_name [-DBSCHEMA schema_name] -MAP {map_name_in_database map_file_URL} [-URL file_URL -DOCID doc_ID] -TRANSFORM [-KEEP] [-ALLDOCS] [data_from_map]	Yes	No

- Command aliases**

Use the SPE adapter alias to use the Standards Processing Engine (SPE) adapter on input and output cards and in **GET** and **PUT** map rules.

- The SPE database configuration file**

The required **-DBURL** parameter of the **-ENVELOPE**, **-DEENVELOPE**, and **-TRANSFORM** commands specifies either the URL of the Standards Processing Engine (SPE) database or the file URL of a database configuration file. The configuration file must specify the database connection URL and driver. If the database requires them, the configuration file also must specify the database user name, password, and schema.

- **[Database connection persistence](#)**
Database connection information remains in effect for the duration of a map. After you configure the database URL, driver, user name, password, and schema on a map rule or in the configuration file, you can omit them from subsequent rules in the same map. The database connection values remain in effect until the map completes or another map rule specifies a different configuration file or keyword value.
- **[The data_from_map option](#)**
Some of the Standards Processing Engine (SPE) adapter action commands that follow include the data_from_map option. The data_from_map option represents the data that is passed as the third parameter of a **GET** function. It is not a parameter on the adapter command line.
- **[Add document \(-ADOC\) command](#)**
The **-ADOC** command adds one or more files on the file system as a document in memory and returns the document ID to the map. Alternatively, the **-ADOC** command can add dynamic data from a map as a document in memory and return the document ID to the map.
- **[Get document data \(-GDOC\) command](#)**
The **-GDOC** command returns data from a document in memory.
- **[Remove document \(-RDOC\) command](#)**
The **-RDOC** command removes one or more documents from memory. By default, documents are removed from memory when map processing completes. Use this command if too many intermediate documents accumulate in memory during map processing.
- **[Replace document \(-UDOC\) command](#)**
The **-UDOC** command replaces an existing document in memory with a new one and returns the new document ID.
- **[Run a map \(-TRANSFORM\) command](#)**
The **-TRANSFORM (-TFM)** command runs a map on the Standards Processing Engine (SPE) and returns a response from SPE in XML format. The **-TRANSFORM** command can run a IBM Sterling Transformation Extender map, a Sterling B2B Integrator map, or an XSLT map.
- **[De-envelope a document \(-DEENVELOPE\) command](#)**
The **-DEENVELOPE (-DENV)** command de-envelopes a document as specified in the Standards Processing Engine (SPE) database and returns a response from SPE in XML format.
- **[Envelope a document \(-ENVELOPE\) command](#)**
The **-ENVELOPE (-ENV)** command envelopes a document as specified in the Standards Processing Engine (SPE) database and returns a response from SPE in XML format.

Command aliases

Use the SPE adapter alias to use the Standards Processing Engine (SPE) adapter on input and output cards and in **GET** and **PUT** map rules.

Specify adapter commands by using a command string on the command line or by creating a command file that contains adapter commands. The command syntax is:

```
-IA[alias]card_num
-OA[alias]card_num
```

where :

-IA
The Input Source Override execution command

-OA
The Output Target Override execution command

alias
The adapter alias

card_num
The number of the map card

To override an input card:

-IASPEcard_num

To override an output card:

-OASPEcard_num

The SPE database configuration file

The required **-DBURL** parameter of the **-ENVELOPE**, **-DEENVELOPE**, and **-TRANSFORM** commands specifies either the URL of the Standards Processing Engine (SPE) database or the file URL of a database configuration file. The configuration file must specify the database connection URL and driver. If the database requires them, the configuration file also must specify the database user name, password, and schema.

When the **-DBURL** keyword specifies the configuration file URL, the SPE adapter ignores any driver, user name, password, or schema that is specified on the adapter command line.

The format of the configuration file is:

```
javax.persistence.jdbc.url=db_URL
javax.persistence.jdbc.user=user_name
javax.persistence.jdbc.password=password
javax.persistence.jdbc.driver=driver_name
openjpa.jdbc.Schema=schema_name
```

You can specify an alias on the **-DBURL** keyword to support multiple configuration files, for example **-DBURL %dbcfgfile%**. You also can create aliases for the other keyword values in the adapter command line. See the Resource Registry documentation for details about resource aliases.

Database connection persistence

Database connection information remains in effect for the duration of a map. After you configure the database URL, driver, user name, password, and schema on a map rule or in the configuration file, you can omit them from subsequent rules in the same map. The database connection values remain in effect until the map completes or another map rule specifies a different configuration file or keyword value.

The data_from_map option

Some of the Standards Processing Engine (SPE) adapter action commands that follow include the data_from_map option. The data_from_map option represents the data that is passed as the third parameter of a **GET** function. It is not a parameter on the adapter command line.

Add document (-ADOC) command

The **-ADOC** command adds one or more files on the file system as a document in memory and returns the document ID to the map. Alternatively, the **-ADOC** command can add dynamic data from a map as a document in memory and return the document ID to the map.

-ADOC command syntax

```
>>-----+-- -ADOC-----><
  +- -URL--file_URL-----+
  |   .;-----.
  |   V-----.
  '--- -BATCH-----file_URL---'
    '- H-----'
```

-URL

Adds a single file, specified by a file URL, as a document in memory and returns a document ID to the map. The **-URL** keyword is optional, but you must specify one of the **-BATCH**, **-URL**, or **data_from_map** options on the **-ADOC** command.

-BATCH

-H

Adds multiple files, specified by a list of semi-colon-delimited (;) file URLs, to documents in memory and returns a list of semi-colon-delimited document IDs to the map. The **-BATCH** keyword is optional, but you must specify one of the **-BATCH**, **-URL**, or **data_from_map** options on the **-ADOC** command.

data_from_map

Adds dynamic data from a map as a document in memory and returns the document ID to the map. The **data_from_map** is optional, but you must specify one of the **-BATCH**, **-URL**, or **data_from_map** options on the **-ADOC** command.

Examples

The following example adds the parsewds.txt file as a document in memory and returns the document ID to the map:

```
GET("SPE", "-URL file:///C:/parsewds.txt -ADOC")
```

The following example adds the Hello World!! text string as a document in memory and returns the document ID to the map:

```
GET("SPE", "-ADOC", "Hello World!!")
```

Get document data (-GDOC) command

The **-GDOC** command returns data from a document in memory.

-GDOC command syntax

```
>>-- -DOCID---doc_ID-- -GDOC-----><
  '- -ID---'
```

-DOCID

-ID

Specifies the document ID of a document in memory from which data is returned. The **-DOCID** keyword is required.

Remove document (-RDOC) command

The **-RDOC** command removes one or more documents from memory. By default, documents are removed from memory when map processing completes. Use this command if too many intermediate documents accumulate in memory during map processing.

-RDOC command syntax

```
>>--- -DOCID---doc_ID-----+ -RDOC-----><
  | '- -ID---'
```

```
| .-----.
| V | |
'-- -BATCH-----doc_ID---'
`- H-----'
```

-DOCID

-ID

Removes a single file, specified by a document ID, from memory. You must specify either the -DOCID keyword or the -BATCH keyword on the **-RDOC** command.

