All sessions in the queue must specify the same scheduler activation (*Actvn*) value in milliseconds. If *Actvn* is not specified, the default scheduler activation is 3000. *ScdWt* and *Hrtbt* are required before you can specify *Actvn*.

Note: The Distributed Queue adapter command (**-DQ**) must be accompanied by the Subject Name adapter command (**-SBN**) to specify the message subject name. For example, to implement a distributed queue named **dq.local** that will listen for messages from the subject **rv.msg** and set the scheduler weight to 5, the scheduler heartbeat to 2000 (2 seconds), and the scheduler activation to 6000 (6 seconds), the syntax would be:

```
-SBN rv.msg -DQ dq.local, 5, 2000, 6000
```

Note: The Distributed Queue adapter command (**-DQ**) cannot be used with the Certified Session Name adapter command (**-CMN**). To set listener options for members of a distributed queue, see the [Queue Options \(-QQ\)](#) adapter command.

Error Subject Name (-ERN)

Use the Error Subject Name adapter command (**-ERN**) to specify the subject to which a message is re-posted in the event of a map failure.

-ERN subject_name

Option

Description
<i>subject_name</i>
This is the TIBCO Rendezvous subject name for error messages.
If the message is not capable of being re-sent, a warning message is published to the specified error subject name. The error subject name specified with this command cannot be shared across input and output map cards, although the same subject name might be used in multiple input cards or multiple output cards.
Re-posted error messages are non-certified (reliable) messages. The initial map failure creates an adapter-generated error message with the -ERN-specified subject name and the following content: Map failed. Message to follow.
The message is then re-sent. If that re-posting is unsuccessful for any reason, a second error message with the -ERN-specified subject name is created with the following content: Message resend failure.
Map cards are processed in sequence; therefore, an input or output card using the Error Subject Name adapter command (-ERN) should be the first map card defined. If the -ERN map card follows a map card that causes a map failure, the -ERN map card is not invoked to re-send the message.
Note: The Error Subject Name adapter command (-ERN) is valid only on the TIBCO Rendezvous messaging system.

Header (-HDR)

Use the Header adapter command (-HDR) for data sources to specify to the adapter that header information should be included in the returned data.

-HDR

When the TIBCO Rendezvous Adapter is invoked without the Header adapter command (-HDR), the data consists of only the body of the message. The header information includes the optional subject name and reply name that allows the subject name and reply name data to be mapped when the Opaque adapter command (-OPAQUE) is specified.

The Header adapter command (-HDR) is not required for data targets because the adapter detects the presence of header data.

If the message contains any header information, the header information overrides the Subject Name adapter command (-SBN) and the Reply Subject Name adapter command (-REPLY).

Listener Certified Session Name (-LCMN)

Use the Listener Certified Session Name adapter command (-LCMN) for data targets to specify the name of the receiving certified session.

-LCMN session_name

Option

Description
<i>session_name</i>
This is the name of the receiving certified session.
When the TIBCO Rendezvous Adapter is used as a data target that is intended to publish point-to-point certified messages to a participating certified message listening endpoint (subscriber), the Listener Certified Session Name adapter command (-LCMN) specifies the certified session name of the listening endpoint.
Specifying the certified session name of the listening endpoint with the Listener Certified Session Name adapter command (-LCMN) allows the certified receiver to begin receiving certified messages immediately from the adapter target as the messages are sent. Without this information, the receiver must rely upon the registration discovery exchange preceding the publication of the first message. It is possible that the name of the certified session used by the adapter will not be available to the certified receiver for the initial message.
The following is an example of a target command line that could be used to publish certified messages to the rvcmlistener listening endpoint subject having the RVCMLISTEN certified session name from the RVCMSENDER target certified session:

-SBN rvcmlistener -CMN RVCMSENDER -LCMN RVCMLISTEN

Note: The Certified Session Name adapter command (-CMN) must also be specified.

Ledger File Name (-LFN)

The Ledger File Name adapter command (-LFN) specifies for data sources and data targets the ledger file name for the logging of the TIBCO Rendezvous certified delivery for a particular certified session.

-LFN [ledger_name]

Option

Description
<i>ledger_name</i>
Specify the ledger file name for certified delivery TIBCO Rendezvous logging.

For example, to specify the **TIBCOout.fil** ledger file name, the syntax would be:

```
-LFN TIBCOout.fil
```

The ledger file name must be unique for each certified session name. The Certified Session Name adapter command (**-CMN**) must also be specified.

If the Ledger File Name adapter command (**-LFN**) does not specify the name of the ledger file or if the Certified Session Name adapter command (**-CMN**) is used without the Ledger File Name adapter command (**-LFN**), a process-based ledger for certified message tracking is automatically maintained.

The TIBCO Rendezvous certified message delivery stores messages in a ledger file until confirmations from registered certified receivers have been received (certified delivery). The ledger file is the permanent, disk-based, storage mechanism that TIBCO Rendezvous uses to ensure data retention for certified message delivery.

Listen (-LSN)

Use the Listen adapter command (**-LSN**) for data sources to indicate the length of time (in seconds) that the TIBCO Rendezvous Adapter waits for a message to be received. Map execution is suspended until the message is received or until the specified time lapses. The default value is one hour (3600 seconds).

```
-LSN {0|S|wait_time_in_sec}
```

Option

Description

0

Do not wait at all. If there is no input available, the adapter does not wait for more messages.

S

This is an infinite wait time.

wait_time_in_sec

This is the number of seconds that the adapter waits for a message.

For example, to specify a wait time of two minutes, the syntax would be:

```
-LSN 120
```

The maximum period of time available is 128 hrs (460800 seconds). The Listen adapter command (**-LSN**) is ignored when dealing with certified messages.

Message (-MSG)

The Message adapter command (**-MSG**) is used on data sources to instruct the adapter to return a unique message ID for each message triggered back to the Launcher.

```
-MSG *
```

For data sources, on the Integration Flow Designer Sources tab of the execution settings, use the **-MSG * message** adapter command. The incoming message data is returned with the * wildcard character expanded to form the unique output name.

The Message adapter command (**-MSG**) is a mechanism that allows the adapter to generate a unique name that corresponds to each TIBCO Rendezvous message. If the Message command (**-MSG ***) is defined with a data source, use * to designate a unique file or resource name. The * can then be used in subsequent cards to link the resources.

Network (-NETWORK)

The Network adapter command (**-NETWORK**) is used for data sources and data targets to specify the network name or address that the TIBCO Rendezvous software uses for all communications involving the current session.

```
-NETWORK name
```

Option

Description

name

This is the name or address of the network to use.

For example, to specify the network address of a server, the syntax would be:

```
-NETWORK 101.55
```

The adapter uses a single session for all TIBCO Rendezvous non-certified messages and a separate session for each TIBCO Rendezvous PRO certified subject.

No Old Messages (-NOM)

The No Old Messages adapter command (**-NOM**) is valid only for data sources and allows unacknowledged messages sent from a certified sender to be deleted from the ledger file regardless of whether confirmation of receipt was obtained.

-NOM

The default behavior when the No Old Messages adapter command (**-NOM**) is not used requires the associated certified sender to retain any unacknowledged messages in the ledger until the listener has confirmed receipt of the message.

Note: The Certified Session Name adapter command (**-CMN**) also must be specified. The No Old Messages adapter command (**-NOM**) is valid only on TIBCO Rendezvous PRO messaging systems that support certified message delivery.

Opaque Message Format (-OPAQUE)

The Opaque Message Format adapter command (**-OPAQUE**) is used for data sources and data targets to define the message data type as opaque, not self-describing.

-OPAQUE

The Opaque Message Format adapter command (**-OPAQUE**) informs the adapter to receive the input data and format only the raw message data as a blob (opaque) data type (not a self-describing message type). For data targets, the entire data is sent as a binary buffer of variable length (RVMSG_OPAQUE).

Point-to-Point (-PP)

The Point-To-Point adapter command (**-PP**) is used only on data sources. If this command is specified, a unique inbox subject name is created and one message is published on a subject specified using the Subject Name adapter command (**-SBN**) with its reply subject set to the inbox name.

-PP

For example, to implement point-to-point connection between a sending map (**Map1**) and a receiving map (**Map2**), see the following procedure.

To implement point-to-point connection

1. Select the **my.pp.connection** subject name upon which information about the unique inbox name will be exchanged.
2. Specify the following **GET > Source > Command** settings for the **Card1** input card of **Map1**:

```
-SBN my.pp.connection -HDR
```

3. Map the data object representing the header reply from the **Card1** input card of **Map1** to the data object representing the header subject in an output card for the **Card2** example.
4. Specify the following **GET > Source > Command** setting for the **Card1** input card of **Map2**:

```
-SBN my.pp.connection -PP
```

5. Run **Map1**.
6. Run **Map2**.

The adapter of the **Card1** input card of **Map2** will create a unique inbox name called **_INBOX.something** with a call to the **tibrvTransport_CreateInbox()** function. Then it will publish a message on the **my.pp.connection** subject with the reply subject of the message set to the **_INBOX.something** unique inbox subject name. It will then start to listen for messages on the **_INBOX.something** subject name.

Queue Options (-QO)

Use the Queue Options adapter command (**-QO**) to assign listener options for members of a distributed queue.

```
-QO LstWt[, AccTm[, CplTm[, Tasks]]]
```

Option

Description

LstWt

This is the listener weight, which is a value that determines the listener that receives a task from the scheduler. The member with the highest listener weight (largest numerical value) takes precedence.

AccTm

This is the listener accept time.

If non-zero, this is the length of time (in milliseconds) the scheduler waits for a listener member to accept an assigned task before reassigning the task.

If zero, there is no limit on the acceptance time. Therefore, the scheduler does not set a timer and does not reassign the task.

CplTm

This is the listener complete time.

If non-zero, this is the length of time (in milliseconds) the scheduler waits for a listener member to complete an assigned task before reassigning the task.

If zero, there is no limit on the completion time. Therefore, the scheduler does not set a timer and does not reassign the tasks.

Tasks

This is the maximum number of tasks a listener can accept.

When the scheduler receives a task, it assigns the task to the available listener with the greatest listener weight (*LstWt*). If *LstWt* is not defined, the default listener weight is 1.

If the accept time (*AccTm*) lapses before the scheduler receives acceptance from the listener member, the scheduler reassigns the task to another listener member. Zero is a special value (the default) that specifies no limit on the acceptance time. In this case, the scheduler does not set a timer and does not reassign tasks when the task has not been accepted. *AccTm* is specified in milliseconds and must be less than the complete time (unless complete time is zero). If *AccTm* is not specified, the default listener accept time is 0.

If complete time (*CplTm*) elapses before the scheduler is notified that the listener member has completed its task, the scheduler reassigns the task to another listener member. Zero is a special value (the default) that specifies no limit on the completion time, in which case the scheduler does not set a timer and does not reassign tasks when the task has not been completed. *CplTm* is specified in milliseconds and must be greater than the *AccTm* (unless complete time is zero). If *CplTm* is not specified, the default listener complete time is 0. *AccTm* is required before you can specify *CplTm*.

When the number of accepted tasks reaches the maximum set in listener tasks (*Tasks*), the listener cannot accept additional tasks until it completes one or more of them. When the scheduler receives a task, it assigns the task to the listener with the greatest *LstWt* unless the pending tasks assigned to that listener exceed its task capacity. When the preferred listener has too many tasks, the scheduler assigns the new inbound task to the listener with the next greatest *LstWt*. The value must be 1 or greater. If *Tasks* is not specified, the default listener tasks value is 1. *AccTm* and *CplTm* are required before you can specify *Tasks*.

Note: The Queue Options adapter command (-*QO*) must be accompanied by the Subject Name adapter command (-*SBN*) and the Distributed Queue adapter command (-*DQ*).

The following example demonstrates how to implement a distributed queue named **dq.local** that listens for messages from the **rv.msg** subject using the following specifications:

- The scheduler weight is 5.
- This scheduler heartbeat is 2000 (2 seconds).
- The scheduler activation is 6000 (6 seconds).
- The listener weight is 50.
- The accept time is 5000 (5 seconds).
- The complete time is 10000 (10 seconds).

```
-SBN rv.msg -DQ dq.local, 5, 2000 6000 -QO 50, 5000, 10000
```

For assigning a correspondent name identifying data sources as members of a distributed queue and for setting scheduling parameters, see the [Distributed Queue \(-DQ\)](#) adapter command.

Quantity (-QTY)

Use the Quantity adapter command (-*QTY*) to specify the number of messages to retrieve on the subject name as specified using the Subject Name adapter command (-*SBN*). For the TIBCO Rendezvous Adapter, this value always equals 1.

-QTY {value|S}

Option

Description

S

For TIBCO Rendezvous, this returns one message on the subject name.

value

This is a positive integer representing the number of concurrent multiple messages to be retrieved. The TIBCO Rendezvous Adapter overwrites this to equal 1.

The Quantity adapter command (-*QTY*) defines the maximum number of messages across all bursts for a map.

The number of bursts in a single map invocation can be controlled using the combination of values set in the Map Designer **SourceRule > FetchAs > FetchUnit** setting and the Quantity adapter command (-*QTY*).

Note: When using the Quantity adapter command (-*QTY*) with the **S** option through either the Launcher or the Command Server, the Listen adapter command (-*LSN*) is also required with a value specified other than **S**.

Reply (-REPLY)

Use the Reply adapter command (-*REPLY*) to specify the subject name to receive the confirmation message receipt (the reply). The Reply adapter command (-*REPLY*) is used on data targets only.

-REPLY reply_name

Option

Description

reply_name

This is the subject name of the reply message.

For example, to specify the **tixrecv** subject name for the data target messages, the syntax would be:

```
-SBN output_RCV -REPLY tixrecv
```

If a reply name is specified in the header information, the header information takes precedence over the Reply adapter command (-*REPLY*). The adapter assumes that the listener for the reply is operational and has established delivery tracking with the receiver of the output map message.

To implement a reply in a map receiving a message, use an input card to receive a message from a subject that has published a message using the Reply adapter command (-REPLY). Next, map the data object representing the header reply from an input card to the data object representing the header subject in an output card. Format the output to send the appropriate reply message. The presence of the subject in the header forces the adapter to publish the reply to the subject.

Request Listen (-RQSTLSN)

Use the Request Listen adapter command (-RQSTLSN) to set the maximum listen time (in seconds) to wait for the reply when the message is sent using the Request Reply adapter command (-RQSTRPL). If it is not specified, the **tibrvTransport_SendRequest** or the **tibrvcvTransport_SendRequest** function call will block until the receipt of the replied message.

-RQSTLSN requestlsntime

Option

Description
<i>requestlsntime</i>

This is the maximum listen time (in seconds) to wait for the reply when the message is sent using the Request Listen adapter command (-RQSTLSN).

Request Reply (-RQSTRPL)

Use the Request Reply adapter command (-RQSTRPL) to request to receive the confirmation message receipt (the reply). The Request Reply adapter command (-RQSTRPL) is used on data targets only.

-RQSTRPL

For example, to send the message to the **output_RCV** subject name with the request for confirmation for the message receipt, the syntax would be:

-SBN output_RCV -RQSTRPL

The adapter assumes that the listener for the reply is operational and has established delivery tracking with the receiver of the output map message. When the Request Reply adapter command (-RQSTRPL) is specified, the adapter invokes either the TIBCO Rendezvous **tibrvTransport_SendRequest** function call (without certified messaging) or the **tibrvcvTransport_SendRequest** (with certified messaging) function call. This function call blocks until either the receipt of the replied message or until the call times out, whichever is first to occur. The timeout period for which to wait until the reply can be specified using the [Request Listen \(-RQSTLSN\)](#) adapter command.

When the subscribing application (recipient) receives the message, the TIBCO Rendezvous callback function is activated and the subscribing application extracts the inbox reply subject name from the received message. This inbox subject name is automatically generated by the **tibrvTransport_SendRequest** or the **tibrvcvTransport_SendRequest** function call. The subscribing application must then format the reply message and send it to the subject.

To implement a reply in a map receiving a message, use an input card to receive a message from a subject that has published a message using the **tibrvTransport_SendRequest** function call. Next, map the data object representing the header reply from an input card to the data object representing the header subject in an output card. The presence of the subject in the header forces the adapter to publish the reply to the subject.

Subject Name (-SBN)

Use the Subject Name adapter command (-SBN) for data sources and data targets to specify the message subject name.

-SBN subject_name

Option

Description
<i>subject_name</i>

This is the TIBCO Rendezvous source or target message subject name. Wildcards are permitted.

For specific wildcard use rules, see "[Wildcard Support](#)". The usage of wildcards with the Subject Name adapter command (-SBN) allows subscribers to listen to collections of related subjects. No other checking is performed to confirm TIBCO Rendezvous syntax compliance.

For example, to specify the **output_RCV** subject name for the data target messages, the syntax would be:

-SBN output_RCV

To specify a subject name using the wildcard right angle bracket (>) to match all subjects beginning with **recv** and containing any characters that follow the > symbol, use the syntax:

-SBN recv>

For data sources, this is the subject name of the incoming message. For data targets, this is the subject name of the message to which to subscribe as a listener for message receipt.

If the message header contains any information, the header information overrides the Subject Name adapter command (-SBN).

Note: The Point-To-Point Subject Name adapter command (-PPN) might not be used on the same output card as the Subject Name adapter command (-SBN).

Service (-SERVICE)

Use the Service adapter command (-SERVICE) for data sources or data targets to specify the service group or port that the TIBCO Rendezvous daemon will use for the current session.

```
-SERVICE service_name
```

Option

Description

service_name

This is the service group or port to be used for the current session.

For example, to specify the **7501** service port , the syntax would be:

```
-SERVICE 7501
```

The adapter uses a single session for all TIBCO Rendezvous non-certified messages and a separate session for each TIBCO Rendezvous PRO certified subject.

Trace (-T)

Use the Trace adapter command (-T) to produce a log file with the default name **m4rv.log** in the map execution directory. The Trace adapter command (-T) is used with data sources or data targets to enable adapter tracing. The trace file contains information about internal adapter states.

```
-T[E] [full_path]
```

Option

Description

E

Produce a trace file containing only the adapter errors that occurred during map execution.

full_path

This is the name of the trace file. If no name is specified, the default file name is **m4rv.log**.

For example, to specify the **tibrcv.log** trace file name in the map directory, the syntax would be:

```
-T tibrcv.log
```

Note: You can override the adapter command line trace options dynamically using the Management Console. See "Dynamic Adapter Tracing" in the *Launcher* documentation for detailed information.

Syntax summaries

The following are syntax summaries listed for the TIBCO Rendezvous Adapter commands for data sources and targets.

- [Data Sources](#)
- [Data Targets](#)
- [Example Files](#)

Data Sources

The following is the syntax of the TIBCO Rendezvous Adapter commands used for data sources:

```
-SBN subject_name [-CMN [session_name] [-CONFIRM] [-NOM] [-LFN [ledger_name]]]  
[-DAEMON full_path]  
[-DQ QName[, ScdWt[, Hrtbt][, Actvn]]]  
[-ERN subject_name]  
[-HDR]  
[-LSN {0|S|wait_time_in_sec}]  
[-MSG *]  
[-NETWORK name]  
[-OPAQUE]  
[-PP]  
[-QO LstWt[, AccTm[, CplTm][, Tasks]]]  
[-QTY {value|S}][  
[-SERVICE name]  
[-T[E] [full_path]]
```

Data Targets

The following is the syntax of the TIBCO Rendezvous Adapter commands used for data targets:

```
-SBN subject_name [-CMN session_name [-REPLY reply_name] [-LFN [ledger_name]]]
[-LCMN session_name]
[-DAEMON full_path]
[-ERN subject_name]
[-NETWORK name]
[-OPAQUE]
[-REPLY reply_name]
[-RQSTLSN request_lsn_time]
[-RQSTRPL]
[-SERVICE name]
[-T[E] [full_path]]
```

Example Files

The TIBCO Rendezvous Adapter example files are located in the following directory: *install_dir\examples\adapters\tibrv*.

- [Type Tree Example](#)
 - [Map Example](#)
-

Type Tree Example

The **tibco_rv.mtt** type tree is suitable for receiving and sending complex, opaque, or simple, self-described data. To send and receive opaque data, use the **OpaqueMessage** group. This group represents the structure of the data that is being passed to the adapter in the mapping process.

Map Example

The following TIBCO Rendezvous map is provided.

- **rvmsg.mms** - This is a map source file that contains the following six maps:
 - **request** is a map that publishes a message on the **rv.test.out** subject with the request for a reply. It waits three seconds for the reply.
 - **requestreply** is a map that listens on the **rv.test.out** subject. When it receives the message, it maps the reply subject name from the input data header field to the subject name in the output data header field and publishes the message on that subject.
 - **rvcmsg_in** is a map that listens for certified messages on the **rv.test.out** subject. When it receives the message, it maps the data to **out.txt**. Because the **receiver.ldg** ledger file name is specified, the **receiver** acts as the persistent certified correspondent.
 - **rvcmsg_send** is a map that publishes a certified message on the **rv.test.out** subject. The certified correspondents are **sender** and **receiver**. Because the **ledgerout.ldg** ledger file name is specified, **sender** acts as the persistent certified correspondent.
 - **rvmsg_in** is a map that listens for messages on the **rv.test.out** subject. When it receives the message, it maps the data to **out.txt**. Because the **receiver.ldg** ledger file name is specified, the **receiver** acts as the persistent correspondent.
 - **rvmsg_send** is a map that publishes a message on **rv.test.out** subject. The certified correspondents are **sender** and **receiver**. Because the **ledgerout.ldg** ledger file name is specified, **sender** acts as the persistent correspondent.
-

Troubleshooting

For information about error codes and messages returned by the adapter, see [Return Codes and Error Messages](#).

- [Trace Log](#)
 - [Advisory messages](#)
-

Trace Log

Use the Trace adapter command (-T) to create a trace file that reports adapter activity information, recording the events that occur while the adapter is retrieving and sending data. The trace command produces a log file with the default name **m4rv.log** file in the map execution directory.

The trace file contains information about connections to TIBCO Rendezvous, message sizes, error messages, and adapter error messages.

Advisory messages

The TIBCO Rendezvous software generates advisory messages to notify users of warnings and error conditions. The default advisory subject has the base name **_RV.>**. It is possible to map TIBCO Rendezvous advisory and error subjects by specifying them as the subject name on the command line of an input map card.

For the Command Server only, the TIBCO Rendezvous Adapter registers the subject **_RV.>** by default, for non-certified messages only and logs these message receipts to the **m4rv.log** file in the map directory when the Trace adapter command (-T) is specified.

Return Codes and Error Messages

Return codes and messages are returned when the particular activity completes. Return codes and messages might also be recorded as specified in the audit logs, trace files, execution summary files, and so on.

- [Messages](#)
-

Messages

The following is a listing of all the return codes and messages that can be returned as a result of using the TIBCO Rendezvous Adapter for sources or targets.

In addition to the following return codes, the TIBCO Rendezvous Adapter can return TIBCO Rendezvous error codes. Consult the TIBCO Rendezvous documentation for descriptions of these error codes.

Note: Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Return Code	Message
1	Could not close RV
2	Extraneous data in the complex message found
3	WARNING: Extra messages were fetched and not processed
4	WARNING: Timeout period has expired
-1	Command line is in error
-2	Could not open RV
-3	Could not connect to RV transport
-4	Unknown error encountered
-5	Could not publish message
-6	Could not retrieve message
-7	Failed to allocate memory
-8	Triggering failed
-9	Error in specified number of watches
-10	Function could not initialize: improper parameter
-13	Message not in the cache
-14	Exceeded the max thread count
-19	Timed out waiting for rvcm_Confirm
-20	Overflowed buffer

Archive (Zip) Adapter

This is an introduction to the Archive (Zip) Adapter. Use the adapter with a Command Server, Launcher, Software Development Kit, or map in a map rule.

- [Overview](#)
 - [System requirements](#)
 - [Command alias](#)
 - [Archive \(Zip\) Adapter commands](#)
 - [Syntax summary](#)
 - [Return codes and error messages](#)
-

Overview

Use the Archive (Zip) adapter to compress or extract files.

System requirements

The minimum system requirements and operating system requirements for the Archive (Zip) adapter are detailed in the release notes. It is assumed that a Command Server has already been installed on the computer where the adapter is to be installed for run-time purposes.

Command alias

Adapter commands can be specified by using a command string on the command line or by creating a command file that contains adapter commands. The execution command syntax is:

```
-IA[alias] card_num  
-OA[alias] card_num
```

where -IA is the Input Source Override execution command and -OA is the Output Target Override execution command, *alias* is the adapter alias, and *card_num* is the number of the input or output card. The following table shows the adapter alias and its execution command.

Adapter	Alias	As Input	As Output
Archive (Zip)	ZIP	-IAZIP <i>card_num</i>	-OAZIP <i>card_num</i>

Archive (Zip) Adapter commands

This is a description of the functions and use of the Archive (Zip) adapter commands and their options.

- [List of commands](#)

List of commands

The following table lists valid commands for the Archive (Zip) Adapter, the command syntax, and whether the command is supported (✓) for use with data sources, data targets, or both.

The Archive (Zip) Adapter commands do not require a hyphen before the command. The Archive (Zip) Adapter commands do not follow the command syntax of other adapters.

Command	Syntax	Source	Target
Archive File (FILE)	FILE,archive_name,files_to_zip		✓
Archive Data (MEMORY)	MEMORY,archive_name,filename_of_archived_data		✓
Archive Restore	archive_name,files_to_unzip	✓	

- [Archive File \(FILE\)](#)
- [Archive Data \(MEMORY\)](#)
- [Archive Restore](#)

Archive File (FILE)

Use the Archive File adapter command (FILE) to produce a compressed archive file in the map directory. Data passed from the output card is ignored.

FILE,archive_name,files_to_zip

Option

Description

archive_name

Specify the name of the resulting archive file.

,

The comma is a required separator between options.

files_to_zip

Specify the file to be archived. The *files_to_zip* must be a fully qualified path. If the file name is not a fully qualified path, the adapter returns a success status, but the file is not added to the archive.

Specify multiple files as a space-delimited list of file names and paths. You can also use standard DOS wildcards (*) and (?). Enclose long filenames in double quotation marks ("longfilename"). Do not include spaces before the first file name or after the last file name.

Archive Data (MEMORY)

Use the Archive Data adapter command (MEMORY) to produce a compressed archive file from the data supplied by the output card or PUT rule. The data is added to the archive.

MEMORY,archive_name,filename_of_archived_data

Option

Description
<code>archive_name</code>
Specify the name of the resulting archive file.
,
The comma is a required separator between options.
<code>filename_of_archived_data</code>
Specify the file name that will be used to represent the archived data. Enclose a long file name in double quotation marks ("longfilename").

Archive Restore

Use the Archive Restore command to retrieve files from a specified archive. Specify the following arguments with no preceding adapter command:

`archive_name,files_to_unzip`

Option

Description

archive_name
Specify the name of the archive that contains the files to be restored.

,
The comma is a required separator between options.

`files_to_unzip`

Specify the files to be restored from archive. The `files_to_unzip` must be a fully qualified path. If the file name is not a fully qualified path, the adapter returns a success status, but the file is not restored from the archive.

Specify multiple files as a space-delimited list of file names and paths. You can use standard DOS wildcards (*) and (?). Enclose long filenames in double quotation marks ("longfilename"). Do not include spaces before the first file name or after the last file name.

Note: The Archive Restore command restores multiple files only to memory and only as one continuous data stream that concatenates all the selected data files. Multiple files cannot be individually restored to disk.

Syntax summary

This is a description of the Archive (Zip) adapter syntax summary and how it is used.

- [Data sources](#)
- [Data targets](#)
- [Examples](#)

Data sources

The following is the syntax of the Archive (Zip) adapter commands used for data sources:

`archive_name,files_to_unzip`

Data targets

The following is the syntax of the Archive (Zip) Adapter commands used for data targets:

`FILE,archive_name,files_to_zip
MEMORY,archive_name,filename_of_archived_data`

Examples

For the **Source** setting in an input card, select Archive (Zip). In the GET->Source->Command field, enter the Restore adapter command:

`SavRecord,data.txt`

The **Archive Restore** command extracts and restores a file named **data.txt** from an archive file named **SavRecord**.

This example extracts multiple files to memory as a continuous data stream:

`SavRecord,data.txt *.dat abc\def\notes.txt "documents and settings\Administrator\listing.txt"`

From an archive file named **SavRecord**, the **Archive Restore** command extracts and restores:

- A file named **data.txt**
- All files with the ***.dat** extension
- The file **abc\def\notes.txt**

- The file documents and settings\Administrator\listing.txt

To override Archive (Zip) adapter settings for the first output card and create an archive file named **SavRecord** containing the file **data.txt**, the Archive file adapter command string is:

```
-OAZIP1 'FILE,SavRecord,data.txt'
```

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages might also be recorded as specified in the audit logs, trace files, execution summary files, and so on.

- [Messages](#)

Messages

The following is a listing of all the codes and messages that can be returned as a result of using the Archive (Zip) adapter for sources or targets.

Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Return Code	Message
0	OK
-1	Invalid command line: missing zip file name after 'file' keyword.
-1	Invalid command line: missing zip file name after 'memory' keyword.
-1	Invalid command line: missing zip file name after 'echo' keyword.
-1	Invalid command line: missing zip member name (after zip file name).
-1	Invalid command line: expected 'file', 'memory', or 'echo' as first argument.
-1	Invalid command line: missing zip file name.
-600	Internal Error: Resource Manager Error
-?	ZIP_ADD: DynaZip error occurred (????).
-?	ZIP_MEMTOFILE: DynaZip error occurred (????).
-?	UNZIP_COUNTALLZIPMEMBERS: DynaZip error occurred (????).
-?	UNZIP_COUNTNAMEDZIPMEMBERS: DynaZip error occurred (????).
-?	UNZIP_GETNEXTNAMEDZIPINFO: DynaZip error occurred (????).
-?	UNZIP_FILETOMEM: DynaZip error occurred (????).
-?	-? is a DynaZip API error return (non-zero) made negative if > 0 and where ???? is a DynaZip API supplied error message.

Resource Registry overview

The Resource Registry application can be used to define resource name aliases for source and target resources that are specified in map cards.

A resource name is an alias that has different values defined for multiple deployment environments. A resource value can be either a command card setting for a map, an adapter command override setting for a map or system component, or an argument to environment functions within a map rule (**RUN**, **PUT**, **GET**, **DBLOOKUP**, **DBQUERY**, and **EXIT**). In addition, other resources that can be aliased include:

- backup files
- audit files and locations
- trace files and locations
- work space locations
- external parser location (defined in the Type Designer)
- map server location (defined in the Integration Flow Designer)

Using the Resource Registry, a resource name is associated with one or more logical virtual servers (deployment environments). Each logical virtual server might have a different resource value for a given resource name.

For example, suppose **Payroll** is a resource name. **Payroll** is associated with a **Test**, **Development**, and **Production** logical server. For **Test**, **Payroll** might be an SQL Server query. For **Development**, **Payroll** might be an Oracle query. For **Production**, **Payroll** could be a DB2® query.

This feature minimizes the maintenance of systems and maps when moving them to different environments.

With the Resource Registry you define the various resource values once, and those values get resolved at run-time (map execution) by the map server (Command Server, Launcher, or Transformation Extender Programming Interface), thereby eliminating the need to modify maps during design-time.

Without the Resource Registry, you must manually edit input and output card settings for each platform the system and/or maps are moved to in order to reflect the appropriate parameters (resource value) for that environment.

For the purpose of this documentation, the generic term **map server** is used when referencing the Command Server, Launcher, or Transformation Extender Programming Interface.

See the Command Server documentation for information on items to take into consideration if you use resource names in maps running on a OS/390® Batch or CICS® version of the Command Server.

Tip:

A Resource Registry example is provided with the Design Studio at *install_dir/examples/general/rsrcreg*.

- [**Resource Registry files**](#)

The Resource Registry files include the resource name file, the resource configuration file, and the master key file.

The Resource Registry provides a graphical user interface to create and manage resource aliases.

- [**Resource Registry map deployment overview**](#)

Resource configuration files are used by a map server to determine available resources and their values when executing a map. Configuration files are specified for a map server through an application option, initialization function, or the config.yaml file.

- [**Creating a Resource Registry resource name alias**](#)

Prior to using the Resource Registry, you must create a resource name alias.

- [**Access to the Resource Registry**](#)

The IBM Transformation Extender installation program adds an entry for the Resource Registry to the Design Studio programs menu.

Resource Registry files

The Resource Registry files include the resource name file, the resource configuration file, and the master key file.

Resource name file (.mrn)

Contains a named set of virtual servers and a named set of resources.

Resource configuration file (.mrc)

Specifies the associated resource name file and which virtual servers are active for a map server.

Master key file (.mkf)

Contains one or more keys that are used to encrypt resource values in the .mrn files.

The resource name, resource configuration, and master key files are in XML format.

Resource Registry interface overview

The Resource Registry provides a graphical user interface to create and manage resource aliases.

- [**Resource Registry navigator overview**](#)

The Resource Registry navigator graphically presents all of the opened resource name and configuration files, and the resource values that they contain.

- [**Resource Registry menu commands**](#)

Actions are performed in the Resource Registry using menu commands.

Resource Registry navigator overview

The Resource Registry navigator graphically presents all of the opened resource name and configuration files, and the resource values that they contain.

Resource Registry menu commands

Actions are performed in the Resource Registry using menu commands.

When working with resource aliases, there are several ways you can activate commands:

- Select functionality using the menu bar.
- Right-click an entry in the Resource Registry window to display its context menu.
- Press **Insert** to add resources and map systems.
- Press **Delete** to delete resources and map systems.

Resource Registry commands are available as listed above; however, most procedural information in this documentation uses the menu access as a default method. Use the activation method most convenient for you.

Resource Registry map deployment overview

Resource configuration files are used by a map server to determine available resources and their values when executing a map. Configuration files are specified for a map server through an application option, initialization function, or the config.yaml file.

See "[Specifying Configuration Files for a Map Server](#)" for more information.

Creating a Resource Registry resource name alias

Prior to using the Resource Registry, you must create a resource name alias.

To create a resource name alias, you must first define the resource and virtual server names, and then define the value for each resource name and virtual server combination.

To define a resource name alias

1. Create a resource name (**.mrn**) file.
2. Define the resource name(s).
3. Define the virtual servers.
4. Define the resource values for each resource name and virtual server combination.
5. Save the **.mrn** file.
6. Create a resource configuration file (**.mrc**).
7. Associate the **.mrn** file and active server with map server.
8. Save the **.mrc** file.
9. Specify the name and location of the **.mrc** file for the Command Server or Launcher through an application option.

Access to the Resource Registry

The IBM Transformation Extender installation program adds an entry for the Resource Registry to the Design Studio programs menu.

For UNIX platforms, the Resource Registry can be accessed from:

`install_dir\resourceregistry.sh`

Resource name files

With the Resource Registry, you define the resource and then associate that resource to a deployment environment (virtual server).

For example, a resource could be defined as an Oracle query on a **Development** server (Windows) and an SQL Server query on a **Test** server (HP-UX).

Each named resource has a specified value for that resource for each virtual server. If a resource value contains sensitive data (such as passwords), you can encrypt the value.

The resource name and virtual server name must be unique and are case-sensitive.

The value of the **Command** setting (adapter-specific commands) in input and output cards and in a **GET** or **PUT** function within a map rule cannot exceed 2000 bytes. The expansion of the resource value is included in this limitation.

See the Map Designer documentation for more information about settings and map rules.

- [Creating Resource Registry name files](#)

You need to define a name file for the Resource Registry.

You need to define a name file for the Resource Registry.

The resource name (**.mrn**) file contains specifications for the resource such as:

- Resource name
- Resource value
- Virtual server that the resource is associated with
- Encryption setting for the resource value, encryption key ID, and master key file

You can use the same resource name across all platforms. The **.mrn** file is platform-independent.

You can define an unlimited number of sets of resources and virtual servers in one **.mrn** file.

See the Command Server documentation for information on items to take into consideration if you use resource names in maps running on a z/OS® Batch or CICS® version of the Command Server.

To create a resource name file:

1. In the navigator, select Resource Files.
2. From the **File** menu, choose **New**.
The New dialog appears.
3. Specify the location of the resource name file by browsing your file structure.
4. In the **File name** field, enter the name of the resource name file.
5. Click **New**.
The resource name file displays in the navigator.

- **[Defining Resource Registry names](#)**

Resource names are defined for the currently active resource name file in the Resource Registry.

- **[Defining resource names with environment variables](#)**

You can avoid customizing resource name and configuration files for specific deployments by defining resources as operating system environment variables. At run time, the Resource Registry **\$GETENV()** function resolves resource aliases that are defined as environment variables. The **\$GETENV()** function can be used with or without Resource Registry encryption.

- **[Defining Resource Registry virtual servers](#)**

Virtual servers are created to represent the deployment environment for the Resource Registry.

- **[Defining Resource Registry values](#)**

After you have defined the resource and virtual server names for the Resource Registry, the value for each resource name and virtual server combination is defined. The resource value can be encrypted in the .mrn file as a security precaution.

Defining Resource Registry names

Resource names are defined for the currently active resource name file in the Resource Registry.