-BATCH

-H

Removes multiple files, specified by a list of semi-colon-delimited (;) document IDs, from memory. You must specify either the -BATCH keyword or the -DOCID keyword on the **-RDOC** command.

Replace document (-UDOC) command

The **-UDOC** command replaces an existing document in memory with a new one and returns the new document ID.

-UDOC command syntax

```
>>-- -DOCID---doc_ID---+-----+
  '- ID----'      '- URL--file_URL--'

>-- -UDOC---+-----+-----><
  '-data_from_map-'
```

-DOCID

-ID

Specifies the ID of the document in memory that is to be replaced. The -DOCID keyword is required.

-URL

Specifies the file URL of the document that is to replace the document in memory. Either the -URL or the data_from_map option is required.

data_from_map

Replaces the document in memory with dynamic data from a map. Either the data_from_map or the -URL option is required.

Run a map (-TRANSFORM) command

The **-TRANSFORM (-TFM)** command runs a map on the Standards Processing Engine (SPE) and returns a response from SPE in XML format. The **-TRANSFORM** command can run a IBM Sterling Transformation Extender map, a Sterling B2B Integrator map, or an XSLT map.

The XML response file contains information about the documents after SPE processing. The metadata schema of the XML response is defined by the wtx_install_dir\Response.xsd file.

A Sterling B2B Integrator map or an XSLT map has a single input card and a single output card. The document data from a file, from memory, or from a map overrides the input card. The **-TRANSFORM** command overrides the output card with the final document after the transformation completes.

IBM Sterling Transformation Extender maps can have multiple input cards and multiple output cards. The document data from a file, from memory, or from a map overrides the first input card. The **-TRANSFORM** command overrides the last output card of a IBM Sterling Transformation Extender map and returns the final document after the transformation completes.

A IBM Sterling Transformation Extender map, XSLT map, or Sterling B2B Integrator map can run from the local file system or from the SPE database.

-TRANSFORM command syntax

```
>>-- -DBURL---+---+db_URL---+-----+
  '- DURL--'  '-db_cfg_file-'  +- -DBUSER--user_name-
  '- U--user_name----'

>-----+--- -DBDRIVER--driver_name-----+

>-----+---+---+TRANSFORM---+---+---+
  +- -URL--file_URL----+  '- -TFM-----'  '- -KEEP-
  '- -DOCID---doc_ID-
  '- -ID----'

>-----+---+---+---+---+---+ALLDOCS---+  '- data_from_map-' <

-DBURL
-DURL
```

Identifies the SPE database by either the database URL or the file URL of a configuration file that contains the database connection information. If you specify a configuration file, the SPE adapter uses only the database connection information in the configuration file. The adapter ignores any -DBDRIVER, -DBUSER, -DBPSWD, or -DBSCHEMA keywords on the adapter command line. The -DBURL keyword is required.

-DBUSER

-U

Specifies the SPE database user name. The -DBUSER keyword is required only for certain types of databases.

-DBPSWD

-P

Specifies the SPE database password. The keyword -DBPSWD is required only for certain types of databases.

-DBDRIVER

Specifies the name of the JDBC driver that connects to the SPE database. The -DBDRIVER keyword is required for all database types.

-DBSCHEMA

Specifies the name of the SPE database schema. The -DBSCHEMA keyword is required only for certain types of databases.

-MAP

-M

Specifies the name of the map in the SPE database or, for IBM Sterling Transformation Extender maps only, the file URL of the map on the local file system. The -MAP keyword is required.

-URL

Specifies the URL of a file that is to override the first input card of the map. The -URL keyword is optional, but you must specify one of the -URL, -DOCID, or data_from_map options.

-DOCID

-ID

Specifies the document ID of the document in memory that overrides the first input card of the map. The adapter passes the document data to the -TRANSFORM command as the PrimaryDocument. The -DOCID keyword is optional, but you must specify one of the -URL, -DOCID, or data_from_map options.

-KEEP

Retains the documents that are returned in the SPE response by storing the documents in the local file system with the document ID as the file name. The -KEEP keyword is optional. If you omit it, the SPE adapter does not save documents after the map or card transaction completes.

-ALLDOCS

Specifies that SPE is to return all documents in the XML response file, including type=INTERMEDIATE documents. The -ALLDOCS keyword is optional. If you omit it, SPE returns only type=FINAL documents in the XML response file.

data_from_map

Specifies the data bytes that are passed from a map that are to override the first input card of the map. The data_from_map is optional, but you must specify one of the -URL, -DOCID, or data_from_map options.

De-envelope a document (-DEENVELOPE) command

The **-DEENVELOPE (-DENV)** command de-envelopes a document as specified in the Standards Processing Engine (SPE) database and returns a response from SPE in XML format.

The XML response file contains the document IDs of the de-enveloped documents. The metadata schema of the XML response file is defined by the wtx_install_dir\Response.xsd file.

-DEENVELOPE command syntax

```
>>-- -DBURL---+---db_URL-----+-----+----->
  '- -DURL-'  '-db_cfg_file-'  +- -DBUSER--user_name+-
                                '- -U--user_name-----'

>-----+--- -DBDRIVER--driver_name----->
  +- -DBPSWD--password+
  '- -P--password-----'

>-----+----->
  '- -DBSCHEMA--schema_name-'

>--- -URL--file_URL-----+---+ -DEENVELOPE----->
  +- -DOCID---+---doc_ID-----+  '- -DENV-----'
  |  '- -ID----'  |
  |          .;-----.
  |          V      |
  |  '- -BATCH---+---file_URL---+'
  |  '- -H-----' | .;-----.
  |          V      |
  |  '--doc_ID---'

>-----+-----+-----+-----><
  '- -KEEP-'  '- -ALLDOCS-'  '-data_from_map-'
```

-DBURL

-DURL

Identifies the SPE database by either the database URL or the file URL of a configuration file that contains the database connection information. If you specify a configuration file, the SPE adapter uses only the database connection information in the configuration file. The adapter ignores any -DBDRIVER, -DBUSER, -DBPSWD, or -DBSCHEMA keywords on the adapter command line. The -DBURL keyword is required.

-DBUSER

-U

Specifies the SPE database user name. The -DBUSER keyword is required only for certain types of databases.

-DBPSWD

-P

Specifies the SPE database password. The -DBPSWD keyword is required only for certain types of databases.

-DBDRIVER

Specifies the name of the JDBC driver that connects to the SPE database. The -DBDRIVER keyword is required for all database types.

-DBSCHEMA

Specifies the name of the SPE database schema. The -DBSCHEMA keyword is required only for certain types of databases.

-URL

Specifies the file URL of the document to de-envelope. A relative path for the file URL resolves to the directory of the map that invokes the **-DEENVELOPE** command. The -URL keyword is optional, but you must specify one of the -URL, -DOCID, -BATCH or data_from_map options.

-DOCID

-ID

Specifies the document ID of a single document to de-envelope. The -DOCID keyword is optional, but you must specify one of the -URL, -DOCID, -BATCH or data_from_map options.

-BATCH

-H

Specifies a list of documents to de-envelope with semi-colon-delimited (;) file URLs or document IDs. The -BATCH keyword is optional, but you must specify one of the -URL, -DOCID, -BATCH or data_from_map options.

-KEEP

Retains the documents that are returned in the SPE response. The SPE adapter stores the documents in the local file system and uses the document ID as the file name. The -KEEP keyword is optional. If you omit it, the SPE adapter does not save documents after the map or card transaction completes.

-ALLDOCS

Specifies that SPE is to return all documents in the XML response file, including type=INTERMEDIATE documents. The -ALLDOCS keyword is optional. If you omit it, SPE returns only type=FINAL documents in the XML response file.

data_from_map

Specifies the data bytes to be de-enveloped. The data_from_map bytes are returned from the third parameter of a **GET** function in the map.

Envelope a document (-ENVELOPE) command

The **-ENVELOPE (-ENV)** command envelopes a document as specified in the Standards Processing Engine (SPE) database and returns a response from SPE in XML format.

The XML response file contains the document IDs of the enveloped documents. The metadata schema of the XML response is defined by the wtx_install_dir\Response.xsd file.

The **-ENVELOPE** command supports both deferred and immediate enveloping

-ENVELOPE command syntax

```
>>-- -DBURL---+--+db_URL-----+-----+----->
  '- -DURL--'  '-db_cfg_file-'  '+- -DBUSER--user_name-+
    '- -U--user_name-----'
```

```
>-----+--+ -DBDRIVER--driver_name----->

```

-DBURL

Identifies the SPE database by either the database URL or the file URL of a configuration file that contains the database connection information. If you specify a configuration file, the SPE adapter uses only the database connection information in the configuration file. The adapter ignores any -DBDRIVER, -DBUSER, -DBPSWD, or -DBSCHEMA keywords on the adapter command line. The -DBURL keyword is required.

-DBUSER

-U

Specifies the SPE database user name. The -DBUSER keyword is required only for certain types of databases.

-DBPSWD

-P

Specifies the SPE database password. The -DBPSWD keyword is required only for certain types of databases.

-DBDRIVER

Specifies the name of the JDBC driver that connects to the SPE database. The -DBDRIVER keyword is required for all database types.

-DBSCHEMA

Specifies the name of the SPE database schema. The -DBSCHEMA keyword is required only for certain types of databases.

-URL

Specifies the file URL of the document to envelope. A relative path for the file URL resolves to the directory of the map that invokes the -ENVELOPE command. The -URL keyword is optional, but you must specify one of the -URL, -DOCID, -BATCH or data_from_map options.

-DOCID

-ID

Specifies the document ID of a single document to envelope. The -DOCID keyword is optional, but you must specify one of the -URL, -DOCID, -BATCH or data_from_map options.

-BATCH

-H

Identifies a group of documents to envelope by file URLs or document IDs. The -BATCH keyword is optional, but you must specify one of the -URL, -DOCID, -BATCH or data_from_map options.

-SENDER

-S

Specifies the document sender that is used to locate the envelope information in the SPE database. The -SENDER keyword is required.

-RECEIVER

-R

Specifies the document receiver that is used to locate the envelope information in the SPE database. The -RECEIVER keyword is required.

-ALIAS

-A

Specifies the acceptor look-up alias to locate the envelope information in the SPE database. The -ALIAS keyword is required.

-EDISTANDARD

-E

Specifies the EDI standard that is used to locate the envelope information in the SPE database. The -EDISTANDARD keyword is optional; however, you must specify the -EDISTANDARD keyword if you specify the -SENDERQUAL or -RECEIVERQUAL keywords.

-SENDERQUAL

-SNDQ

Specifies the document sender qualifier that is used to locate the envelope information in the SPE database. The -SENDERQUAL keyword is optional. If you specify the -SENDERQUAL keyword, you must specify the -EDISTANDARD keyword.

-RECEIVERQUAL

-RCVQ
Specifies the document receiver qualifier that is used to locate the envelope information in the SPE database. The -RECEIVERQUAL keyword is optional. If you specify the -RECEIVERQUAL keyword, you must specify the -EDISTANDARD keyword.

-DEFERRED

-DEF
Specifies deferred enveloping mode. The-DEFERRED keyword is optional. If you omit the keyword, enveloping is immediate. The -DEFERRED keyword and the -GETDEFERRED keyword are mutually exclusive.

-GETDEFERRED

-GETDEF
Gets the deferred documents from the SPE database to envelope them. The-GETDEFERRED keyword is optional. The -DEFERRED keyword and the -GETDEFERRED keyword are mutually exclusive.

-INTERCHANGE

-I
Specifies the customer-defined interchange identifier that is associated with the documents in the SPE database. You can use the interchange identifier later to select only the documents that were prepared with a particular identifier. The interchange identifier is optional with the -DEFERRED or the -GETDEFERRED keywords.

-KEEP
Retains the documents that are returned in the SPE response. The SPE adapter stores the documents in the local file system and uses the document ID as the file name. The -KEEP keyword is optional.

-ALLDOCS
Specifies that SPE is to return all documents in the XML response file, including type=INTERMEDIATE documents. The -ALLDOCS keyword is optional. If you omit it, SPE returns only type=FINAL documents in the XML response file.

data_from_map
Specifies the data bytes to be enveloped. The data_from_map bytes are returned from the third parameter of a **GET** function in the map. The data_from_map bytes are optional.

Archive (Tar) Adapter

This documentation introduces the Archive (Tar) adapter. You can use the adapter with a Command Server, Launcher, Software Development Kit, or map in a map rule.

- [Overview](#)
 - [System requirements](#)
 - [Command alias](#)
 - [Archive \(Tar\) Adapter commands](#)
 - [Syntax summary](#)
 - [Troubleshooting](#)
 - [Return codes and error messages](#)
-

Overview

Use the Archive (Tar) adapter to create, delete, update, add to, or extract from UNIX tape archive files. The Archive (Tar) adapter supports standard UNIX permissions, user ID attributes, and group ID attributes. This adapter is only for UNIX platforms and z/OS® UNIX Systems Services (USS). To archive files on Windows platforms, use the Archive (Zip) Adapter.

Converting data to ASCII on z/OS

The Archive (Tar) adapter cannot be used to convert your data to ASCII format when you are running your maps on a z/OS operating system on an IBM® z/Architecture® platform. To convert your data to ASCII format, you must use your map, along with the appropriate rules, to perform the conversion.

System requirements

The minimum system requirements and operating system requirements for the Archive (Tar) adapter are detailed in the release notes. It is assumed that a Command Server has already been installed on the computer where the adapter is to be installed for run-time purposes.

Command alias

Adapter commands can be specified by using a command string on the command line or by creating a command file that contains adapter commands. The execution command syntax is:

-IA[alias] card_num

-OA[alias] card_num

where -IA is the Input Source Override execution command and -OA is the Output Target Override execution command, alias is the adapter alias, and card_num is the number of the input or output card. The following table shows the adapter alias and its execution command.

Adapter	Alias	As Input	As Output
Archive (Tar)	TAR	-IATARcard_num	-OATARcard_num

Archive (Tar) Adapter commands

This is a description of the functions and use of the Archive (Tar) adapter commands and their options.

- [List of commands](#)

List of commands

The following table lists valid commands for the Archive (Tar) adapter, the command syntax, and whether the command is supported (✓) for use with data sources, targets, or both.