To create a resource name

1. In the navigator, right-click Resources and select Add.
The **Add** New Resource dialog appears.
2. In the **Name** field, enter the name of the resource.
3. Click OK.
The resource displays in the navigator.

Defining resource names with environment variables

You can avoid customizing resource name and configuration files for specific deployments by defining resources as operating system environment variables. At run time, the Resource Registry **\$GETENV()** function resolves resource aliases that are defined as environment variables. The **\$GETENV()** function can be used with or without Resource Registry encryption.

1. Use an operating system environment variable to define the resource. For example, on a Microsoft Windows system, use Control Panel > System > Advanced system settings > Advanced > Environment Variables. The environment variable might be case-sensitive, depending on the operating system.
2. In the Resource Registry resource name (.mrn) file, specify the Resource Value as **\$GETENV(env_var)** where **env_var** is the environment variable name. The string must not contain any spaces. The **\$GETENV()** function is not case sensitive.
If the specified environment variable is not defined, the **\$GETENV()** function resolves to an empty (zero-byte) string.

An informational log file message like the following indicates environment variable usage. For example:

```
DTXLN2154I - Fri Feb 10 07:32:21 2017 - tid: 12068 inst: -1 - Resource Registry Info : Alias [username] uses environment variable [USERNAME] (mresname.c:1243)
```

Defining Resource Registry virtual servers

Virtual servers are created to represent the deployment environment for the Resource Registry.

To create a server resource

1. In the navigator, select Servers.
2. From the **Edit** menu, choose **Add**.
The **Add** New Server dialog appears.
3. In the **Name** field, enter the name of the server resource.
It is good practice to keep the same naming conventions for the server resources in the Resource Registry as used for the server definitions in the Integration Flow Designer. See the Integration Flow Designer documentation for more information.
4. Click OK.
The server resource displays in the navigator.

Defining Resource Registry values

After you have defined the resource and virtual server names for the Resource Registry, the value for each resource name and virtual server combination is defined. The resource value can be encrypted in the .mrn file as a security precaution.

To define the resource value:

1. In the navigator, select the resource name.
2. From the **Edit** menu, choose **Edit**.
The Edit Resource dialog appears.
3. In the **Resource Value** field, enter the value of the resource for a specified server.
Note: The resource value is only validated during map execution, not during the design phase.
4. In the **Encryption** field, select ON to protect the resource name file or accept OFF as the default.
5. Click OK.

Implementing Resource Registry resource names

To use a Resource Registry resource name, enclose the resource name with the percent (%) symbol.

For example, to use a different root file path on different virtual servers without changing the system definition, the resource name **RootPath** is specified in an output card. At execution time, the resource value for %RootPath% is resolved.

- [**Resource Registry alias overview**](#)

If aliases are used with the Resource Registry, a single % sign in a command is ignored. If a command requires more than one % sign, an alias must exist that contains the % sign.

- [**Resource Registry alias usage overview**](#)

When resource aliases are used with the Resource Registry, aliases are resolved for the resources when each map is initialized.

- [**Resource Registry alias expansion in external interface functions**](#)

During Resource Registry map execution, aliases are resolved for external interface functions.

- [**Resource Registry aliases in audit and debug files**](#)

Resource Registry aliases are also used in audit and debug files.

Resource Registry alias overview

If aliases are used with the Resource Registry, a single % sign in a command is ignored. If a command requires more than one % sign, an alias must exist that contains the % sign.

For example, if a command requires %TID%, then an alias should exist that has a value of %TID%.

Aliases in commands are interpreted in three ways depending on the following:

- Aliases are used and the alias has a value
- Aliases are used but the alias name does not exist
- Aliases are not used, which means that:
 - No configuration file was specified
 - The configuration file does not exist
 - There is an invalid configuration file (or resource files)

To demonstrate alias meanings, the following table shows the values of the command cat_%verb%_dog in three different scenarios:

Action	Result
Aliases are used and verb has a value of fights	cat_fights_dog
Aliases are used but verb is not defined	cat_dog
Aliases are not used	cat_%verb%_dog

Resource Registry alias usage overview

When resource aliases are used with the Resource Registry, aliases are resolved for the resources when each map is initialized.

When the Command Server or Launcher is started, or for users of the Transformation Extender Programming Interface or Java API, if the resource configuration file does not exist or is not specified, resource aliases are not used and any aliases in any commands remain unaliased (keeping the % signs in the command).

When resource aliases are used, aliases are resolved for the following resources upon each map initialization:

Each input card's **FilePath** or **Command**

2000 bytes

Each output card's **FilePath** or **Command**

2000 bytes

Each card's backup path

255 bytes

Audit file path and name

259 bytes

Trace file path and name
259 bytes
Work file path
259 bytes
Map server location
259 bytes

Resource Registry alias expansion in external interface functions

During Resource Registry map execution, aliases are resolved for external interface functions.

During map execution, aliases can be resolved for the following external interface functions and can expand the string up to 256 bytes greater than the original length.

Function	What's Resolved	Size
EXIT	library name function name	256 bytes extra 256 bytes extra
DDEQUERY	application name topic text	256 bytes extra 256 bytes extra 256 bytes extra
RUN	map name	256 bytes extra
DBQUERY	SQL_statement mdq_filename database_name parameters	256 bytes extra 256 bytes extra 256 bytes extra 256 bytes extra
DBLOOKUP	SQL_statement mdq_filename database_name parameters	256 bytes extra 256 bytes extra 256 bytes extra 256 bytes extra
GET	adapter type adapter command	256 bytes extra 256 bytes extra
PUT	adapter type adapter command	256 bytes extra 256 bytes extra
external parser (document verification)	Location property associated with the Document type property of a type tree object	256 bytes extra

Resource Registry aliases in audit and debug files

Resource Registry aliases are also used in audit and debug files.

When you select the **Encrypt** option for Resource Registry resource aliases, the aliases appear masked (with asterisks) anywhere they are displayed in audit logs and debug files.

The masked resource alias is represented by five asterisks (*****) followed by a space, followed by the resource alias in parenthesis. The masked resource aliases could appear in the following:

- Source and target command lines/filenames
- Backup files
- Audit directories/files
- Trace directories/files
- Work file directories

Resource aliases used in **GET**, **PUT** and **RUN** rules do not appear in environment trace or log files.

- [Resource Registry trace file usage overview](#)

Use the `/runtime/Launcher/log` logging options in the config.yaml configuration file to set the Resource Registry trace options. The trace file logs encrypted aliases and displays them as masked values.

- [Resource Registry encrypted alias usage with masked command lines](#)

Resource Registry aliases can use masked command lines in some system components.

Resource Registry trace file usage overview

Use the `/runtime/Launcher/log` logging options in the config.yaml configuration file to set the Resource Registry trace options. The trace file logs encrypted aliases and displays them as masked values.

Resource Registry encrypted alias usage with masked command lines

Resource Registry aliases can use masked command lines in some system components.

Masked command lines are displayed in the following areas:

- Audit log
 - Execution summary
 - Map settings
 - Data (card) settings
- Launcher log (**Launcher.txt**)
 - Map errors
 - Map warnings
 - System configuration information
- Compound****.log
- GPF/abort logs

Resource Registry encryption overview

You can encrypt resource values that contain sensitive data, such as user credentials and database passwords. The Resource Registry uses a secure encryption key that it stores separately from the resource values. This means that you can share a resource name file but withhold the key file to protect confidential information.

The Resource Registry uses the Advanced Encryption Standard (AES) algorithm to encrypt and decrypt resource alias values by using a secure encryption key.

Encrypting a resource value:

1. Generates an encryption key.
2. Assigns an ID to the key.
3. Encrypts the key itself, creating the master encryption key.
4. Generates a master key (.mkf) file and stores the master encryption key in it.
5. Stores the key ID and .mkf file name and path in the resource name (.mrn) file.

During map execution, IBM Transformation Extender uses the master encryption key that is identified in the .mrn file to decrypt the resource value.

You can specify a custom passphrase when you generate a new .mkf file. The passphrase lets you regenerate the master encryption key if the .mkf file is damaged or lost. When you don't supply a custom passphrase, the Resource Registry randomly generates one. A randomly generated passphrase is more secure. You cannot regenerate the master encryption key with a randomly generated passphrase.

- [Resource Registry name files and encryption keys](#)

Each Resource Registry master encryption key has a numeric key ID that uniquely identifies it. A resource name (.mrn) file that has encrypted values specifies the key ID and file name of its master encryption key.

- [Resource Registry master key file and encrypted value display](#)

The presence of the master key file for an encrypted resource determines whether the resource value displays as plain text or as an encrypted string.

- [Encrypting and resetting Resource Registry values](#)

You can encrypt a resource value, remove resource encryption, or reset encrypted values. You can convert a legacy resource name (.mrn) file to use the Advanced Encryption Standard. With the correct passphrase, you can regenerate a lost or damaged master encryption key.

Resource Registry name files and encryption keys

Each Resource Registry master encryption key has a numeric key ID that uniquely identifies it. A resource name (.mrn) file that has encrypted values specifies the key ID and file name of its master encryption key.

The default master key file name is itx.mkf, located in the .mrn file directory.

For example, the following .mrn file is encrypted by the key with ID 6734, which is stored in the itx.mkf file:

```
<MRN version="1.0" key_id="6734" key_file="itx.mkf">
...
<Resource>
  <Name>db_password</Name>
  <Value Server="Production" encrypt="ON"
id="_home_markdown_jenkins_workspace_Transform_in_SSVD8_11.0.1_com.ibm.websphere.dtx.rsrcreg.doc_references_r_adaptref_master_
key_file_5623" iv="240b35b4358e185a071548a0b0ac7d22">
9ad3d263a52819cf944cb4b20106784e0747ac006e7e8d5af4053cd06ed64469</Value>
  <Value Server="Development" encrypt="OFF">dev_password</Value>
</Resource>
...
</MRN>
```

In the master key file, the entry for the master encryption key with ID 6734 has a format that is similar to the following example:

```
<MasterKeys>
  <entry>
    <cipher>AES-256-CBC</cipher>
    <key>0be4d263a52819cf944cb4b20106784e0747ac006e7e8d5af4053cd06ed64460</key>
    <iv>351c464c5469f296b182659a1c1ad8e3</iv>
    <id>6734</id>
  </entry>
</MasterKeys>
```

A master key file can contain multiple master encryption keys. You manually edit a master key file to append keys to it or remove keys from it.

Resource Registry master key file and encrypted value display

The presence of the master key file for an encrypted resource determines whether the resource value displays as plain text or as an encrypted string.

When the .mkf file is present on the computer, the Resource Registry displays encrypted values as plain text ("in the clear"). To allow access to encrypted values in an .mrn file, you can either:

- Provide the master key (.mkf) file that decrypts the resource values.
- Provide the passphrase that regenerates the .mkf file.

Alternatively, you can withhold the .mkf file and passphrase to protect sensitive resource values. When the .mkf is not present or does not contain the correct master encryption key, the Resource Registry displays encrypted values as encrypted strings. Without the .mkf file, you can use the Resource Registry to view the read-only encrypted values or to clear the values and enter new ones. Optionally, you can encrypt the new values with a new key in a new .mkf file.

Encrypted resource values always display as encrypted strings when you open the .mrn file in a text editor.

On UNIX® systems, only the user who generates the .mkf file has permission to read and write to it. Other users cannot read or write to the .mkf file.

Encrypting and resetting Resource Registry values

You can encrypt a resource value, remove resource encryption, or reset encrypted values. You can convert a legacy resource name (.mrn) file to use the Advanced Encryption Standard. With the correct passphrase, you can regenerate a lost or damaged master encryption key.

- [Encrypting a Resource Registry value and generating a master key file](#)

Encrypting a resource value in a resource name (.mrn) file for the first time creates a master encryption key and the master key (.mkf) file where the key is stored. When you subsequently encrypt other resource values in that .mrn file, the Resource Registry uses the same master encryption key and .mkf.

- [Converting a Resource Registry name file to AES encryption](#)

You can convert a legacy resource name (.mrn) file that contains encrypted resources to the Advanced Encryption Standard (AES) encryption format by using a new or existing master encryption key. If you do not want to convert to AES format, you can continue to use your existing .mrn files without converting them.

- [Resetting encrypted Resource Registry values](#)

When the master key (.mkf) file is present with Resource Registry, you control encryption at the individual resource level. When the .mkf file is not present and you reset the encryption of a single resource value, the Resource Registry resets the encryption of all of the values in the .mrn file. The Resource Registry clears the encrypted strings and sets the encryption flags to OFF. It also removes the master key file name and key ID from the .mrn file.

- [Regenerating a Resource Registry master key file](#)

You can regenerate a lost or damaged Resource Registry master encryption key with its custom password.

Encrypting a Resource Registry value and generating a master key file

Encrypting a resource value in a resource name (.mrn) file for the first time creates a master encryption key and the master key (.mkf) file where the key is stored. When you subsequently encrypt other resource values in that .mrn file, the Resource Registry uses the same master encryption key and .mkf.

1. In the Resource Registry, edit the resource that you want to encrypt or the virtual server that includes the resource.
2. In the Edit window, set the Encryption field to ON and click OK.
3. Click Yes to enable the Advanced Encryption Standard format.
4. Select Change master key file or regenerate master key.
5. In the Encryption Master Key window:
 - a. Select Generate a new master key.
 - b. Accept the default master key file name itx.mkf, or specify your own master key file name and path.
The path to the master key file must be relative to the .mrn file location.
 - c. Choose whether to use a custom passphrase:
 - If you do not select Use custom passphrase, the Resource Registry generates the key with a random passphrase. A randomly generated passphrase is more secure, but you cannot use it to regenerate a master encryption key.
 - To create an encryption key that you can regenerate, select Use custom passphrase. Enter a passphrase up to 32 bytes in length in the Passphrase field.
 - d. Click OK.

The Resource Registry encrypts the resource value and creates the .mkf file.

6. Save the changes to the .mrn file.

Converting a Resource Registry name file to AES encryption

You can convert a legacy resource name (.mrn) file that contains encrypted resources to the Advanced Encryption Standard (AES) encryption format by using a new or existing master encryption key. If you do not want to convert to AES format, you can continue to use your existing .mrn files without converting them.

1. Open the legacy .mrn file in the Resource Registry.
2. Open the encrypted resource or server and click OK to display the Encryption prompt.
If you click Cancel, the .mrn file retains the legacy encryption format.
3. Click Yes to enable AES encryption format.
 - Select Use an existing master key to browse to an existing master key file (.mkf) and choose a key ID.
 - Select Generate new master key and follow the procedure to generate a new master encryption key and .mkf file.
4. Click OK.

Related tasks

- [Encrypting a Resource Registry value and generating a master key file](#)
-

Resetting encrypted Resource Registry values

When the master key (.mkf) file is present with Resource Registry, you control encryption at the individual resource level. When the .mkf file is not present and you reset the encryption of a single resource value, the Resource Registry resets the encryption of all of the values in the .mrn file. The Resource Registry clears the encrypted strings and sets the encryption flags to OFF. It also removes the master key file name and key ID from the .mrn file.

1. Use the Resource Registry to open an .mrn file that contains encrypted values on a computer where the .mkf file is not present.
 2. Open an encrypted resource or a server that contains encrypted resources.
 3. Click Reset encrypted values to empty plain text and click OK.
 4. Save the resource or server file.
-

Regenerating a Resource Registry master key file

You can regenerate a lost or damaged Resource Registry master encryption key with its custom password.

1. Use the Resource Registry to open an encrypted resource or its server.
 2. Click Change master key file or regenerate master key.
 3. In the Encryption Master Key window:
 - a. Click Generate new master key.
 - b. Click Use custom passphrase.
 - c. Enter the passphrase of the missing or damaged master key file.
 4. Click OK to create the master key file and close the resource or server.
-

Resource configuration files overview

Resource configuration files (**.mrc**) specify the associated resource name file and which virtual servers are active for a map server.

- [**Creating resource configuration files**](#)
After defining your resources and their associated virtual servers, you need to create a resource configuration file.
- [**Creating a Launcher resource configuration file**](#)
After defining your resources and their associated virtual servers, you need to create a resource configuration file.

After defining your resources and their associated virtual servers, you need to create a resource configuration file.
- [**Transformation Extender Programming Interface and Java API resource configuration files**](#)
After defining your resources and their associated virtual servers, you need to create a resource configuration file.
- [**Saving resource configuration files**](#)
After defining your resources and their associated virtual servers, you need to create and save resource configuration files.
- [**Resource configuration files for map servers**](#)
After defining your map server, you need to create a resource configuration file.

Creating resource configuration files

After defining your resources and their associated virtual servers, you need to create a resource configuration file.

After you have defined your resources and their associated virtual servers, the next step is to create a configuration file. This file is used by the Command Server, Launcher, Transformation Extender Programming Interface, Java API, and Map Designer in determining which virtual servers are active for that map server when executing maps.

The resource configuration file is the key to tying everything together. This file defines the active virtual server (in a resource name file), for the map server and the available resources for that virtual server.

The .mrc file contains specifications for the map server such as:

- Active virtual server(s) for a map server
 - Associated.mrn file
- Resource name files are associated with the Launcher at the system level.

The specified active resource configuration file is used at runtime for dynamic resource resolution. Because an .mrn file and its file path are specified, the .mrc file is platform-dependent.

To create a resource configuration file

1. In the navigator, select Configuration Files.
2. From the **File** menu, choose **New**.
The Save As dialog appears.
3. Specify the location of the configuration name file by browsing your file structure.

4. In the **File name** field, enter the name of the configuration file.

Note: A default filename, resource.mrc, is specified in the config.yaml file. If you use a different filename and want to specify the .mrc file for a map server through the .ini file, you must manually modify the .ini file with the correct filename. See "[Initialization File](#)" for more information.

5. Click Save As.

The resource configuration file appears in the navigator.

Creating a Launcher resource configuration file

After defining your resources and their associated virtual servers, you need to create a resource configuration file.

A resource name file (**.mrn**) and active virtual server are associated with the Launcher at the system level. Launcher system files (**.msl**) are created using the Integration Flow Designer.

At runtime, if an **.mrn** file is not specified for Launcher, the **.mrn** file specified for **Global** is used by default. If **.mrn** files are specified for both Launcher and **Global**, the **.mrn** file specified for Launcher takes precedence.

Adding a system for the Launcher

1. In the navigator, select Launcher.
2. From the **Edit** menu, choose **Add**.

The Add New System dialog displays.

3. Click **Browse** to select the system file to associate with the Launcher.
4. Click OK.

The associated system displays in the navigator.

Activating a server for the Launcher

1. In the navigator, select the system.
2. From the **Edit** menu, choose **Edit**.

The Edit Resources dialog displays.

3. Click Add.
4. The Select dialog displays.

5. Select the resource name file (**.mrn**) to associate with the map server.
6. In the **Active Virtual Server** field, select the server to activate for the map server.

The specified **.mrn** file and active virtual server are associated with the map server.

Creating a Command Server resource configuration file

After defining your resources and their associated virtual servers, you need to create a resource configuration file.

A resource name file is used by the Command Server in determining which virtual servers are active when executing maps.

At runtime, if the **.mrn** file is not specified for Command Server, the file specified for **Global** is used. If **.mrn** files are specified for both Command Server and **Global**, the Command Server file takes precedence.

To activate a server for the Command Server

1. In the navigator, select Command Server.
2. From the **Edit** menu, choose **Edit**.

The Edit Resources dialog displays.

3. Click Add.
4. The Select dialog displays.

5. Select the resource name file (**.mrn**) to associate with the Command Server.
6. In the **Actual Virtual Server** field, select the server to activate for the Command Server.

The specified **.mrn** file and active virtual server are associated with the Command Server.

Transformation Extender Programming Interface and Java API resource configuration files

After defining your resources and their associated virtual servers, you need to create a resource configuration file.

A resource name file (**.mrn**) is used by the Transformation Extender Programming Interface and Java API in determining which virtual servers are active for a map server when executing maps.

To associate a resource name file and activate a server for the Transformation Extender Programming Interface or Java API, follow the instructions outlined in section "[Command Server](#)". However, select the **Global** object instead of the Command Server object when associating .mrn files and active virtual servers. The **Global** object represents the Map Designer, Transformation Extender Programming Interface, and Java API map servers.

Saving resource configuration files

After defining your resources and their associated virtual servers, you need to create and save resource configuration files.

After you have created the configuration file and associated .mrn file(s) and active server(s) with the map server, you need to save the .mrc file.

To save the configuration file

1. In the navigator, select the resource configuration file.
2. From the **File** menu, choose **Save**.

The resource configuration file is saved.

Resource configuration files for map servers

After defining your map server, you need to create a resource configuration file.

A configuration file is specified for a map server using one of the following methods:

- Menu option in the Map Designer or Launcher Administration
- Transformation Extender Programming Interface
- Java API
- config.yaml initialization file
- [Map Designer resource configuration file](#)
You need to create a resource configuration file for the Map Designer.
- [Launcher resource configuration file](#)
You need to create a resource configuration file for the Launcher.
- [Transformation Extender Programming Interface resource configuration file](#)
You need to create a resource configuration file for the Transformation Extender Programming Interface (TX PI).
- [Java API resource configuration file](#)
You need to create a resource configuration file for the Java API.
- [Initialization resource configuration file](#)
There are various scenarios in which you need to modify the initialization file (config.yaml).

Map Designer resource configuration file

You need to create a resource configuration file for the Map Designer.

An .mrc file can be specified for maps as a run option. When a map runs, the .mrc file defers to the .mrn file, and the virtual server used is derived from the **Global** setting.

To access run options in the Map Designer, from the Design Studio, select **Window** > **Preferences** > **Transformation Extender** > **Map** > **Run Options**.

See the Map Designer documentation for more information.

Launcher resource configuration file

You need to create a resource configuration file for the Launcher.

The associated .mrc file for the Launcher is specified on the General tab in the Launcher Administration interface.

See the Launcher documentation for more information.

Transformation Extender Programming Interface resource configuration file

You need to create a resource configuration file for the Transformation Extender Programming Interface (TX PI).

The associated .mrc file is specified using the **mpiInitAPI (lpszConfigFile)** initialization function or the **mpiInitAPIEx (lpszResourceConfigFile)** initialization function when invoking maps using the Transformation Extender Programming Interface.

See the Transformation Extender Programming Interface documentation for more information.

Java API resource configuration file

You need to create a resource configuration file for the Java API.

The Java API uses the MMap Java™ class and the initializeAPI(java.lang.String resourceConfigFile) method to specify the Resource Registry .mrc configuration file.

See the Java API documentation for more information.

Initialization resource configuration file

There are various scenarios in which you need to modify the initialization file (config.yaml).

If an .mrc file has not been specified for the Command Server or Launcher through an application option, then the map server looks in the config.yaml file for the specified .mrc file. A default filename, resource.mrc, is specified in the config.yaml file. If you create an .mrc file using a different name, and do not specify the filename through an application option, then you need to manually modify the configuration file.

In the config.yaml file, the .mrc file is specified in the **/runtime/Command Server/resourcefile** path for the Command Server and in the **/runtime/launcher/ResourceCfgFile** path for the Launcher. To determine where to specify the .mrc file, search for the string **ResourceCfgFile** and modify the current default .mrc filename.

See the Launcher documentation for more information.

Execution maps

This documentation includes information about the various ways to use execution commands and their options when executing maps. Execution commands are used to specify how to execute a map.

- [Command Server overview](#)
- [Using Command Server commands](#)

Command Server overview

Use execution commands to override the map settings or card settings in a compiled map when a map is run using one of the following methods:

- from a command line prompt
- from the Map Designer
- from the Command Server user interface
- using the `RUN()` function in a map rule
- using the API

Use the map settings and input and output card settings of the Map Designer or the execution settings in the Integration Flow Designer to define map execution. These map execution settings are included in the compiled map file. Many settings compiled into the map can be overridden (or partially overridden) using executions commands and options.

Some execution commands are limited because they can only be used with a Command Server and cannot be used from within a `RUN()` function or using the Platform API. Also, some commands are not available on all platforms. See ["Command Availability"](#) for more information.

- [Coordinating execution commands with compiled settings](#)
- [Compiled map files](#)
- [Command files](#)

Coordinating execution commands with compiled settings

The following table lists valid execution commands and the **MapSetting** or input/output card settings that they override.

- [Map settings](#)
- [Card settings](#)

Map settings

Execution Command	Map Setting
MapAudit (-A)	MapAudit
Close Window (-B)	-
Century (-D)	Century
Fail on Warnings (-F)	Warnings
Ignore Validation Options (-G)	

```
Validation > RestrictionError, SizeError, PresentationError
List (-I)

    Retry
Ignore Warnings (-Z)
    Warnings
```

Card settings

```
Execution Command
Card Setting
Input Overrides (-I)
WorkFiles (W)
    SourceRule > FetchAs > WorkArea
Retry (R)
    SourceRule > GET > Retry
Rollback (B)
    SourceRule > GET > Transaction > onFailure
Delete (X)
    SourceRule > GET > Transaction > onSuccess
Output Overrides (-O)
Retry (R)
    TargetRule > PUT > Target > Retry
Append (+)
    TargetRule > PUT > Transaction > Target > onSuccess
Delete (X)
    TargetRule > PUT > Transaction > onSuccess
Rollback (B)
    TargetRule > PUT > Transaction > onFailure
```

Compiled map files

You can create compiled map (.mmc) files using the Map Designer, Integration Flow Designer, or Command Server commands.

- [Map Designer](#)
 - [Integration Flow Designer](#)
-

Map Designer

Using the Map Designer, specify how you want each map to run. These specifications, which are compiled into the map file, include map settings and card settings, as well as execution command overrides for `RUN()` functions which execute a map from a map rule. See the *Map Designer* documentation for more information about map and card settings and the *Functions and Expressions* documentation for information about the `RUN()` function.

Integration Flow Designer

Using the Integration Flow Designer, you can create systems of maps and define execution settings, map settings, and input/output settings. These settings are recorded into the compiled map file that results from building the map within the Integration Flow Designer.

If the system has an execution mode of Command, a command file can be generated that can be executed with a Command Server. Edit this command file using the appropriate execution commands and options.

The following is an example of a command file generated by the Integration Flow Designer for a system named **Inbound EDI**:

```
;;
;;
; Date:   Wed Jun 16 18:15:15 2001 (Version 6.0(126))
; File:  D:\MapsAndTrees\ANSIACK\ProcessEDI.msd
```

```

; System: Inbound EDI
;
; Component: ReceiveEDI
; Map File: D:\MapsAndTrees\ANSIACK\Audit997.mms
; Executable Map: ReceiveEDI
;
D:\MapsAndTrees\ANSIACK\ReceiveEDI.mmc
    -GR
;
; Component: ACK997
; Map File: D:\MapsAndTrees\ANSIACK\Audit997.mms
; Executable Map: ACK997
;
D:\MapsAndTrees\ANSIACK\ACK997.mmc
    -OF1BR10:2 'OutboundACK.EDI'
;
; End System: Inbound EDI
;
```

Notice that the execution settings defined in an Integration Flow Designer command file correspond with the execution commands and options. See the *Integration Flow Designer* documentation for more information.

Command files

You can create command files that contain listings of maps to execute with execution commands that specify how you want each map to run. A command file is a text file that can contain multiple maps to run, as well as multiple execution commands and options for each map; however, a command file cannot run another command file.

Using Command Server commands

When you run a map, you can:

- Override sources and targets for the cards used in the map
- Create trace and audit log files
- Control a variety of characteristics of the run-time environment

The execution commands entered when you run a map do not permanently affect the compiled map file.

The command options that you specify override the settings compiled into the map file. If you do not use a specific execution command, the corresponding map and card settings compile into the map.

- [General rules for execution commands](#)
- [From a command line](#)
- [From the Platform API](#)
- [From a RUN\(\) function in a map rule](#)

General rules for execution commands

The general rules that apply when specifying execution commands are:

- Each execution command must begin with a hyphen.
- At least one space is required between commands (for example, `-T -v`).
- There are no spaces within an option except for the commands that allow you to override sources and targets (for example, `-I` and `-O`), which require a space before the source or target name.
- If a source or target name contains a space, enclose the entire name in single quotes.
- Execution commands and options are not case-sensitive.
- If spaces or single quotes can occur in echoed data specified using the `-IE` execution command, the size option should be used (`-IExs`).
- Multiple options can be specified for a single map.
- Command files can contain multiple lines. Line breaks can be used to replace of the required space that must exist between commands. The line breaks are converted to spaces before to processing.

From a command line

You can execute a particular map or a command file containing a list of maps to execute from the command line of the system hosting your Command Server. The syntax is:

```
DTXCMDSV {map [exec_command...] | @command_file}...
```

Ensure your current directory is where the Command Server is located, or specify the relative path or full path, as applicable, when entering the command.

Option

Description

DTXCMDSV

Specifies the name of the Command Server execution command for both UNIX and Windows platforms.

map Specifies the name of the compiled map (.mmc) file to run. If applicable, include the full path or a relative path to the directory that contains the map file.

exec_command Specifies any execution command and its associated options that you want to use to override the settings compiled into the map file when the specified map is run.

command_file Specifies the name of a command file that contains a list of maps to execute. If applicable, include the full path or a relative path to the directory that contains the command file.

- [Command line help](#)

Command line help

You can access Help from the command line by typing:

```
DTXCMDSV -?
```

From the Platform API

To run the server using a Platform API, as part of an argument to the **RunMap()** function, specify:

```
map [exec_command...] |@command_file
```

Option	Description
<i>map</i>	Specify the name of the compiled map (.mmc) file to run. If applicable, include the full path or a relative path to the directory that contains the map file.
<i>exec_command</i>	Specify any execution command and its associated options you want to override the settings compiled into the map file when the specified map is run.
<i>command_file</i>	Specify the name of a command file that contains a list of maps to execute. If applicable, include the full path or a relative path to the directory that contains the command file.

From a RUN() function in a map rule

To execute a map from a map rule, use the **RUN()** function as follows:

```
RUN ( "map" , "exec_command..." ] )
```

Option	Description
<i>map</i>	Specify the name of the compiled map (.mmc) file to run. If applicable, include the full path or a relative path to the directory that contains the map file.
<i>exec_command</i>	Specify any execution command and its associated options you want to override the settings compiled into the map file when the specified map is run.

Execution commands

This documentation contains information about the execution commands and associated options, including the syntax of each command and its particular usage.

Command availability

Some commands are limited because they can only be used with a Command Server and cannot be used from within a `RUN()` function or using the Platform API. Also, there are some commands that are not available on all platforms. The Integration Flow Designer, the Map Designer, and the Command Server have a user interface for these commands where they apply.

The following table lists the execution commands and where they can be executed (Y), as well as those commands that have limited platform availability.

Execution Command	Command Server	RUN Function	Platform API	Platform Availability
MapAudit (-A)	Y	Y	Y	
Close Window (-B)	Y			Windows only
Century (-D)	Y	Y	Y	
Fail on Warnings (-E)	Y	Y	Y	
Ignore Validation (-G)	Y	Y	Y	
Application (-IA)	Y	Y	Y	
Database (-ID)	Y	Y	Y	
Echo (-IE)	Y	Y	Y	
File (-IF)	Y	Y	Y	
Message (-IM)	Y	Y	Y	
List Sources/Targets (-L)	Y			Non-Windows only
Initialization File Override (-N)	Y			
Application (-OA)	Y	Y	Y	
Database (-OD)	Y	Y	Y	
Echo (-OE)	Y*	Y	Y	
File (-OF)	Y	Y	Y	
Message (-OM)	Y	Y	Y	
WorkSpace PageSize (-P)	Y	Y	Y	
Refresh Status (-R)	Y			
MapTrace (-T)	Y	Y	Y	
Stop Validation (-V)	Y	Y	Y	
WorkSpace (-W)	Y	Y	Y	
Retry (-Y)	Y	Y	Y	
Ignore Warnings (-Z)	Y	Y	Y	

MapAudit (-A)

Use the MapAudit execution command (-A) to control the creation of audit log information. Using this command, audit information is recorded which can include data audit information and execution audit information.

When used *with* other specified options, the **MapAudit** settings specified with the **MapAudit** command (-A) override *all* **MapAudit** settings compiled into the map. When used *without* other specified options, no audit log is produced.

```
-A[D[R|W]{1|2}][E[R|W]][B[R|W]][C[R|W]][P[R|W]]
[M[S] | [U] [+!+][={file|dir}]]
```

For information about the audit log files, see the *Map Designer* documentation.

Option

Description

D

Include data audit information in the audit log. The recorded information is based on the **MapAudit** settings configured in the Map Designer for a particular map. The sub-options for D include: R, W, and 1 or 2

R

Generate audit files each time the map is run only if the outcome of the map's execution is an error condition. Used with the burst audit data information (D), execution summary audit information (E), burst execution information (B), card (data) settings (C), and map settings (P) options.

W

Generate audit files each time the map is run only if the outcome of the map's execution is a warning or an error condition. Used with the burst audit data information (D), execution summary audit information (E), burst execution information (B), card (data) settings (C), and map settings (P) options.

1|2

1 is the audit code for fail size (**WrongSize**).

2 is the audit code for fail minimum size or fail maximum size (**TooLongTooShort**).

Note If using the 1 or 2 option as well as the R or W option with the D sub-option, the 1 or 2 must follow the R or W. For example:

-AEDW2

This example represents SummaryAudit Execution, SummaryAudit Data, OnWarning, and TooLongTooShort.

B

The burst execution information includes:

- the burst return value
- the time it took for the burst to execute
- the number of bytes, the adapter return value, and the content return value for each card

Example:

```
<ExecutionLog burstreturn="0" ElapsedSec="0.6846">
  <inputstatus card="1" bytes="4904" adapterreturn="0" contentreturn="0"/>
  <inputstatus card="2" bytes="270" adapterreturn="0" contentreturn="0"/>
  <outputstatus card="1" bytes="18695" adapterreturn="0" contentreturn="0"/>
</ExecutionLog>
```

E

The execution summary audit information includes:

- return codes resulting from the map execution
- execution time (in seconds)
- command line used to execute the map
- number of input objects found and output objects built (Command Server only)
- details about the map sources and destinations
- work file names and sizes

C

The card (data) settings audit information includes:

- the data settings for sources and target cards

P

The map settings audit information includes:

- the map settings

M

The memory setting can be used only when the map is run by the `RUN()` function or an API. If memory is set, audit information is stored in memory and appended to the last set of data returned during map execution.

When the map is run by a Command Server or Launcher, this setting is ignored and the audit log is created in a file in the map directory, using the `<mapname>.log` naming convention.

If the audit in memory fails or there is insufficient available memory, a `Disk write error or Not enough memory to execute map` message can be returned.

S

Only use with the memory option (M). This option prefixes the audit data with a text number indicating the size (in bytes) of the audited data followed by a space. This option causes the resulting audit log entry to be returned as an ASCII number followed by a space, then followed by the specified number of bytes of data. This helps to distinguish it from multiple character strings in the returned data when at least one output and the audit log are echoed.

For example, if used in a `RUN()` function:

```
RUN ("mymap.mmc","-OE3S -ADEMS")
```

If the data resulting from output card #3 was This and That, the string returned by this `RUN()` function is:

```
13 This and That1031 BEGIN RUN Function for Windows....
```

U

Generate audit files with unique names each time the map is run. The name of the audit log for top-level maps is:

```
mer_mapname_processkey_mapcounter_hostname.bak
```

where `processkey` is a combination of the process id from the operating system and the time the process started, `mapcounter` is a value representing each unique instance of a map within the same process, and `hostname` is the host name of the computer where Transformation Extender is running.

Run maps use:

```
run_mapname_processkey_mapcounter_hostname.bak
```

Unique names are globally unique; each process has a unique value.

Unique log file names are typically used in a multi-threaded environment so that more than one instance of the same map can run at the same time. In a command environment, unique log file names are typically used when more than one command specifies the same map to run and you do not want one log file to overwrite the other. Or, use this option when multiple servers run the same map. This option prevents one log file from overwriting another log file.

This option cannot be used with the append option (+).

+

Each time the map is run, append specified information to the audit log. If no audit log exists at the start of map execution, an audit log is created. Turn off the + option. Discontinue appending specified information to the audit log. This option cannot be used with the U option for unique names.

!+

Turn off the **+ option**. Discontinue appending specified information to the audit log. This option cannot be used with the **U** option for unique names.
=file/dir
Specify a file name for appending audit information or specify a full directory path and file name in which you want the audit log file created. By default, the audit log file is created in the same directory as the compiled map (.mmc) file, using the <mapname>.bak naming convention.