Command	Syntax	Source	Target
Tar File Archive (-ARCHIVE)	-ARCHIVE tarfile	✓	✓
Archive File (-FILE)	-FILE filename [-UNIQUE]	✓	✓
Group ID (-GID)	-GID gid_num	✓	✓
Tar File Member (-MEMBER)	-MEMBER filename [-D -X -A -C -DI -U]	✓	✓
File Permissions (-PERM)	-PERM perm_num	✓	✓
Trace (-T)	-T[E][+][full_path]	✓	✓
User ID (-UID)	-UID uid_num	✓	✓

You can append trace information to the existing trace file by using either the A or + option.

- [Tar File Archive \(-ARCHIVE\)](#)
- [Archive File \(-FILE\)](#)
- [Group ID \(-GID\)](#)
- [Tar File Member \(-MEMBER\)](#)
- [File Permissions \(-PERM\)](#)
- [Trace \(-T\)](#)
- [User ID \(-UID\)](#)

Tar File Archive (-ARCHIVE)

Use the Tar File Archive adapter command (-ARCHIVE) to specify which tar file will be accessed.

-ARCHIVE tarfile

Option

Description

tarfile

Required value. Specify the name of the tar file being used.

For example, to specify the **edi_in.tar** file to be accessed:

-ARCHIVE /vault/backup/edi_in.tar

Archive File (-FILE)

Use the Archive File adapter command (-FILE) to extract a member to a file or instruct the adapter to add the contents of a file on disk to the specified archive in the map directory. Data passed from the output card is ignored.

-FILE filename [-UNIQUE]

Option

Description

filename

Required value. Specify the name of the resulting archive file.

-UNIQUE

When extracting a member from the archive, this creates a file with a unique name to hold the data from the member.

When the Archive File adapter command (-FILE) is not specified, data passed to and from the adapter is through memory. For example, when extracting a member from an archive, the data is read into memory and then returned to the map. Similarly, when adding a member, the data is normally passed to the adapter in memory.

For example, to specify the **edi_08011999.dat** file as the resulting archive file:

```
-FILE edi_08011999.dat -UNIQUE
```

Group ID (-GID)

Use the Group ID adapter command (-GID) to set the group ID of the member to be archived or extracted.

```
-GID gid_num
```

Option

Description

gid_num

Specify a group ID to be archived or extracted.

When adding a member and -GID is not specified, the group ID is set to 0, the root, unless -FILE is specified, in which case the member inherits the GID of the file.

When extracting a member and -GID is not specified, but -FILE is specified, the group ID of the file to which the member is extracted is set to the same GID as the extracted member.

The Group ID adapter command (-GID) is only supported in environments that support group IDs.

Tar File Member (-MEMBER)

Use the Tar File Member adapter command (-MEMBER) to specify which tar file member is to be modified.

```
-MEMBER filename [-A|-C|-D|-X|-U]
```

Option

Description

filename

Required value. Specify the name of the member file.

-A

Add the member file specified by *filename* to the archive. This option is only valid for data targets.

-C

Create the new member file specified by *filename*. This option is only valid for data targets.

-D

Delete the member file specified by *filename* from the archive. This option is valid for either data sources or data targets.

-X

Extract the member file specified by *filename* from the archive. This option is only valid for data sources.

-U

Update the member file specified by *filename* in the archive. This option is only valid for data targets.

The Tar File Member adapter command (-MEMBER) also requires the use of the Tar File Archive adapter command (-ARCHIVE).

File Permissions (-PERM)

Use the File Permissions adapter command (-FILE) to set UNIX permissions on the file to be extracted or archived.

```
-PERM perm_num
```

Option

Description

perm_num

Specify the permission number. Standard UNIX octal codes are supported.

For example, to specify the UNIX permission number of **0777** on the file to be extracted or archived:

```
-PERM 0777
```

When adding a member through memory the default permissions of 0777 are used. When adding a member using the Archive File adapter command (-FILE), the permissions on the file are used.

When doing an extract, specify the -PERM command to set the permissions for the extracted file if the -FILE adapter command was used. If the -FILE adapter command is not specified, the -PERM command is ignored.

The File Permissions adapter command (-PERM) is only supported in environments that support permissions.

Trace (-T)

Use the Trace adapter command (-T) to produce a diagnostics file that contains detailed information about Archive (Tar) adapter activity.

The default filename is **m4tar.mtr** or **map_name.mtr**, depending on the options you select, and the file is created in the map directory unless otherwise specified.

-T[E] [+] [*full_path*]

Option

Description

E

Produce a trace file containing only the adapter errors that occurred during map execution. The adapter trace file is produced by default in the map directory, using the full name of the map file with an **.mtr** filename extension (**map_name.mtr**).

+

Append trace information to the existing trace file by using either the A or + option.

full_path

Creates a trace file with the specified name in the specified directory.

You can override the adapter command line trace options dynamically using the Management Console. See "Dynamic Adapter Tracing" in the *Launcher* documentation for detailed information.

User ID (-UID)

Use the User ID adapter command (-UID) to set the user ID of the member to be archived or extracted.

-UID uid_num

Option

Description

uid_num

Specify a user ID to be archived or extracted.

When adding a member and -UID is not specified, the user ID is set to 0, the root, unless -FILE is specified, in which case the member inherits the UID of the file.

When extracting a member and -UID is not specified, but -FILE is specified, the user ID of the file to which the member is extracted is set to the same UID as the extracted member.

The User ID adapter command (-UID) is only supported in environments that support IDs.

Syntax summary

This documentation discusses the Archive (Tar) syntax summary and how it is used.

- [Data sources](#)
- [Data targets](#)
- [Examples](#)

Data sources

The following is the command syntax of the Archive (Tar) adapter commands used for data sources:

```
-ARCHIVE tarfile -MEMBER filename [-D|-X]
[-FILE filename [-UNIQUE]]
[-PERM perm_num]
[-GID gid_num]
[-UID uid_num]
[-T[E] [+]] [full_path]]
```

Data targets

The following is the command syntax of the Archive (Tar) adapter commands used for data targets:

```
-ARCHIVE tarfile -MEMBER filename [-A|-C|-D|-U]
[-FILE filename [-UNIQUE]]
[-PERM perm_num]
[-GID gid_num]
[-UID uid_num]
[-T[E] [+]] [full_path]]
```

Examples

For the GET...Source setting in an input card, select Archive (Tar). In the GET...Source...Command field, enter:

```
-ARCHIVE in.tar -MEMBER data.txt -X -TA
```

This command extracts a member file named **data.txt** from a tar file named **in.tar** and appends the trace file.

To override output map card 1 using the Archive (Tar) adapter, add a file named **new.txt** to the **in.tar** tar file with permissions of 0777, enter:

```
-OATAR1 -ARCHIVE in.tar -MEMBER new.txt -A -PERM 0777
```

Troubleshooting

For information about error codes and messages returned by the adapters, see [Return codes and messages](#).

- [Adapter trace file](#)

Adapter trace file

The adapter trace file contains detailed information provided by the adapter, including recorded information about the actions that are taking place such as connections established and statements executed. The trace file is produced during the adapter execution and can be used as a debugging aid.

For information about -T, see [Archive \(Tar\) Commands](#).