- [Examples using MapAudit \(-A\)](#)

Examples using MapAudit (-A)

```
-AD
    BurstAudit Data
-AD1
    BurstAudit Data, WrongSize
-AD2
    BurstAudit Data, TooLongTooShort
-AB
    BurstAudit Execution
-AE
    SummaryAudit Execution
-AC
    SettingsAudit Data
-AP
    SettingsAudit Map
-ABD
    BurstAudit Execution and BurstAudit Data
-AEB
    SummaryAudit Execution and BurstAudit Execution
-ABDE
    BurstAudit Execution, BurstAudit Data, and SummaryAudit Execution
-AEDW2
    SummaryAudit Execution, SummaryAudit Data, OnWarning, and TooLongTooShort
-AER
    SummaryAudit Execution and OnError
-ADW
    BurstAudit Data and OnWarningOrError
AERCWPW
    SummaryAudit Execution and OnError and SettingsAudit Data and OnWarningOrError and SettingsAudit Map and OnWarningOrError
-ADR2BW=c:\install_dir\mymap.log
    SummaryAudit Execution, and SummaryAudit Data, OnError, TooLongTooShort, and BurstAudit Data, OnWarningOrError written to c:\install_dir\mymap.log
-ADEU=/install_dir
    AuditData and AuditExecution using the unique filename mechanism and writing the log file to the install directory
-ADER+=mymap.log
    AuditData and AuditExecution. If the map execution failed, the data audit information (AuditData) and execution summary and audit information (AuditExecution) content is appended to the mymap.log file that is in the map directory.
-AERM
    AuditExecutionSummary in memory, only if map OnExecutionFailure
```

Close Window (-B)

When executing a map using a Command Server for Windows or AS/400 OS/400®, use the Close Window execution command (-B) to exit the Command Server application after the map has completed.

-B [I]

Option	Description
I	When using a Command Server for Windows, specify to exit the Command Server application only when the map completes successfully.

Century (-D)

Use the Century execution command (-D) to specify the start of a 100-year range used to supply a missing century portion for a Date & Time. This command is useful for the transition to the year 2000 so that dates with a YYMMDD format can be interpreted properly for the correct century.

-D [ccyy|0]

Option

Description

ccyy	A missing century for a Date & Time item is derived based on the ccyy value.
0	Turn off the Century execution command.

For example, if you specify **-D1960**, a YYMMDD-formatted date between 60mmdd and 99mmdd is interpreted as having a century value of 19. Dates between 00mmdd and 59mmdd are interpreted as having a century value of 20. In this example, data with a date of 580101 is assigned a century of 20; however, data with a date of 600101 is assigned a century of 19.

Fail on Warnings (-F)

Use the Fail on Warnings (-F) execution command to specify that the map should fail when any of the selected warning codes are returned. When used *with* one or more warning codes, a map-failed condition is returned for those warning codes. When used *without* other options specified, all warning codes result in a map-failed condition. Using this command impacts **OnSuccess** settings, **OnFailure** settings, and so on.

-F[!][warning_code[:warning_code...]]

Option

Description

!

Use to specify warning codes that remain in their default states, that is, as warnings, when they are detected, and as a result, do not cause the mapping process to return a map failed message.

When used with **-F** only, for example, **-F!**, a map-failed condition is returned if any of the warning codes is detected.

warning_code

Specify the warning codes that the mapping process needs to detect, and, depending on how the other Fail on Warnings command options are set, use to determine if it should return a map failed message. Valid warning code selections include: 14, 18, 21, 26, 27, 28, 29, and 34.

- [Examples using Fail on Warnings \(-F\)](#)

Examples using Fail on Warnings (-F)

-F

A map-failed message is returned when any of the warning codes is encountered.

-F!

A map-failed message is returned when any of the warning codes is encountered.

-F18

A map-failed message is returned when a Page Usage Count Error (18) is encountered.

-F!18

Excluding the Page Usage Count Error (18), a map-failed message is returned for all of the other warning codes.

-F18:27:28

A map-failed message is returned when any of the specified warning codes is encountered (18, 27, or 28 in this case).

-F34

A map-failed message is returned when a Too Few Pages Requested, More Allocated Error (34) is encountered.

If the **-F** command is used and the map fails due to the cause associated with the specified warning, the execution audit includes an Error map status with the appropriate warning code preceded by a minus sign and the map-failed message.

For example:

```
<Summary MapStatus="Error" Return="-28">
  <Elapsed TimeInSec>0.0898</Elapsed TimeInSec>
  <Message>Input type contains errors.</Message>
  <CommandLine>'install_dir\example\ansiack\receiveEDI.mmc'
  </CommandLine>
  <ObjectsFound>0</ObjectsFound>
  <ObjectsBuilt>0</ObjectsBuilt>
</Summary>
```

When using this command, you cannot specify the same warning code using the **-Z** command. If you do, the setting of the latter command in the command line is used. For example, if your command line included **-F18:26 -Z18:27:28**, a return code of 18 (Page Use Count error) would be ignored because the Ignore Warnings command (**-Z**) follows the Fail on Warnings command (**-F**).

A map-failed message is returned when any of the warning codes is encountered for both the **-F** and **-F!** commands.

Ignore Validation Options (-G)

Use the Ignore Validation Options execution command (-G) to specify the item properties, if any that should be ignored during validation. When used *with* other specified options, only those item properties are ignored. When used *without* other specified options, no item properties are ignored.

-G[R][P][S][T][C]

Option

Description

R

Ignore restrictions for all items appearing in the input data.

Restrictions of syntax items are not ignored because they are used in determining the value of a syntax object.

P

Ignore the presentation settings of items.

For example, if a number is defined as an integer but it appears in the data as a decimal number, it validates anyway.

If the Ignore command is used and an item has an invalid presentation, it is mapped as if it were NONE. However, if the input is converted to text using the TEXT function, it is mapped.

S

Ignore the minimum and maximum size of items that appear in delimited data.

For example, if an item is defined as having a minimum of three bytes, but the data contains only two bytes, it validates anyway.

T

Ignore restrictions for all items appearing in the input data with no warnings.

C

Prevents a component rule from being evaluated when either:

- The group does not include a component that has a group identifier attribute.
- The component rule occurs on a component that is after the component that has the group identifier attribute.

Use this option to run a map without validating component rules, for example, when your data does not conform exactly to a particular type tree.

Input Source Override - Application (-IA)

Use the Input Source Override - Application execution command (-IA) to override specifications in the compiled map file for a specific input card for a single execution of a map. Only those adapter settings specified are used to override the settings compiled into the map.

For example, if the WorkArea option (w or !w) is not specified, the **WorkArea** setting compiled into the map is used.

```
-IA[alias]card_num[M['filename']]  
[W|!W][Rcount:interval][B][EN][EA][EF][ES][EW]  
[AF][AI][PM][PB][PC][F'n'][U][!U]  
[K['filename']]|[+'filename']|[U'filepath']|[U]|  
[1'filename']|[+filename']|[U1'filepath']|[U1]  
[library],[function],[application_command_line]|  
{src-adptr-cmd|..}
```

Option

Description

alias

This is the adapter alias for the specific application adapter. For example, **FTP** is the adapter alias for the FTP adapters. If the *alias* command option is not used, you must use *library*, *function*, and *application_command_line*. If *alias* is used, you must use *src-adptr-cmd* or *".*. See the appropriate adapter documentation in the *Resource Adapters* documentation.

card_num

This is the card number of the input to override.

M'filename'

This is the metadata (XML schema or DTD) file location of the input card to override.

Specify *filename* as an absolute path along with the file name and enclosed in single quotes, for the metadata when parsing input XML. An example is:

```
M'k:\my_project_folder\myschema.xml'
```

Use this command option to override the Metadata location setting for the root type specified on an input card in the Map Designer GUI.

W

After a map runs for the first time, the work area created for the input card is not deleted. For subsequent executions of the same map, the data for this input card is not validated and the work area information for the card is retrieved from the existing work area.

!W

The work area for input is created when map execution begins.

Rcount:interval

Specify **Retry** settings. If the source is unavailable, the adapter will attempt to access the source as many times as specified by the *count* setting at the interval specified by the *interval* setting.

count number of attempts to access the application

interval number of seconds to wait between attempts

Note: If this option is not specified, the **Retry** settings compiled into the map are used. To eliminate adapter retry, specify **RO:0**.

B

If the map, burst, or card does not successfully complete, roll back any changes that were made to this data source.

Note: If this option is not specified, the **OnFailure** setting compiled into the map is used.

EN

Use this command option to never call the external parser for document verification.

EA

Use this command option to always call the external parser for document verification.

EF

Use this command option to call the external parser for document verification only if validation fails.

ES

Use this command option to call the external parser for document verification only if validation is successful.

EW

Use this command option to call the external parser for document verification only for the well-formed document.

AF

Use this command option to fail on adapter warnings.

AI

Use this command option to ignore adapter warnings.

PM

Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of the map execution.

PB Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of each burst.

PC Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of the input card processing

Fn FetchUnit defines the number of units of data to retrieve. The default value for FetchUnit is S (unspecified all).

U Use this command option to apply the burst setting.

IU Use this command option to not burst (integral mode).

K When the map, burst, or card runs, no backup file will be created.

K'filename' When the map, burst, or card runs, a backup file will always be created to *filename*.
Note: If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

K+'filename' When the map, burst, or card runs, a backup file will always be appended to *filename*.
Note: If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

KU'filepath' When the map, burst, or card runs, a backup file will always be created using a unique backup name in the directory *filepath*.
Note: If '*filepath*' is not an absolute path, the map directory will be appended as a prefix to it.

KU When the map, burst, or card runs, a backup file will always be created using a unique backup name in the map directory.

K1'filename' If the map, burst, or card does not successfully complete, a backup file will be created to *filename*.
Note: If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

K1+'filename' If the map, burst, or card does not successfully complete, a backup file will be appended to *filename*.
Note: If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

KU1'filepath' If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the directory *filepath*.
Note: If '*filepath*' is not an absolute path, the map directory will be appended as a prefix to it.

KU1 If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the map directory.

library This command option specifies the user library name for the adapters when using an application adapter as a source. The user library name should be followed by the function name and application command line, separated by commas. This option, along with the function name and application command line, must be used when *alias* is not specified.

function This command option specifies the function name for the adapters when using an application adapter as a source and should be prefaced by the user library name and followed by the application command line, separated by commas.

application_command_line This command option specifies the application command line for the adapters when using an application adapter as a source and should be prefaced by the user library name and the function name, separated by commas.

src-adptr-cmd This command option provides the adapter-specific commands to connect to the data source and retrieve the input data. Either this option or ":" must be used if the *alias* option is specified. See the adapter-specific information in the *Resource Adapters* documentation.

Use **Command** in the compiled map file. Either this option or **src-adptr-cmd** must be used if the *alias* option is specified.

Input Source Override - Database (-ID)

Use the Input Source Override - Database execution command (-ID) to override specifications in the compiled map file for a specific input card for a single execution of a map. Only those adapter settings specified are used to override the settings compiled into the map.

For example, if the WorkArea option (W or !W) is not specified, the **WorkArea** setting compiled into the map is used.

```
-IDcard_num[M['filename']]
[W|!W][Rcount:interval][B][EN][EA][EF][ES][EW]
[AF][AI][PM][PB][PC][F'n'][U][!U]
[K]['filename']|[+'filename']|[U'filepath']|[U]
[1'filename']|[1+'filename']|[U1'filepath']|[U1]
{src-adptr-cmd}|.
```

Option

Description

card_num

This is the card number of the input to override.

M'filename'

This is the metadata (XML schema or DTD) file location of the input card to override.

Specify *filename* as an absolute path along with the file name and enclosed in single quotes, for the metadata when parsing input XML. An example is:

```
M'k:\my_project_folder\myschema.xml'
```

Use this command option to override the Metadata location setting for the root type specified on an input card in the Map Designer GUI.

W

After a map runs for the first time, the work area that is created for the input card is not deleted. Then, on subsequent executions of the same map, the data for this input card is not validated and the work area information for the card is retrieved from the existing work area.

IW

Input's work area is created when map execution begins.

Rcount:interval

Specify **Retry** settings. If the source is unavailable, the adapter attempts to access the source as many times as specified by the *count* setting at the interval specified by the *interval* setting.

count number of attempts to access the database

interval number of seconds to wait between attempts.

If this option is not specified, the **Retry** settings compiled into the map are used. To eliminate adapter retry, specify **R0:0**.

B

If the map, burst, or card does not complete successfully, roll back any changes that were made to this data source. If this option is not specified, the **OnFailure** setting compiled into the map is used.

EN

Use this command option to never call the external parser for document verification.

EA

Use this command option to always call the external parser for document verification.

EF

Use this command option to call the external parser for document verification only if validation fails.

ES

Use this command option to call the external parser for document verification only if validation is successful.

EW

Use this command option to call the external parser for document verification only for the well-formed document.

AF

Use this command option to fail on adapter warnings.

AI

Use this command option to ignore adapter warnings.

PM

Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of the map execution.

PB

Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of each burst.

PC

Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of the input card processing

Fn

FetchUnit defines the number of units of data to retrieve. The default value for FetchUnit is S (unspecified all).

U

Use this command option to apply the burst setting.

!U

Use this command option to not burst (integral mode).

K

When the map, burst, or card runs, no backup file will be created.

K'filename'

When the map, burst, or card runs, a backup file will always be created to *filename*. If *filename*' is not an absolute path, the map directory will be appended as a prefix to it.

K+'filename'

When the map, burst, or card runs, a backup file will always be appended to *filename*. If *filename*' is not an absolute path, the map directory will be appended as a prefix to it.

KU'filepath'

When the map, burst, or card runs, a backup file will always be created using a unique backup name in the directory *filepath*. If '*filepath*' is not an absolute path, the map directory will be appended as a prefix to it.

KU

When the map, burst, or card runs, a backup file will always be created using a unique backup name in the map directory.

K1'filename'

If the map, burst, or card does not successfully complete, a backup file will be created to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

K1+'filename'

If the map, burst, or card does not successfully complete, a backup file will be appended to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

KU1'filepath'

If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the directory *filepath*. If '*filepath*' is not an absolute path, the map directory will be appended as a prefix to it.

KU1

If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the map directory.

src-adptr-cmd

Specify the settings for the source using the adapter-specific commands. See the specific database adapter documentation in the *Resource Adapters* documentation.

Use **Command** in the compiled map file.

Input Source Override - Echo (-IE)

Use the Input Source Override - Echo execution command (-IE) to override specifications in the compiled map file for a specific input card for a single execution of a map.

-IEcard_num[M['filename']]

[Ssize] [W|!W] [EN] [EA] [EF] [ES] [EW] [AF] [AI] [PM] [PB] [PC] [F' n'] [U] [|U] source

Option

Description

card_num

This is the card number of the input to override.

M'filename'

This is the metadata (XML schema or DTD) file location of the input card to override.

Specify *filename* as an absolute path along with the file name and enclosed in single quotes, for the metadata when parsing input XML. An example is:

M'k:\my_project_folder\myschema.xml'

Use this command option to override the Metadata location setting for the root type specified on an input card in the Map Designer GUI.

Ssize

This is the size of the data specified by *source* in bytes.

W

After a map runs for the first time, the WorkArea created for the input card is not deleted. On subsequent executions of the same map, the data for this input card is not validated and the WorkArea information for the card is retrieved from the existing WorkArea.

!W

The WorkArea for input is created when map execution begins.

EN

Use this command option to never call the external parser for document verification.

EA

Use this command option to always call the external parser for document verification.

EF

Use this command option to call the external parser for document verification only if validation fails.

ES

Use this command option to call the external parser for document verification only if validation is successful.

EW

Use this command option to call the external parser for document verification only for the well-formed document.

AF

Use this command option to fail on adapter warnings.

AI

Use this command option to ignore adapter warnings.

PM

Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of the map execution.

PB

Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of each burst.

PC

Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of the input card processing

Fn

FetchUnit defines the number of units of data to retrieve. The default value for FetchUnit is S (unspecified all).

U

Use this command option to apply the burst setting.

!U

Use this command option to not burst (integral mode).

source

This is the data to be used for the input.

For example, to pass the value ABC123XYZ to a map as the data for input card #2, type the following command:

-IE2 ABC123XYZ

If the data to be echoed contains spaces or hyphens, it must be surrounded by single quotes as shown in the following example:

-IE2 `ABC 123 XYZ`

If the echoed data contains single quotes or the null character (hex 00), use the **S** option to specify the number of bytes of echoed data. Changing the example above to use to the **S** option, the single quotes are omitted:

-IE1S11 ABC 123 XYZ

The examples above demonstrate using the Input Source Override - Echo execution command (-IE) in a map rule.

If you are using the Input Source Override - Echo execution command (-IE) in the Command Server command line and the data contains spaces or hyphens, in addition to surrounding the data to be echoed with single quotes, you must then add double-quotes outside the single-quotes as shown in the following example:

-IE2 " `ABC 123 XYZ` "

Also, if you are using the Input Source Override - Echo execution command (-IE) in the Command Server command line and the data contains single quotes or the null character (hex 00), in addition to using the **S** option to specify the number of bytes of echoed data, and omitting the single quotes, if the data contained them, you must also surround the data with double-quotes as shown in the following example:

-IE1S11 "ABC 123 XYZ"

One use for echoed input data is in conjunction with the **RUN** function to pass data from one map to another. For an example of using an echoed data source as an input argument using the **RUN** function, see the **RUN** function in the *Functions and Expressions* documentation. Another example of using an echoed data source is provided in the *Platform API* documentation.

Input Source Override - File (-IF)

Use the Input Source Override - File execution command (**-IF**) to override specifications in the compiled map file for a specific input card for a single execution of a map. Only the specified adapter settings are used to override the settings compiled into the map.

For example, if the WorkArea option (**w** or **!w**) is not specified, the **WorkArea** setting compiled into the map is used.

```
-IFcard_num[M['filename']]  
[W|IW][X|X0][Rcount:interval][B][EN][EA][EF][ES][EW]  
[AF][AI][PM][PB][PC][F'n'][U][!U]  
[K['filename']]|[+'filename']|[U'filepath']|[U]|  
[1'filename']|[1+'filename']|[U1'filepath']|[U1]|  
{source|..}
```

Option

Option	Description
<i>card_num</i>	This is the card number of the input to override.
<i>M'filename'</i>	This is the metadata (XML schema or DTD) file location of the input card to override. Specify <i>filename</i> as an absolute path along with the file name and enclosed in single quotes, for the metadata when parsing input XML. An example is: M'k:\my_project_folder\myschema.xml'
<i>W</i>	Use this command option to override the Metadata location setting for the root type specified on an input card in the Map Designer GUI.
<i>IW</i>	After a map runs the first time, the WorkArea created for the input card is not deleted. For subsequent executions of the same map, the data for this input card is not validated and the WorkArea information for the card is retrieved from the existing WorkArea.
<i>X</i>	The WorkArea of the input is created when map execution begins.
<i>X0</i>	If the map, burst, or card completes successfully, the input data file is deleted.
<i>Rcount:interval</i>	Specify Retry settings. If the source is unavailable, the adapter attempts to access the source as many times as specified by the <i>count</i> setting at the interval specified by the <i>interval</i> setting. <i>count</i> number of attempts to access the data file <i>interval</i> number of seconds to wait between attempts . If this option is not specified, the Retry settings compiled into the map are used. To eliminate adapter retry, specify RO:0 .
<i>B</i>	If the map, burst, or card does not complete successfully, roll back any changes made to this data source. If this option is not specified, the OnFailure setting compiled into the map is used.
<i>EN</i>	Use this command option to never call the external parser for document verification.
<i>EA</i>	Use this command option to always call the external parser for document verification.
<i>EF</i>	Use this command option to call the external parser for document verification only if validation fails.
<i>ES</i>	Use this command option to call the external parser for document verification only if validation is successful.
<i>EW</i>	Use this command option to call the external parser for document verification only for the well-formed document.
<i>AF</i>	Use this command option to fail on adapter warnings.
<i>AI</i>	Use this command option to ignore adapter warnings.
<i>PM</i>	Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of the map execution.
<i>PB</i>	Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of each burst.
<i>PC</i>	Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of the input card processing
<i>Fn</i>	FetchUnit defines the number of units of data to retrieve. The default value for FetchUnit is S (unspecified all).
<i>U</i>	Use this command option to apply the burst setting.
<i>IU</i>	Use this command option to not burst (integral mode).
<i>K</i>	When the map, burst, or card runs, no backup file will be created.
<i>K'filename'</i>	When the map, burst, or card runs, a backup file will always be created to <i>filename</i> . If ' <i>filename</i> ' is not an absolute path, the map directory will be appended as a prefix to it.
<i>K+'filename'</i>	

When the map, burst, or card runs, a backup file will always be appended to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

KU'filepath'

When the map, burst, or card runs, a backup file will always be created using a unique backup name in the directory *filepath*. If '*filepath*' is not an absolute path, the map directory will be appended as a prefix to it.

KU

When the map, burst, or card runs, a backup file will always be created using a unique backup name in the map directory.

K1'filename'

If the map, burst, or card does not successfully complete, a backup file will be created to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

K1+'filename'

If the map, burst, or card does not successfully complete, a backup file will be appended to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

KU1'filepath'

If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the directory *filepath*. If '*filepath*' is not an absolute path, the map directory will be appended as a prefix to it.

KU1

If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the map directory.

source

Specify the name of the input file. If the input file is not located in the same directory as the map file, the full path must be specified using the platform-specific syntax.

Use the **FilePath** in the compiled map file.

Input Source Override - Message (-IM)

Use the Input Source Override - Message execution command (-IM) to override specifications in the compiled map file for a specific input card for a single execution of a map. Only the specified adapter settings are used to override the settings compiled into the map.

For example, if the WorkArea option (w or !w) is not specified, the **WorkArea** setting compiled into the map is used.

```
-IM[alias]card_num[M['filename']]  
[W|!W][X|X0][Rcount:interval][B][EN][EA][EF][ES][EW]  
[AF][AI][PM][PB][PC][F'n'][U][!U]  
[K[filename]]|[+'filename'][U'filepath'][U]  
[1'filename']|[1+'filename'][U1'filepath'][U1]  
{src-adptr-cmd| .}
```

Option

Description

alias

This is the adapter alias for the specific messaging adapter. For example, AQ is the adapter alias for the Oracle AQ adapters. See the adapter-specific information in the *Resource Adapters* documentation. For operating system and version-specific information, see the [system requirements](#) and the [release notes](#).

card_num

This is the card number of the input to override.

M'filename'

This is the metadata (XML schema or DTD) file location of the input card to override.

Specify *filename* as an absolute path along with the file name and enclosed in single quotes, for the metadata when parsing input XML. An example is:

```
M'k:\my_project_folder\myschema.xml'
```

Use this command option to override the Metadata location setting for the root type specified on an input card in the Map Designer GUI.

W

After a map runs the first time, the WorkArea created for the input card is not deleted. For subsequent executions of the same map, the data for this input card is not validated and the WorkArea information for the card is retrieved from the existing WorkArea.

!W

The WorkArea of input is created when map execution begins.

X

If the map, burst, or card completes successfully, the message is deleted from its source.

X0

If the map, burst, or card completes successfully, the message is deleted from its source, only if it has no content. If neither delete option (x or X0) is specified, the **OnSuccess** setting compiled into the map is used.

Rcount:interval

Specify **Retry** settings. If the source is unavailable, the adapter attempts to access the source as many times as specified by the *count* setting at the interval specified by the *interval* setting.
count number of attempts to access the message queue.

interval number of seconds to wait between attempts. If this option is not specified, the **Retry** settings compiled into the map are used. To eliminate adapter retry, specify **R0:0**.

B

If the map, burst, or card does not complete successfully, roll back any changes made to this data source. If this option is not specified, the **OnFailure** setting compiled into the map is used.

EN

Use this command option to never call the external parser for document verification.

EA

Use this command option to always call the external parser for document verification.

EF

Use this command option to call the external parser for document verification only if validation fails.

ES Use this command option to call the external parser for document verification only if validation is successful.
EW Use this command option to call the external parser for document verification only for the well-formed document.
AF Use this command option to fail on adapter warnings.
AI Use this command option to ignore adapter warnings.
PM Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of the map execution.
PB Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of each burst.
PC Use this command option to apply the OnSuccess and OnFailure settings based on the success or failure of the input card processing
Fn FetchUnit defines the number of units of data to retrieve. The default value for FetchUnit is S (unspecified all).
U Use this command option to apply the burst setting.
!U Use this command option to not burst (integral mode).
K When the map, burst, or card runs, no backup file will be created.
K'filename' When the map, burst, or card runs, a backup file will always be created to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.
K+'filename' When the map, burst, or card runs, a backup file will always be appended to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.
KU'filepath' When the map, burst, or card runs, a backup file will always be created using a unique backup name in the directory *filepath*. If '*filepath*' is not an absolute path, the map directory will be appended as a prefix to it.
KU When the map, burst, or card runs, a backup file will always be created using a unique backup name in the map directory.
K1'filename' If the map, burst, or card does not successfully complete, a backup file will be created to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.
K1+'filename' If the map, burst, or card does not successfully complete, a backup file will be appended to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.
KU1'filepath' If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the directory *filepath*. If '*filepath*' is not an absolute path, the map directory will be appended as a prefix to it.
KU1 If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the map directory.
src-adptr-cmd Specify settings for the source using the adapter-specific commands. See the adapter-specific information in the *Resource Adapters* documentation.

Use **Command** in the compiled map file.

-IMALE2F2AFUPBXOR10:5BK'ale.bak'<ale_commands>

In this example, Input 2 is ALE **-IMALE2**. Use 2 as a fetch unit, specified as **F2**. **F** is the **Fetch** unit command option and 2 is the actual fetch unit. Use fail on adapter warnings **AF**, burst **U**, adapter scope is burst **PB**, delete if no content **X0**, retry 10 times every 5 seconds **R10:5**, **B** is the Rollback if failure command option. When **B** is specified, at map run time, if the map, burst, or card does not complete successfully, any changes made to this data source are rolled back and backup is written to the file ale.bak.

B

Note: While the **-IA/-OA** can be used in place of **-IM/-OM** to include the message or application <type>, **-IM/-OM** CANNOT be used to replace **-IA/-OA** when specifying a library and function name for user adapters.

Input Source Override - Pointer (-IP)

The Input Source Override - Pointer execution command (**-IP**) is for platform API users only, and allows data to be passed in via a pointer rather than a buffer.

-IP*card_num\$xxxx yyyy*

Option

Description

card_num

This is the card number of the input to override.

xxxx

This specifies the size of the data that is passed in via pointer.

yyyy

This specifies the address of the data that is passed in via pointer.

List (-L)

When using a Command Server on a platform other than Windows, use the List execution command (-L) to display a list of the data sources and targets that are compiled into a map file.

This command does not execute the map. It displays the list of sources and destinations.

For example, if you are using the Command Server on a UNIX platform, you can display the sources and destinations for the **sinkmap** example map by using the following command:

```
dtxcmdsv sinkmap.mmc -L
```

The result would be similar to the following:

```
Map file: /examples/general/map/sinkmap/sinkmap.mmc -L
Card information for map /examples/general/map/sinkmap/
sinkmap.mmc:
T column is data type: F=File, A=Application, D=Database
  Name          T Data
  ----          -
Input # 1 all_employees      F allemps.txt
Input # 2 employee_to_lookup F employee.txt
Output # 1 week              F
Output # 2 ttlhours          F
Output # 3 emp_hours         F emphours.txt
```

This information can be useful when determining the current source or target names, as well as to confirm the exact source, target types, or locations.

Initialization File Override (-N)

To override the default initialization (config.yaml) file for the Command Server, use the -N command option as the first command to the Command Server, as indicated in the following syntax:

```
-N=<INI_filename>
```

where <

<INI_filename> is the name of the renamed initialization file. If the path is not absolute, it will be resolved to the path relative to the current path. The current path is the path from where the command server was invoked. Also, if spaces exist in this path/name, enclose the <INI_filename> value in single quotes. When running a map using this override, the entire syntax should be written in the following way:

```
[<INI_filename>] [<mapname> <commands> ...]
```

The following example uses the myinit.ini initialization file to run the sdq.mmc map with an execution audit on a Windows operating system:

```
dtxcmdsv64 -n=c:\dtx_n.n\config.yaml sdq.mmc -ae
```

Output Target Override - Application (-OA)

Use the Output Target Override - Application execution command (-OA) to override specifications in the compiled map file for a specific output card for a single execution of a map.

```
-OA[alias]card_num[M['filename']]
[Rcount:interval][B][EN][EA][EF][BS][EW][AF][AI][U][!U]
[K['filename']]|['filename']|[U'filepath']|[U]
[1['filename']]|[1+'filename']|[U1'filepath']|[U1]
[library],[function],[application_command_line]|
{target-adptr-cmd} .
```

Option

Description

alias

This is the adapter alias for the specific application adapter. For example, **FTP** is the adapter alias for the FTP adapters. If the **alias** option is not used, you must use **library**, **function**, and **application_command_line**. If **alias** is used, you must use **target-adptr-cmd** or **"."**.

card_num

This is the card number of the output to override.

M'filename'

This is the metadata (XML schema or DTD) file location of the output card to override.

Specify **filename** as an absolute path along with the file name and enclosed in single quotes, for the metadata when parsing output XML. An example is:

```
M'k:\my_project_folder\myschema.xml'
```

Use this command option to override the Metadata location setting for the root type specified on an output card in the Map Designer GUI.

Rcount:interval

Specify **Retry** settings. If the target is unavailable, the adapter attempts to access the target as many times as specified by the **count** setting at the interval specified by the **interval** setting.

count number of attempts to access the application

interval number of seconds to wait between attempts. If this option is not specified, **Retry** settings compiled into the map are used. To eliminate adapter retry, specify **RO:0**.

B	If the map, burst, or card does not complete successfully, roll back any changes made to this data target. If this option is not specified, the OnFailure setting compiled into the map is used.
EN	Use this command option to never call the external parser for document verification.
EA	Use this command option to always call the external parser for document verification.
EF	Use this command option to call the external parser for document verification only if validation fails.
ES	Use this command option to call the external parser for document verification only if validation is successful.
EW	Use this command option to call the external parser for document verification only for the well-formed document.
AF	Use this command option to fail on adapter warnings.
AI	Use this command option to ignore adapter warnings.
U	Use this command option to apply the burst setting.
!U	Use this command option to not burst (integral mode).
K	When the map, burst, or card runs, no backup file will be created.
K'filename'	When the map, burst, or card runs, a backup file will always be created to <i>filename</i> . If ' <i>filename</i> ' is not an absolute path, the map directory will be appended as a prefix to it.
K+filename'	When the map, burst, or card runs, a backup file will always be appended to <i>filename</i> . If ' <i>filename</i> ' is not an absolute path, the map directory will be appended as a prefix to it.
KU'filepath'	When the map, burst, or card runs, a backup file will always be created using a unique backup name in the directory <i>filepath</i> . If ' <i>filepath</i> ' is not an absolute path, the map directory will be appended as a prefix to it.
KU	When the map, burst, or card runs, a backup file will always be created using a unique backup name in the map directory.
K1'filename'	If the map, burst, or card does not successfully complete, a backup file will be created to <i>filename</i> . If ' <i>filename</i> ' is not an absolute path, the map directory will be appended as a prefix to it.
K1+filename'	If the map, burst, or card does not successfully complete, a backup file will be appended to <i>filename</i> . If ' <i>filename</i> ' is not an absolute path, the map directory will be appended as a prefix to it.
KU1'filepath'	If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the directory <i>filepath</i> . If ' <i>filepath</i> ' is not an absolute path, the map directory will be appended as a prefix to it.
KU1	If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the map directory.
library	This command option specifies the user library name for the adapters when using an application adapter as a target and should be followed by the function name and application command line, separated by commas. This option, along with the function name and application command line, must be used when <i>alias</i> is not specified.
function	This command option specifies the function name for the adapters when using an application adapter as a target and should be prefaced by the user library name and followed by the application command line, separated by commas.
application_command_line	This command option specifies the application command line for the adapters when using an application adapter as a target and should be prefaced by the user library name and the function name, separated by commas.
target-adptr-cmd	This command option provides the adapter-specific commands that connect to the data target and process the output data. Either this option or ":" must be used if the <i>alias</i> option is specified. See the adapter-specific documentation in the <i>Resource Adapters</i> documentation.
	Use Command in the compiled map file. Either this option or <i>target-adptr-cmd</i> must be used if the <i>alias</i> option is specified.

Output Target Override - Database (-OD)

Use the Output Target Override - Database execution command (-OD) to override specifications in the compiled map file for a specific output card for a single execution of a map.

```
-ODcard_num[M['filename']]
 [Rcount:interval] [B] [EN] [EA] [EF] [ES] [EW] [AF] [AI] [U] [+U]
 [K['filename']] [+filename] [U'filepath'] [+U] [+1filename] [+1+filename] [+U1filepath'] [+U1]
 {target-adptr-cmd} .
```

Option

Description

card_num

This is the card number of the output to override.

M'filename'
This is the metadata (XML schema or DTD) file location of the output card to override.
Specify *filename* as an absolute path along with the file name and enclosed in single quotes, for the metadata when parsing output XML. An example is:

```
M'k:\my_project_folder\myschema.xml'
```

Use this command option to override the Metadata location setting for the root type specified on an output card in the Map Designer GUI.

Rcount:interval
Specify **Retry** settings. If the target is unavailable, the adapter attempts to access the target as many times as specified by the *count* setting at the interval specified by the *interval* setting.
count number of attempts to access the database
interval number of seconds to wait between attempts. If this option is not specified, the **Retry** settings compiled into the map are used. To eliminate adapter retry, specify **RO:0**.

B
If the map, burst, or card does not complete successfully, roll back any changes made to this data target. If this option is not specified, the **OnFailure** setting compiled into the map is used.

EN
Use this command option to never call the external parser for document verification.

EA
Use this command option to always call the external parser for document verification.

EF
Use this command option to call the external parser for document verification only if validation fails.

ES
Use this command option to call the external parser for document verification only if validation is successful.

EW
Use this command option to call the external parser for document verification only for the well-formed document.

AF
Use this command option to fail on adapter warnings.

AI
Use this command option to ignore adapter warnings.

U
Use this command option to apply the burst setting.

!U
Use this command option to not burst (integral mode).

K
When the map, burst, or card runs, no backup file will be created.

K'filename'
When the map, burst, or card runs, a backup file will always be created to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

K+'filename'
When the map, burst, or card runs, a backup file will always be appended to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

KU'filepath'
When the map, burst, or card runs, a backup file will always be created using a unique backup name in the directory *filepath*. If '*filepath*' is not an absolute path, the map directory will be appended as a prefix to it.

KU
When the map, burst, or card runs, a backup file will always be created using a unique backup name in the map directory.

K1'filename'
If the map, burst, or card does not successfully complete, a backup file will be created to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

K1+'filename'
If the map, burst, or card does not successfully complete, a backup file will be appended to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

KU1'filepath'
If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the directory *filepath*. If '*filepath*' is not an absolute path, the map directory will be appended as a prefix to it.

KU1
If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the map directory.

target-adptr-cmd
Specify the settings for the target using the adapter-specific commands. See the appropriate adapter information in the *Resource Adapters* documentation.

Use **Command** in the compiled map file.

Output Target Override - Echo (-OE)

Use the Output Target Override - Echo execution command (-OE) to override specifications in the compiled map file for a specific output card for a single execution of a map.

Use this command when you want the data resulting from one or more output cards passed back to a calling application or a map, rather than being directed to a file, database, application, or message. If this command is used to override more than one output, the results of the outputs are concatenated without separators.

For example, use this command in conjunction with the **RUN()** function to pass data from one map to another:

```
-OEcard_num[M['filename']]
[S|X][EN][EA][EF][ES][EW][AF][AI][U][!U]
```

Option	Description
<i>card_num</i>	This is the card number of the output to override.
M'filename'	This is the metadata (XML schema or DTD) file location of the output card to override. Specify <i>filename</i> as an absolute path along with the file name and enclosed in single quotes, for the metadata when parsing output XML. An example is: M'k:\my_project_folder\myschema.xml'
S	Use this command option to override the Metadata location setting for the root type specified on an output card in the Map Designer GUI.
	Return the size (in bytes) of the output data. This option causes the resulting output data to be returned as an ASCII number representing the size of the data, followed by a space, followed by the data itself. For example, if used in a RUN() function: RUN ("mymap.mmc", "-AE -OE2S -OE4S")
	If the data resulting from output card #2 is This and That and the output from output card #4 is 19439.27, the string returned by this example RUN() function is 13 This and That 8 19439.27.
	If the size option is not used, the data returned by this example RUN() function is This and That 19439.27.
X	Exclude this card from echo. The output is stored in memory and not echoed back to the specified map or application. You might use this option to optimize performance when a map has an output used strictly as a <i>scratch</i> card, that is, it is built only to be used by a later output.
EN	Use this command option to never call the external parser for document verification.
EA	Use this command option to always call the external parser for document verification.
EF	Use this command option to call the external parser for document verification only if validation fails.
ES	Use this command option to call the external parser for document verification only if validation is successful.
EW	Use this command option to call the external parser for document verification only for the well-formed document.
AF	Use this command option to fail on adapter warnings.
AI	Use this command option to ignore adapter warnings.
U	Use this command option to apply the burst setting.
!U	Use this command option to not burst (integral mode).

Output Target Override - File (-OF)

Use the Output Target Override - File execution command (-OF) to override data destination specifications for a specific output card in a compiled map file for a single execution of a map.

```
-OFcard_num[+!+][M['filename']]  
[X|X0][Rcount:interval][B][EN][EA][EF][ES][EW][AF][AI][U][!U]  
[K['filename']]|[+'filename']|[U'filepath']|[U]|  
[1'filename']|[1+'filename']|[U1'filepath']|[U1]|  
{target}..
```

Option	Description
<i>card_num</i>	This is the card number of the output to override.
+	If the map, burst, or card completes successfully, the output data is appended to an existing data file. If the data file does not exist, it is created.
!+	The data file is created at the start of map execution. If the file exists, it is overwritten. If more than one burst occurs, data is appended to the same data file.
M'filename'	This is the metadata (XML schema or DTD) file location of the output card to override. Specify <i>filename</i> as an absolute path along with the file name and enclosed in single quotes, for the metadata when parsing output XML. An example is: M'k:\my_project_folder\myschema.xml'
R <i>count:interval</i>	Use this command option to override the Metadata location setting for the root type specified on an output card in the Map Designer GUI.
	Specify Retry settings. If the target is unavailable, the adapter attempts to access the target as many times as specified by the <i>count</i> setting at the interval specified by the <i>interval</i> setting. <i>count</i> number of attempts to access the file <i>interval</i> number of seconds to wait between attempt. If this option is not specified, the Retry settings compiled into the map are used. To eliminate adapter retry, specify RO:0 .

	If the map, burst, or card does not complete successfully, roll back any changes made to this data target. If this option is not specified, the OnFailure setting compiled into the map is used.
EN	Use this command option to never call the external parser for document verification.
EA	Use this command option to always call the external parser for document verification.
EF	Use this command option to call the external parser for document verification only if validation fails.
ES	Use this command option to call the external parser for document verification only if validation is successful.
EW	Use this command option to call the external parser for document verification only for the well-formed document.
AF	Use this command option to fail on adapter warnings.
AI	Use this command option to ignore adapter warnings.
U	Use this command option to apply the burst setting.
!U	Use this command option to not burst (integral mode).
K	When the map, burst, or card runs, no backup file will be created.
K'filename'	When the map, burst, or card runs, a backup file will always be created to <i>filename</i> . If ' <i>filename</i> ' is not an absolute path, the map directory will be appended as a prefix to it.
K+'filename'	When the map, burst, or card runs, a backup file will always be appended to <i>filename</i> . If ' <i>filename</i> ' is not an absolute path, the map directory will be appended as a prefix to it.
KU'filepath'	When the map, burst, or card runs, a backup file will always be created using a unique backup name in the directory <i>filepath</i> . If ' <i>filepath</i> ' is not an absolute path, the map directory will be appended as a prefix to it.
KU	When the map, burst, or card runs, a backup file will always be created using a unique backup name in the map directory.
K1'filename'	If the map, burst, or card does not successfully complete, a backup file will be created to <i>filename</i> . If ' <i>filename</i> ' is not an absolute path, the map directory will be appended as a prefix to it.
K1+'filename'	If the map, burst, or card does not successfully complete, a backup file will be appended to <i>filename</i> . If ' <i>filename</i> ' is not an absolute path, the map directory will be appended as a prefix to it.
KU1'filepath'	If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the directory <i>filepath</i> . If ' <i>filepath</i> ' is not an absolute path, the map directory will be appended as a prefix to it.
KU1	If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the map directory.
target	Specify the name of the output file. If the output file is not located in the same directory as the map file, the full path must be specified using the platform-specific syntax.
	Use the FilePath in the compiled map file.

Output Target Override - Message (-OM)

Use the Output Target Override - Message execution command (-OM) to override data destination specifications for a specific output card in a compiled map file for a single execution of a map.

```
-OM[alias]card_num[M['filename']]
[X|X0][Rcount:interval][B][EN][EA][EF][ES][EW][AF][AI][U][!U]
[K['filename']]|[+'filename']|[U'filepath']|[U]
[1'filename']|[1+'filename']|[U1'filepath']|[U1]
{target-adptr-cmd} .
```

Option

Option	Description
alias	This is the adapter alias for the specific messaging adapter. For example, <code>MSMQ</code> is the adapter alias for the Microsoft MSMQ adapters. See the adapter-specific information in the <i>Resource Adapters</i> documentation.
card_num	This is the card number of the output to override.
M'filename'	This is the metadata (XML schema or DTD) file location of the output card to override. Specify <i>filename</i> as an absolute path along with the file name and enclosed in single quotes, for the metadata when parsing output XML. An example is: <code>M'k:\my_project_folder\myschema.xml'</code>
X	Use this command option to override the Metadata location setting for the root type specified on an output card in the Map Designer GUI.
X0	If the map, burst, or card completes successfully, the message is deleted from its target.

If the map, burst, or card completes successfully, the message is deleted from its target only if it has no content. If neither delete option (x or x0) is specified, the **OnSuccess** setting compiled into the map is used.

Rcount:interval

Specify **Retry** settings. If the target is unavailable, the adapter attempts to access the target as many times as specified by the *count* setting at the interval specified by the *interval* setting.
count number of attempts to access the message queue.

interval number of seconds to wait between attempts. If this option is not specified, the **Retry** settings compiled into the map are used. To eliminate adapter retry, specify **R0:0**.

B

If the map, burst, or card does not complete successfully, roll back any changes made to this data target. If this option is not specified, the **OnFailure** setting compiled into the map is used.

EN

Use this command option to never call the external parser for document verification.

EA

Use this command option to always call the external parser for document verification.

EF

Use this command option to call the external parser for document verification only if validation fails.

ES

Use this command option to call the external parser for document verification only if validation is successful.

EW

Use this command option to call the external parser for document verification only for the well-formed document.

AF

Use this command option to fail on adapter warnings.

AI

Use this command option to ignore adapter warnings.

U

Use this command option to apply the burst setting.

IU

Use this command option to not burst (integral mode).

K

When the map, burst, or card runs, no backup file will be created.

K'filename'

When the map, burst, or card runs, a backup file will always be created to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

K+'filename'

When the map, burst, or card runs, a backup file will always be appended to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

KU'filepath'

When the map, burst, or card runs, a backup file will always be created using a unique backup name in the directory *filepath*. If '*filepath*' is not an absolute path, the map directory will be appended as a prefix to it.

KU

When the map, burst, or card runs, a backup file will always be created using a unique backup name in the map directory.

K1'filename'

If the map, burst, or card does not successfully complete, a backup file will be created to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

K1+'filename'

If the map, burst, or card does not successfully complete, a backup file will be appended to *filename*. If '*filename*' is not an absolute path, the map directory will be appended as a prefix to it.

KU1'filepath'

If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the directory *filepath*. If '*filepath*' is not an absolute path, the map directory will be appended as a prefix to it.

KU1

If the map, burst, or card does not successfully complete, a backup file will be created using a unique backup name in the map directory.

trgt-adptr-cmd

This option provides the adapter-specific commands that connect to the data source and retrieve the input data. See the adapter-specific information in the *Resource Adapters* documentation.

Use **Command** in the compiled map file.

Output Target Override - Pointer (-OP)

The Output Target Override - Pointer execution command (-OP) is for platform API users only, and allows data to be returned via a pointer rather than a buffer.

-OPcard_nums

Option

Description

card_num

This is the card number of the output to override.

S

The data is returned in the form **xxxx yyyy** where xxxx is the size of the data being returned and yyyy represents the address of the returned data.

WorkSpace PageSize (-P)

When a file-based WorkSpace is used, the amount of memory accessed at a given time depends on the number of pages and the size of pages you configure for a map to run. Use the WorkSpace PageSize execution command (-P) to specify the size of and number of pages to be used.

If this execution command is used without a corresponding WorkSpace execution command (-w), the WorkSpace settings in the compiled map are used.

Generally, for large data files, you might want to increase the number of pages by specifying a large count. For maps that include a large number of type references, you might want to increase the page size.

-Psize: count

Option

Description

size

Size in kilobytes of a single page of memory used during map execution. Page size is measured in kilobytes and is specified as a multiple of 2 between 2 and 1024.

count

Number of pages used during map execution. The count is specified as an integer greater than 0.

Refresh Status (-R)

The Refresh Status execution command (-R) is used to specify the frequency of map status update when displayed in the Command Server window when using the Windows operating system or in the console when using all other operating systems. To reflect execution time, as well as the number of input objects found and output objects built, specify the interval at which the map status is refreshed.

-Rupdate_rate

Option

Description

update_rate

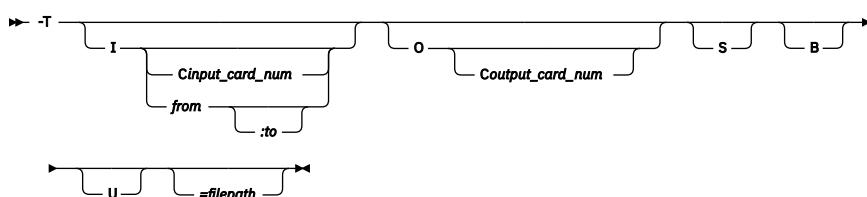

This is the number of times per second the map status is refreshed. The default refresh interval is approximately twice per second. If you specify 0 as the refresh interval, the map status is not displayed.

MapTrace (-T)

The MapTrace execution command (-T) creates a trace file that you can use to diagnose invalid data or incorrect type definitions. For more information about the trace file, see the *Map Designer* documentation.

Use this command to trace a particular input or output card, a range of input data objects, or to produce a trace summary. When the **-T** command is used without other options, no trace log is produced.

The MapTrace (-T) execution command overrides all trace settings in the compiled map. You cannot override individual map settings. When you run the **-T** command, only the trace options that you specify on the command are in effect.

Option

Description

I

Produces detailed trace information for all input cards.

Cinput_card_num

Produces detailed trace information for a single input card. For example, the command **-TIC3** produces detailed trace information for input card 3.

from[:to]

Produces detailed trace information for a range of input objects. For example, to produce trace information for objects 1000 to 1320, specify **-TI1000:1320**. The upper limit of the object range is optional. To trace from input object 1000 to the end of the file, you can specify **-TI1000**.

O

Produces detailed trace information for all output cards.

Coutput_card_num

Produces detailed trace information for a single output card. For example, the command **-TOC3** produces detailed trace information for output card 3.

S

Produces summary level trace information for all input and output cards providing a message for each card. For example, the message for a particular card might be Input 1 was valid, but 34 bytes of unknown data found or Output 2 built successfully.

B

Creates the trace file in binary format.

U

Creates the trace file with a unique name, in the format *Mer_mapname_processKey_mapCounter_hostname.mtr*.

=filepath

Specifies a file name, file path, or file name and path for the trace file. By default, the trace file is created as *mapname.mtr* in the directory of the compiled map (.mmc) file.

If you specify **=filepath**, it must be the last option on the **-T** command.

- [Examples of the MapTrace \(-T\) command](#)

Examples of the MapTrace (-T) command

The commands in the following table show combinations of the **-T** command options:

```
-T [I [C | [from[:to]]] [O [C]] [S] [B] [U] [=filepath]
```

The table is not an exhaustive list of all possible option combinations.

The command options are not positional, with these exceptions:

- If specified, the *filepath* option must be the last option on the command.
- The *C* and *from:to* variables must follow the *I* option. The *C* must follow the *O* option.

For example, in the **-TIC30C4B** command, 3 is the number of the input card and 4 is the number of the output card. However, **-TBOC4IC3** is an identical command.

Table 1. Example MapTrace commands

MapTrace command	Trace target	Trace file format	Trace file name	Trace file location
-T	Do not trace	text	<i>mapname.mtr</i>	map directory
-TI	Trace all inputs	text	<i>mapname.mtr</i>	map directory
-TI2:10	Trace input objects 2 through 10	text	<i>mapname.mtr</i>	map directory
-TIC7	Trace input card 7	text	<i>mapname.mtr</i>	map directory
-TIB	Trace all input objects	binary	<i>mapname.mtr</i>	map directory
-TIBU	Trace all inputs	binary	unique	map directory
-TIBU=C:\TXTRACES	Trace all inputs	binary	unique	C:\TXTRACES directory
-TI2:10BU=C:\TXTRACES	Trace input objects 2 through 10	binary	unique	C:\TXTRACES directory
-TO	Trace all output cards	text	<i>mapname.mtr</i>	map directory
-TOC3BU=C:\TXTRACES\Card3Trc.mtr	Trace output card 3	binary	Card3Trace.mtr	C:\TXTRACES directory
-TIC30C4	Trace input object 3 and output card 4	text	<i>mapname.mtr</i>	map directory
-TI2:22OC1	Trace input objects two through 22 and output card 1	text	<i>mapname.mtr</i>	map directory
-TS	Trace all input and output cards and provide a message for each card	text	<i>mapname.mtr</i>	map directory

Stop Validation (-V)

The Stop Validation execution command (**-v**) specifies to stop validation at the card where the first error is detected. When this command is used, validation occurs only through the input card where the first error is encountered. Map execution is stopped after validating that input card, even if there are multiple input cards.

Under certain circumstances, multiple errors are detected during validation. You can stop by using **-V** at the first error detected or continue (with no **-V** validating data until all errors are found).

If you use the **-V** command, validation only occurs through the input card where the first error occurred. It stops executing the map after validating that input card, even if there are multiple input cards. If the **-V** command is not used, the Validation OnValidationError setting is used.

In all situations, if an error is found in the input, no output objects are built.

WorkSpace (-W)

When you run a map, the Command Server uses its own paging scheme to access information about the data as efficiently as possible. Portions of both workspace data and actual data are paged as needed. The workspace can be either a combination of files and memory or memory-based. When file-based workspace is used, the amount of memory accessed at a given time depends on the number of pages and the count of pages configured for map execution.

When the WorkSpace execution command (**-W**) is used without other specified options, a file-based WorkSpace is used and the work files are named using the map name; they are placed in the same directory as the compiled map file. If the **-W** command is used without a corresponding WorkSpace PageSize execution command (**-P**), the **WorkSpace** settings in the compiled map are used.

You can optimize the speed of map processing using the workspace configuration setting. When processing a large amount of input data in a map, use the file-based workspace with default paging. When small amounts of data are processed, smaller page sizes and memory-based workspaces are recommended. When using burst processing, adjust the workspace configuration for the size of burst data.

```
-W [M] | { [D] [U] [=dir] }
```

Option	Description
D	A file-based WorkSpace is used. The work files are deleted after a map is executed. All work files are deleted, except those being saved for reuse as specified on the input cards for each map.

U

A file-based WorkSpace is used. A unique name is generated for each work file created and the files are automatically deleted after the map is executed. Unique work file names are useful if you are running more than one instance of the same map at the same time. Each time a map is run, a work file is created with a unique name, which eliminates any conflict between work files.

Unique workfiles are automatically deleted upon completion. The format of the unique workfile name is:

`Mer_mapname_processID_time_xxxxxxx_hostname[I|O].cardnumber`

mapname

The executable map name.

processID

The process id from the operating system.

time

The time when the process started, in number of seconds since midnight on January 1, 1970.

xxxxxx

The mapping instance for the process, as an incremental hex number starting at 1 (thru 0xFFFFFFF).

hostname

The host name of the computer where Transformation Extender is running.

[I|O]

I is an input and **O** is an output

cardnumber

The input or output card number.

M

A memory-based WorkSpace is used. This might enhance performance for specific maps depending on work file requirements and the amount of available memory by keeping the work file information in memory and eliminating the I/O necessary with file-based work files. If there is insufficient memory available to build the work file, the map returns a *Disk write error* message.

When this option is used, none of the other work file options can be used. For example, **D** - deleting work files, **U** - unique work file names, and **=dir** - specifying the directory.

=dir

Specify the directory path in which you want the work files to be created. By default, work files are created in the same directory as the compiled map (.mmc) file.

Retry (-Y)

The Retry execution command (-y) is used to specify the retry rate for non-data files accessed during map execution. This includes the compiled map file, as well as, work files, the trace file, and the audit log. If one of these files cannot be accessed at execution time, an attempt is made to access the file as specified.

-Ycount:interval

Option

Description

count

This is the number attempts to be made to access the file.

interval

This is the number of seconds to wait between each attempt.

Ignore Warnings (-Z)

The execution Ignore Warnings execution command (-z) specifies for a map that selected warning codes should be ignored and a 0 return code should be issued. When -z is used with one or more warning codes, a 0 return code is issued for those warning codes. When used without other options specified, all warning codes result in a 0 return code. Using this command impacts **OnSuccess** settings, **OnFailure** settings, and so on.

-Z[!][warning_code[:warning_code...]]

Option

Description

!

Use to specify those warning codes that, when encountered, remain in their default state; they will remain as warnings and a 0 return code is not issued. The default warning code is followed by the warning code message.

When used with -z only (-z!), a 0 return code followed by the warning code message is returned if any one of the warning codes is encountered.

warning_code

Specify the warning codes to be acted upon when encountered.

Valid warning code selections include: 14, 18, 21, 26, 27, 28, 29, and 34.

- [Examples using Ignore Warnings \(-Z\)](#)

Examples using Ignore Warnings (-Z)

-Z

This command causes a 0 return code with the warning message to be returned when any of the warning codes is encountered.

-Z!

This command causes a 0 return code with the warning message to be returned when any of the warning codes is encountered.

-Z18
This command causes a 0 return code with the warning message to be returned when a Page Usage Count Error (18) is encountered.

-Z!18
This command excludes the Page Usage Count Error (18), a 0 return code with the warning message is returned for all of the other warning codes.

-Z18:27:28
This command causes a 0 return code with the warning message to be returned when any of the specified warning codes is encountered (18, 27, or 28 in this case).

-Z34
This command causes a 0 return code with the warning message to be returned when a Too Few Pages Requested, More Allocated Error (34) is encountered.

If the Ignore Warnings command (-Z) is enabled and a map encounters the condition for any warning code as specified, the execution section of the audit log includes a Valid map status with a 0 return code and the associated warning message. For example:

```
<Summary MapStatus="Valid" Return="0">
  <ElapsedTimeInSec>0.1026</ElapsedTimeInSec>
  <Message>Input type contains errors.</Message>
  <CommandLine>'install_dir\examples\ansiack\receiveEDI.mmc'
  </CommandLine>
  <ObjectsFound>0</ObjectsFound>
  <ObjectsBuilt>0</ObjectsBuilt>
</Summary>
```

When using the -Z command, you cannot specify the same warning code using the Fail on Warnings command (-F).

Both the -Z and -Z! commands cause a 0 return code with the warning message to be returned when any of the warning codes is encountered.

Examples

This documentation presents a variety of examples involving the execution of maps using various execution commands in a **RUN()** function and from the command line in UNIX and Windows environments.

- [Running a map located in a different directory](#)
- [Creating work files in an alternate directory](#)
- [Executing multiple maps from a single command](#)
- [Overriding a database target](#)
- [Overriding the schema location at run time](#)
- [Executing a command file](#)
- [Using a run function and echoed outputs in memory](#)
- [Audit Log in memory](#)

Running a map located in a different directory

From a UNIX command line, enter:

```
/install_dir/dtxcmdsv /x12/edi.mmc -TIO -IF2!WXR5:1 dtin -OF1B out.txt
```

Option

Description

/X12/edi.mmc

This specifies the full path and name of the map to be executed.

-TIO

A trace file is created or all input and output objects are placed in the same directory as the map and named using the **<mapname>.mtr** file naming convention.

-IF2!WXR5:1 dtin

This changes the source of input card #2 to be a file named **dtin**. The other adapter settings for this card include:

Do not re-use workfiles.

If the map successfully executes, delete the **dtin** file.

If the file is not available, attempt to access it five more times at one-second intervals.

-OF1B out.txt

This changes the destination for the data from output card #1 to be a file named **out.txt**. The **B** option causes any changes to **out.txt** to be backed out (rolled back), if the map does not successfully execute. All other adapter settings are as compiled into the map file.

The file locations in this example are relative to the location of the compiled map file.

Creating work files in an alternate directory

From a Windows command line, enter:

```
install_dir\dtxcmdsv k:\maps\invoices.mmc -AE -T -WD=c:\tmp
```

Option

Description

k:\maps\invoices.mmc

-AE	This specifies the name of the map to be executed.
-T	This produces an execution audit log using the AuditLocation settings for MapAudit compiled into the map file.
-WD=c:\tmp	This specifies that no trace information is to be produced.
	This creates the work files in the c:\tmp directory and deletes the work files after the map file is executed.

Executing multiple maps from a single command

From a Windows command line, enter:

```
dtxcmdsv mymap.mmc -R2 -D1949 flatfile.mmc -F -Y10:2
```

Option	Description
mymap.mmc	This specifies the name of the first map to be executed, mymap.mmc .
-R2	This causes the server display to be updated two times per second.
-D1949	This command option specifies that dates without a century value should be converted. Years between 00 and 49 are interpreted as 20xx and years between 50 and 99 are interpreted as 19xx.
flatfile.mmc	This command option specifies the name of another map to be executed, flatfile.mmc . When flatfile.mmc is executed, it uses the default options, not the options that precede it on the command line.
-F	Fail on the return of any warning code.
-Y10:2	If any non-data file resource is unavailable, such as the map file, audit log file, work file, and so on, up to ten attempts should be made at two-second intervals to access the unavailable resource.

Overriding a database target

Suppose you want to run the map **multitran.hp**, overriding some of the settings for the fourth output card, which is a database target.

Use the following command:

```
/install_dir\dtxcmdsv multitran.hp -G -OD4R5:3B "``-DELETE -TRACE ERROR``"
```

Option	Description
multitran.hp	This specifies the name of the map to be executed, multitran.hp .
-G	All item properties, including size, presentation, and restrictions, are fully validated.
-OD4R5:3B "``...``"	This changes settings for the database target for the data of output card #4 as follows: R5:3 <ul style="list-style-type: none"> • If the database resource is unavailable, attempt to make the connection five more times at three-second intervals
B	<ul style="list-style-type: none"> • If the map does not complete successfully, roll back any changes made to the database table
"``-DELETE -TRACE ERROR``"	These database-specific adapter commands described in the <i>Resources Adapters</i> documentation indicate that all rows in the target database table should be deleted before processing the output data and a trace file should be generated that only contains error information.

Overriding the schema location at run time

When you have a map that is designed to parse input XML data, but want to use a different schema location than what was set up in the Metadata location setting for the root type on the input card in the Map Designer GUI, run the map from the command line and override the map settings. Use the Input Source Override - File execution command (-IF) and specify the card number and the metadata location (M) command line option with the schema file location, enclosed in single quotes.

From a Windows command line, enter:

```
install_dir\dtxcmdsv mymap.mmc -IF1M'k:\billing_project\myschema.xsd' myfile.txt
```

Option	Description
--------	-------------

```

mymap.mmc
  This specifies the name of the compiled map file to be run.
-IF1
  This will change the source file specification on input card 1 in the mymap.mmc compiled map file to myfile.txt.
M'k:\billing_project\myschema.xsd'
  This specifies the new metadata location for input card 1.
myfile.txt
  This is the source file, specified on the -IF execution command, that will override the file specified on input card 1.

```

Executing a command file

As an alternative to typing execution commands on the command line, you can run maps using maps and execution commands in a command file. To use a command file named **cmd_file.txt**, from a UNIX command line, enter:

```
dtxcmdsv @cmd_file.txt
```

A command file can contain spaces and new lines to separate arguments and maps to be run. The following is an example of a command file to be executed on a UNIX platform:

```

/x12/edi.mmc -TIO -IF2!WXR5:1 dtin -OF1B out.txt
/maps/invoices.mmc -AE -T -WD=/tmp
mymap.mmc -R2 -D1949
flatfile.mmc -F -Y10:2
/maps/daily/multitran.hp -G -OD4R5:3B ` -DELETE -TRACE ERROR'

```

Using this command file, the maps are executed sequentially. These command files can be manually created or can be generated by the Integration Flow Designer for systems with an execution mode of Command.

Using a run function and echoed outputs in memory

When using the Output Target Override - Echo execution command (-OE) with the X option, the output is stored in memory and is not echoed back to the calling map or application. A typical scenario in which this is useful and can serve to optimize performance is when a map has an output that is only used as a *scratch* card. That is, it is built to be used only by a subsequent output.

For example, if used in a **RUN()** function:

```
RUN ("some_map.mmc", "-WM -OE1 -OE3X -OE4")
```

In this example, a memory-based WorkSpace is used and the data for output cards 1 and 4 are echoed back to the rule in which the **RUN** function is located. All other map settings and input and output card settings for executing this map, such as **MapAudit**, **Century**, and so on, would use the settings compiled into **some_map.mmc**.

This results in the execution of **some_map.mmc**. The data produced for output card 1 and 4 is concatenated and *echoed* back to the rule containing the **RUN** function. The data for output card 3 is not *echoed* back to the rule because of the use of the X option. Given that output card 1 builds 103910^ABC, output card 3 builds justsomedata, and output card 4 builds 01/23/98, the **RUN** function returns 103910^ABC01/23/98.

The most common use for this feature of echoed outputs is when the data for an output card is needed only during the execution of the map, perhaps for use on a later output card, and can be discarded after the map has completed execution.

For another example of using an echoed data destination, see the *Platform API* documentation.

Audit Log in memory

Similar to how the data built for an output card can be echoed back to a calling map or application, the audit log, including Data and Execution information, can be placed in memory using the MapAudit execution command (-A) with the M option and echoed back to its calling map or application with the E option.

If the audit in memory fails, either of these messages might be returned from the Command Server: Disk write error or Not enough memory to execute map.

The -AEM audit option can be useful when using a **RUN** function or the Platform API to place the audit log in memory during map execution and then to return it, along with any outputs being echoed back. Placing the audit log in memory avoids the file I/O necessary if the audit log was written to disk.

For example, if used in a **RUN()** function, enter:

```
RUN ("some_map.mmc", "-AEM -WM -OE1")
```

This results in the execution of **some_map.mmc** and returns the concatenation data created for output card 1 and the audit log data.

When the audit log data is returned in this function implementation, it still adheres to the format described by the **audit.mtt** type tree included in the examples directory.

When the audit log is written to memory and is echoed back to the calling map or application, it is appended to any echoed outputs. Therefore, if output cards 2 and 4 were echoed, along with the audit log, the data for output card 2 is followed by the data for output card 4, which is followed by the contents of the audit log.

INI commands for debugging maps

This documentation presents the **config.yaml** file setting you can use for the debugging of adapter connections for maps run using non event-driven execution methods not run through events using the Launcher. This includes using a command-driven execution method such as the Command Server, a command parameter file, batch file, shell script, graphical user interface (GUI), scheduling program, and JCL on the mainframe, or an application-embedded execution method using components of the Development Kit in which maps can be embedded in specific third-party applications for web-based integration scenarios.

For information about debugging maps run using event-driven execution methods, see the *Launcher* documentation, *Map Designer* documentation and individual adapter documentation.

The logging feature is used to help you debug adapter connection issues. To use this feature, configure the debugging paths under /runtime/Connections Manager/log paths in the config.yaml file. .

- [Logging](#)

Logging

The logging feature (non-Launcher usage) enables you to specify the type of information you want to capture about adapter connections in log files. You do this by configuring the following severity classes and debug components. They are listed in the order of impact of these severity classes and debug components referred to as logging categories, from lowest to highest, along with their equivalent entry in the **/runtime/Connections Manager/log** logging entry. The logging categories in the **config.yaml** file will be configured to `false` to turn that category off or `true` to turn that logging category on.

Logging Category

Logging Category in the Connections Manager

Trace	/runtime/Connections Manager/log/trace
Debug	/runtime/Connections Manager/log/debug
Info	/runtime/Connections Manager/log/info
Warn	/runtime/Connections Manager/log/warning
Error	/runtime/Connections Manager/log/error
Fatal	/runtime/Connections Manager/log/fatal

- [Logging categories](#)
- [Debug](#)

Logging categories

The logging categories, non-Launcher usage, provide a variety of debugging information. They are used to determine which severity levels and components to debug.

```
/runtime/Connections Manager/log/X=  
Provide the specific category, such  
as trace, debug, info, warning, error or fatal,  
for X and false to turn that logging category off, or true (to turn that category  
on) for n.  
Example: trace: true
```

Provide the specific category, such as Trace, Debug, Info, Warning Or Fatal, for X and false to turn that logging category off, or true (to turn that category on) for n.

Example: LogTrace=true

Logging Category	Value	Description
LogTrace	false	Disabled
	true	Enables the logging of sequence of events Example Results: Before Resource Pending <map> After Resource Pending <map>
LogDebug	false	Disabled
	true	Enables the logging of information to diagnose adapter connection behavior Example Results: New audit file name <name> Adapter wildcard.<wildcard>
LogInfo	false	Disabled
	true	Enables the logging of general information about the state of adapter connections Example Results: :Map started InitPendingHigh reached
.LogWarning	false	Enabled

Logging Category	Value	Description
	true	Enables the logging of issues that are not severe, but might be important to know Example Results: Resource Manager table too small - using default Map warning <map>
.LogError	false	Enabled
	true	Enables the logging of critical adapter connection errors Example Results: Map failure <map> Socket failure <socket_type>
LogFatal	false	Enabled
	true	Enables the logging of a fatal error Example Results: Corrupted MMC file during initialization <mmc_name> Adapter listener Initialization failure <adapter>

Debug

Use the **DebugName** and **DebugAppend** commands configured in the **config.yaml** file under /runtime/Connections Manager to specify how you want to create the output log file.

- [DebugName](#)
- [DebugAppend](#)

DebugName

Use this setting to define the complete file name of the debug file. Remember that this logging category is only for non-Launcher usage and cannot be configured dynamically in the Management Console. When the map is started, it will use the settings that were configured in the **config.yaml** file.

The default file name is **dtxconn.log**.

The syntax is the following:

DebugName: [file_name]

Option

Description

file_name

The file name of the debug file for the Connections Manager

DebugAppend

Use this setting to append the debug information to an already existing debug log file. Remember that this logging category is only for non-Launcher usage and cannot be configured dynamically in the Management Console. When the map is started, it will use the settings that were configured in the **config.yaml** file.

The default file name is **dtxconn.log**.

The syntax is the following:

DebugAppend: {false | true}

Option

Description

false

Disables the append specification so that the debug information is written to a new debug log file.

true

Enables the append specification so that the debug information overwrites the contents of an existing debug log file.
This is the default.

Expressions and evaluations

You can use functions and expressions to create component rules in the Type Designer and to create map rules in the Map Designer.

The **Examples** directory, located in the product installation directory, contains type trees and maps that can help you learn how to accomplish your mapping tasks. These type trees and maps contain component and map rules that show the use of many functions and expressions.

- [Expressions](#)
 - [Literals](#)
 - [Data object names](#)
 - [Evaluating expressions](#)
 - [Operators](#)
 - [Using functions in expressions](#)
 - [Map names in expressions](#)
 - [Expressions that evaluate to NONE](#)
 - [Evaluated expressions assigned to output items](#)
 - [Automatic item format conversions](#)
-

Expressions

An expression is a statement about data objects. Expressions are used in component rules in the Type Designer and in map rules in the Map Designer.

The following are examples of expressions:

```
Account Balance = Credits - Debits
TrunkRoom < 15
PRESENT (Store#:StoreInfo)
```

As you enter an expression, you can add spaces before and after component names and operators to make the expression more readable. Additional spaces have no effect on an expression.

Expressions are a combination of literals, object names, operators, functions, and map names.

- [Component rule expressions evaluate to true or false](#)
 - [Map rule expressions evaluate to data](#)
-

Component rule expressions evaluate to true or false

Component rules are expressions that evaluate to "true" or "false". For example, the result of each of the following component rules is "true" or "false".

```
WHEN (PRESENT (Qualifier), PRESENT (Address))
COUNT (Exchange) < COUNT (Purchase)
Invoice#:Item = Invoice#:Item[1]
```

Map rule expressions evaluate to data

Map rules are expressions that evaluate to data.

For example, the result of each of the following map rules is data:

```
= "Florida"
= Price:Input
= COUNT ( Name:Roster )
= RecordMap ( FixedRecord )
```

Literals

A literal is a constant value. A literal may be a number or a text string.

The rules for using numeric literals are:

- A numeric literal is in integer or decimal format and can be signed.
- A comma separator should not be included in a numeric literal.
- A numeric literal cannot be greater than 254 digits.

The rules for using text literals are:

- A text literal is enclosed in double quotes.
- A double-quote included in a text literal is released by another double quote.

Literals are encoded in UTF-16 (Unicode).

The following are some examples of literals:

```
"This is a text literal"
"ABC Company"
"Some ""quoted data"" to show use of a double double-quote."
1.23
-9
1045
```

Carriage return/line feeds cannot be within a quoted string. To use a carriage return/line feed the string must be broken into two strings with <CR><LF> between them. For example:

```
="username=?????\" + "<CR><LF>" + "&password=?????"
```

will place the output username and password information on separate lines.

<CR><LF> must be within quotation marks.

Data object names

A data object is referenced in an expression by its name. An object name can be as simple as a card name or a local type name. It can also be complex depending on the object you want to reference.

- [Object names in map rules](#)
- [Object names in component rules](#)
- [Card name](#)
- [Local type name](#)
- [Partition list](#)
- [Component path](#)
- [Indexed object names](#)
- [Component paths separated by a colon](#)
- [Component paths separated by IN](#)
- [Comment object name](#)
- [Shorthand notation](#)

Object names in map rules

In a map rule, data object names always refer to the card name that contains the data object name. So, in a map rule, a data object name ends with a card name. In the following example image, the object name for the component **Contact** of the card **ContactFile** is **Contact:ContactFile**.

The general definition of an object name in a map rule can be divided into three parts as described in the following table. If one of these parts is used, it must be sequenced according to the order in the table.

Parts of an Object Name

Required

Component name

No

Set of component-paths, each ending with either a colon or the reserved word **IN**

No

Card name

Yes

When **IN** is used, there must be a space before and after it, such as **Dependent**

IN Claim.

Object names in component rules

In a component rule, data object names always refer to components in the same component list. In a component rule, a data object name ends with a component name. For example, if **LineItem** is in a component list, the object name for the **Qty Info** component of **LineItem** is **Qty Info:LineItem**.

In the preceding **Qty Info:LineItem** example, the colon would be interpreted as "is a component of". If the example was **Qty Info LineItem**, the space between **Info** and **LineItem** would be interpreted as "is a subtype of".

The general definition of a component rule object name can be divided into the two parts described in the following table. If one of these parts is used, it must be sequenced according to the order in the table.

Parts of an Object Name	Required
Set of one or more component-paths , infix separated with either a colon or the reserved word, IN	At least one is required
The reserved word, COMPONENT	No

IN and **COMPONENT** are reserved words. Reserved words are not case sensitive.

Card name

A map rule can reference the object of an entire card. A card name is a simple type name from 1 to 32 bytes in length in UTF-8 encoding. For example, if the input card name is **Invoice**, the name for the card object would be **Invoice**.

Local type name

An object name can be a local type name. A local type name is specified as one or more simple type names separated by spaces, such as:

City Field

Local type names are typically used to refer to a component. If used in a component rule, for example, the component referenced in a rule is specified as a local type name. In a map rule, local type names refer to components contained in a card object.

Local type names can also be used to refer to the partitioned type of a component. When a type is partitioned, you can refer to all of its partitions by simply referring to the partitioned type.

For this example, the type **Record** is partitioned into **Header**, **Detail**, and **Trailer**. The object name that references **Header**, **Detail**, and **Trailer Record** is: **Record**

Here is another example: the type **Transcript** has **Header Record**, **Detail Record**, and **Trailer Record** as components contained within it. The object name that references all **Header**, **Detail**, and **Trailer Records** within **Transcript** would be **Record IN Transcript**.

Partition list

A partition list is a set of partition names separated by the symbols <>. A partition name is the simple name that represents the partitions found under the parent, or partitioned, type. For example, the partition Header of the type Record would have this component path: **Header<>Record**

Component path

A component path is specified as an optional partition list, followed by a local type name and then followed by an optional index. Here are some examples of component paths:

```
Grand<>Ball Room[5]
Ball Room[LAST]
Really<>Grand<>Ball Room
Ball Room
```

Indexed object names

An object name can refer to a particular occurrence of a data object. The index of the occurrence appears in square brackets immediately after its name. For example, the object name of the third **Note** would be:

Note[3]

The index between the square brackets can be an integer or the reserved word, "LAST" (a special index value that refers to the last data object of a particular series). The index cannot be another object name. To use a variable index, use the **CHOOSE** function.

LAST is interpreted in the context in which it is used.

- [Using LAST in a map rule to reference an input](#)
- [Using LAST in a component rule](#)
- [Using LAST in a map rule to reference an output](#)

Using LAST in a map rule to reference an input

In a map rule, when referencing an input, LAST refers to the very last occurrence of that input. For example, the last **Note** of the input **Report** would have the name:

Note[LAST] :Report

In this context, all of the input has been validated before map rules are evaluated.

Using LAST in a component rule

In a component rule, LAST refers to the last occurrence found. For example, in the rule:

PO# Field:Order = PO# Field:Order[LAST]

LAST refers to previous occurrence of **Order** because when this rule is evaluated, the last known **Order** is the last one found.

Using LAST in a map rule to reference an output

In a map rule, when referencing an output, LAST refers to the last built occurrence of that object. For example, using the same expression:

PO# Field:Order = PO# Field:Order[LAST]

LAST refers to the previous occurrence of **Order** because, when this rule is evaluated, the last known **Order** is the last one built.

LAST is a reserved word and is not case sensitive.

Component paths separated by a colon

A component in the component list of another object is always referenced by a colon (:). The local type name of the nested component precedes the colon. The name of the object that contains the component follows the colon. For example, the **Line Item** component of **PO** would have this name:

Line Item:PO

The **Last Name** component of **Client**, which is in turn a component of **Account**, would have this name:

Last Name:Client:Account

Component paths separated by IN

To reference all occurrences of an object contained in another object, use the keyword **IN**.