If adapter tracing is enabled, but the trace file is not created, any of the following could be indicated:

- The path to the Archive (Tar) adapter is incorrect
- The adapter is not located on your path
- The Trace adapter command name is misspelled
- The case for the Trace adapter command is incorrect

If the trace file is created, the shared object has been found and is being loaded. If this is true, there might be an invalid adapter command line or a problem with the tar file.

- [Sample adapter trace file](#)

Sample adapter trace file

```
==== M4TAR Adapter Log ====
Performing initialization for M4TAR_PutArchive
Command line in <-C -MEMBER output1 -ARCHIVE tarout.tar -T>
2 arguments detected

a rwxrwxrwx 0/0    119 output1
a output1 1 blocks
PutArchive succeeded

==== End run. Elapsed time: 00:00:00 ====

```

Return codes and error messages

Return codes and error messages are returned when the particular activity completes. Return codes and error messages might also be recorded as specified in the audit logs, trace files and execution summary files.

- [Messages](#)

Messages

This list contains all the codes and error messages that can be returned as a result of using Archive (Tar) adapter for sources or targets.

Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Return Code	Message
0	GetArchive succeeded
0	

```

PutArchive succeeded
-1   Can't open the file %s
-1   Unable to allocate %d bytes
-1   '%s' does not exist
-1   '%s' name too long
-1   '%s' not a file
-1   '%s' not found
-1   '%s' seek error
-1   '%s' unknown file type `%c'
-1   Data not available
-1   Failed to open archive (%s)
-1   Insufficient memory: allocation of %d bytes failed
-1   Insufficient memory: allocation of %d bytes failed
-1   Invalid command line - missing data file name
-1   Invalid command line - missing entry name
-1   Invalid option (-a, -c, or -u) request for M4TAR_GetArchive
-1   Member ` %s not found in archive
-1   Out of memory
-1   Unable to allocate memory (%Id bytes)
-1   Unable to create directory %s
-1   Unable to read archive
-1   Archive read error
-1   Bad directory structure
-1   Can't create ` %s'
-1   Can't delete ` %s'
-1   Can't delete scratch file
-1   Can't link ` %s' - data stay in ` %s'
-1   Can't open directory ` %s'
-1   Can't append ` %s'
-1   Delete option (-d) is for file archives only
-1   Directory checksum error
-1   Error extracting ` %s'
-1   Error reading ` %s'
-1   Tape blocksize error
-1   Tape close error
-1   Tape read error
-1   Tape read failed
-1   Tape seek failed
-1   Tape write error

```

The following is a listing of all the codes and messages that can be returned as a result of using the Archive (Tar) adapter on RS/6000® AIX® only:

Return Code
Message
-2 Invalid Entry Point. Must specify M4TAR_GetArchive or M4TAR_PutArchive.

TIBCO Rendezvous Adapter overview

The TIBCO Rendezvous Adapter facilitates mapping of data to and from the TIBCO Rendezvous product, as well as launching maps based upon a message arrival from a TIBCO Rendezvous messaging system.

The TIBCO Active Enterprise Release 7 or later, including Rendezvous, provides a substantial improvement in transport stability and efficiency as compared to previous releases. A main feature is that the Rendezvous sub-system is completely thread-aware, whereas, in previous releases the system was thread-safe, but not thread-aware. This necessitated adapter dependence upon an existing operating system transport such as TCP or pipes to implement thread-safe behavior. This restriction has been removed in the latest release.

Several central features of earlier releases have been made obsolete in TIBCO Rendezvous Release 7 or later: sessions, event manager contexts, signal events, and unitary message (that is, a message containing a single datum and no fields).

In earlier releases, the session was a key architectural element, encapsulating a TIBCO Rendezvous daemon connection, an event manager context, an event queue, and an event dispatcher-all in a single object. Release 6 separates these roles for greater flexibility and ease of use:

- Programs (the adapter) create transport objects to send outbound messages and receive inbound messages. Some types of transport connect to the TIBCO Rendezvous daemon; others do not.
- Programs (the adapter) create event queues for inbound messages and other events.
- The TIBCO Rendezvous event driver places events on the correct event queues.
- Programs (the adapter) dispatch events from their event queues.

When a program from an earlier release sends a unitary message and a program using Release 6 or later receives it, the receiver reformats the inbound message, placing the single datum in a field named `_data_` with no field identifier.

The subject of a message defines a mailbox name for which a message listener will accept and process received messages. To receive messages, a TIBCO Rendezvous listener must be registered to receive a subject of interest. The subject name might consist of a single element subject (`mySubject`) or hierarchical multiple element subjects (`mySubject.myData.myName`). Wildcards are supported for use with the Subject Name adapter command (-SBN). Subject names are, at most, 255 characters in length. The maximum element length is 252 characters.

The TIBCO Rendezvous Adapter supports both regular and certified message delivery based upon the specified adapter commands and the capability of the installed TIBCO Rendezvous product.

- [Syntax summaries](#)
- [Troubleshooting](#)
- [Return Codes and Error Messages](#)

System Requirements

The minimum system requirements and operating system requirements for the TIBCO Rendezvous Adapter are detailed in the release notes. In addition to these, the following are additional requirements to install and run the TIBCO Rendezvous Adapter:

- TIBCO Rendezvous software must be installed on the same machine that is running the Command Server.
- If a remote Rendezvous daemon is not used, the workstation upon which the TIBCO Rendezvous Adapter and the Command Server are installed must have the TIBCO Rendezvous software installed and activated (rvd daemon running).
- If a remote Rendezvous daemon is used (using the `-DAEMON` adapter command), the TIBCO Rendezvous software must be installed, although the local Rendezvous daemon need not be activated.
- [TIBCO Rendezvous Message Content](#)
- [Data format for TIBCO Rendezvous messages](#)
- [TIBCO Rendezvous](#)

TIBCO Rendezvous Message Content

TIBCO Rendezvous messages are self-describing messages unless the Opaque adapter command (`-OPAQUE`) is specified.

A generic message contains an optional header and a message body. The header might contain the reply subject for messages as a data target sent to a certified receiver and a subject name.

The message body follows the optional header. The message body consists of either a single data object corresponding to a single, self-described, simple RV message or an RVMsg that implies a composite, complex RV message.

The RVMsg might contain multiple message content(s), each of which is either a single datum or a nested RVMsg. Each of these items has a corresponding XML tag that is automatically put in place because of the type tree initiator and terminator definitions. All messages start with the `<Message>` tag and terminate with a `</Message>` tag.