For this example, **ShipSchedules** appears as a component of different components within **OrderAck**.

The object name for all occurrences of **ShipSchedules** within **ORD_ADR_OUT_WD Record** is:

ShipSchedules IN ORD_ADR_OUT_WD Record:OrderAck

When **IN** is used, the contained object name must refer to the same type. In the example, the **ShipSchedules** component of **ORD_ADR_OUT_WD Record** and the **ShipSchedules** component of **OrderLine Structure** must be of the same type.

In the Map Designer, you can refer to all occurrences of an object contained in a card object. The object name for all occurrences of **ShipSchedules** within **OrderAck** is:

ShipSchedules IN OrderAck

- [Referring to all occurrences with IN COMPONENT](#)

Referring to all occurrences with IN COMPONENT

In the Type Designer, you can refer to all occurrences of an object contained in a component list. To refer to all components in a component list, up to a given component, the word **COMPONENT** is used.

For example, the rule on the component **Conclusion Topic** needs to count all of the valid **Topics** up to, and including, **Conclusion Topic**.

The **IN COMPONENT** expression can be used:

#Topic Field:\$ = COUNT (Topic IN COMPONENT)

The above component rule works only if **Topic** is partitioned.

Comment object name

A comment name can be either an in-comment name or an @-comment name.

An in-comment name references all comment objects within a specified object. An in-comment name is specified as a component-path, a space, the reserved word **IN**, followed by another space, followed by the component path of the component on which the floating component type is defined. For example, given the data structure shown below, to reference all **INPUT Parameters** for a particular **Input**, regardless of whether they followed **Method OpenFile** or **Method GetEntry**, the object name would be **INPUT Parameters IN Input**.

An @-comment name references all comment objects that follow immediately after a specified object. An @-comment name is specified as the component path of the comment, followed by the reserved symbol "@" , followed by the component path of the component that follows the comment. For example, to reference only the **INPUT Parameters** that follow immediately after the **Method OpenFile** (and before **Method GetEntry**), the object name would be **INPUT Parameters @ Method OpenFile:Input**.

Shorthand notation

In a rule, a dollar sign (\$) can be used to refer to the object to the left of the rule cell. In the Type Designer, the \$ sign refers to the object you are qualifying. In the Map Designer, the \$ refers to the object to which the rule evaluates.

In certain cases, you can also use a period between colons to shorten the reference to a data object name. The **Use Ellipses** command can be used to automatically shorten data object names you drag into rule expressions.

- [Using the dollar sign \(\\$\)](#)
- [Using ellipses](#)

Using the dollar sign (\$)

The dollar sign can be used to refer to the object to the left of a rule cell.

For example, the component rule below applies to the component **RunRule**.

The **RunRule** in the rule can be replaced by **\$**. You can remember it this way: a dollar sign always means "whatever component appears to the left of the rule".

Here is an example of a Map Designer rule that uses the dollar sign:

```
Order:Invoice = MapMyOrder ( Order:PO , Index ( $ ) )
```

In this example, each time this rule is evaluated, the index of the **Order:Invoice** being built is the object referred to by the **\$**.

Using ellipses

A single period can be used, like ellipses, in place of object names, as long as that object name can be interpreted as a unique object.

For example, if you have the following object name:

```
City Field:BillTo Customer:Account:File
```

you can replace it with

```
City Field:..:File
```

If file also contains another **City Field**, such as

```
City Field:ShipTo Customer:Account:File
```

and you use the **Use Ellipses** option, the system returns

```
City Field:BillTo Customer:..:File
```

Evaluating expressions

Expressions are evaluated based on the context in which data object names, literals, operators, function names and map names appear in the expression, and the data on which it operates. A component rule always evaluates once for each occurrence of a component. A map rule can evaluate many times.

When a map rule evaluates, the Map Designer selects an evaluation set of values and then evaluates the rule. Then it selects another evaluation set of values, if there is one, and evaluates the rule again. This continues until all the different evaluation sets have been used.

The same number of evaluations is always produced, but output objects can be ordered differently, depending on how you define your map.

For a selected evaluation set, a particular instance of a rule is evaluated using parentheses, operator precedence rules, and left-to-right precedence rules to get one result.

- [Card order can influence the order of evaluation sets](#)
- [Functions influence the number of evaluation sets](#)
- [Object names influence the number of evaluation sets](#)

Card order can influence the order of evaluation sets

When an evaluation set is selected, card object names are ordered by their position in the map: card 1 before card 2, and so on. The card order for a map can affect the order of output results.

For example, suppose you want to evaluate the following map rule.

```
NumberSet ( s ) = B:Card2 + A:Card1
```

In this example, an evaluation set for this rule consists of one value for B and one value for A. One evaluation set produces one **NumberSet**.

As an example, here there are three As and three Bs in the data:

A Values	B Values
1	3
2	2
3	1

There are nine evaluation sets. The order of the cards might affect the order of the evaluation sets.

If Card 1 is the first card, you get the following results:

Evaluation #	A	B	Result
1	1	3	4
2	2	3	5
3	3	3	6

Evaluation #	A	B	Result
4	1	2	3
5	2	2	4
6	3	2	5
7	1	1	2
8	2	1	3
9	3	1	4

If Card 2 is the first card, you get the following results:

Evaluation #	B	A	Result
1	3	1	4
2	2	1	3
3	1	1	2
4	3	2	5
5	2	2	4
6	1	2	3
7	3	3	6
8	2	3	5
9	1	3	4

If both A and B are contained in the same card object, evaluation sets are selected based on the order A and B appear in the rule. Leftmost objects are selected first. If you change the rule to this:

```
NumberSet ( s ) = B:Card2 + A:Card2
```

the same results are produced as when card 2 is the first card.

Functions influence the number of evaluation sets

For this example, you have the following rule:

```
NumberSet ( s ) = A:Card1 + SUM ( B:Card1 )
```

Using the same values for A and B, there are only three evaluation sets as shown.

NumberSet[1] = 7

A Values	B Values
1	3
2	2
3	1

NumberSet[2] = 8

A Values	B Values
1	3
2	2
3	1

NumberSet[3] = 9

A Values	B Values
1	3
2	2
3	1

If your rule looks like:

```
NumberSet ( s ) = SUM ( A:Card1 ) + SUM ( B:Card1 )
```

there is one evaluation set: NumberSet[1] = 12

A Values	B Values
1	3
2	2
3	1

If you have the following rule:

```
NumberSet ( s ) = A:Card1 + EXTRACT ( B:Card2 , B:Card2 != 2 )
```

the order of the operands does not affect the order of evaluation set selected. This is because an A is selected, then the **EXTRACT** is evaluated, then evaluation sets are determined for that A and a given **EXTRACT** result. When all **EXTRACT** results are used, the next A is selected, and so on.

Given the same data, this time you get the following results:

Evaluation #	A	B Extract Values	Result
1	1	3	4
2	1	1	2
3	2	3	5
4	2	1	3
5	3	3	6
6	3	1	4

As another example, the following map rule applies to the output Status(s):

```
= IF ( Quantity:Order Record:Order > 10 &
OR ( Store:Order Record:Order = "A" ) ,
      "Accept" , "Reject" )
```

The first argument of the **IF** function is an expression. One evaluation set of this expression requires:

- the **Order**
- one **Order Record**
- one **Quantity** of the selected **Order Record**
- all the **Stores** of the selected **Order Record**

The **IF** function evaluates once for each **Quantity** of each **Order Record**. Other than the first argument of the **IF** function, nothing else in the map rule affects the number of times the map rule will be evaluated. So, if there are 1000 **Quantity** data objects contained in **Order**, this map rule will evaluate 1000 times.

Object names influence the number of evaluation sets

In some expressions, the same data object name might appear more than once. The same data object name always refers to the same data object. The same data object name influences the combinations of evaluation sets that are selected. For example:

```
BackOrder(s) = Qty Ordered:Record:Order - Qty Received:Record:Order
```

When a **BackOrder** evaluation set is selected, the **Record** that contains **Qty Ordered** is always the same **Record** that contains **Qty Received**. And an **Order** is always the same one for one evaluation set. When the same object name is used more than once in the same expression, both references bind to the same object.

If there is always one **Qty Ordered** per **Record** and one **Qty Received** per **Record**, the following would be sample data:

Record #	Qty Ordered	Qty Received
1	5	4
2	4	4
3	6	2

This would produce three **Back Orders**, one for each **Record**.

You can coordinate nested data objects easily by the way an object name is used.

- [Using object names to coordinate evaluation sets](#)
- [Using IN to decouple object name coordination](#)
- [Using IN to decouple different partitions in the same rule](#)

Using object names to coordinate evaluation sets

In the following example, common object names are used to coordinate **Qty** and **UnitPrice** so they do not get mixed up across different **Records**:

```
Extension = SUM ( Qty:Detail Record:Order * UnitPrice:Detail Record:Order )
```

This rule has only one evaluation set because the **SUM** consumes all the objects referenced in the rule.

Using IN to decouple object name coordination

Suppose you have a situation in which you do not want to coordinate common objects. You might, for example, want to count different objects contained in the same object, as in:

```
Summary = COUNTabs ( Header:Order:Message ) + COUNTabs ( Line Item:Order:Message )
```

If there are multiple **Orders** in your data, the **Summary** would not be evaluated correctly. This rule would only count the **Headers** of the first **Order** and add it to the count of all Line Items of the first **Order**. To count all the **Headers** and all the **Line Items** in all the **Orders**, use IN:

```
Summary = COUNTabs ( Header IN Message ) + COUNTabs ( Line Item IN Message )
```

Using IN to decouple different partitions in the same rule

If data objects in an expression are different partitions of the same type, the expression might evaluate to "none".

For example:

```
MyMap ( Good<>Design , Best<>Design )
```

Good and **Best** are partitions of the same type, **Design**. A given **Design** could never be both a **Good<>Design** and a **Best<>Design**; therefore, the second argument of **MyMap**, **Best<>Design**, evaluates to "none".

To reference both the **Good** and **Best** partitions, use IN:

```
MyMap ( Good IN Design , Best IN Design )
```

Operators

Operators are used for arithmetic functions and text functions on items. If an operator requires two operands, the operator symbol appears between them. For example, in the expression **a + b**, the operator symbol "+" appears between the operands **a** and **b**.

Operators are reserved symbols that cannot be used in type names.

- [Arithmetic operators](#)
 - [Text operators](#)
 - [Logical operators](#)
 - [Comparison operators](#)
 - [Order of operator evaluation](#)
 - [Operands](#)
-

Arithmetic operators

Operator	Description
+	addition
-	subtraction
*	multiplication
/	division

Text operators

Operator	Description
+	concatenation

Logical operators

Logical operators are used in expressions that evaluate to "true" or "false".

Operator	Description
^	exclusive or
&	and
	or
!	not
=	equals

Comparison operators

Operator	Description
=	equal to
>	greater than
<	less than
>=	greater than or equal to
<=	less than or equal to
!=	not equal to

NOT=

alternative for not equal to

The results of comparison operators are based on the native collating sequence of the machine used to run the map.

Order of operator evaluation

Use parentheses to group operations. Expressions within parentheses are evaluated before performing other operations. For example:

`(UnitPrice - Discount) * Tax`

The expression **UnitPrice - Discount** is evaluated before the rest of the expression.

Some operators are evaluated before others according to standard rules of precedence. Operators are evaluated in the following order:

Precedence	Operators	Description
first	()	Operations within parentheses
second	+ and -	unary plus and minus The sign indicates a positive or negative expression, for example: - quantity*rate
third	=, <, >, <=, >=, !=	comparative operators
fourth	^	logical operator "exclusive or"
fifth	&	logical operator "and"
sixth		logical operator "or"
seventh	* and /	multiplication and division
eighth	+ and -	addition and subtraction

Operators of equal precedence are evaluated left to right.

Operands

Operands are the arguments for an operator. For example, in the expression **a + b**, the **+** is the operator symbol, and **a** and **b** are the operands.

An operand can be any of the following types:

- a literal
- a data object name
- a function
- another operator

Using functions in expressions

Functions perform a particular action on its input arguments. A function is written like this:

`FUNCTION (argument1, argument2, ... argumentn)`

The arguments of the function appear inside the parentheses, separated by commas. A function might require a fixed number of arguments or might allow a varying number of arguments. You can use functions anywhere in an expression.

- [Function arguments](#)
- [Input arguments](#)
- [Nested input arguments](#)
- [Output arguments](#)
- [Function arguments and evaluation](#)

Function arguments

Input arguments themselves can be expressions. Some functions limit the type of expression that can be used as an input argument. The syntax specification tells you the number of data objects that can be used for one function evaluation.

There is *always* one output argument for a function. The specification of the output argument tells you: 1) the type of the result produced by a function and 2) the number of objects that can be produced when the function evaluates once.

You need to know the type of the output argument because functions can be used as other arguments. The result of a function can also be used to directly produce an output data object contained in an output destination.

When the Map Designer analyzes the interfaces of expressions in rules during the build process, it ensures that the output argument of a function matches the input argument it is used for. The analysis also checks the type of the output argument when that function is used to directly produce an output data object.

The output argument of a function specifies the result that the function produces for one evaluation. For example, one evaluation of the ABS function produces one positive number. One function evaluation might produce multiple outputs. If it does, the expression that contains that function might produce multiple evaluation sets.

Input arguments

The input arguments for a function specify the information the function uses to return a result. Some functions require an exact number of input arguments. For other functions, the number of input arguments can vary. Optional arguments for a function are shown in brackets [].

To correctly use a function, you must use the correct arguments in the correct order.

Each argument can, itself, be an expression. In general, an input argument might be any of the following:

- an object name
- a literal
- a function-name and its arguments
- an operator and its arguments
- an enumerated series of literals, such as {a, b, c}
- a map name and its arguments

For example, some valid expressions that use the **ABS** function are:

```
ABS ( Quantity:LineItem )
ABS ( UNIQUE ( Quantity:LineItem ) )
ABS ( Quantity:LineItem - 300 )
```

Each function has its own expression syntax for its input arguments. For example, the **ABS** function cannot use a map as an argument. See [Syntax of a Function](#) for notation used to specify valid expression syntax.

Nested input arguments

When a function, operator, or map is used as an input argument, each of these has arguments of its own. Arguments of other arguments are said to be *nested*. For example, in the use of the **ABS** function, you can use a function as an argument:

```
ABS ( UNIQUE ( Quantity:LineItem ) )
```

The output of the **UNIQUE** function becomes the input argument to the **ABS** function.

Output arguments

The output argument of a function indicates the type of object the function produces and the number of objects a function can produce. An output argument is specified as one of the following object types or values:

- A single data object of a type
- A series of data objects of the same type
- "True" or "False"

If the output of a function is a series, that function can be used only in a map rule in the Map Designer. It cannot be used in a component rule in the Type Designer.

For example, you cannot use the **CLONE**, **EXTRACT**, **REJECT**, **SORTDOWN**, **SORTUP** or **UNIQUE** functions in the Type Designer.

Function arguments and evaluation

When a function is evaluated, the number of argument objects used for one evaluation depends on the function. In the specification of the syntax for a function, the number of input objects that can be used for each argument for one function evaluation is expressed as "single" or "series".

Some functions use a single object as the value of an argument for one evaluation. For example, the **ABS** function uses a single object as the value of its argument for one evaluation.

```
ABS ( Quantity:LineItem )
```

When a single object is used for one evaluation, the function itself can evaluate many times if there is more than one data object that fits the argument definition. For example, if there were ten **Quantity:LineItem** data objects, the **ABS** function could evaluate ten times.

Some functions use an entire series of objects as the value of an argument for one evaluation. For example, the **COUNT** function uses an entire series of data objects as the value of its argument for one evaluation.

```
COUNT ( LineItem:PO )
```

When a series of data objects is used for one evaluation, the function evaluates just once when there is more than one data object that fits the argument definition. For example, if there are ten **LineItem:PO** data objects, the **COUNT** function would evaluate only once.

Some functions use an entire series as input and produce a series as output. For example, the evaluation set for the **EXTRACT** function produces a series from an input series. When a function produces a series, each output can be selected for different evaluation sets of the expression that contains that function.

Consider the following expression:

```
Line Item(s) = EXTRACT ( Line Item:Order, Qty:Line Item:Order > 1000 )
```

Each **Line Item** that fits the specified criteria produces a **Line Item** of **Order**. In this example, the map rule is evaluated many times, once for each **Line Item** produced by the **EXTRACT** function.

When functions are part of other expressions, the number of evaluation sets for that function depends on the object names used in the entire expression. For example:

```
Debit ( s ) = ABS ( Debit:Account:Input )
```

There might be many evaluation sets for the above expression. The ABS function might be evaluated many times, once for each **Debit** of each **Account** of **Input**. However, if the ABS function is part of a more complex expression, common objects of the expression might determine the number of ABS evaluations.

Map names in expressions

Map names in expressions that are used in map rules represent calls to functional maps.

The syntax of a functional map call in an expression is the same as the syntax of a function:

```
FunctionalMapName ( argument1 , argument2 , ... argumentn )
```

At run time, when a rule calls a functional map, the functional map writes the output, in the format defined by its output card type, directly to the output of the executable map. The functional map also places the information about the type or types that it builds in the output work file of the executable map, if necessary. So the type that the functional map builds is the type of the output card of the functional map, which must match the output type of the rule on which the functional map call is placed.

When the output type of the functional map is a group, map build analysis verifies that the type of the output card of the functional map matches the output type of the rule on which the call is placed. When the output type of the functional map is an item, map build analysis checks that the item classes match, but it does not require that the type of the output card of the functional map be the exact same type as the output type of the rule on which the functional map call is placed. Because of this way that map build analysis operates, functional maps can behave more like subroutines. You can use the same functional map to build various output objects that all have the same characteristics, as long as you do not try to reference the output objects of the calling rules in later rules.

A functional map does not behave like a function because when the functional map completes processing, it has already written its output to the output of the calling rule. That calling rule cannot access the data that the functional map built. This behavior is different from the behavior of a function call, which returns the value that the function produced to the point of invocation. The calling rule can manipulate the value that a function returned. The calling rule cannot manipulate the value that a functional map produced.

When the output of a functional map is an item, you can use the **ASFUNCTION** general function to return the output to the invoking map rule instead of to the output card.

Since the type that the functional map builds is the type of the output card of the functional map, later references to the output type of the rule, in subsequent rules, cannot work properly unless the type of the output card of the functional map exactly matches the output type of the rule. If the rule is on some type, for example, A, and the output type of the functional map is some different type, for example, B, the object that is reflected in the work file for the rule is B. If a subsequent rule tries to reference the instance of type A, that reference returns **NONE**.

The following examples show two ways, one that is valid and one that is not valid, to specify map rules that use map names in expressions. For both examples, the names of the functional maps are prefixed by **F_**.

Valid example:

```
=IF ( A > 10 , F_BigMap ( X ) , F_LittleMap ( Y ) )
```

This example is valid because the rule does a comparison on an item, and then calls one of two functional maps, which sends the results directly to the output of the executable map. If the value of A is greater than **10**, the rule calls the **F_BigMap** functional map; otherwise, the rule calls the **F_LittleMap** functional map.

Not valid example:

```
=IF ( F_Map ( A ) > 10 , F_BigMap ( X ) , F_LittleMap ( Y ) )
```

This example is not valid because the rule attempts to use the output of the **F_Map** functional map in a comparison. The rule calls the **F_Map** functional map, and after **F_Map** completes processing, it writes the results directly to the output of the executable map. The value that **F_Map** produced is not available to the calling rule; therefore, the rule cannot perform the comparison operation.

- [Evaluation of functional maps in an expression](#)

Evaluation of functional maps in an expression

A single evaluation of a functional map requires one object for each input argument. The result of the evaluation is always one output object. As with functions and operators, when a functional map is used in an expression, evaluation sets for that expression might cause the functional map to be evaluated many times.

Consider the following expression:

```
MakeForm ( EntryForm:Input , GroupInfo:Input )
```

If there are two occurrences of **GroupInfo** and four occurrences of **EntryForm**, the map **MakeForm** will be evaluated once per combination of **EntryForm** and **GroupInfo**-a total of $(2 \times 4) = 8$ times.

Consider another expression:

```
Fmap ( a:Input , b:Input , c:Input )
```

The objects **a**, **b**, and **c** have only **Input** in common. The expression that contains the **Fmap** reference will be evaluated once per combination of **a**, **b**, and **c**.

To illustrate how the functional map will be evaluated, use a very simple data file of **a**'s, **b**'s, and **c**'s. Each time the map is evaluated, one **a** object, one **b** object, and one **c** object are selected. The first time the map is evaluated, the data objects are **a1**, **b1**, and **c1**. The next time it is evaluated, the data objects are **a2**, **b1**, and **c1**, and so on.

An important difference in how the Map Designer evaluates a functional map in an expression is when an input argument evaluates to **none**.

See [When an Input Argument of a Function Evaluates to NONE](#).

Expressions that evaluate to NONE

The following discussion explains how the Map Designer evaluates an expression when expressions within it evaluate to "none".

- [When an operand evaluates to NONE](#)
- [When an input argument of a function evaluates to NONE](#)
- [When an input argument of a functional map evaluates to NONE](#)
- [When an input of an executable map evaluates to NONE](#)
- [Impact of track setting on order of output](#)

When an operand evaluates to NONE

The following table explains how an operator expression evaluates when an operand evaluates to none.

The symbol **A** represents one operand of the expression and **B** represents the other operand. The symbol **!=** means "not equal to".

Operator Expression	Condition	Evaluates to:
A / B	A = NONE B = NONE	NONE
A*B	A = NONE B = NONE	NONE
A / B	A != NONE B = NONE	0
A*B	A != NONE B = NONE	0
A + B	A = NONE B = NONE	NONE
A - B	A = NONE B = NONE	NONE
A + B	A = NONE B != NONE	B
A - B	A = NONE B != NONE	-B
A + B	A != NONE B = NONE	A
A - B	A != NONE B = NONE	A
A > B	A = NONE B = NONE	FALSE
A < B	A = NONE B = NONE	FALSE
A = B	A = NONE B = NONE	TRUE
A > B	A = NONE B != NONE	FALSE
A < B	A = NONE B != NONE	TRUE
A = B	A = NONE B != NONE	FALSE
A > B	A != NONE B = NONE	TRUE
A < B	A != NONE B = NONE	FALSE
A = B	A != NONE B = NONE	FALSE

For example, in this operator expression:

```
Total = #Guests + 1
```

if **#Guests** evaluates to "none", the value for **Total** will be 1.

When an input argument of a function evaluates to NONE

If any input argument of a function evaluates to "none", the function might not evaluate to "none". For example, **ABS(NONE)=NONE**, but **COUNT(NONE)=0**.

When an input argument of a functional map evaluates to NONE

If any argument of a functional map evaluates to "none", the functional map will not be evaluated for that evaluation set.

For example:

```
MakeForm ( EntryForm:Input , GroupInfo:Input )
```

Where the object **GroupInfo** is optional; it has a component range of (0:3). If there are no occurrences of **GroupInfo** in the **Input** data object, the map **MakeForm** will not be evaluated at all.

Here is another example:

```
OrderMap ( OrderRecord:Order:Input , SummaryRecord:Order:Input )
```

If **SummaryRecord** has a component range of (0:1) and it is missing in a particular **Order**. The map **OrderMap** will not be evaluated for that **Order**.

If you want **OrderMap** to be evaluated even when **SummaryRecord** is missing, use the entire **Order** as an input argument, rather than **SummaryRecord**. This will ensure that **OrderMap** will be evaluated, even if **SummaryRecord** is missing. Then, in the map **OrderMap**, you can still map from **SummaryRecord**.

The rule you should use is this:

When an input of an executable map evaluates to NONE

The evaluation of a map referenced in an expression differs from the evaluation of that map when it is executed as a functional map and the evaluation of a function because of how the NONE is treated.

The evaluation of a map used as a function is different from the evaluation of that map when it is run as an executable map. When a map is run as an executable, if any input card data object has no content, the map will still run. This is not true when that map is referenced as a function. If any input argument of a functional map evaluates to "none", the map will not evaluate.

Impact of track setting on order of output

This property setting determines whether objects are tracked according to content or according to their position within a series. This setting will determine the sequence in which those objects are evaluated when referenced.

For example, assume that **RunsByInning** is a component of **BallGame**. **BallGame** is defined as an explicit format, delimited (by a colon) group. The data for **BallGame** is as follows:

`2::1:1::1::3`

- **Track Content.** If **BallGame** has a **Track** setting of **Content**, all instances of **RunsByInning** with content will be mapped before any empty instances. So, if **BallGame** was mapped to itself, the output would be:
- `2:1:1:1::3`
- **Track Places.** If **BallGame** has a **Track** setting of **Places**, instances of **RunsByInning** will be mapped in the sequence in which they occur, including those instances that are empty. So, if **BallGame** was mapped to itself, the output would match the input.

`2::1:1::1::3`

Track Places will only have an impact on the sequence of the output when *both* the input group object and output group object are defined as **Track Places**.

However, **Track Places** will have an impact in situations in which an input defined with **Track Places** is referenced by index. For instance, in the above example,

- If **RunsByInning** was defined as **Track Places**, **RunsByInning[2]:BallGame** would have a value of **2** because the value in the second "place" in **BallGame** is a **2**.
- On the other hand, if **RunsByInning** was defined as **Track Content**, **RunsByInning[2]:BallGame** would have a value of **1** because the second instance of **BallGame** with content has a value of **1**.

Evaluated expressions assigned to output items

NONE assigned to an output number

When an output item is defined as a number, its value is determined from the result of the evaluated expression that is then converted to its output form as follows:

Output is specified as:	Evaluated value	Output value
Required	0	0
Required	NONE	0
Optional	0	0
Optional	NONE	NONE

Automatic item format conversions

When an item is assigned an output value, the Map Designer will automatically convert an item with the same interpretation (either number, text, date, or time) from one presentation to another. For example, if you want to map an item that is a number and whose presentation is integer to an item that is also a number but whose presentation is decimal, the Map Designer will automatically convert it.

The Map Designer fills in missing information in date and time conversions in the following way:

- **Dates with a year, but no century.** The century will be determined using the **CenturyDerivation** map setting.
- **Missing part of an output date format.** If a portion of the format of an output date cannot be derived from the input date, the missing part will have pound characters (#) in its place. For example, if **09/98** is the date for an input with a format string of **MM/YY** and that date was mapped to an output date with a format of **MM/DD/YY**, the output date would be built as **09/##/98**.
- **Missing part of an output time format.** If a portion of the format of an output time cannot be derived from the input time, the missing part will have zeroes (0) in its place. For example, if **12:14** is the data for an input with a format string of **HH12:MM** and that time was mapped to an output time with a format of **HH:MM:SS**, the output date would be built as **12:14:00**.

To convert a number to text, a date or time, or vice versa, you must use a function to perform the conversion. For example, to convert a date to text, use the function **DATETOTEXT**.

- [Numeric precision](#)

Numeric precision

All numbers in the input and numeric literals in map rules are converted to multiple precision and converted to the format required at output time.

- If the multiple precision number does not overflow but does not fit into the maximum size of a numeric item, that item is filled with the number sign character (#) up to its maximum size.
- An arithmetic overflow is recognized when an arithmetic expression includes:
 - Divide by zero
 - A multiple precision number greater than 1.0E254

Arithmetic overflow is designated in the output object with up to a maximum of ten number sign (#) characters.

Using functions

A function is an expression that generates an output by performing a certain operation on one or more inputs. Most functions can be used in both component rules and map rules. Those that produce a series can only be used in map rules.

- [Functions in a component rule](#)
- [Functions in a map rule](#)

Functions in a component rule

For example, the object **TotalQty** in your data is the sum of all the **Qty** objects in your data; in a component rule for **TotalQty**, you can use the SUM function to verify this relationship.

Functions in a map rule

Suppose you want to map your data differently according to the presence of a certain input data object. In your map rule, to check the presence of the data object, use the function PRESENT. To create the output according to whether the input data was present, use the function IF. Examples of the IF function can be found in "[Logical Functions](#)". Examples of the PRESENT function can be found in "[Inspection Functions](#)".

Syntax of a function

The following is an example of a function:

```
FUNCTION ( argument1, argument2, ... argumentn )
```

When you use a function, substitute the name of a specific function for FUNCTION and substitute a specific expression for each input argument. Each input argument is separated by a comma and the set of arguments is surrounded by parentheses.

Function argument syntax

Arguments typically have some restrictions on the expression used for that argument. For example, the input argument to the INDEX function can only be an object name. Depending on the function, one or many data objects can be used for an input argument for one function evaluation.

For each function listed in this documentation, the input argument has a syntax definition that indicates:

- the number of objects that can be used for each argument for one function evaluation, expressed as either **single** or **series**

followed by

- the type of expression that can be used for each argument.

For the output argument, the syntax specification is similar to the input argument syntax, except that the output is always used as a specific type of object, not an expression.

For example, single-item-expression means one evaluation operates on a single item that can be defined as an item expression. Series-item-expression means one evaluation operates on one or more input argument items that can be defined as an item expression.

In this documentation, the terms listed in the following table are used to describe the syntax of function arguments.

Term

Explanation

general-expression

Any valid combination of object names, literals, operators, function names, and map names.

condition-expression

Any valid combinations of object names, literals, conditional operators, and functions whose output arguments are specified as true or false.

item-expression

Any valid combination of object names, literals, operators, and functions whose output argument is specified as an item.

If an item must be interpreted as a date, time, or number, the item is referenced by its interpretation. For example, if an item-expression must be text, it is specified as text-expression.

object-expression

An object name or a series producing function.

If an object expression is further limited to be an item, it is specified as item-object-expression.

object-name

The name of a data object, as defined in [Data Object Names](#). If an object name is further limited, it is specified as a prefix. For example, simple-object-name refers to a simple type name.

...

Indicates that the function can take on any number of additional similar arguments.

[]

Indicates that the argument is optional.

{ literal , literal ...}

An enumerated series of literals.

The syntax specification shows each input argument, using terms as described in the previous table, preceded by the word **single** or **series**. For example:

Syntax:

ALL (series-condition-expression)

The arguments are defined using a name that describes its use by the function. A simple example is:

Meaning:

DATETONUMBER (date_to_convert)

Function names are shown in uppercase letters in this documentation. However, function names are not case sensitive.

There is also a description of what each function returns.

Returns:

A single integer

Functions that convert character-set encoding to the native code page

Functions that use the IBM Transformation Extender **EXIT** architecture convert data to the native character set of the platform as part of the function call.

These functions use the IBM Transformation Extender **EXIT** architecture:

- **DBLOOKUP**
- **DBQUERY**
- **DDEQUERY**
- **EXIT**
- **JEXIT**
- **GET**
- **PUT**
- **RUN**
- **XQUERY**
- **XSLT**
- **MATHLIB** functions
- **XMLLIB** functions (except **XPATH** and **XPATHEX**)
- **RESOURCELIB** functions
- Customer-developed functions that use the **EXIT** architecture

Maps that use these functions must take the data conversion into account. For example, a map that uses the **EXIT** architecture converts non-EBCDIC data to EBCDIC when the map runs on a z/OS® platform. To prevent the data conversion, the map must use a function like:

`CTEXT(object, "Native")`

If the function returns the data from the z/OS platform to another platform, the map must specify that the data to return is non-EBCDIC by using a function like:

`CTEXT(object, "data language")`

General functions

• **ASFUNCTION**

When you run a functional map with the **ASFUNCTION** function, the output of the functional map returns to the map rule that invoked the functional map. The invoking rule can work with the output from the functional map. The type of the output card must be an item.

• **CLONE**

The **CLONE** function creates a specified number of copies of some object.

• **DEFAULT**

The **DEFAULT** function allows a predefined value to be introduced into an expression.

• **ECHOIN**

The **ECHOIN** function returns a command (or property) to be used in a **RUN** function argument.

- **HANDLEIN**
The **HANDLEIN** function returns a command (or property) to be used in a RUN function argument.
 - **PARSE**
The **PARSE** function analyzes a data object and validates it against the metadata of a component type. The resulting data structure is available to the calling map for further processing.
 - **REFORMAT**
The **REFORMAT** function returns a type object that results from replacing the syntax of the input type with the syntax of the output type.
 - **RESOLVETYPE**
The **RESOLVETYPE** function resolves the provided component path to a specific type tree reference when the map is being compiled.
-

ASFUNCTION

When you run a functional map with the **ASFUNCTION** function, the output of the functional map returns to the map rule that invoked the functional map. The invoking rule can work with the output from the functional map. The type of the output card must be an item.

Without **ASFUNCTION**, a functional map writes to the output card before the rest of the invoking rule is evaluated.

If **ASFUNCTION** runs a functional map that calls a second functional map, the output of the second map also returns to the map rule, as if the second map had been invoked by **ASFUNCTION**. If the output of each map is a number and the outputs are concatenated, **ASFUNCTION** adds the numbers instead of concatenating them.

Syntax:

ASFUNCTION (*general-expression*)

Meaning:

ASFUNCTION (*FunctionalMapName* (*argument-1*, *argument-2*, ... *argument-n*))

Returns:

item

Example 1

Rule:

```
Output_name = FMAP1 (rule) + " and " + Fmap2 (rule) + "."
```

Result:

```
Output_of_FMap1Output_of_FMap2 and .
```

Rule:

```
Output_name = ASFUNCTION(FMAP1 (rule)) + " and " + Fmap2 (rule) + "."
```

Result:

```
Output_of_FMap1 and Output_of_FMap2.
```

Example 2

Rule:

```
Output_name = IF (FMap1 (rule) = "abc", "equal", "not equal")
```

Result:

- If FMap1 produces **abc**:

```
abcnot equal
```

- If FMap1 produces **def**:

```
defnot equal
```

Rule:

```
Output_name = ASFUNCTION(IF (FMap1 (rule) = "abc", "equal", "not equal"))
```

Result:

- If FMap1 produces **abc**:

```
equal
```

- If FMap1 produces **def**:

```
not equal
```

Example 3

Rule:

```
Output_name = ASFUNCTION(FMAP1(rule1)) + FMAP2(rule2)
```

Result:

- If FMAP1 produces 1 and FMAP2 produces 2:

- If FMAP1 produces A and FMAP2 produces B:

AB

CLONE

The **CLONE** function creates a specified number of copies of some object.

This function can be useful when the number of output objects to be built depends on a data value, rather than the number of objects that exist in the data.

Syntax:

CLONE (single-object-name , single-integer-expression)

Meaning:

CLONE (object_to_copy , number_of_copies)

Returns:

A series-object

The **CLONE** function returns a series of the object specified by *object_to_copy*. The output series consists of as many copies of the object as specified by *number_of_copies*. The value of each member of the resulting output series is the same as *object_to_copy*.

Examples

- LineItem Segment (s) = LotsOf (**CLONE** (Detail Row , Quantity:Detail Row))

In this example, the input contains an object named **Detail Row** that has a **Quantity** item component. You want to create multiple **Line Item Segments** for every **Detail Row** in your input based on the value of **Quantity**. So, if **Quantity** has the value 5, you want to build five **Line Item Segments** for that **Detail Row**.

DEFAULT

The **DEFAULT** function allows a predefined value to be introduced into an expression.

DEFAULT, which is typically used with the **EITHER** function, returns the value assigned as the default value when the type was defined.

Syntax:

DEFAULT(single-type-expression)

Meaning:

DEFAULT(type_whose_defined_default_value_is_desired)

Returns:

A single-object

Examples

- **DEFAULT(ZipCode)**

In this example, the defined default value for ZipCode is returned. When used with **EITHER**, **DEFAULT** might appear like this:

EITHER(ZipCode,DEFAULT(ZipCode))

If the first argument evaluates to a value other than "none", that value is used. If the first argument evaluates to "none", the default value for **ZipCode** is used.

ECHOIN

The **ECHOIN** function returns a command (or property) to be used in a **RUN** function argument.

Syntax:

ECHOIN (single-integer-expression, single-text-expression)

Meaning:

ECHOIN (card#, item_or_group_interpreted_as_text)

Returns:

A single object

Examples

Before **ECHOIN** was introduced, the **RUN** function was used in this way:

```
RUN ("MyMap", "-IE1S"+NUMBERTOTEXT (SIZE(Data))+ "
" + TEXT(Data)))
```

You can use **ECHOIN** with **RUN**, similar to the following example:

```
RUN
("MyMap", ECHOIN(1,(Data)))
```

Related functions

HANDLEIN

The **HANDLEIN** function returns a command (or property) to be used in a RUN function argument.

You can use the **HANDLEIN** function when deriving large amounts of data from a parent map for use in a RUN map. The **HANDLEIN** function works by using the same instance of the parent map's data set in the RUN map, instead of duplicating it as the **ECHOIN** function does.

The result of the **HANDLEIN** function is a text object that defines the characteristics of the data to be used. This includes an internal handle, offset, and length of the data. The result of this can be seen in an execution audit log:

```
<ExecutionSummary MapStatus="Valid" mapreturn="0" ElapsedSec="0.1803"
BurstRestartCount="0">
  <Message>Map completed successfully</Message>
  <CommandLine>install_dir\sdq20.mmc -IH1 4:512:1024 -ae</CommandLine>
  <ObjectsFound>85</ObjectsFound>
  <ObjectsBuilt>23</ObjectsBuilt>
<SourceReport card="1" adapter="Handle" bytes="1024" adapterreturn="0">
  <Message>Success</Message>
  <Settings>4:512:1024</Settings>
  <TimeStamp>05:06:07 January 27, 2004</TimeStamp>
</SourceReport>
```

You cannot use a **GETANDSET** function against an input that is passed using **HANDLEIN**.

Syntax:

HANDLEIN (single-integer-expression, single-text-expression)

Meaning:

HANDLEIN (card_to_override, data_object)

Returns:

A character text item

When the **HANDLEIN** function returns a character text item, the string is prefixed with: **IHx**, where **x** is the first parameter.

String format:

-IHx <internal-handle>.<offset>.<length>

Example:

-IH1 4.4096.512

A *single-integer-expression* is the number item that specifies the card number to override. A *single-text-expression* specifies the data object to use for the override.

In a RUN map rule, you can override a source card with a handle of a current map's card by specifying the card to override and the object to override it with.

Examples

In the following rule, the data is object c:b:a for input card 2 of the RUN map:

HANDLEIN(2, c:b:a)

The second parameter can be more complex if needed. For example,

HANDLEIN(2, SUBSTITUE(c:b:a, "a", "A"))

Any data in object **c:b:a** that contains a lowercase "a" would change it to an uppercase "A" for the call to the RUN map. In cases such as this, where the data cannot be expressed contiguously within the original card or cards, a scratch file is used to hold the expression and the calling map's handle is that of the scratch file.

There is no correlation between the handle returned in the output of **HANDLEIN** and the actual card number of the second parameter.

Related functions

Generally, the **ECHOIN** function is used to return a command or property to be used in a **RUN** function argument. However, for large amounts of data, using the **HANDLEIN** function can be more efficient.

For best results, use the **ECHOIN** function for small quantities of data, such as less than 100K, and the **HANDLEIN** function for larger quantities of data of more than 100K.

PARSE

The **PARSE** function analyzes a data object and validates it against the metadata of a component type. The resulting data structure is available to the calling map for further processing.

The input to the **PARSE** function is any data that can be processed as a text blob, for example, the result of a functional map invocation, a **GET** function, or a **RUN** map.

Syntax

PARSE (general_expression)

Meaning

PARSE (*data_to_parse*)
Returns
A mapped data object in a work file

Examples

The data structure that results from the **PARSE** function is available to the calling map. When you use a **RUN** map to parse data, the resulting data structure is available to the **RUN** map rather than to the calling map. By using the **PARSE** function instead of the **RUN** map implementation, you have fewer maps to configure and maintain.

The following examples:

1. Receive an input document from the SPE adapter
2. Extract the data objects from the document envelope
3. Return a response

Example 1: RUN map implementation

In this example, the DEENVELOPE map calls the **RUN** map named DUMPRESPONSE to extract the data from the document.

The DUMPRESPONSE map has two input cards:

- SpeResponse (Response global XSD)
- Test Root (text root)

The output card of the DUMPRESPONSE map has the following rule:

```
=WriteDocument(Document:sequence:Documents:sequence:SpeResponse,  
TestRoot;  
TEXT(INDEX(Document:sequence:Documents:sequence:SpeResponse))) + "<NL>"
```

The DEENVELOPE map has two input cards:

- DataIn (text root)
- Test Root (text root)

The DEENVELOPE map has two output cards:

- DOCOUTPUT:

```
= RUN ("DumpResponse", ECHOIN( 1 , Deenvelope ) + ECHOIN( 2 , TestRoot ) + " -OE1" )
```
- DEENVELOPE:

```
=VALID(GET("SPE", "-DURL jdbc:derby://localhost:1527/spe2  
-DBUSER derbyuser -DBPSWD derbypw  
-DBDRIVER org.apache.derby.jdbc.ClientDriver -DENV", DataIn),  
FAIL ("SPE Deenvelope failed: " + LASTERRORMSG() ))  
  
/*  
=VALID(GET("SPE", "-DURL jdbc:db2://bobdb9.bcr.ibm.com:50000/spetest  
-DBDRIVER com.ibm.db2.jcc.DB2Driver -DBUSER spetest -DBPSWD Seer5r12  
-DENV -T ", DataIn),  
FAIL ("SPE Deenvelope failed: " + LASTERRORMSG() ))  
*/  
  
/*  
=VALID(GET("SPE", "-DURL jdbc:db2://localhost:60000/SPETEST  
-DBDRIVER com.ibm.db2.jcc.DB2Driver -DBUSER fred -DBPSWD org13asd  
-DENV -T ", DataIn),  
FAIL ("SPE Deenvelope failed: " + LASTERRORMSG() ))  
*/
```

Example 2: PARSE function implementation

In this example, a single map uses the **PARSE** function to perform the processing of the two maps in Example 1.

The DEENVELOPE_PARSE map has two input cards:

- DataIn (text root)
- Test Root (text root)

The DEENVELOPE_PARSE map has two output cards:

- RESPONSEINFO:

```
= WriteDocument( Document:sequence:Documents:sequence:SpeResponse,  
TestRoot,  
TEXT( INDEX( Document:sequence:Documents:sequence:SpeResponse ) ) ) + "<NL>"  
  
= "Response - Status: " + Status:sequence:SpeResponse + ",  
Advanced status: " + AdvancedStatus:sequence:SpeResponse + "<NL>"
```
- SPERESPONSE (Response Global XSD):

```
=PARSE( VALID(GET("SPE", "-DURL jdbc:derby://localhost:1527/spe2  
-DBUSER derbyuser -DBPSWD derbypw  
-DBDRIVER org.apache.derby.jdbc.ClientDriver -DENV", DataIn),  
FAIL ("SPE Deenvelope failed: " + LASTERRORMSG() )) )
```

REFORMAT

The **REFORMAT** function returns a type object that results from replacing the syntax of the input type with the syntax of the output type.

The initiator and terminator of the output type are built. The content result rules are determined based on the Input type and the Output type. Groups and Items can be used with **REFORMAT**.

REFORMAT cannot be used as an argument to a function, operator, or functional map.

Syntax:

REFORMAT (single-object-expression)

Meaning:

REFORMAT (type-to-convert)

Returns:

A type object

REFORMAT returns a type object whose content matches the input type object, but whose syntax matches the output type object. The following table details the expected results based on the input and output.

Input Type	Output Type	Result
Group	Group	The content for each output component results from the content of the corresponding input group component content. For example, output component 1 is matched with input component 1, output component 2 is matched with input component 2, and so on. The components of the groups must be items, not another group. If there is no matching input component for an output component, the output component's required occurrences are built as "none". If there is no matching output component for an input component, the data of that input component is ignored. When a component occurrence is built, the delimiter (if any) of the contained output group is built and an object of the component's output type is built from the corresponding input type using the REFORMAT algorithm.
Group	Item	The text of a corresponding input group content.
Item	Group	The input item content is applied as though it were the first component of the output group.
Item	Item	The input item content is applied to the output item content.

Examples

- MyXMLPurchaseOrder = **REFORMAT**(MyCOBOL_PurchaseOrder)

This function is useful when the same type structure might come from different type trees, such as different versions of the same EDI, or when converting traditional formats to XML.

RESOLVETYPE

The **RESOLVETYPE** function resolves the provided component path to a specific type tree reference when the map is being compiled.

This function returns the type of the component for the component path that you provided as an argument. It is used only with the **IN** keyword, to resolve the provided component path to a specific type tree reference. Use it when more than one type that has the same name occurs within (**IN**) the containing component or card. Specify this function only in map rules, not in component rules.

Syntax:

RESOLVETYPE (single-text-expression)

Meaning:

RESOLVETYPE (component_path_to_resolve)

Returns:

A single type reference

For more information about using the **IN** keyword to reference all occurrences of an object contained in another object, see [Component paths separated by IN](#).

Example

```
NetWorth = SUM (RESOLVETYPE  
(Price:Cars:East:Regions) IN Inventory)
```

In the example, you have an inventory of cars and trucks in dealerships in different geographic regions: East, West, North, and South. The price of the cars and trucks are represented by two different types in the type tree with the same name, Price. You want to determine the net worth of the inventory of just cars from all of the dealerships in all of the regions.

The **RESOLVETYPE** function is used to return the type of the component path. In this example, the function is set up to return the type, Price, for Cars, for the component path, **Price:Cars:East:Regions**, specified in the argument of the function. This function also returns the same type, Price, for Cars, if the argument of the function specifies any of the Regions in the following component paths: **Price:Cars:West:Regions**, **Price:Cars:North:Regions**, and **Price:Cars:South:Regions**. Then Price, for Cars, is used as the criteria for the selection process in your total Inventory. The mapping process calculates the net worth by summing the values of Price for all Cars in all of the Regions in the total Inventory.

If you do not specify the **RESOLVETYPE** function, and instead, specify a rule such as **NetWorth = SUM (Price IN Inventory)**, the mapping process uses either one of the types, Price for Cars, or Price for Trucks, as the criteria for the selection process in your total Inventory. If you do specify the **RESOLVETYPE** function, the mapping process uses the returned type of the component path, specified in the argument of the function, as the criteria for the selection process in your total Inventory.

If you want to determine the net worth of just Trucks in the Inventory from all of the dealerships in all of the Regions, you can specify the **RESOLVETYPE** function in the following way: **NetWorth = SUM (RESOLVETYPE (Price:Trucks:North:Regions))**

IN Inventory). Again, the function also returns the same type, Price, for Trucks, if the argument of the function specifies any of the Regions in the following component paths: **Price:Trucks:West:Regions**, **Price:Trucks:East:Regions**, and **Price:Trucks:South:Regions**.

Bidirectional functions

Bidirectional languages such as Arabic and Hebrew are languages in which the text is presented to the user ordered from right to left, but numbers and Latin alphabetic strings within the text are presented left to right. In addition, the order in which characters appear within program variables can vary. The text is usually stored in logical order, the order in which the characters are entered in the input field. These differences in ordering and in other associated presentation characteristics require the program to have the ability to convert bidirectional text strings from one format to another.

Use the **SETLOGICALORDER**, **SETVISUALORDER**, **SETORIENTATIONLTR**, **SETORIENTATIONRTL**, **SETTEXTSHAPING**, and **SETTEXTSHAPINGOFF** functions for specific transformation needs when dealing with bidirectional data.

About the order of text

The order of text generally corresponds with way it is stored in memory or on disk. In general, the order of text is displayed, on the screen for example, in visual order so that a person can read it the way it is subjectively meant to be read. That is, left-to-right characters are displayed from left-to-right, and right-to-left characters are displayed with the first character of the text block beginning from the right.

Storage in memory or on disk generally occurs in a logical manner so that the left-to-right characters are stored left-to-right (that is, one after another), and require no processing to display properly. However, when right-to-left characters are stored in a logical manner, they are also stored one after another from left-to-right. These text blocks, when in Logical order, are usually enclosed by markers that identify the start and end positions of the right-to-left text blocks.

Logical to visual reordering

To display these logical sequences on a screen would require that any left-to-right text is simply read and displayed. When right-to-left text is encountered, it must be turned around to the appropriate direction. This is logical-to-visual reordering.

Examples

In the following example, lowercase characters are considered left-to-right (LTR) and uppercase characters are considered right-to-left (RTL).

Text=	a	b	c	F	E	D	g	h	i
Visual order	0x61	0x62	0x63	0x46	0x45	0x44	0x67	0x68	0x69
Logical order	0x61	0x62	0x63	0x44	0x45	0x46	0x67	0x68	0x69

- [SETLOGICALORDER](#)
- [SETORIENTATIONLTR](#)
- [SETORIENTATIONRTL](#)
- [SETTEXTSHAPING](#)
- [SETTEXTSHAPINGOFF](#)
- [SETVISUALORDER](#)

SETLOGICALORDER

Use this function to convert a bidirectional data object from visually ordered (characters ordered as they are presented for reading) to logically ordered (the order in which text is typed on a keyboard or phonetic order).

This function is only for use with text objects that have bidirectional properties. The function will have no affect on objects that have no bidirectional properties.

Syntax:

SETLOGICALORDER (single-text-expression , single-text-expression)

Meaning:

SETLOGICALORDER (visually_ordered_text_object , TRUE_or_FALSE_text_object)

Returns:

A logically ordered text object.

The **SETLOGICALORDER** function changes the order of the data as held in memory (order scheme) of a text object that is being passed as a parameter. The function returns a text object that reflects the order scheme change.

The output of the function will be the data from the original bidirectional item, transformed to match the specified layout (as it would be if it were assigned to a bidirectional item with the specified characteristics). This allows you to use text manipulation functions, such as LEFT or MID, on bidirectional data using the proper understanding of the bidirectional data. For example, LEFT of the logical ordering of a bidirectional item would actually take the rightmost characters of the visual ordering of that item.

Example

The properties of the text objects define the orientation and memory order of data objects found in the data stream.

Text objects defined as right-to-left would be considered as starting from the right character and progressing to the left, until the end of the data. However, the data can be held in memory with the start character (the right most character) being held in the left most position. This memory ordering is defined by the ordering scheme of the object.

SETORIENTATIONLTR

The SETORIENTATIONLTR function converts the orientation of a text object from right-to-left (RTL) to left-to-right (LTR).

Syntax:

SETORIENTATIONLTR (single-text-expression, Boolean-expression)

Meaning:

SETORIENTATIONLTR (right_to_left_oriented_text_object, true_or_false_text_object)

Returns:

A text object with left-to-right orientation.

The second parameter, a Boolean expression, indicates whether symmetric swapping should be applied.

Example

```
SETORIENTATIONRTL( VLTRData:In1, "FALSE"  
 ) )
```

SETORIENTATIONRTL

Use the SETORIENTATIONRTL function to convert the orientation of a text object from left-to-right (LTR) to right-to-left (RTL).

Syntax:

SETORIENTATIONRTL (left_to_right_oriented_text_object, true_false_text_object, TRUE_or_FALSE_text_object)

Meaning:

SETORIENTATIONRTL (XML fragment)

Returns:

A text object with right-to-left orientation.

Example

```
SETORIENTATIONRTL( VLTRData:In1, "FALSE")
```

SETTEXTSHAPING

The SETTEXTSHAPING function converts a bidirectional text object from non-shaped to shaped.

Syntax:

SETTEXTSHAPING (single-text-expression)

Meaning:

SETTEXTSHAPING (unshaped_text_object)

Returns:

A shaped text object.

SETTEXTSHAPINGOFF

The SETTEXTSHAPINGOFF function removes the shaping from a bidirectional text object.

Syntax:

SETTEXTSHAPINGOFF (single-text-expression)

Meaning:

SETTEXTSHAPINGOFF (shaped_text_object)

Returns:

A text object with no shaping.

SETVISUALORDER

The SETVISUALORDER function converts a bidirectional data object from logically ordered to visually ordered.

This function can only be used with bidirectional data.

Syntax:

SETORDERVISUAL (single-text-expression , single_text_expression)

Meaning:

SETORDERVISUAL (text_object , text_object)

Returns:

A visually ordered text object.

When IBM Transformation Extender processes bidirectional data, this function changes the order scheme of the text object that is passed as a parameter.

Example

```
SETVISUALORDER(SETORIENTATIONRTL(LSRTLData:In1,"FALSE"), "FALSE")
```

True or false indicates whether the text object has symmetric swapping enabled. A visual ordering scheme would have the data being read and stored with the start character in the rightmost position in both memory and visually.

Bit manipulation and testing functions

- [SETOFF](#)
- [SETON](#)
- [TESTOFF](#)
- [TESTON](#)

SETOFF

The **SETOFF** function sets to zero a specified bit in a binary number. You can use this function to manipulate (turn off) a bit in a binary number.

Syntax:

SETOFF (single-binary-number-expression, single-integer-expression)

Meaning:

SETOFF (*binary_number_to_change*, *bit_to_turn_off*)

Returns:

A single binary number

The **SETOFF** function uses *bit_to_turn_off* to specify the bit of *binary_number_to_change* to be set to the value 0. The result is a binary number item of the same size as *binary_number_to_change*.

The value of *bit_to_turn_off* represents the position of the single bit in *binary_number_to_change* to be set off. (Bits are numbered from left to right, with the leftmost bit being bit 1.) If *bit_to_turn_off* is less than one or greater than the number of bits of *binary_number_to_change*, **SETOFF** returns *binary_number_to_change* unchanged.

Examples

- **SETOFF (A , 16)**
Assume **A** is the two-byte binary value of "1" (which is all zeros except for bit **16**). The binary representation of the value in **A** is 0001.
The result is the two-byte binary value, "0"
- **SETOFF (A , 38)**
Results in the two-byte binary value "1", the original value of **A**, because bit **38** does not exist in **A**.

SETON

You can use the **SETON** function to "turn on" a specific bit in a binary number. **SETON** sets the specified bit in the number to "1".

Syntax:

SETON (single-binary-number-expression, single-integer-expression)

Meaning:

SETON (*binary_number_to_change*, *bit_to_turn_on*)

Returns:

A single binary number

SETON uses the value of *bit_to_turn_on* to specify the bit of *binary_number_to_change* that should be set to the value 1. The result is a binary number item of the same size as *binary_number_to_change*.

Bit_to_turn_on represents the position of the single bit in *binary_number_to_change* to be set on. (Bits are numbered from left to right, with the leftmost bit being bit 1.) If *bit_to_turn_on* is less than one or greater than the number of bits of *binary_number_to_change*, **SETON** returns *binary_number_to_change*, unchanged.

Examples

- **SETON (A , 15)**
In this example, assume **A** is the two-byte binary value of 1 (which is all zeros except for bit 16). The binary representation of the value in **A** is 0001.
The function returns the two-byte binary value, 0011, which is the decimal value of 3.
- **SETON (A , 40)**
Returns the two-byte binary value of 1-the original value of **A**- because bit 40 does not exist in **A**.

TESTOFF

The **TESTOFF** function tests a specified bit in a binary number item to see whether it is off.

Syntax:

TESTOFF (single-binary-number-expression , single-integer-expression)

Meaning:

TESTOFF (binary_number_to_test , bit_to_test)

Returns:

"True" or "false"

The value of *bit_to_test* specifies which bit of *binary_number_to_test* should be tested for the value 0. If *bit_to_test* has the value 1, it refers to the leftmost bit of *binary_number_to_test*.

The **TESTOFF** function returns "true" if the specified bit is off and returns "false" if the specified bit is on.

If *bit_to_test* is less than one or greater than the number of bits of *binary_number_to_test*, **TESTOFF** returns "false".

Examples

- **TESTOFF** (A, 16)

Assume **A** is the two-byte binary value of "1", which is all zeros except for bit **16**. The binary representation of the value in **A** is 0001.

This example returns "false".

- **TESTOFF** (A, 20)

Returns "false" because bit **20** does not exist.

TESTON

The **TESTON** function tests a specified bit in a binary number to see if it is on.

Syntax:

TESTON (single-binary-number-expression, single-integer-expression)

Meaning:

TESTON (binary_number_to_test ,bit_to_test)

Returns:

"True" or "false"

The value of *bit_to_test* specifies the bit of *binary_number_to_test* to test for the value 1. If *bit_to_test* has the value 1, it refers to the leftmost bit of *binary_number_to_test*.

The function returns "true" if the specified bit is on; it has the value 1. It returns "false" if the specified bit is off; it has the value 0.

If *bit_to_test* is less than one or greater than the number of bits of *binary_number_to_test*, **TESTON** returns "false".

Examples

- **TESTON** (A , 16)

Assume **A** is the two-byte binary value of "1", which is all zeros except for bit **16**. The binary representation of the value in **A** is 0001.

This example returns "true".

- **TESTON** (A , 20)

Returns "false" because bit **20** does not exist in a two-byte value.

Cache functions

Use cache functions to specify a value for each of the cache variables defined for a flow, and additionally, to alter an already specified value for a cache variable.

Cache variables act as an means to process information throughout a flow instance without requiring the use of data links.

Cache variables are name value pairs that persist until the flow instance completes execution. Cache variables are case-sensitive. Cache variables are also instance specific. Instance-specific means that no two flow-instances that are running simultaneously can share the same set of variables.

- **CACHEDELETE**

The **CACHEDELETE** function is same as **CACHEREAD**. This function returns a default value for cache variable if specified, or an empty value if the cache variable has not been defined.

- **CACHEREAD**

The **CACHEREAD** function reads the value associated to a cache variable.

- **CACHEWRITE**

The **CACHEWRITE** function sets a new or updates an existing cache variable. This function specifies the name of a cache variable if one does not already exist. Otherwise, it updates the value of an existing cache variable with the new value.

CACHEDELETE

The **CACHEDELETE** function is same as **CACHEREAD**. This function returns a default value for cache variable if specified, or an empty value if the cache variable has not been defined.

Syntax:

CACHEDELETE (single-text-expression [, single-text-expression])

Meaning:

CACHEDELETE (variable_name [, default_value])

Returns:

A single text item if found, otherwise none.

Examples

- `flowlib->CACHEDELETE ("Greeting")`
Deletes cache variable, Greeting, and returns empty (NONE).
 - `flowlib->CACHEDELETE ("Greeting", "Hi")`
Deletes cache variable, Greeting, and returns default value (Hi).
-

CACHEREAD

The **CACHEREAD** function reads the value associated to a cache variable.

This function returns a default value if specified, or an empty value if the cache variable has not been defined, or if it has been deleted prior to making this function invocation. Otherwise, it returns the associated value of the cache variable to the map in text format. The value associated to a internal cache variable can be retrieved with this function for further transformation purposes. Wildcards are not supported in this map rules because there is no good way to return multiple values.

The value associated to a cache variable is a text expression and returns the new value to the map. Empty value skips creating or updating of a cache variable.

Syntax:

CACHEREAD (single-text-expression [, single-text-expression])

Meaning:

CACHEREAD (variable_name [, default_value])

Returns:

A single text item.

Examples

- `flowlib->CACHEREAD ("Greeting")`
Returns the current value of custom cache variable, Greeting, to the map if it exists. Otherwise, returns the default value, empty value.
 - `flowlib->CACHEREAD ("Greeting", "Hi")`
Returns the current value of custom cache variable, Greeting, to the map if it exists. Otherwise, returns the default value, Hi, to the map.
-

CACHEWRITE

The **CACHEWRITE** function sets a new or updates an existing cache variable. This function specifies the name of a cache variable if one does not already exist. Otherwise, it updates the value of an existing cache variable with the new value.

The value associated to a cache variable is a text expression and returns the new value to the map. Empty value skips creating or updating of a cache variable.

Syntax:

CACHEWRITE (single-text-expression, single-text-expression)

Meaning:

CACHEWRITE (variable_name, variable_value)

Returns:

A single text item.

Examples

- `flowlib->CACHEWRITE ("Greeting", "Hello")`
Writes cache variable, Greeting, with Hello and returns Hello.
-

BASE64TOTEXT

Use the BASE64TOTEXT decoding function to convert previously encoded data from BASE64 back to the original text. The data is converted to the character set of the output object used. For example, if the output object is EBCDIC the output will be EBCDIC.

Syntax:

BASE64TOTEXT (single-object-expression)

Meaning:

BASE64TOTEXT (BASE64_object_to_convert)

Returns:

A single-text-item

This function receives a text object in Base64-encoded format, converts the object to text, and returns a single data object that represents the original text object that was encoded. If an error occurs during conversion, no data is returned.

Example

```
BASE64TOTEXT("U29tZSBFeGFtcGxlIERhdGE=")
```

Output: Some Example Data

BCDTOHEX

The **BCDTOHEX** function converts an item from binary coded decimal (BCD) format to hexadecimal format. The binary value that is returned always has the high-order byte first, regardless of the operating system. This is useful for testing a specific bit position for a specific value.

Syntax:

BCDTOHEX (single-text-expression, single-integer-expression)

Meaning:

BCDTOHEX (BCD_item_to_convert, length_of_output)

Returns:

A single binary bytestream

When using the **BCDTOHEX** function, the input argument is converted from BCD format to its binary value.

Numbers in BCD format have two decimal digits in each byte. Each half-byte, therefore, can contain a binary value from 0000 (which represents the digit 0) through 1001 (which represents the digit 9). Based on this definition, the following behavior applies:

- If any half-byte of the BCD number contains the binary values 1101 or 1111, that half-byte is ignored.
- If any half-byte contains the binary values 1010, 1011, 1100, or 1110, the output of the function is "none".

The length of the output argument is specified as the value of the second input argument. The length must be 1, 2, or 4. If it is any other value, the length is assumed to be 2.

Examples

- You can use **BCDTOHEX** to test a specific bit position for a specific value. For example, **BCDTOHEX** is useful when the BCD value represents flag bits. The conversion performed by **BCDTOHEX** results in a predictable location for the flag bits across operating systems where the bytes might otherwise be reversed.
- **TESTON (BCDTOHEX (ProcessIndicator, 2) 10)**

Tests for the x`0040' bit in a two-byte result.

Note: This same test, using **BCDToInt** on a PC, tests the x`4000' bit.

Related functions

- **BCDTOTEXT**
 - **BCDToInt**
 - **TEXTTOBCD**
-

BCDToInt

The **BCDToInt** function converts an item from BCD (binary coded decimal) format to integer format. The binary value that is returned has a form native to the machine on which the map is being run.

Syntax:

BCDToInt (single-text-expression , single-integer-expression)

Meaning:

BCDToInt (BCD_item_to_convert , length_of_output)

Returns:

A single-binary-number

BCD_item_to_convert is converted from BCD (binary coded decimal) format to its integer value.

Numbers in BCD format have two decimal digits in each byte. Each half-byte, therefore, can contain a binary value from 0000 (which represents the digit 0) through 1001 (which represents the digit 9). Based on this definition, the following behavior applies:

- If any half-byte of the BCD number contains the binary values 1101 or 1111, that half-byte is ignored.
- If any half-byte contains the binary values 1010, 1011, 1100, or 1110, the output of the function is "none".

The length of the output binary number is specified by *length_of_output*. The length must be 1, 2, or 4. If it is any other value, the length is assumed to be 2.

BCDToInt returns a binary value of the form native to the machine on which the map is being run. The value can therefore be used in arithmetic operations or compared to other numeric values. It should *not* be used for bit manipulations, because the order of the bytes in the number is dependent on the operating system on which the map is being run. For example, on a personal computer, the low-order byte is first, while on a mainframe, the high-order byte is first.

Examples

- **BCDToInt** (bcdAmount Field , 2)
If the **bcdAmount** Field contains x'37' in BCD format, this example returns the integer value of 37.

Related functions

- **BCDTOTEXT**
 - **BCDToHEX**
 - **TEXTTOBCD**
-

BCDTOTEXT

The **BCDTOTEXT** function converts the digits in a BCD (Binary Coded Decimal) item to a text item containing the digits of the BCD-encoded item as a string of characters.

Syntax:

BCDTOTEXT (single-text-expression)

Meaning:

BCDTOTEXT (BCD_item_to_convert)

Returns:

A single text item

BCD_item_to_convert is converted from BCD format to a text string containing the digits of the BCD-encoded value as a string of characters.

Numbers in BCD format have two decimal digits in each byte. Each half-byte, therefore, can contain a binary value from 0000 (which represents the digit 0) through 1001, which represents the digit 9). Based on this definition, the following behavior applies:

- If any half-byte of the BCD number contains the binary value 1101 or 1111, that half-byte is ignored.
- If the BCD item contains the binary value 1010, 1011, 1100, or 1110, the output of the function is "none".

Examples

- **BCDTOTEXT** (Qty:Item)
If **Qty** is x`1234', the result is 1234.
- **BCDTOTEXT** (DiscountAmt)
If **DiscountAmt** is x`0123', the result is 0123.
- **BCDTOTEXT** (TotalDollars)

If **Total** is x' F123', the result is 123.

Related functions

- **BCDTOHEX**
 - **BCDTOINT**
 - **TEXTTOBCD**
-

CONVERT

The **CONVERT** function replaces each byte of a byte stream or text expression with a byte from another byte stream or text expression. The decimal value of each byte of the first argument is used to locate the corresponding byte in the second argument that will replace it.

Syntax:

CONVERT (single-byte-stream-or-text-expression , single-byte-stream-or-text-expression)

Meaning:

CONVERT (bytes_to_replace , replacement_bytes)

Returns:

A single byte stream or text item

The **CONVERT** function replaces each byte of *bytes_to_replace* with a byte from *replacement_bytes*. The byte chosen from *replacement_bytes* is the one whose index is the decimal value of *bytes_to_replace*. The first byte of *replacement_bytes* has the index value of zero. If there is no corresponding byte in *replacement_bytes*, **CONVERT** returns "none".

You can use the **CONVERT** function to convert ASCII to EBCDIC or EBCDIC to ASCII data. See the **convert.mms** map source file in the **examples\general\portdata** folder of the product installation directory. One of the maps in **convert.mms** is **ASCII_TO_EBCDIC**, which converts ASCII to EBCDIC. The **EBCDIC_TO_ASCII** map converts EBCDIC to ASCII.

ASCII to EBCDIC conversion can be performed automatically by defining the appropriate data language (ASCII or EBCDIC) for each data item.

Examples

- **CONVERT (SYMBOL (0),"AB")**
Returns A
 - **CONVERT (SYMBOL (1),"AB")**
Returns B
 - **CONVERT (SYMBOL (2),"AB")**
Returns "none"
 - **CONVERT (ASCII , ATOETable)**
Converts ASCII text to EBCDIC based on values in a table named **ATOETable**
-

DATETONUMBER

Use **DATETONUMBER** to perform arithmetic on dates.

The **DATETONUMBER** function returns an integer that results from counting the number of days from December 31, 1864, to the specified date.

Syntax:

DATETONUMBER (single-date-expression)

Meaning:

DATETONUMBER (date_to_convert)

Returns:

A single integer

The **DATETONUMBER** function converts a date to an integer. The resulting integer represents the number of days since December 31, 1864, where using **DATETONUMBER** with a date of January 1, 1865 returns the integer value 1.

If the input argument is in error, the function returns the value "none".

If the date format specified by the input argument does not include century, the century is determined based on the **Century** map setting using the **CCLookup** parameter or the current century.

Examples

- DaysBetween = **DATETONUMBER** (StopDate) - **DATETONUMBER** (StartDate)
This expression could be used in a map rule to produce a value for **DaysBetween**. It converts the **StopDate** and the **StartDate** to integers, then subtracts the resulting two integers, and returns the result as **DaysBetween**.
-

Related functions

- **ADDDAYS**
- **NUMBERTODATE**

DATETOTEXT

The **DATETOTEXT** function converts a date object or expression to a text item.

Syntax:

DATETOTEXT (single-date-expression)

Meaning:

DATETOTEXT (date_to_convert)

Returns:

A single text item

If *date_to_convert* is a date object name, this returns the date as a text item formatted according to the presentation of the date object.

If *date_to_convert* is a date expression produced by a function, this returns the date as a text item formatted according to the presentation of the output argument of that function.

Examples

- **DATETOTEXT** (ShipDate)

In this example, **ShipDate** is converted from a date to text. If **ShipDate** has a CCYYMMDD presentation, the resulting text item will have that presentation, as well.

- **DATETOTEXT** (**CURRENTDATETIME** ("{MM/DD/CCYY}"))

In this example, **CURRENTDATETIME** evaluates and returns a date in MM/DD/CCYY format. Then **DATETOTEXT** evaluates and returns a text string that is that date in MM/DD/CCYY format.

For example, use **DATETOTEXT**, to do text concatenation. The **FROMDATETIME** function provides greater flexibility in specifying the format of the resulting text item.

Related Functions

- **FROMDATETIME**
- **NUMBERTOTEXT**
- **TEXT**
- **TEXTTODATE**
- **TEXTTONUMBER**
- **TEXTTOTIME**
- **TIMETOTEXT**
- **TODATETIME**

FROMBASESETEN

You can use **FROMBASESETEN** when you need to convert numbers to a base other than 10.

The **FROMBASESETEN** function converts an integer to a text item that can be interpreted as a number, using positional notation of the base specified.

Syntax:

FROMBASESETEN (single-integer-expression, single-integer-expression)

Meaning:

FROMBASESETEN (positive_integer_to_convert, base_to_convert_to)

Returns:

A single text item

FROMBASESETEN returns a text item that results from converting *positive_integer_to_convert* to a text item that can be interpreted as a number using positional notation of the base specified by *base_to_convert_to*.

If *base_to_convert_to* is less than 2 or greater than 36, **FROMBASESETEN** evaluates to "none". Resulting text item characters A-Z are interpreted as digits having decimal values from 10-35, respectively. The characters returned are uppercase.

Example

- **FROMBASESETEN** (18, 2)
Returns the value 10010
- **FROMBASESETEN** (123, 8)
Returns the value 173

Related function

- **TOBASESETEN**

FROMDATETIME

The **FROMDATETIME** function converts a date/time item to a text string of a specified format. For example, you can use **FROMDATETIME** to convert a date-time item into a string for parsing or concatenation. You can also use this function to access the individual parts of a date or time, such as the month, day, year, and so forth.

Syntax:

```
FROMDATETIME (single-character-date-time-item  
[ , single-text-expression ])
```

Meaning:

```
FROMDATETIME (date_time [ , date_time_format_string ])
```

Returns:

A single character text item

FROMDATETIME returns the date/time specified by *date_time* as a text item with the format specified by *date_time_format_string*. If *date_time_format_string* is not specified, *date_time* will be returned in the same format as the *date_time*.

The *date_time_format_string* must conform to the date/time format strings as described in the "Format strings" topic.

Examples

- HeaderLine="Today is" + **FROMDATETIME (CURRENTDATE (), "{MON DD, CCYY}")**
If the current system date is March 3, 1999, this rule evaluates to Today is Mar 03, 1999.
- FROMDATETIME (TransactionTimeStamp Column:::TransHistory)**
If the value of **TransactionTimeStamp Column** is 10:14 A.M. on February 3, 2000 and its format is defined as "{CCYYMMDDHH24MM}", this rule evaluates to 200002031014.
- EXTRACT (Expense:Report, FROMDATETIME (Date:Expense:Report, "{MM}") = "03")**
In this example, the **FROMDATETIME** function is used in the condition expression of the **EXTRACT** function to identify all expenses in the month of March.

Related functions

- CURRENTDATE**
- CURRENTDATETIME**
- CURRENTTIME**
- DATETOTEXT**
- TODATETIME**

FROMNUMBER

The **FROMNUMBER** function converts a number to a text string of a specified format.

Use **FROMNUMBER** when you need to convert a number item into a string for parsing or concatenation.

Syntax:

```
FROMNUMBER (single-character-number-item  
[ , single-text-expression ])
```

Meaning:

```
FROMNUMBER (number_to_convert [ , number_format_string ])
```

Returns:

A single character text item

FROMNUMBER returns the number specified by *number_to_convert* as a text item with the format specified by *number_format_string*. If *number_format_string* is not specified, *number_to_convert* will be returned in the same format as the *number_to_convert*.

The *number_format_string* must conform to the number format strings as described in the "Format strings" topic.

Examples

- Greeting = "You are caller number " + **FROMNUMBER (SeqNo:::History, "#'###'!" + "!"**
If the value of **SeqNo** is 2348192, this rule evaluates to "You are caller number 2,348,192!"
- "\$" + **FROMNUMBER(CurrentRate Field:::Schedule, "#'###.'2##2")**
If the value of **CurrentRate Field** is 15.875, "\$15.88".

Related functions

- DATETONUMBER**
- NUMBERTODATE**
- NUMBERTOTEXT**
- TONUMBER**

HEXTXTTOSTREAM

HEXTXTTOSTREAM is the reverse of **STREAMTOHEXTXT**. You can use the **HEXTXTTOSTREAM** function to assign a binary text value to a character text item represented by hexadecimal pairs.

HEXTEXTTOSTREAM returns a binary text stream whose value is the evaluation of input character text represented by hexadecimal pairs.

Syntax:

HEXTEXTTOSTREAM (single-text-expression)

Meaning:

HEXTEXTTOSTREAM (series_of_hex_pairs)

Returns:

A single byte stream item

This function returns a binary text stream item whose value is the evaluation of input character text in *series_of_hex_pairs*, ignoring <WSP> characters between the hexadecimal pairs. White space characters include space, horizontal tab, carriage return, and line feed characters.

Input formats

The following table shows an example of input in its character text representation as viewed through the character editor, and in its ASCII code representation (binary text stream) as viewed through the hex editor. Each pair of binary text in the hex view represents one character in the character view of the character text.

Input ("41 42 43 44")	Editor View	Value
Character text (hex pairs)	Character	"41 42 43 44"
ASCII code representation (binary text stream)	Hex	0x3431203432203433203434

Examples

- **HEXTEXTTOSTREAM** ("41 42 43 44")
Returns the evaluated value of the input (ASCII) character text string "41 42 43 44" as the output (ASCII) character text string "ABCD" as viewed in the character editor. (The hex view of the input is 0x3431203432203433203434. The hex view of the output is 0x41424344.)
- **HEXTEXTTOSTREAM** ("0D 0A 00")
Returns the evaluated value of the input (ASCII) character text string "0D 0A 00" as the output (ASCII) character text string "<CR><LF><NULL>" as viewed in the character editor. (The hex view of the input is 0x3044203041203030. The hex view of the output is 0xD0A00.)