- [Complex messages](#)

Simple Messages

An example of a simple message consisting of the `Hello` string with a null field name has an internal adapter representation of the following:

```
<Message>
<Body.Datum><Tuple.Item><Name></Name><String>Hello
</String></Tuple.Item></Body.Datum>
</Message>
```

Complex messages

The following three data objects are included in complex message example:

Field Name	Data Type	Data
INT_VAL	4-byte integer	****
FLOAT_VAL	4-byte float	****
STRING_VAL	String	String Data

This complex message data has an internal adapter representation of the following:

```
<Message>
<Body.RVMsg>
<Content.Datum><Tuple.Item><Name>INT_VAL</Name><I32>****</I32></Tuple.Item></
Content.Datum>
<Content.Datum><Tuple.Item><Name>
</Name><F32>*****</F32></Tuple.Item>
</Content.Datum>
<Content.Datum><Tuple.Item><Name>STRING_VAL</Name>
<String>String Data</String></Tuple.Item>
</Content.Datum>
</Body.RVMsg>
</Message>
```

Data format for TIBCO Rendezvous messages

TIBCO Rendezvous Release 7 or later has implemented an expanded set of wire format data types that includes array types. This change is reflected in the new type tree template for the adapter: `tibco_rv.mtt` in the `install_dir\examples\adapters\tibrv` example directory. The new type tree includes the addition of new types as described in the following sections:

- [Binary.Datum Item Types](#)
- [Tuple Array of Binary.Datum Item Types](#)
- [Binary.Datum item types](#)
- [Tuple Array of Binary.Datum Item Types](#)

Binary Datum item types

For the new data types for the single datum fields, as well as their pre-Release 7 analogs, see the following table:

Note: The datatype `RVMMSG_ENCRYPTED` from previous releases of TIBCO is obsolete for Release 7 or later. With regards to backward compatibility, inbound messages from older programs containing fields of this type will produce an error when the receiving program attempts to extract them from the message.

Type Tree Field	TIBCO Wire Format Type Name	Storage	Type Tree Field	TIBCO Pre-7 Wire Format Type Name
I8	TIBRVMMSG_I8	8-bit signed integer	INT1	RVMMSG_INT
I16	TIBRVMMSG_I16	16-bit signed integer	INT2	RVMMSG_INT
I32	TIBRVMMSG_I32	32-bit signed integer	INT4	RVMMSG_INT
I64	TIBRVMMSG_I64	64-bit signed integer	n/a	n/a
U8	TIBRVMMSG_U8	8-bit unsigned integer	UINT1	RVMMSG_UINT
U16	TIBRVMMSG_U16	16-bit unsigned integer	UINT2	RVMMSG_UINT
U32	TIBRVMMSG_U32	32-bit unsigned integer	UINT4	RVMMSG_UINT
U64	TIBRVMMSG_U64	64-bit unsigned integer	n/a	n/a
F32	TIBRVMMSG_F32	32-bit floating point	REAL4	RVMMSG_REAL
IPPort16	TIBRVMMSG_IPPORT16	2-byte IP port	IPData2	RVMMSG_IPDATA
IPAddr32	TIBRVMMSG_IPADDR32	4-byte IP address	IPData4	RVMMSG_IPDATA

Note: Corresponding data types for all TIBCO Rendezvous message types, as well as the type tree files and replies for non-certified messages and composite messages, are provided with the TIBCO Rendezvous Adapter.

Tuple Array of Binary Datum Item Types

See the following table for the new types for the tuple fields that are all sized datums.

Type Tree Field	TIBCO Wire Format Type Name	Storage	TIBCO Pre-7 Wire Format Type Name
Tuple.I8Array	TIBRVMMSG_I8ARRAY	8-bit integer array	n/a
Tuple.I16Array	TIBRVMMSG_I16ARRAY	16-bit integer array	n/a
Tuple.I32Array	TIBRVMMSG_I32ARRAY	32-bit integer array	n/a
Tuple.I64Array	TIBRVMMSG_I64ARRAY	64-bit integer array	n/a
Tuple.U8Array	TIBRVMMSG_U8ARRAY	8-bit unsigned integer array	n/a
Tuple.U16Array	TIBRVMMSG_U16ARRAY	16-bit unsigned integer array	n/a
Tuple.U32Array	TIBRVMMSG_U32ARRAY	32-bit unsigned integer array	n/a
Tuple.U64Array	TIBRVMMSG_U64ARRAY	64-bit unsigned integer array	n/a
Tuple.F32Array	TIBRVMMSG_F32ARRAY	32-bit floating point array	n/a
Tuple.F64Array	TIBRVMMSG_F64ARRAY	64-bit floating point array	n/a

TIBCO Rendezvous

The TIBCO Rendezvous messaging system uses point-to-point and broadcast communications of self-describing messages based upon the message subject. The Rendezvous messaging system is a reliable, non-certified delivery system.

The TIBCO Rendezvous software retains outbound messages for a duration of 60 seconds, after which the message is destroyed. Therefore, TIBCO Rendezvous maintains no significant data latency. If a message listener is not registered or enabled when a message arrives, the message is lost.

- [High Data Rates](#)

High Data Rates

TIBCO strongly recommends that you not use certified message delivery in situations that require high data rates. In comparison with base-level reliable delivery, certified delivery requires additional processing time, exchanges more control messages and consumes more process memory (and optional disk storage as well). Usage of these resources grows in proportion to the following:

- the number of certified messages sent
- the size of the data in these certified messages
- the number of listeners that receive certified delivery

Therefore, for optimal performance, TIBCO strongly recommends limiting the use of certified delivery.

Distributed queuing

Distributed queuing combines features of Rendezvous certified messaging and fault-tolerance functionality to provide load balancing and fault-tolerant process redundancy in the TIBCO Active Enterprise environment. Specifically, the TIBCO Rendezvous Adapter can use distributed queues to implement one-of- n certified delivery in which there are n listeners defined in a distributed queue. For a description of distributed queue features and guidance in the selection of distributed queue configuration parameters, see the *TIBCO Rendezvous Concepts* documentation.

Each distributed queue member session has two distinct roles: as a listener member and as a potential scheduler. In the listener member role, queue member sessions listen for task messages and process inbound task messages as assigned by the scheduler. TIBCO Rendezvous fault tolerance software maintains one active scheduler in each queue. If the scheduler process terminates, another member assumes the role of scheduler. The queue member session in the scheduler role assigns inbound tasks to listener members in the queue.

The member sessions of a distributed queue share the same reusable correspondent name indicating that they are members of that queue. This correspondent name is specified with the XXXXDISTRIBUTEDQUEUECH3 adapter command (-DQ). Each member session of a distributed queue must listen for messages with the same subject. Even when multiple members listen, only one member processes the message for each inbound message (or task).

You can control distributed queue attributes by using the Distributed Queue adapter command (-DQ) and the Queue Options adapter command (-QO).

To implement multiple distributed queue listeners, create multiple instances of map components that contain the Distributed Queue adapter command (-DQ), specifying the same distributed queue name and the same subject name using the Subject Name adapter command (-SBN). The mapping functionality should be identical across the maps.

Distributed queues do not use ledger files and distributed queue member sessions automatically require old messages from certified senders.

TIBCO Rendezvous Command Aliases

Adapter commands can be specified by using an execution command string on the command line or by creating a command file that contains adapter commands dictating the desired execution settings. For information about all of the options you can use with the execution commands for adapters or how to create a command file, see the *Execution Commands documentation*.

Use the Input Source Override - Message execution command (`-IM`) and the Output Target Override - Message execution command (`-OM`) with the TIBCO Rendezvous Adapter alias. The execution command syntax is:

```
-IM[alias] card_num  
-OM[alias] card_num
```

where `-IM` is the Input Source - Override execution command and `-OM` is the Output Target - Override execution command, `alias` is the adapter alias, and `card_num` is the number of the input or output card, respectively. The following table shows the adapter alias and execution commands.