See Design Studio Introduction documentation for a list of special symbols.

Related functions

- **SYMBOL**
- **STREAMTOHEXTEXT**

INT

You can use the **INT** function when you need only the integer portion of a number.

Syntax:

INT (single-number-expression)

Meaning:

INT (number_to_convert)

Returns:

A single integer

INT returns the integer portion of a number. The result is the integer part of *number_to_convert*. Any fractional part after the decimal point is dropped.

Examples

- **INT** (1.45)
Returns 1
- **INT** (3.6)
Returns 3
- **INT** (Purchase:Amt - Discount:Amt)
Subtracts **Discount:Amt** from **Purchase:Amt** and returns the result as a whole number.

Related functions

- **MOD**
- **ROUND**
- **TRUNCATE**

NUMBERTODATE

You can use the **NUMBERTODATE** function to perform a calculation on a date.

NUMBERTODATE converts an integer to a date, where the integer is the number of days from December 31, 1864, to the specified date. Only positive, non-zero values can be specified as valid parameters.

Syntax:

NUMBERTODATE (single-integer-expression)

Meaning:

NUMBERTODATE (integer_to_convert)

Returns:

A single date

After converting an integer to a date, if the result is being assigned to a date object, the resulting date is in the presentation for that output. If the resulting date is not being assigned to an object, it has a CCYYMMDD presentation.

When the year exceeds four digits, the output will display hash characters (#) for the CCYY values because the field is defined to be only four digits in length.

Examples

- **NUMBERTODATE** (StartDate)

This example converts the **StartDate** value from an integer to a date that is in CCYYMMDD format.

Related functions

- **ADDDAYS**
 - **DATETONUMBER**
 - **FROMDATETIME**
 - **TODATETIME**
-

NUMBERTOTEXT

The **NUMBERTOTEXT** function converts a character number to a text item that looks like the original object.

You can use **NUMBERTOTEXT** when you need an object that is defined as a number converted to an object defined as text. This is useful when you need to concatenate text, however, the **FROMNUMBER** function provides greater flexibility in specifying the format of the resulting text item.

Syntax:

NUMBERTOTEXT (single-number-expression)

Meaning:

NUMBERTOTEXT (number_to_convert)

Returns:

A single text item

The resulting text looks like the input argument. The result is truncated, if necessary.

Examples

- **NUMBERTOTEXT** (ROUND (1000 - 24.75, 3))

This example converts the result of the calculation (rounded to 3 decimal places) to text, resulting in 975.250.

- **NUMBERTOTEXT** (PurchaseNumber)

This example converts **PurchaseNumber** from a number to text.

Related functions

- **FROMNUMBER**
 - **TEXTTONUMBER**
 - **TODATETIME**
 - **TONUMBER**
-

PACK

The **PACK** function converts an integer to a text item that can be interpreted as a packed decimal number.

The sign values for packed data are as follows:

- C for positive (+)
- D for negative (-)
- F for unsigned, which is read as positive

Syntax:

PACK (single-integer-expression)

Meaning:

PACK (integer_to_convert)

Returns:
A single text item

In a packed decimal number, each half-byte is a digit, except for the last half-byte of the rightmost byte, which contains a sign.

Examples

- **PACK (314)**
Returns "1L" and results in the hex value 31 4C (which, in ASCII, looks like 1L)
- **PACK ((Unit Price * Quantity) * 100)**
In this example, the packed number has two implied decimal places. Because **PACK** does not accept decimal places, including implied ones, the nested arithmetic expression, **Unit Price * Quantity**, is multiplied by 100 before rounding.
Define items as having a packed decimal number presentation. Then, when mapping to or from these items, the conversion to and from packed decimal is automatically performed as needed.

Related function

- **UNPACK**
-

PACKAGE

The **PACKAGE** function converts a group or item object to a text item, including its initiator, terminator, and any delimiters it contains.

Syntax:
PACKAGE (single-object-expression)

Meaning:
PACKAGE (object_to_convert)

Returns:
A single text item

The **PACKAGE** function converts *object_to_convert*, which must be a type reference to a text item, including the type reference's initiator, terminator, and all delimiters. **PACKAGE** differs from **TEXT** in that it includes the initiator and terminator of the specified type reference.

Examples

- **PACKAGE (Record:Card)**
Returns: #1339X10A,491.38,Green,42x54@

For this example, the group **Record** has an initiator of "#", a terminator of "@" and a delimiter of ",". The data looks like this: "#1339X10A,491.38,Green,42x54@".

Related functions

- **DATETOTEXT**
- **NUMBERTOTEXT**
- **SERIESTOTEXT**
- **TIMETOTEXT**
- **TEXT**

PACKAGE differs from **TEXT** because it includes the initiator and terminator of the input object.

JSON native schema package

JSON schema fields with _V following the name and fields starting with oneOf, allOf and anyOf are the virtual fields.

Virtual JSON fields do not appear in the data and have no syntax. Syntax is controlled by real fields above these virtual fields.

Real fields are fields that appear in the JSON data.

Using a virtual field in a package command will give incomplete syntax. Use a real field either above or below the virtual fields for complete syntax.

QUOTEDTOTEXT

The **QUOTEDTOTEXT** decoding function converts a single (text or binary) data object in Quoted-Printable format to a single data object that represents the original text or binary object.

Syntax:
QUOTEDTOTEXT (single-object-expression)

Meaning:
QUOTEDTOTEXT (quoted_printable_object_to_convert)

Returns:
A single-text-item

You can use this function to decode data that was previously encoded to RFC 1767 Quoted-Printable encoding. Any hexadecimal representations are decoded to the appropriate ASCII character and any soft breaks are removed.

If an error occurs during conversion, no data is returned.

Example

```
QUOTEDTOTEXT("Unencoded data=0CEncoded")
```

Output: Unencoded data<FF>Encoded

SERIESTOTEXT

You can use the **SERIESTOTEXT** function to project your input data as a series and to interpret it as a text item for output.

SERIESTOTEXT converts a contiguous or non-contiguous series to a text item.

Syntax:

```
SERIESTOTEXT (series-object-expression)
```

Meaning:

```
SERIESTOTEXT (series_to_convert)
```

Returns:

A single text item

SERIESTOTEXT returns a text item containing the concatenation of the series of the input argument, including nested delimiters but excluding initiators and terminators.

Examples

In this example, you have the following data that represents bowler information for a bowling league:

Andrews, Jessica:980206:JBC:145:138:177:159

Little, Randy:980116:BBK:175:168

Wayne, Richard:980102:JBC:185:204:179:164:212

Each record consists of the bowler's name, the date of their last game played, a team code and one or more bowling scores. **Record** is defined as a group that is infix-delimited by a colon.

Using the rule:

```
= SERIESTOTEXT (Score Field:Bowler:Input)
```

the following results are produced, which is the concatenation of all of the scores for all of the bowlers, even though the scores are not all contiguous within the data:

145138177159175168185204179164212

However, if the rule was changed, for instance, to concatenate the list of scores to the bowler's name:

```
= BowlerName Field:Bowler:Input + " ->" +  
SERIESTOTEXT (Score Field:Bowler:Input)
```

the following output would be produced:

Andrews, Jessica -> 145138177159

Little, Randy -> 175168

Wayne, Richard -> 185204179164212

In this example, you have an input number that is of variable size, followed by a name. There is no syntax that separates the number from the name. You can define the number as a group with **Byte(s)** as a component and provide a component rule for **Byte(s)**, such as:

```
ISNUMBER ($)
```

STREAMTOHEXTEXT

Use **STREAMTOHEXTEXT** to assign a character text value to a binary text stream item.

The **STREAMTOHEXTEXT** function returns a character text string represented by hex pairs whose value is the evaluation of an input binary text stream.

This function is the reverse of the **HEXTXTTOSTREAM** function.

Syntax:
STREAMTOHEXTEXT (single-byte-stream-item)

Meaning:
STREAMTOHEXTEXT (single-byte-stream-item)

Returns:
A series of hex pairs

STREAMTOHEXTEXT returns a string of hex pairs whose value is the evaluation of input binary text in *series_of_hex_pairs*.

Input formats

The following table shows an example of input in its ASCII code representation (binary text stream) as viewed through the hex editor, and in its character text representation as viewed through the character editor. Each four-character grouping of binary text in the hex view represents one character in the character view.

Input (0x41424344)	Editor View	Value
ASCII code representation (binary text stream)	Hex	0x41424344
	Character	"ABCD"

Examples

- **STREAMTOHEXTEXT** (0x41424344)

Returns the evaluated value of the input (ASCII) binary text stream **0x41424344** as the output (ASCII) binary text stream 0x3431343234333434 as viewed in the hex editor. (The character view of the input is "ABCD". The character view of the output is "41424344".)

- **STREAMTOHEXTEXT** (0x0D0A00)

Returns the evaluated value of the input binary text stream **0x0D0A00** as the output 0x304430413030 as viewed in the hex editor. (The character view of the input is "<CR><LF><NULL>". The character view of the output is "0D0A00".)

Related functions

- **HEXTXTTOSTREAM**
- **SYMBOL**

SYMBOL

You can use **SYMBOL** to include a symbol in your output.

The **SYMBOL** function returns a one-byte character that is the ASCII character equivalent of a specified decimal value.

Syntax:
SYMBOL (single-integer-expression)

Meaning:
SYMBOL (decimal_value)

Returns:
A single one-byte text item

The value of the resulting item is the ASCII character equivalent of *decimal_value*. Valid input values are 0 to 255. Values outside of this range return "none".

A listing of decimal values (0-127) and their ASCII character equivalents is included in the Design Studio Introduction documentation.

Examples

- **SYMBOL** (13)
Produces a carriage return
- **SYMBOL** (13) + **SYMBOL** (10)
Produces a carriage return/linefeed

You can accomplish the same result using the angle-brackets around the decimal value. For example, the second example above would be equivalent to <CR><LF> or <>0D><>0A>>

Related functions

- **HEXTXTTOSTREAM**
- **STREAMTOHEXTEXT**

TEXTTOBASE64

The TEXTTOBASE64 encoding function converts a text item to Base64 format.

Syntax:
TEXTTOBASE64 (single-object-expression)
Meaning:

TEXTTOBASE64 (text_object_to_convert)
Returns:
A single-text-item

The **TEXTTOBASE64** function receives a text object and uses the MIME implementation to convert the text to Base64 format. The MIME implementation adds the <CR><LF> character sequence after every 76 bytes and also at the end of the output string.

TEXTTOBASE64 returns a single data object that represents the Base64 encoding of the original text object. If an error occurs during conversion, no data is returned.

Example

```
TEXTTOBASE64("Some Example Data")
Output: UwBvAG0AZQAgAEUAeABhAG0AcABsAGUAIABEAGEAdABhAA==
```

TEXTTOBCD

The **TEXTTOBCD** function converts a text item from decimal digits to BCD (Binary Coded Decimal) format.

Syntax:
TEXTTOBCD (single-integer-text-expression)
Meaning:
TEXTTOBCD (text_to_be_converted)
Returns:
A single BCD-formatted text item

TEXTTOBCD converts *text_to_be_converted* (which consists of decimal digits) to BCD format. In this format, each byte contains two decimal digits represented as binary numbers. If there is an odd number of decimal digits in the input, the high-order half-byte of the leftmost output byte will contain the decimal value 15 (hex "F").

If anything other than a decimal digit is encountered in the input, **TEXTTOBCD** returns "none".

Examples

- **TEXTTOBCD ("1234")**
Returns the hexadecimal value x'1234'
- **TEXTTOBCD ("123A")**
Returns "none"
- **TEXTTOBCD ("123")**
Returns the hexadecimal value x'F123'

In this example, the values shown as input ("123") are meant to represent character items in the native character set to the machine on which the map is running. On a personal computer, "123" would contain the ASCII characters for the digits that have the hexadecimal values "31", "32", and "33". The output, described as "the hexadecimal value 'F123'", consists of the two binary bytes "F1" and "23".

On an IBM mainframe the input string would contain EBCDIC characters for the digits that have the hexadecimal values "F1", "F2", "F3", etc., but the output would be the same as the personal computer output.

Related functions

- **BCDTOHEX**
- **BCDToint**
- **BCDTOTEXT**

TEXTTODATE

The **TEXTTODATE** function converts text item from CCYYMMDD or YYMMDD format to a date.

You can use the **TEXTTODATE** to convert a text item to a date, however, the **TODATETIME** function provides greater flexibility for specifying the resulting date-time format.

Syntax:
TEXTTODATE (single-text-expression)
Meaning:
TEXTTODATE (text_to_convert_to_date)
Returns:
A single date

The *text_to_convert_to_date* must be in either CCYYMMDD or YYMMDD format. If the *text_to_convert_to_date* is in error (for example, it is not a valid date), the result is "none".

If *text_to_convert_to_date* is in YYMMDD format and is being assigned to a date format that includes a century, the century is determined based on the century run option setting using the **CCLookup** parameter or the current century.

Examples

- **TEXTTODATE ("990114")**
Returns a single date item with the value of January 14 in the year 99
- **TEXTTODATE (OrderDate)**
Returns **OrderDate** as a single date item.

Related functions

• DATETOTEXT	• TEXTTOTIME
• NUMBERTOTEXT	• TIMETOTEXT
• TEXTTONUMBER	• TODATETIME

TEXTTONUMBER

Use **TEXTTONUMBER** to convert text to a number.

The **TONUMBER** function provides greater flexibility for specifying the format of the text item that is to be converted to a number.

Syntax:

TEXTTONUMBER (single-text-expression)

Meaning:

TEXTTONUMBER (text_to_convert_to_number)

Returns:

A single character number

The *text_to_convert_to_number* must be in integer or ANSI-formatted (floating point) presentation. The resulting number looks like the input argument, however, nonsignificant zeroes to the right of the decimal separator will be truncated. If the input argument is in error (for example, it is not a recognizable as a valid number), the result is "none".

When specified as in ANSI-formatted presentation, the text string must meet the following requirements:

- The decimal point can be a period, a comma, or "none".
- The leading sign can be a plus sign, a minus sign, or "none".
- No thousands separator is allowed.

Examples

- **TEXTTONUMBER** (OrderQty)
Returns **OrderQty** as a character number item

Related functions

- **DATETOTEXT**
- **FROMNUMBER**
- **NUMBERTOTEXT**
- **TEXTTODATE**
- **TEXTTOTIME**
- **TIMETOTEXT**

TEXTTOQUOTED

The TEXTTOQUOTED encoding function converts a text or binary item to Quoted-Printable format.

Syntax:

TEXTTOQUOTED (single_object_expression)

Meaning:

TEXTTOQUOTED (object_to_convert)

Returns:

A single text or binary item

You can use this function to encode data that largely consists of octets that correspond to printable characters in the US-ASCII character set. It encodes the data in such a way that the resulting octets are unlikely to be modified by mail transport.

Quoted-Printable lines cannot be longer than 76 characters. Data with lines greater than 76 characters are broken up and indicated with soft breaks of "<CR><LF>".

If an error occurs during conversion, no data is returned.

Example

This example converts the <FF> (form feed) character, into a hexadecimal representation, and indicates the end of data with a soft break.

```
TEXTTOQUOTED("Unencoded data<FF>Encoded")
```

Output: Unencoded data=0CEncoded=

The data is converted using the Quoted-Printable encoding as per RFC 1767.

TEXTTOTIME

Use **TEXTTOTIME** when you want to convert an object defined as text that is in HHMM or HHMMSS presentation, to an item defined as time. For greater flexibility, use the **TODATETIME** function for specifying the format of the text item that is to be converted to a date/time.

Syntax:

```
TEXTTOTIME (single-text-expression)
```

Meaning:

```
TEXTTOTIME (text_to_convert_to_time)
```

Returns:

A single time

The *text_to_convert_to_time* must be in HHMM or HHMMSS presentation. HH is a two-digit hour in a 24-hour format. If the result is being assigned to a time object, the resulting time looks like the output object. Otherwise, the resulting time looks like the input argument. If the input argument is in error (for example, it is not a valid time), the result is "none".

Examples

- **TEXTTOTIME (CallTime)**

Returns **CallTime** as a time item

Related functions

• DATETOTEXT	• TEXTTONUMBER
• FROMDATETIME	• TIMETOTEXT
• NUMBERTOTEXT	• TODATETIME
• TEXTTODATE	

TIMETOTEXT

You can use the **TIMETOTEXT** function to perform text concatenation. For greater flexibility, use the **FROMDATETIME** function for specifying the format of the resulting text item.

TIMETOTEX converts a time object or expression to a text item.

Syntax:

```
TIMETOTEXT (single-time-expression)
```

Meaning:

```
TIMETOTEXT (time_to_convert_to_text)
```

Returns:

A single text item

If *time_to_convert_to_text* is a time object name, this returns the time as a text item formatted according to the presentation of the input date object.

If *time_to_convert_to_text* is a time expression produced by a function, this returns the time as a text item formatted according to the presentation of the output argument of that function.

Examples

- **TIMETOTEXT (LeadTime)**

In this example, **LeadTime** is converted from a time to text. If **LeadTime** has an HH:MM presentation, the resulting text item will be of that presentation.

- **TIMETOTEXT (CURRENTDATETIME ("{HH:MM:SS}"))**

Here, **CURRENTDATETIME** evaluates and returns a time in HH:MM:SS format. Then, **TIMETOTEXT** evaluates and returns a text string that is that time in HH:MM:SS format.

Related functions

• DATETOTEXT
• FROMDATETIME
• NUMBERTOTEXT
• TEXTTODATE

- TEXTT tonumber
 - TEXTT otim
 - TODATETIME
-

TOBASETEN

The **TOBASETEN** function converts a text item that can be interpreted as a number, using positional notation of the base specified, to a base 10 number.

Syntax:

TOBASETEN (single-text-expression, single-integer-expression)

Meaning:

TOBASETEN (text_to_convert, base_to_convert_from)

Returns:

A single integer

TOBASETEN returns a number that results from converting *text_to_convert* that can be interpreted as a number, using positional notation of the base specified by *base_to_convert_from*, to its base 10 representation. Text item characters A-Z are interpreted as digits having decimal values from 10-35, respectively.

If *base_to_convert_from* is less than 2 or greater than 36, **TOBASETEN** evaluates to "none". If *text_to_convert* contains a character that is not alphanumeric or is not in the range specified by *base_to_convert_from*, **TOBASETEN** returns "none".

Examples

- **TOBASETEN** ("A", 16)
Returns the value 10
- **TOBASETEN** ("10", 36)
Returns the value 36
- **TOBASETEN** ("A0", 15)
Returns the value 150
- **TOBASETEN** ("A0", 5)
Returns the value "none"

Related functions

- **FROMBASETEN**
-

TODATETIME

The **TODATETIME** function converts a text string of a specified format to a date-time item.

Syntax:

TODATETIME (single-character-text-expression
[, single-text-expression])

Meaning:

TODATETIME (text_to_convert [, date_time_format_string])

Returns:

A single character date item

TODATETIME returns the date-time that corresponds to the value specified by *text_to_convert*, which is in the format specified by *date_time_format_string*. If *date_time_format_string* is not specified, it will be assumed that *text_to_convert* is in [CCYYMMDDHH24MMSS] format.

The *date_time_format_string* must conform to the date-time format strings as described in "Format strings".

Examples

- **TODATETIME** ("05/14/1999@10:14pm", "[MM/DD/CCYY]@[HH12:MMAM/PM]")
In this example, a text string containing a date and time is converted to a date-time item.
- RptDate = **TODATETIME** (**RIGHT** (**GETRESOURCENAME** () , 8) , "CCYYMMDD")
Assume that you receive a file that contains historical data. The name of the file identifies the date of the historical data. For example, a filename of **19960424** indicates that the data was produced on April 24, 1996. To map this date to **RptDate**, the **TODATETIME** function could be used with the **RIGHT** and **GETRESOURCENAME** functions.

Related functions

- **CURRENTDATE**
- **CURRENTDATETIME**
- **CURRENTTIME**
- **TEXTTODATE**
- **TEXTTOTIME**

TONUMBER

The **TONUMBER** function converts a text string of a specified format to a number.

Syntax:

```
TONUMBER ( single-character-text-expression  
[ , single-text-expression ] )
```

Meaning:

```
TONUMBER ( text_to_convert [ , number_format_string ] )
```

Returns:

A single character number item

TONUMBER returns the number that corresponds to the value specified by *text_to_convert*, which is in the format specified by *number_format_string*. If *number_format_string* is not specified, it will be assumed that *text_to_convert* is in ANSI decimal format (for example, "{L-####[.'##]}").

The *number_format_string* must conform to the number format strings as described in the "Format strings" topic.

Examples

- **TONUMBER(text_to_convert, "{L+'\$'#[.###}")**
L+\$ indicates the leading dollar sign is positive. That leading sign and the comma separators are removed when the text is converted to a number.

Input String: \$123,000,000

Output: 123000000

- **TONUMBER(text_to_convert, "####[T-]")**
Four number signs are required for each whole number, regardless of the actual number of digits in the number.

Input string:	Output:	Note:
12345-	-12345	The output becomes a negative number.
67890	67890	No change occurs.
345-	-345	The output becomes a negative number.

- **TONUMBER(text_to_convert, "####[T+'K'-]")**

If an invalid character, such as an X, is encountered, nothing is returned.

If a **K** is encountered, it is treated as a positive indicator.

Input string:	Output:	Note:
11212-	-11212	The output becomes a negative number.
67890X		The X is an invalid character. No number is returned.
54354	54354	No change occurs.
34567K	34567	The K is recognized as a positive sign. The character is removed and the number is returned as a positive.
345-	-345	The output becomes a negative number.

- **TONUMBER(text_to_convert, "L-'('#[.###[T-]')")**

The parentheses indicating a negative number are removed and replaced with a negative sign.

Comma separators are removed when the text is converted to a number.

Input string:	Output:	Note:
(12,345)	-12345	The output becomes a negative number. The comma separator is removed.
67,890	67890	The comma separator is removed.
(345)	-345	The output becomes a negative number.

- **TONUMBER(text_to_convert, "#['#[.###[T+'K'-]')")**

The optional comma separators are removed, but the decimal points and decimal values are retained.

Input string:	Output:	Note:
54,345.098	54354.098	The comma separator is removed.
67890.0X		The X is an invalid character. No number is returned.
11213-	-11213	The output becomes a negative number.
34567K	34567	The K is recognized as a positive sign. The character is removed and the number is returned as a positive.
345.1-	-345.1	The output becomes a negative number.

- **FROMNUMBER**
- **NUMBERTODATE**
- **NUMBERTOTEXT**

UNPACK

You can use the **UNPACK** function to do arithmetic with a packed decimal number or to move a packed decimal value into a numeric item.

UNPACK converts text that can be interpreted as a packed decimal number to a signed integer item.

The sign values for packed data are as follows:

- C for positive (+)
- D for negative (-)
- F for unsigned, which is read as positive

Syntax:

UNPACK (single-fixed-size-text-expression)

Meaning:

UNPACK (*text_to_unpack*)

Returns:

A single signed integer

UNPACK returns a signed integer representing the value *text_to_unpack*, which is a packed decimal number. If the *text_to_unpack* cannot be interpreted as a valid packed decimal, **UNPACK** evaluates to "none".

In a packed decimal number, each half-byte is a digit, except for the last half-byte of the rightmost byte, which contains a sign.

Examples

- **UNPACK** ("1L") returns 314

The ASCII string "1L" in hex is 31 4C, which, when interpreted as a packed number, results in (positive) 314. This example returns the value "+314".

The hexadecimal representation of the value "1L" is x`14C', where C in the rightmost half-byte represents a positive sign.

- **UNPACK** (*UnitPrice*) / 100 * *QuantityOrdered*

UnitPrice is unpacked and divided by 100 (to convert it from an integer to a number with two decimal places) and then multiplied by the *QuantityOrdered*.

You can define items as having a packed decimal number presentation. Then, when mapping to or from these items, the conversion to and from packed decimal is automatically performed as needed.

Related functions

- **PACK**

UNZONE

You can use the **UNZONE** function to convert a text item that represents a zoned (signed) number to an integer.

UNZONE converts a text item that can be interpreted as a number with a super-imposed sign in the rightmost byte (called zoned or signed data) to a signed integer item.

Syntax:

UNZONE (single-text-expression)

Meaning:

UNZONE (*text_to_unzone*)

Returns:

A single integer

UNZONE returns a signed integer representing the value *text_to_unzone* that is an integer in zoned (signed) format. If the *text_to_unzone* cannot be interpreted as a valid zoned number, **UNZONE** evaluates to "none".

Zoned integers have a series of digits except for the rightmost byte. The rightmost byte is a digit with a super-imposed sign. See "Positive zoned values" for a list of rightmost byte values.

Examples

- **UNZONE** ("123D")

Returns 1234

- **UNZONE** ("1234")

Returns 1234

- **UNZONE** (*TaxRate*) / 1000 * *Income*

TaxRate is converted from zoned format to a signed decimal and divided by 1000 (to convert it to a number with three decimal places), and then multiplied by **Income**.

You can define items as having a zoned character number presentation. Then, when mapping to or from these items, the conversion to and from zoned decimal is automatically performed as needed.

Related functions

- **ZONE**

ZONE

Use **ZONE** to convert a number to a zoned (signed) number.

The **ZONE** function converts a signed integer item to a text item that can be interpreted as a number with a superimposed sign in the rightmost byte (called zoned or signed).

You can define items as having a zoned character number presentation. Then, when mapping to or from these items, the conversion to and from zoned decimal is performed automatically, as needed.

Syntax:

ZONE (single-integer-expression , single-integer-expression)

Meaning:

ZONE (integer_to_convert , sign_indicator)

Returns:

A single text item

ZONE returns a text string that represents a zoned (signed) number representing *integer_to_convert*.

Zoned integers have a sequence of digits except for the rightmost byte. The rightmost byte is a digit with a super-imposed sign. The *sign_indicator* specifies whether a super-imposed sign is required for positive integers, where 0 specifies no sign is required and any other value specifies that a sign is required for positive integers.

The following tables show positive and negative values of the numbers 1230 to 1239, with a sign indicator of 0 (no sign is required for positive values) or a sign of 1 (include a sign for both positive and negative values) in the rightmost byte.

Table 1. Positive Zoned Values

Integer Value	sign_indicator = 0	sign_indicator = 1
1230	1230	123{
1231	1231	123A
1232	1232	123B
1233	1233	123C
1234	1234	123D
1235	1235	123E
1236	1236	123F
1237	1237	123G
1238	1238	123H
1239	1239	123I

Table 2. Negative Zoned Values

Integer Value	sign_indicator = 0	sign_indicator = 1
-1230	123{	123}
-1231	123J	123J
-1232	123K	123K
-1233	123L	123L
-1234	123M	123M
-1235	123N	123N
-1236	123O	123O
-1237	123P	123P
-1238	123Q	123Q
-1239	123R	123R

Examples

- **ZONE** (1234,0)
Returns 1234
- **ZONE** (1234,1)
Returns 123D
- **ZONE** (-1234,1)
Returns 123M
- **ZONE** (INT(UnitPrice * 100),1)
UnitPrice is multiplied by 100 to move the first two decimal places to the left of the decimal sign. The result of this calculation is converted to an integer using the **INT** function. Finally, the result of the **INT** is converted to zoned format, using a sign for positive values.

Related function

- **UNZONE**

 - [TODATETIME](#)
-

ADDDAYS

The **ADDDAYS** function adds a specified number of days to a given date.

You cannot use **ADDDAYS** on a date/time object that does not specify the day of the month because an error will occur.

Syntax:

ADDDAYS (single-date-expression, single-integer-expression)

Meaning:

ADDDAYS (any_date, number_of_days_to_add)

Returns:

A single date

The **ADDDAYS** function returns the date, which results from adding *number_of_days_to_add* to *any_date*. If *any_date* has a presentation that does not contain a century, the century is determined based on the Century > CCLookup map setting (when the Century > Switch = ON), or the current century (when the Century > Switch = OFF).

When the year exceeds four digits, the output will display hash characters (#) for the CCYY values because the field is defined to be only four digits in length.

Examples

- You can use the **ADDDAYS** function to increment a date by a fixed number of days, such as to calculate a **DueDate** that is always 30 days after the **InvoiceDate**. To produce a date in the output, such as a ship date, you might need to add a variable number of days to a date in the input. For example: **ADDDAYS** (PODate, LeadTime).
- **ADDDAYS** (InvoiceDate, 10)
Returns the date, which results from adding 10 days to the value of **InvoiceDate**.
- **ADDDAYS** (InvoiceDate, DaysTilDue)
Returns the date that results from adding the value of **DaysTilDue** to the **InvoiceDate** value.
- **ADDDAYS** (TODATETIME ("000101"), -1)
Returns 991231
- **ADDDAYS** (TODATETIME ("20000101"), 1)
Returns 20000102
- **ADDDAYS** (TODATETIME ("10/20/1996", "[MM/DD/CCYY"])), 5
Returns 10/25/1996

In the examples containing **TODATETIME**, the text literal is first converted to a date, and then the specified number of days is added to that date.

-

ADDHOURS

The **ADDHOURS** function returns a time value that is the result of adding a specified number of hours to a given time.

Syntax:

ADDHOURS (single-datetime-item-expression, hours-expressed-as-signed-integer-expression)

Meaning:

ADDHOURS (any_datetime, number_of_hours_to_add)

Returns:

A single datetime item

The **ADDHOURS** function returns a single datetime item that is advanced from the original value of the single-datetime-item-expression by the specified number of hours-expressed-as-signed-integer-expression.

Examples

- **ADDHOURS (TODATETIME ("Dec 31, 1999 23:59:00"), 2)**
Returns: Jan 1, 2000 01:59:00
- **ADDHOURS (TODATETIME ("Dec 31, 1999 23:59:00"), -25)**
Returns: Dec 30, 1999 22:59:00
- **ADDHOURS (TODATETIME ("23:59:00"), 2)**
Returns: 01:59:00

If either argument is invalid, the result is "none". If the second argument is "none", the result is the first argument. If the first argument contains only a time portion, date changes are ignored. If the first argument contains only a date portion, the time portion 00:00:00 will be used in the calculation. If both arguments are "none", the result is "none".

Related functions

- **ADDDAYS**
- **DATETONUMBER**
- **NUMBERTODATE**
- **TEXTTODATE**

ADDMINUTES

The **ADDMINUTES** function returns a time value that is the result of adding a specified number of minutes to a given time.

Syntax:

ADDMINUTES (single-datetime-item-expression, minutes-expressed-as-signed-integer-expression)

Meaning:

ADDMINUTES (any_datetime, number_of_minutes_to_add)

Returns:

A single datetime item

The **ADDMINUTES** function returns a single datetime item, advanced from the original value of the single-datetime-item-expression by the specified number of minutes-expressed-as-signed-integer-expression.

Examples

- **ADDMINUTES (TODATETIME ("Dec 31, 1999 23:59:00"), 2)**
Returns: Jan 1, 2000 00:01:00
- **ADDMINUTES (TODATETIME ("Dec 31, 1999 23:59:00"), -25)**
Returns: Dec 31, 1999 23:34:00
- **ADDMINUTES (TODATETIME ("23:59:00"), 2)**
Returns: 00:01:00

If either argument is invalid, the result is "none". If the second argument is "none", the result is the first argument. If the first argument contains only a time portion, date changes are ignored. If the first argument contains only a date portion, the time portion 00:00:00 will be used in the calculation. If both arguments are "none", the result is "none".

Related Functions

- **DATETONUMBER**
- **NUMBERTODATE**
- **TEXTTODATE**
- **TODATETIME**

CURRENTDATE

You can use **CURRENTDATE** when you need the current date as a transaction processing date, an order received date, or other date that reflects when the data was mapped.

When you need to parse the system date, use **CURRENTDATE** with the **TEXT** or **FROMDATETIME** functions. The function returns the current system date.

Syntax:

CURRENTDATE ()

Meaning:

CURRENTDATE ()

Returns:

A single date

CURRENTDATE has no arguments but it does require parentheses.

If being assigned to a date/time output item, the current date is returned in the format specified by that output item. Otherwise, the system date is returned in an MM/DD/YY presentation.

Examples

- **StartDate** = CURRENTDATE ()

In this example, **StartDate** is assigned the value of the current **date**. In this example, because **CURRENTDATE** is assigned to an output, it is automatically converted to the presentation of **StartDate**.

If **CURRENTDATE** evaluates to 06/24/37 and **StartDate** has a YYMMDD presentation, the result is 370624.

- **FROMDATETIME (CURRENTDATE () , "DD.MON.CCYY")**

In this example, the current date is returned in DD.MON.CCYY format. If today's date is January 5, 1999, the date returned would be 05.JAN.1999.

Related functions

- CURRENTDATETIME
- CURRENTTIME
- FROMDATETIME
- DATETOTEXT

CURRENTDATETIME

The **CURRENTDATETIME** function returns the current system date and time. If the system is configured to use daylight saving time, then it is used if daylight saving time is in effect.

You can use this function when you need to map the current system date and time to an item that includes both a date and time portion.

Syntax:

CURRENTDATETIME ([single-text-expression])

Meaning:

CURRENTDATETIME ([date_time_format_string])

Returns:

A single date-time

CURRENTDATETIME has no arguments but it does require parentheses.

The **CURRENTDATETIME** function returns the system date and time in the format specified by *date_time_format_string* or with a CCYYMMDDHHMMSS presentation if no *date_time_format_string* is provided.

The *date_time_format_string* must conform to the date/time format strings as described in "Format strings".

Note: The output format for the native schema XML date/time field is always:

{CCYY-MM-DD}T{HH24:MM:SS.3-3+/-ZZ:ZZ}

To specify a different output format, use Xerces XML instead.

Examples

- **StartTime** = CURRENTDATETIME ()

In this example, **StartTime** is assigned the value of the current date and time. Because **CURRENTDATETIME** is assigned to an output, it is automatically converted to the presentation of **StartTime**.

If **CURRENTDATETIME** evaluates to 3:04pm on 6/24/1999 and **StartTime** has a YYMMDDHH12MM presentation, the result is 9906240304.

- **CURRENTDATETIME ("MM.DD.CCYY HH24:MM")**

In this example, the current date is returned in MM.DD.CCYY HH24:MM format. If it is currently 4:12 pm on January 5, 1999, the date returned would be 01.05.1999 16:12.

Related Functions

- CURRENTDATE
- CURRENTTIME
- FROMDATETIME
- DATETOTEXT

CURRENTTIME

The **CURRENTTIME** function returns the current system time. If the system is configured to use daylight saving time, then it is used if daylight saving time is in effect.

You can use **CURRENTTIME** when you need the system time as a transaction processing time, an order-received time, or a time that reflects when the data was mapped.

Syntax:
CURRENTTIME ()

Meaning:
CURRENTTIME ()

Returns:
A single time

The **CURRENTTIME** function returns the system time. If assigned to a date-time output item, the current time is returned in the format specified by that output item. Otherwise, the system time is returned in HH:MM:SS presentation.

Note: **CURRENTTIME** has no arguments but it does require parentheses.

Examples

- End Time = CURRENTTIME ()

In this example, **End Time** is assigned the current time. Because **CURRENTTIME** is assigned to an output, it is automatically converted to the presentation of **End Time**.

If **CURRENTTIME** evaluates to 10:15:02 and **End Time** has an HH12:MM presentation, the result is 1015.

- FROMDATETIME (CURRENTTIME () , "{HH24MMSS}")

In this example, the current time is returned in HH24MMSS format. If the current time is 10:15:02 pm, the result is 221502.

Related functions

- CURRENTDATETIME
- FROMDATETIME
- DATETOTEXT

DATETONUMBER

Use **DATETONUMBER** to perform arithmetic on dates.

The **DATETONUMBER** function returns an integer that results from counting the number of days from December 31, 1864, to the specified date.

Syntax:
DATETONUMBER (single-date-expression)

Meaning:
DATETONUMBER (date_to_convert)

Returns:
A single integer

The **DATETONUMBER** function converts a date to an integer. The resulting integer represents the number of days since December 31, 1864, where using **DATETONUMBER** with a date of January 1, 1865 returns the integer value 1.

If the input argument is in error, the function returns the value "none".

If the date format specified by the input argument does not include century, the century is determined based on the **Century** map setting using the **CCLookup** parameter or the current century.

Examples

- DaysBetween = **DATETONUMBER** (StopDate) - **DATETONUMBER** (StartDate)

This expression could be used in a map rule to produce a value for **DaysBetween**. It converts the **StopDate** and the **StartDate** to integers, then subtracts the resulting two integers, and returns the result as **DaysBetween**.

Related functions

- ADDDAYS
- NUMBERTODATE

DATETOTEXT

The **DATETOTEXT** function converts a date object or expression to a text item.

Syntax:
DATETOTEXT (single-date-expression)

Meaning:
DATETOTEXT (date_to_convert)

Returns:
A single text item

If *date_to_convert* is a date object name, this returns the date as a text item formatted according to the presentation of the date object.

If *date_to_convert* is a date expression produced by a function, this returns the date as a text item formatted according to the presentation of the output argument of that function.

Examples

- **DATETOTEXT** (*ShipDate*)

In this example, **ShipDate** is converted from a date to text. If **ShipDate** has a CCYYMMDD presentation, the resulting text item will have that presentation, as well.