Adapter	Alias	As Input	As Output
TIBCO Rendezvous	RV	<code>-IMRV</code> <i>card_num</i>	<code>-OMRV</code> <i>card_num</i>

When using an adapter alias with the execution command, the TIBCO Rendezvous Adapter commands can be issued on the command line or in a command file. You can use the adapter commands to specify the message subject name, the TIBCO Rendezvous service name, the timeout period, the certified message delivery name, and more.

For example, the command string for the adapter in the TIBCO Rendezvous environment might be:

```
-IMRV1 '-SBN rvcm.test.in -REPLY rvcm.reply -CMN output_CM  
-LFN rvcmrpout.lgr -T'
```

This example command line retrieves incoming messages with the subject name defined as `rvcm.test.in` using the Subject Name adapter command (`-SBN rvcm.test.in`). The Reply adapter command (`-REPLY rvcm.reply`) specifies the subject name of `rvcm.reply` to the confirmation of the message receipt (the reply). The adapter listens for messages with the certified session named `output_CM` using the required Certified Session Name adapter command (`-CMN input_CM`). The ledger file named `rvcmrpout.lgr` is specified as the ledger file to log the TIBCO Rendezvous certified delivery for this particular certified session using the Ledger File Name command (`-LFN rvcmrpout.lgr`). The Trace adapter command (`-T`) indicates that a trace file will be created to report adapter activity information, recording the events that occur while the adapter is retrieving this data.

- [Wildcard support](#)
- [GET ▶ Source Settings](#)
- [PUT ▶ Target Settings](#)

Wildcard support

The TIBCO Rendezvous messaging system supports two wildcard characters for the Subject Name adapter command (`-SBN`). This allows subscribers to listen for collections of related subjects. It is invalid to send messages to wildcard subjects.

- An asterisk (*) represents a single element wildcard in a subject name. The element position is context-sensitive. The subject name specified as `rv.*.in` finds `rv.data.in`, but not `rv.run.data.in`.
- The right angle bracket (>) represents a wildcard for all elements that follow the > in a subject name. The subject name specified as `rv.test.>` returns `rv.test.in.any`, `rv.test.out`, and `rv.test`, but not `rv`, or `test.rv`.
- [Wildcard usage with the Launcher](#)
- [Using wildcards to generate unique message IDs](#)

Wildcard usage with the Launcher

The Launcher supports wildcard matching and expansion only with the ">" wildcard character. If a triggering map contains wildcards, within this map, any data source and data target specified with a wildcard is expanded at run time, based upon the command line that the adapter returns to the Launcher at the time of the trigger.

To specify a TIBCO Rendezvous subject name that has a wildcard and to perform expansion when triggering a map in a system, do not use the release character. The expansion of the subject name wildcard is limited to the TIBCO Rendezvous semantics of the ">" wildcard character.

For example, assume that a map specifies the data source as messages from `rv1.>`. You want to return the message in a file with a name matching the wildcard portion of the subject, appended with `.txt`. The output file name is specified as `*.txt`. The command line for the data source is `-SBN rv1.*`. When messages from the `rv1.abc.xyz` subject are received, the trigger function expands the subject name and the output map card file name is set to `abc.xyz.txt`.

Using wildcards to generate unique message IDs

When triggering on messages, output files with a unique name can be generated based upon the messages received as input by invoking the Launcher wildcard facility within the adapter. For data sources, specify the wildcard Message ID adapter command `-MSG *` for the `GET>.Source>.Command` setting in the Map Designer or Integration Flow Designer. The adapter generates a unique message ID for each triggered message received as an input. This data is returned with the wildcard character * that is expanded to form the output subject name.

GET ▶ Source Settings

Use the Map Designer **GET** settings to configure options for input map cards using the TIBCO Rendezvous Adapter. For the `GET>.Source` setting, select TIBCO RV to use the TIBCO Rendezvous Adapter as the data source.

- [GET ▶ Source ▶ Command Setting](#)
- [Source ▶ Transaction ▶ OnSuccess Setting](#)

- [Source ▶ Transaction ▶ OnFailure Setting](#)
 - [Source ▶ Transaction ▶ Scope Setting](#)
 - [Source ▶ Transaction ▶ Warnings Setting](#)
-

GET ▶ Source ▶ Command Setting

Use the **Command** setting to enter adapter commands. For the syntax of the commands, see the [List of Commands](#).

Source ▶ Transaction ▶ OnSuccess Setting

This setting is ignored by the TIBCO Rendezvous Adapter. There is no transactional support for this publish-and-subscribe messaging system. (There is no message queue.)

To achieve message tracking, use the certified adapter commands. The TIBCO Rendezvous certified adapter commands include:

- Certified Session Name (-CMN)
 - Confirm (-CONFIRM)
 - Ledger File Name (-LFN)
 - Reply (-REPLY)
-

Source ▶ Transaction ▶ OnFailure Setting

This setting is ignored by the TIBCO Rendezvous Adapter. There is no transactional support for this publish-and-subscribe messaging system. (There is no message queue.)

To achieve message tracking, use the certified adapter commands. The TIBCO Rendezvous certified adapter commands include:

- Certified Session Name (-CMN)
 - Confirm (-CONFIRM)
 - Ledger File Name (-LFN)
 - Reply (-REPLY)
-

Source ▶ Transaction ▶ Scope Setting

Use the **Scope** setting to specify when to check for success (**OnSuccess**) or failure (**OnFailure**) of a map, card, or burst in order to perform the rollback and retry options. The default value is **Map**.

Value	Description
Map	Check for success or failure at the completion of each map. If the map completes successfully, use the OnSuccess setting. If the map fails, use the OnFailure setting.
Burst	Check for success or failure at the completion of each burst. If the burst is successful, use the OnSuccess setting. If the burst fails, use the OnFailure setting.
Card	Check for success or failure at the completion of each card. If the card is processed successfully, use the OnSuccess setting. If the card fails, use the OnFailure setting.

Source ▶ Transaction ▶ Warnings Setting

Use the **Warnings** setting to choose whether to fail or ignore warning conditions for the specific input map card. The default value is **Ignore**.

Value	Description
Ignore	Ignore warnings for this map card.
Fail	Fail the map upon receiving a warning for this map card.

PUT ▶ Target Settings

Use the Map Designer **PUT** settings to configure options for output map cards using the TIBCO Rendezvous Adapter. For the **PUT ▶ Target** setting, select TIBCO RV to use the TIBCO Rendezvous Adapter as the data target.

- [PUT ▶ Target ▶ Command Setting](#)

- [Target ▶ Transaction ▶ OnSuccess Setting](#)
- [Target ▶ Transaction ▶ OnFailure Setting](#)
- [Target ▶ Transaction ▶ Scope Setting](#)
- [Target ▶ Transaction ▶ Warnings Setting](#)

PUT ▶ Target ▶ Command Setting

Use the **Command** setting to enter adapter commands. For syntax of these commands, see the [List of Commands](#).

Target ▶ Transaction ▶ OnSuccess Setting

Use the **OnSuccess** setting with adapter targets to prevent a message from being created unnecessarily. The default value is **Create**.

Value	Description
Create	Upon successful completion of the burst, map, card, or rule (determined by the Scope settings), create the message.
CreateOnContent	Upon successful completion of the burst, map, card, or rule (determined by the Scope settings), create the message only if it is not an empty message.

Target ▶ Transaction ▶ OnFailure Setting

This setting is ignored by the TIBCO Rendezvous Adapter. There is no transactional support for this publish-and-subscribe messaging system. (There is no message queue.)

Target ▶ Transaction ▶ Scope Setting

Use the **Scope** setting to specify when to check for success (**OnSuccess**) or failure (**OnFailure**) of a map, burst, or card in order to perform the rollback and retry options. The default value is **Map**.

Value	Description
Map	Check for success or failure at the completion of each map. If the map completes successfully, use the OnSuccess setting. If the map fails, use the OnFailure setting.
Burst	Check for success or failure at the completion of each burst. If the burst is successful, use the OnSuccess setting. If the burst fails, use the OnFailure setting.
Card	Check for success or failure at the completion of each card. If the card is processed successfully, use the OnSuccess setting. If the card fails, use the OnFailure setting.

Target ▶ Transaction ▶ Warnings Setting

Use the **Warnings** setting to choose whether to fail or ignore warning conditions for the specific output map card. The default value is **Ignore**.

Value	Description
Ignore	Ignore warnings for this map card.
Fail	Fail the map upon receiving a warning for this map card.

TIBCO Rendezvous Adapter commands

The following table lists valid commands for the TIBCO Rendezvous Adapter, the adapter command syntax, and whether the adapter command is supported (✓) for use with data sources, data targets, or with both.

TIBCO RV Command Name	Syntax	Source	Target
Certified Session Name (-CMN)	-CMN [session_name]	✓	✓
Confirmation (-CONFIRM)	-CONFIRM	✓	
Daemon (-DAEMON)	-DAEMON full_path	✓	✓
Distributed Queue (-DQ)	-DQ QName[, ScdWt[, Hrtbt][, Actvn]]	✓	
Error Subject Name (-ERN)	-ERN subject_name	✓	✓

TIBCO RV Command Name	Syntax	Source	Target
Header (-HDR)	-HDR	✓	
Listener Certified Session Name (-LCMN)	-LCMN <i>session_name</i>		✓
Ledger File Name (-LFN)	-LFN [<i>ledger_name</i>]	✓	✓
Listen (-LSN)	-LSN {0 S <i>wait_time_in_sec</i> }	✓	
Message (-MSG)	-MSG *	✓	
Network (-NETWORK)	-NETWORK <i>name</i>	✓	✓
No Old Messages (-NOM)	-NOM	✓	
Opaque Message Format (-OPAQUE)	-OPAQUE	✓	✓
Point-to-Point (-PP)	-PP	✓	
Queue Options (-QO)	-QO <i>LstWt</i> [, <i>AccTm</i> [, <i>CplTm</i> [, <i>Tasks</i>]]	✓	
Quantity (-QTY)	-QTY { <i>value</i> S}	✓	
Reply (-REPLY)	-REPLY <i>reply_name</i>		✓
Request Listen (-RQSTLSN)	-RQSTLSN <i>request_lsn_time</i>		✓
Request Reply (-RQSTRPL)	-RQSTRPL		✓
Subject Name (-SBN)	-SBN <i>subject_name</i>	✓	✓
Service (-SERVICE)	-SERVICE <i>name</i>	✓	✓
Trace (-T)	-T[E] [<i>full_path</i>]	✓	✓

Certified Session Name (-CMN)

The Certified Session Name adapter command (-CMN) allows the sender or receiver to specify the certified session name for data sources and data targets.

-CMN [session_name]

Option

Description

session_name

This is a reusable name under which to register the certified session.

For example, to specify the certified session name **output_CM**, the syntax would be:

-CMN output_CM

The certified session name is the unique label for identifying a certified session. (This is not the same as the subject name.) The certified session name must be unique for each map and card because the certified session name establishes a point-to-point communication link between the sender and receiver that cannot be shared.

If the Certified Session Name adapter command (-CMN) does not specify the name of the certified session, a unique, non-reusable session name is assigned to the certified sender/receiver endpoint.

Note: You are not allowed to specify a NULL-certified session name while requiring that the certified sender retain unacknowledged messages. Omitting the argument for the Certified Session Name adapter command (-CMN) (which is equivalent to specifying a NULL-certified session name) automatically enforces the No Old Messages adapter command (-NOM) requirement for certified data sources.

If the Confirm adapter command (-CONFIRM) is not specified using the Certified Session Name adapter command (-CMN), the Rendezvous daemon generates and sends an automatic confirmation of message receipt to the sender, regardless of successful map completion.

If the Confirm adapter command (-CONFIRM) is specified using the Certified Session Name adapter command (-CMN), the confirmation of message receipt is sent only upon successful completion of the map.

Note: Use the Certified Session Name adapter command (-CMN) to bind the session name to the transport using the `tibrvbcmTransport_Create()` function.

Confirmation (-CONFIRM)

The Confirm adapter command (**-CONFIRM**) is used only on data sources receiving certified messages to specify that confirmation is explicit (non-automatic).

-CONFIRM

After successful completion of the map, the adapter sends a confirmation to the sender that the message was successfully received. The Certified Session Name adapter command (**-CMN**) must also be specified. If the Confirm adapter command (**-CONFIRM**) is not specified, confirmation occurs automatically upon receipt of a message.

Daemon (-DAEMON)

The Daemon adapter command (**-DAEMON**) is used on data sources or data targets to specify the TIBCO Rendezvous daemon location.

-DAEMON full_path

Option

Description

full_path

This is the full path of the TIBCO Rendezvous daemon location.

For example, to specify the location of the daemon on the current system, the syntax would be:

```
-DAEMON tcp:7501
```

Distributed Queue (-DQ)

Use the Distributed Queue adapter command (**-DQ**) to assign a correspondent name identifying data sources as members of a distributed queue and to set scheduling parameters.

-DQ QName[, ScdWt[, Hrtbt][, Actvn]]

Option

Description

Qname

This is a reusable correspondent name that defines a distributed queue.

ScdWt

This is the scheduler weight, which is a value that determines the queue member selected as the scheduler. The member with the greatest scheduler weight takes precedence. Acceptable values range between 1 and 65535, where the higher number has the greater scheduler weight.

Hrtbt

This is the scheduler heartbeat, which is an interval (in milliseconds) that is used to send messages from the scheduler session to inform other members that a member is acting as the scheduler. Acceptable values are unsigned 32-bit integers (except zero).

Actvn

This is the scheduler activation, which is the length of time (in milliseconds) that the heartbeat signal from the scheduler must be silent before the queue member with the greatest scheduler weight takes its place as the new scheduler. Acceptable values are unsigned 32-bit integers (except zero).

The member sessions of a distributed queue share the same reusable correspondent name (*Qname*), indicating that they are members of that queue. Each member of a distributed queue must use the same *Qname*.

The scheduler weight (*ScdWt*) represents the ability of the current session to fulfill the role of scheduler relative to other members of the same queue. If *ScdWt* is not specified, the default scheduler weight is 1.

All sessions in the queue must specify the same scheduler heartbeat value (*Hrtbt*) in milliseconds. If *Hrtbt* is not specified, the default heartbeat is 1000. *ScdWt* is required before you can specify *Hrtbt*.