- **DATETOTEXT** (**CURRENTDATETIME** ("{MM/DD/CCYY}"))

In this example, **CURRENTDATETIME** evaluates and returns a date in MM/DD/CCYY format. Then **DATETOTEXT** evaluates and returns a text string that is that date in MM/DD/CCYY format.

For example, use **DATETOTEXT**, to do text concatenation. The **FROMDATETIME** function provides greater flexibility in specifying the format of the resulting text item.

Related Functions

- **FROMDATETIME**
- **NUMBERTOTEXT**
- **TEXT**
- **TEXTTODATE**
- **TEXTTONUMBER**
- **TEXTTOTIME**
- **TIMETOTEXT**
- **TODATETIME**

FROMDATETIME

The **FROMDATETIME** function converts a date/time item to a text string of a specified format. For example, you can use **FROMDATETIME** to convert a date-time item into a string for parsing or concatenation. You can also use this function to access the individual parts of a date or time, such as the month, day, year, and so forth.

Syntax:

FROMDATETIME (*single-character-date-time-item*
[, *single-text-expression*])

Meaning:

FROMDATETIME (*date_time* [, *date_time_format_string*])

Returns:

A single character text item

FROMDATETIME returns the date/time specified by *date_time* as a text item with the format specified by *date_time_format_string*. If *date_time_format_string* is not specified, *date_time* will be returned in the same format as the *date_time*.

The *date_time_format_string* must conform to the date/time format strings as described in the "Format strings" topic.

Examples

- HeaderLine="Today is" + **FROMDATETIME** (**CURRENTDATE** (), "{MON DD, CCYY}")
If the current system date is March 3, 1999, this rule evaluates to Today is Mar 03, 1999.

- **FROMDATETIME** (*TransactionTimeStamp Column::TransHistory*)

If the value of **TransactionTimeStamp Column** is 10:14 A.M. on February 3, 2000 and its format is defined as "{CCYYMMDDHH24MM}", this rule evaluates to 200002031014.

- **EXTRACT** (*Expense:Report*, **FROMDATETIME** (*Date:Expense:Report*, "[MM]") = "03")

In this example, the **FROMDATETIME** function is used in the condition expression of the **EXTRACT** function to identify all expenses in the month of March.

Related functions

- **CURRENTDATE**
- **CURRENTDATETIME**
- **CURRENTTIME**
- **DATETOTEXT**
- **TODATETIME**

MAX

The **MAX** function returns the maximum value from a series of number, date, time, or text values.

Syntax:

MAX (*series-item-expression*)

Meaning:

MAX (*series_of_which_to_find_max*)

Returns:

A single number

The result is the maximum value in the input argument series: number, text, or date/time.

Examples

- **MAX** (UnitPrice:Input)
If the values for **UnitPrice** are {20, 10, 100}, MAX returns 100.
- **MAX(EXTRACT(** DueDate:Book:Library, CheckedOut:Book:Library = "Y"))
Returns the maximum (latest) **DueDate** for a book that is checked out from the library.

Related functions

- **MIN**

MIN

Use MIN when you need the minimum value from a series of number, date, time, or text values.

The MIN function returns the minimum value from a series.

Syntax:
MIN (series-item-expression)

Meaning:
MIN (series_of_which_to_find_min)

Returns:
A single number

The result is the minimum value of the input series: number, text, or date/time.

Examples

- **MIN** (UnitPrice:Input)
If the values for **UnitPrice** are {20,10,100}, MIN returns 10.
- **MIN** (StartTime:::Schedule)
Returns the minimum (earliest) **StartTime** in **Schedule**.

Related functions

- **MAX**

NUMBERTODATE

You can use the **NUMBERTODATE** function to perform a calculation on a date.

NUMBERTODATE converts an integer to a date, where the integer is the number of days from December 31, 1864, to the specified date. Only positive, non-zero values can be specified as valid parameters.

Syntax:
NUMBERTODATE (single-integer-expression)

Meaning:
NUMBERTODATE (integer_to_convert)

Returns:
A single date

After converting an integer to a date, if the result is being assigned to a date object, the resulting date is in the presentation for that output. If the resulting date is not being assigned to an object, it has a CCYYMMDD presentation.

When the year exceeds four digits, the output will display hash characters (#) for the CCYY values because the field is defined to be only four digits in length.

Examples

- **NUMBERTODATE** (StartDate)
This example converts the **StartDate** value from an integer to a date that is in CCYYMMDD format.

Related functions

- **ADDDAYS**
- **DATETONUMBER**

- **FROMDATETIME**
- **TODATETIME**

TEXTTODATE

The **TEXTTODATE** function converts text item from CCYYMMDD or YYMMDD format to a date.

You can use the **TEXTTODATE** to convert a text item to a date, however, the **TODATETIME** function provides greater flexibility for specifying the resulting date-time format.

Syntax:

TEXTTODATE (single-text-expression)

Meaning:

TEXTTODATE (text_to_convert_to_date)

Returns:

A single date

The *text_to_convert_to_date* must be in either CCYYMMDD or YYMMDD format. If the *text_to_convert_to_date* is in error (for example, it is not a valid date), the result is "none".

If *text_to_convert_to_date* is in YYMMDD format and is being assigned to a date format that includes a century, the century is determined based on the century run option setting using the **CCLookup** parameter or the current century.

Examples

- **TEXTTODATE ("990114")**
Returns a single date item with the value of January 14 in the year 99
- **TEXTTODATE (OrderDate)**
Returns **OrderDate** as a single date item.

Related functions

• DATETOTEXT	• TEXTTOTIME
• NUMBERTOTEXT	• TIMETOTEXT
• TEXTTONUMBER	• TODATETIME

TEXTTOTIME

Use **TEXTTOTIME** when you want to convert an object defined as text that is in HHMM or HHMMSS presentation, to an item defined as time. For greater flexibility, use the **TODATETIME** function for specifying the format of the text item that is to be converted to a date/time.

Syntax:

TEXTTOTIME (single-text-expression)

Meaning:

TEXTTOTIME (text_to_convert_to_time)

Returns:

A single time

The *text_to_convert_to_time* must be in HHMM or HHMMSS presentation. HH is a two-digit hour in a 24-hour format. If the result is being assigned to a time object, the resulting time looks like the output object. Otherwise, the resulting time looks like the input argument. If the input argument is in error (for example, it is not a valid time), the result is "none".

Examples

- **TEXTTOTIME (CallTime)**
Returns **CallTime** as a time item

Related functions

• DATETOTEXT	• TEXTTONUMBER
• FROMDATETIME	• TIMETOTEXT
• NUMBERTOTEXT	• TODATETIME
• TEXTTODATE	

TIMETOTEXT

You can use the **TIMETOTEXT** function to perform text concatenation. For greater flexibility, use the **FROMDATETIME** function for specifying the format of the resulting text item.

TIMETOTEX converts a time object or expression to a text item.

Syntax:

TIMETOTEXT (single-time-expression)

Meaning:

TIMETOTEXT (time_to_convert_to_text)

Returns:

A single text item

If *time_to_convert_to_text* is a time object name, this returns the time as a text item formatted according to the presentation of the input date object.

If *time_to_convert_to_text* is a time expression produced by a function, this returns the time as a text item formatted according to the presentation of the output argument of that function.

Examples

- **TIMETOTEXT** (LeadTime)

In this example, **LeadTime** is converted from a time to text. If **LeadTime** has an HH:MM presentation, the resulting text item will be of that presentation.

- **TIMETOTEXT** (CURRENTDATETIME ("{HH:MM:SS}"))

Here, **CURRENTDATETIME** evaluates and returns a time in HH:MM:SS format. Then, **TIMETOTEXT** evaluates and returns a text string that is that time in HH:MM:SS format.

Related functions

- **DATETOTEXT**
- **FROMDATETIME**
- **NUMBERTOTEXT**
- **TEXTTODATE**
- **TEXTTONUMBER**
- **TEXTTOTIME**
- **TODATETIME**

TODATETIME

The **TODATETIME** function converts a text string of a specified format to a date-time item.

Syntax:

TODATETIME (single-character-text-expression
[, single-text-expression])

Meaning:

TODATETIME (text_to_convert [, date_time_format_string])

Returns:

A single character date item

TODATETIME returns the date-time that corresponds to the value specified by *text_to_convert*, which is in the format specified by *date_time_format_string*. If *date_time_format_string* is not specified, it will be assumed that *text_to_convert* is in [CCYYMMDDHH24MMSS] format.

The *date_time_format_string* must conform to the date-time format strings as described in "Format strings".

Examples

- **TODATETIME** ("05/14/1999@10:14pm" , "{MM/DD/CCYY}@{HH12:MMAM/PM}")

In this example, a text string containing a date and time is converted to a date-time item.

- RptDate = **TODATETIME** (**RIGHT** (**GETRESOURCENAME** () , 8) , "CCYYMMDD")

Assume that you receive a file that contains historical data. The name of the file identifies the date of the historical data. For example, a filename of **19960424** indicates that the data was produced on April 24, 1996. To map this date to **RptDate**, the **TODATETIME** function could be used with the **RIGHT** and **GETRESOURCENAME** functions.

Related functions

- **CURRENTDATE**
- **CURRENTDATETIME**
- **CURRENTTIME**
- **TEXTTODATE**
- **TEXTTOTIME**

Error handling functions

- [**CONTAINSERRORS**](#)
- [**FAIL**](#)
- [**GETXMLERRORMSG**](#)
- Use this function on an output card to return an XML validation error message when a map runs against invalid XML input.
- [**ISERROR**](#)
- [**ONERROR**](#)
- [**REJECT**](#)
- [**QUIT**](#)
- [**VALID**](#)

CONTAINSERRORS

The **CONTAINSERRORS** function tests a valid object to see whether it contains any objects in error.

Syntax:

CONTAINSERRORS (single-object-expression)

Meaning:

CONTAINSERRORS (object_to_test)

Returns:

True or false

The **CONTAINSERRORS** function returns "true" if any object contained in *object_to_test* is in error; it returns "false" if the *object_to_test* is completely valid.

The input object, itself, is a *valid* input object. This function does *not* evaluate for invalid objects. Therefore, if you have map rule:

CONTAINSERRORS (Invoice:InputFile)

and **Invoice[1]** is valid, **Invoice[2]** is invalid, and **Invoice[3]** is valid, then **CONTAINSERRORS** evaluates only twice-once for each *valid* instance of **Invoice**.

Examples

- `Msg (s) = IF (CONTAINSERRORS (Msg:MailBag) &`
`Type:Msg:MailBag = "PRIORITY" ,`
`Msg:MailBag ,`
`"none")`

In this example, if **Msg:MailBag** contains any object in error and **Type:Msg:MailBag** has a value of "PRIORITY", **Msg:MailBag** is mapped; otherwise, "none" is returned for this occurrence of **Msg**. This map rule returns all valid messages (**Msg**) that contain errors with a **Type** of "PRIORITY".

Related functions

- [**ISERROR**](#)
- [**REFORMAT**](#)

FAIL

You can use the **FAIL** function to abort a map based on map or application specific logic.

Syntax:

FAIL (single-text-expression)

Meaning:

FAIL (message_to_return)

Returns:

"None"

The **FAIL** function returns "none" to the output to which the function is assigned, aborts the map, and returns *message_to_return* as the map completion error message included in the execution audit. The map return code will be "30", indicating that the map failed through the **FAIL** function.

Examples

- `AcctID = EITHER (LOOKUP (CustomerID::Xref , MyKey::Xref = ID::Input) ,`
`FAIL ("Unknown Customer (" + ID::Input + "). Processing Terminated.")`

In this example, the **FAIL** function is being used in conjunction with the **EITHER** function to conditionally fail the map if a record in the customer cross-reference file does not exist for a given **CustomerID**.

For example, the **ID** in **Input** is ABC123. If the **LOOKUP** succeeds, the **CustomerID** result is assigned to **AcctID** and the map continues.

If the **LOOKUP** fails, **AcctID** is assigned a value of "none", the map aborts, and the message Unknown Customer (ABC123). Processing Terminated.is written to the execution audit log.

- Message = **VALID** (**RUN** ("Map1Msg.mmc", "-AE -OMMSMQ1B ` -QN .\aqueue -CID 2001"),
FAIL ("Failure on **RUN** (" + TEXT (**LASTERRORCODE** ()) + ":" +
LASTERRORMSG ()))

In this example, the **FAIL** function is being used in conjunction with the **VALID**, **LASTERRORCODE**, and **LASTERRORMSG** functions to fail (abort) the map if the map executed by the **RUN** function (**Map1Msg.mmc**) fails. In this example, the map fails and returns the error code and error message reported by the **RUN** function using the **LASTERRORCODE** and **LASTERRORMSG** functions.

If **Map1Msg** fails because one or more of its inputs was invalid, **Message** is assigned a value of "none". The map aborts and the following message is reported in the execution audit log:

"Failure on **RUN** (8): One or more inputs was invalid."

Related functions

- **LASTERRORCODE**
- **LASTERRORMSG**
- **QUIT**
- **VALID**

GETXMLERRORMSG

Use this function on an output card to return an XML validation error message when a map runs against invalid XML input.

Create the input card with either a native XML schema or an XML-based type tree, and specify the Restart attribute. On the output card, use the **GETXMLERRORMSG** function, passing the number of the input card as the parameter. When the map runs and the input contains invalid XML data, the output card returns a standard XML error message. For example:

```
Error (-1), "XMLParser: Input XML data is invalid."
SAXParseException, Error [line: 162 column: 36]
Datatype error: Type:SchemaDateTimeException,
Message:Incomplete Date ! '2006-09-' .
```

See the Type Designer documentation or the Map Designer documentation for details about the Restart attribute.

Syntax

GETXMLERRORMSG (single-number-expression)

Meaning

GETXMLERRORMSG (input_card_number)

Returns

A text string

Related functions

- **VALIDATE**

ISERROR

The **ISERROR** function tests an object to see if it is in error

You can use **ISERROR** to output your data in exactly the same order as it occurs in your input, both the valid data and the data in error. You can also use **ISERROR** to produce error messages for bad data in the same file in which you map your good data.

Syntax:

ISERROR (single-object-name)

Meaning:

ISERROR (object_to_test)

Returns:

"True" or "false"

ISERROR returns "true" when *object_to_test* is in error and returns "false" when *object_to_test* is completely valid.

Examples

- InfoRec (s) = IF (**ISERROR** (Record:SomeFile), "Bad --> " + **REJECT** (Record:SomeFile), "Ok --> " + TEXT (Record:SomeFile))

In this example, **ISERROR** is used to produce a report for all **Record** objects in **SomeFile**. If the record is in error, the **InfoRec** will have the text Bad --> followed by the data from the input **Record**. If the record is valid, the **InfoRec** will have the text Ok --> followed by the data from the input **Record**, such as:

```
Ok --> SZ-68839,486 Upgrade Microprocessor,186.86,100,W200
Bad --> MK-19309,,369.43,417,W100
Ok --> KL-20349,PCMCIA Network Adaptor,174.82,29,N300
Ok --> WP-37679,AC Adaptor,39.48,245,E100
Bad --> IL-39890,8MB Memory PCMCIA,390.48,0,S100
```

Related functions

- **CONTAINSERRORS**

ONERROR

Use ONERROR in component rules to add user-defined error messages to the data section of the audit log.

The **ONERROR** function adds a user-defined error message to the data section of the audit log. This function is relevant only in Type Designer Component rules.

Syntax:

ONERROR (single-condition-expression , single-text-expression)

Meaning:

ONERROR (condition_to_evaluate , message_to_display)

Returns:

"True" or "false"

If *condition_to_evaluate* evaluates to "true", the function returns "true".

If *condition_to_evaluate* evaluates to "false", the function returns "false".

If data audit is enabled and the object to which the component rule applies will result in a failed component rule message (status E09), *message_to_display* is written to the data audit section of the audit log with an entry type of U, representing user-defined.

If the failed component rule message (E09) appears in the data section of the audit log, one or more user-defined error messages can also be included in the data section of the audit log. If a component rule has one **ONERROR** function, one user-defined error message or none is included in the audit log. If a component rule has two **ONERROR** functions, two user-defined error messages at most are included in the audit log, and so on.

Examples

- Here is a component rule without **ONERROR**:

Claim Date Field > Accident Date Field &

Claim Date Field < **ADDDAYS** (Accident Date Field, 365)

If the component rule fails, the data section of the audit log shows the following information:

```
<DataLog>
<input card="1">
  <object ... status="E07">InsuranceClaim</object>
  <object ... status="E09">Claim Date Field</object>
    <Text>980725</Text>
  <object ... status="E07">InsuranceClaim</object>
  <object ... status="E09">Claim Date Field</object>
    <Text>990526</Text>
</input>
</DataLog>
```

Status code E09 for the **Claim Date Field** indicates that the data for that object failed its component rule, but does not provide any further detail.

- Using **ONERROR**, one or more error messages can be added to the data section of the audit log to provide more information as to how or why the component rule failed. For example,
ONERROR (Claim Date Field > Accident Date Field ,
"Claim date before accident.") &
ONERROR (Claim Date Field < **ADDDAYS** (Accident Date Field , 365) ,
"Claim is more than one year old.")

If the component rule fails and **ONERROR** is used, the data section of the audit log can show the following messages:

```
<DataLog>
<input card="1">
  <object ... status="E07">InsuranceClaim</object>
  <object ... status="E09">Claim Date Field</object>
    <Text>980725</Text>
    <User>Claim date before accident.</User>
  <object ... status="E07">InsuranceClaim</object>
  <object ... status="E09">Claim Date Field</object>
    <Text>990526</Text>
    <User>Claim is more than one year old.</User>
</input>
</DataLog>
```

REJECT

The **REJECT** function returns the content of an object in error as a text item. Use **REJECT** in conjunction with the restart attribute. You can use the **REJECT** function in map rules only, not in component rules.

See the Type Designer and Map Designer documentation for information about the restart attribute.

Syntax:

REJECT (series-object-expression)

Meaning:

REJECT (series_to_look_for_bad_objects)

Returns:
A series text item

REJECT evaluates to a series of text items consisting of all the input series members in error.

Examples

- **REJECT** (Record:File)
This example extracts all **Records** that are in error.
- IF (COUNT (REJECT (Msg IN Batch))) = 0, "OK", "ERROR")
In this example, the total number of invalid (rejected) Msg objects is counted. If the total number of invalid Msg objects is equal to zero, it indicates that there were no invalid Msg objects counted and a message of OK results. Otherwise, a message of ERROR results.

Related functions

- **CONTAINSERRORS**
- **ISERROR**
- **VALID**

QUIT

You can use the **QUIT** function to stop a map at a specific point during map execution. The **QUIT** function logs a successful return code and a custom message in the map audit log.

Syntax:
QUIT (single-text-expression)

Meaning:
QUIT (message_to_return)

Returns:
"None"

The **QUIT** function returns "none" to the output, stops the map, and logs map return code 41 and the message **QUIT** function terminated map successfully: *message_to_return* in the map audit log.

Related functions

- **FAIL**
- **LASTERRORCODE**
- **LASTERRORMSG**
- **VALID**

VALID

You can use the **VALID** function to perform conditional processing based on whether an external interface function executes successfully.

VALID returns the result of the first argument if it is valid; otherwise, returns the second argument.

Syntax:
VALID (single-text-expressions , single-general-expression)
Meaning:
VALID (function_that_can_fail, return_value_if_function_fails)
Returns:
A single text expression

VALID returns the result of the evaluation of *function_that_can_fail* if it is valid. If the function fails, **VALID** returns *return_value_if_function_fails*.

The following functions can fail:

• DBLOOKUP	• GET
• DBQUERY	• PUT
• DDEQUERY	• RUN
• EXIT	

Examples

- SomeObject = VALID (RUN ("mymap.mmc" , "-OF1 mydata.txt") , FAIL ("My RUN failed!"))

If the **RUN** function returns an error return code, the **VALID** functions returns `none`, the map aborts, and the message `My RUN failed!` is reported under Execution Summary in the execution audit log.

- [**EXIT**](#)
- [**GET**](#)
- [**JEXIT**](#)
- [**PUT**](#)
- [**RUN**](#)
- [**RENAMEFILE**](#)

The **RENAMEFILE** function renames the source file to that of the destination file. If the operation succeeds, the returned value is 0; if it fails, then an operating system-specific error number is returned.

- [**HARDLINKFILE**](#)

A hard link points or references to a specific space on the hard drive. Multiple files can be hard linked to the same space in the hard drive. If some data is changed on one of the hard linked files, all the other files reflect that change. The **HARDLINKFILE** function returns the hard link file's command status. On successful execution of this function: 0 is returned; on failure: an operating system-specific error code is returned.

- [**SOFTLINKFILE**](#)

A soft link points to a specific file, which in turn, references to a particular location on the hard drive. The soft link, also known as symbolic link is a second file that exists independently of its target. The **SOFTLINKFILE** function returns the soft (symbolic) link file's command status. On successful execution of this function: 0 is returned; on failure: an operating system-specific error code is returned.

- [**COPYFILE**](#)

The **COPYFILE** function copies the source file to the destination file. It returns the copy file command status. On successful execution of this function: 0 is returned; on failure: an operating system-specific error code is returned.

- [**SLEEP**](#)

The **SLEEP** function suspends the execution of the current map until the time-out interval elapses. The time-out or sleep interval is represented in milliseconds. On successful execution of this function: 0 is returned; on failure: -1 is returned.

DBLOOKUP

The **DBLOOKUP** function executes an SQL statement against a database. The SQL statement can be any permitted by your database management system or ODBC driver.

When the **DBLOOKUP** function is used in a map, the default **OnSuccess** action is adapter specific. The default **OnFailure** action is to rollback any changes made during map processing. The default **Scope** will be integral unless the map is defined to run in bursts (which is the case when one or more inputs have the **FetchAs** property set to **Burst**).

There are two ways to specify arguments for **DBLOOKUP**.

You can use **DBLOOKUP** to execute an SQL statement when you want to execute a **SELECT** statement to retrieve a specific column value in a large table in a database using the value of another input, rather than defining the entire table as an input card and using the **LOOKUP**, **SEARCHDOWN**, or **SEARCHUP** functions.

You can use DBLOOKUP to execute an SQL statement when you want to execute a SELECT statement to retrieve a specific column value from a table or database that might vary based on a parameter file. Using Meaning 2 of the **DBLOOKUP** function allows these parameters to be dynamically specified at run time.

Syntax:

DBLOOKUP (single-text-expression , single-text-expression , [single-text-literal])

Meaning:

1. **DBLOOKUP** (SQL_statement , mdq_filename , database_name)
2. **DBLOOKUP** (SQL_statement , parameters)

Returns:

A single text item

The **DBLOOKUP** function returns the results of the query in the same format as a query specified for a map input card, except that it does not include the last carriage return/linefeed. Because this information is removed, it is easier to make use of a single value extracted from a database.

Arguments for meaning 1

DBLOOKUP (SQL_statement , mdq_filename , database_name)

- **SQL_statement**

The first argument is an SQL statement as a text string. This can be any valid SQL statement permitted by your database management system and supported by your database-specific driver. In addition to a fixed SQL statement, this argument can be a concatenation of text literals and data objects, enabling the concatenation of data values into your SQL statement.

- **mdq_filename**

The second argument is the name of a database query file (**.mdq**) produced by the Database Interface Designer. It contains the definition of the database that the SQL statement is to be executed against. If the **.mdq** file is in a directory other than the directory of the map, the path must be specified.

Note: The **.mdq** file is accessed at map build time and is not needed at run time.

- **database_name**

The third argument is the name of a database in the database query file (**.mdq**) as defined in the Database Interface Designer.

If used in this way, both the **.mdq** filename and database name must be literals.

Arguments for meaning 2

DBLOOKUP (SQL_statement , parameters)

- **SQL_statement**

The first argument is an SQL statement as a text string. This can be any valid SQL statement permitted by your database management system and supported by your database-specific driver. In addition to a fixed SQL statement, this argument can be a concatenation of text literals and data objects, enabling the concatenation of data values into your SQL statement.

- **parameters**

The second argument is a set of parameters, either:

- -MDQ mdqfilename -DBNAME dbname
 - or-

- -DBTYPE database_type [database specific parameters]

The keyword -MDQ is followed by the name of the database query file (**.mdq**) produced by the Database Interface Designer. This **.mdq** file contains the definition of the database. If the **.mdq** file is in a directory other than the directory of the map, the path must be specified. The **.mdq** filename is followed by the keyword -DBNAME and the database name as specified in the Database Interface Designer.

Using this syntax, the **.mdq** file is accessed at run time and must be present.

The keyword -DBTYPE is followed by a keyword specifying the database type (for example, ODBC or ORACLE) followed, optionally, by database-specific parameters.

This syntax does not use an **.mdq** file, because the database-specific parameters provide the information required to connect to the database. See the Resource Adapters documentation for detailed information about the database-specific parameters that can be specified.

When used with Meaning 2, **DBLOOKUP** must conform to these rules:

- All keywords (for example, -DBTYPE) can be upper or lowercase, but not mixed.
- A space is required between the keyword and its value (for example, -DBTYPE ODBC).
- The order of the keywords is not important.
All database-specific parameters are optional.

Examples

Assume that you have a table named "PARTS" that contains the following data:

PART_NUMBER	PART_NAME
1	1/4" x 3" Bolt
2	1/4" x 4" Bolt

Assume that this database has been defined using the Database Interface Designer in a file named **mytest.mdq** and that the name of the database, as specified in the **.mdq** file, is **PartsDB**.

- **DBLOOKUP** ("SELECT PART_NAME from PARTS where PART_NUMBER =1",
"mytest.mdq",
"PartsDB")
Returns: 1/4" x 3" Bolt

Using Meaning 2, you can specify the **DBLOOKUP** this way:

- **DBLOOKUP**("SELECT PART_NAME from PARTS where PART_NUMBER =1",
"-MDQ mytest.mdq -DBNAME PartsDB")
where both the **.mdq** file name and database name is specified.

Using Meaning 2, you can also specify the database type and the appropriate database-specific parameters:

- **DBLOOKUP**("SELECT PART_NAME from PARTS where PART_NUMBER =1",
"-DBTYPE ORACLE -CONNECT MyDB -USER janes")

For more examples using the **DBLOOKUP** function, see the Database Interface Designer documentation.

DBQUERY

The **DBQUERY** function executes an SQL statement against a database. The SQL statement can be any permitted by your database management system or ODBC driver.

When the **DBQUERY** function is used in a map, the default **OnSuccess** action is adapter specific. The default **OnFailure** action is to rollback any changes made during map processing. The default **Scope** will be integral unless the map is defined to run in bursts (which is the case when one or more inputs have the **FetchAs** property set to **Burst**).

There are two ways to specify the arguments for **DBQUERY**. You can use **DBQUERY [Meaning 1]** to execute an SQL statement when you want to look up information in a database using a parameterized query that is based on another value in your data. If your SQL statement is a SELECT statement, the **DBQUERY** function might be used in conjunction with the **RUN** function to issue dynamic SELECT statements whose results can be used as input to another map.

You can also use the DBQUERY function [*Meaning 2*] to execute an SQL statement when the database, table, or other database parameters might vary; perhaps being supplied by a parameter file.

Syntax:

```
DBQUERY (single-text-expression , single-text-expression ,
[ single-text-literal ])
```

Meaning:

1. **DBQUERY** (SQL_statement , mdq_filename , database_name)
2. **DBQUERY** (SQL_statement , parameters)

Returns:

A single text item

If your SQL statement is a SELECT statement, the results of the query in the same format as a query specified as a map input card, including row delimiters and terminators, and so on.

If your SQL statement is anything other than a SELECT statement, "none".

Arguments for meaning 1

DBQUERY (SQL_statement , mdq_filename , database_name)

- **SQL_statement**

The first argument is an SQL statement as a text string. This can be any valid SQL statement that is permitted by your database management system and supported by your database-specific driver. In addition to a fixed SQL statement, this argument can be a concatenation of text literals and data objects, enabling the concatenation of data values into your SQL statement.

- **mdq_filename**

The second argument is the name of a database query file (**.mdq**) produced by the Database Interface Designer. It contains the definition of the database that the SQL statement is to be executed against. If the **.mdq** file is in a directory other than the directory of the map, the path must be specified.

Note: The **.mdq** file is accessed at map build time and is not needed at run time.

- **database_name**

The third argument is the name of a database in the database query file (**.mdq**) as defined in the Database Interface Designer.

If used in this way, both the **.mdq** filename and database name must be literals.

Arguments for meaning 2

DBQUERY (SQL_statement , parameters)

- The first argument is an SQL statement as a text string. This can be any valid SQL statement that is permitted by your database management system and supported by your database-specific driver. In addition to a fixed SQL statement, this argument can be a concatenation of text literals and data objects, enabling the concatenation of data values into your SQL statement.

- The second argument is a set of parameters, either:

- -MDQ mdqfilename -DBNAME dbname
 - or-

- -DBTYPE database_type [database specific parameters]

The keyword -MDQ is followed by the name of the database query file (**.mdq**) produced by the Database Interface Designer. This **.mdq** file contains the definition of the database. If the **.mdq** file is in a directory other than the directory of the map, the path must be specified. The **.mdq** filename is followed by the keyword -DBNAME and the database name as specified in the Database Interface Designer.

Note: Using this syntax, the **.mdq** file is accessed at run time and must be present.

The keyword -DBTYPE is followed by a keyword specifying the database type (for example, ODBC or ORACLE) followed, optionally, by database-specific parameters.

Note: This syntax does not use an **.mdq** file, because the database-specific parameters provide the information required to connect to the database. See the appropriate database adapter documentation for detailed information about database-specific parameters.

When used with Meaning 2, **DBQUERY** must conform to these rules:

- All keywords (for example, -DBTYPE) can be upper or lower case, but not mixed.
- A space is required between the keyword and its value (for example, -DBTYPE ODBC).
- The order of the keywords is not important.

All database-specific parameters are optional.

Examples

Assume that you have a table named "PARTS" that contains the following data:

PART_NUMBER	PART_NAME
1	1/4" x 3" Bolt
2	1/4" x 4" Bolt

Also assume that this database has been defined using the Database Interface Designer in a file named **mytest.mdq** and that the name of the database, as specified in the **.mdq** file, is **PartsDB**.

```
DBQUERY ( "SELECT * from  
PARTS" , "mytest.mdq" , "PartsDB" )  
Returns 1|1/4" x 3" Bolt<cr><lf>2|1/4" x 4" Bolt<cr><lf>
```

where <cr><lf> is a carriage return followed by a line feed.

Using Meaning 2, you can also specify the DBQUERY this way:

```
DBQUERY ( "SELECT * from PARTS" , "-MDQ mytest.mdq -DBNAME PartsDB"  
)
```

where both the **.mdq** file name and database name are specified.

Or, specify it this way, using Meaning 2 by specifying the database type and the appropriate database-specific parameters:

```
DBQUERY ( "SELECT * from PARTS" , "-DBTYPE ORACLE -CONNECT MyDB -USER janes"  
)
```

Assume that you have an input file containing one order record. To map that order to another proprietary format, you also have a parts table with pricing information for every part for every customer, a very large table. Rather than using the entire parts table as the input to your map, you might use the **RUN** function with a **DBQUERY** to dynamically select only those rows from the parts table corresponding to the customer in the order file, as follows:

```
RUN ( "MapOrder.MMC" ,  
"IE2" + DBQUERY ( "SELECT * FROM Parts WHERE CustID = "  
+ CustomerNo:OrderRecord:OrderFile + " ORDER BY PartNo" ,  
"PartsDB.MDQ" , "PartsDatabase" ) )
```

DDEQUERY

The **DDEQUERY** function allows you to interface to other Windows applications such as Trading Partner PC, Excel, and so forth, provided that certain criteria are met. For example, if you receive an Excel spreadsheet file, you must have the appropriate version of the Excel application installed (that is compatible with the file received) and the application must be open.

Syntax:

```
DDEQUERY (single-text-expression , single-text-expression , single-text-expression)
```

Meaning:

```
DDEQUERY (application_name , topic , text)
```

Returns:

A single text item from an application

Examples

- **DDEQUERY ("excel" , "[MKTPRICE.XLS]Sheet1" , "R8C1:R14C3")**

In this example, **DDEQUERY** is used to get data from an Excel spreadsheet. The third argument, **R8C1:R14C3**, specifies the location of the data in the spreadsheet. (In Excel, the 8th row, 1st column to the 14th row, 3rd column is A8:C14.) The content of this spreadsheet range is returned as a single text item.

This example assumes that the application, the map, and the spreadsheet all reside in the same directory. If they are not in the same directory you must add the path. For example:

```
DDEQUERY ("excel" , "c:\spreadsheet[MKTPRICE.XLS]Sheet1" , "R8C1:R14C3")
```

- **DDEQYUERY ("tppc","PartnerX","BGyourEDIode")**

In this example, **DDEQUERY** is used as a request to Trading Partner PC.

EXIT

The **EXIT** function allows you to interface with a function in an external library or application.

You can use EXIT when you need information from an existing function in a library or a program or when you need to use a general function that is not available.

Depending on the execution operating system, there are two different methods for the **EXIT** function: 1) the library method and 2) the program method. The program method is not supported on Windows operating systems.

Syntax:

EXIT (single-text-expression, single-text-expression,

single-text-expression)

Meaning:

1. **EXIT** (library_name, function_name, input_to_the_function)
2. **EXIT** (program_name, command_line_arg1, command_line_arg2)

Returns:

A single text item

Meaning 1 - library method

At run time, the *function_name* function will execute in the library specified by *library_name* passing *input_to_the_function* as a text string. The result of *function_name* is returned as a text item by means of *lpep->lpdataFromApp*.

Set *lpep->nReturn* equal to 0 if the function is to succeed or set it equal to -1 to fail.

For detailed information about the requirements of the library function that is executed by the **EXIT**, see [Implementing a library EXIT function](#).

AIX operating system

On the AIX operating system, the shared library that contains *library_function* must also contain an *entry_point* function. The *entry_point* function must be prototyped in the same manner as *library_function*. The server will invoke the *entry_point* function before invoking *library_function*. The server passes the name of the *library_function* to the *entry_point* function by way of the *szFile* EXITPARAM structure member. The *entry_point* function must then determine the address of the *library_function* and pass this address back to the server by way of the *lpv* EXITPARAM structure member. The server will then use the contents of *lpv* as an address to invoke the *library_function*.

The following example depicts a shared library called **mcshex.so** which contains the *entry_point* function and the *library_function*.

```
#include <stdio.h>
#include <string.h>
#include "runmerc.h"
void AIXEntry(LPEXITPARAM);
void bin2hex(LPEXITPARAM);
unsigned int i;
char *syms[] = { "bin2hex", "AIXEntry" };
void *adr[] = { (void *)bin2hex, (void *)AIXEntry };
void AIXEntry(LPEXITPARAM lpInputStruct)
{
    printf("AIXEntry called\n");
    for (i = 0; i < (sizeof(syms)) / (sizeof(char *)); i++)
        if (!strcmp(lpInputStruct->szFile, syms[i])) {
            lpInputStruct->lpv = adr[i];
            break;
        }
}
void bin2hex(LPEXITPARAM lpInputStruct)
{
    printf("bin2hex called\n");
    printf("argument to library function: %s\n", lpInputStruct->lpszCmdLine);
    lpInputStruct->nReturn = 0;
}
```

To build this shared library, run the following commands:

cc -c share1.c

cc -o mcshex.so share1.o -bE:shrsu.exp -bM:SRE -eAIXEntry

Meaning 2 - program method

The program method of the **EXIT** function is *not* supported on Windows operating systems.

At execution time, the program specified by *program_name* executes and passes the concatenation of *command_line_arg1 + " " + command_line_arg2* as a text string.

Whatever is returned by *program_name* to the standard output device is returned as text.

Examples

- **EXIT** (*program_name*, *command_line_arg1*, *command_line_arg2*)
Returns a text string from the function or application that is executed. If the EXIT function is not available for a particular operating system, EXIT returns `none`.
- **EXIT** ("mydll.dll", "myfunction", "12")
This Windows library example passes the value 12 to **myfunction**, a function in **mydll.dll**. The value of the item returned depends on what **myfunction** does with the 12 passed to it.
- IF (**EXIT** ("mylib.sl", "ckCust", CustID Column:Row:DB) = "OK", MapKnownCust (Row:DB), MapUnknownCust (Row:DB))
Similarly, this UNIX library example passes the value of **CustID** Field to **ckCust**, a function in a UNIX shared library called **mylib.sl**. If the value returned by **ckCust** is OK, a functional map is called to map **Row** for a known customer. Otherwise, another functional map is executed to map **Row** for an unknown customer.
- **EXIT** ("pwd", "", "")
This UNIX program example executes the UNIX print working directory (pwd) command to determine the current directory. The name of the current working directory is then returned as a text string. Notice that although the pwd command does not require additional command line arguments, *command_line_arg1* and *command_line_arg2* must be included as a space enclosed in double quotation marks ("").
- **TEXTT tonumber**((**EXIT** ("GetIncome", Applicant:Form, "*Mortgage")))
This program example passes the value of Applicant concatenated to the text literal *Mortgage to an application called GetIncome. The result is converted to a number.

- **GET**
- **LASTERRORCODE**
- **LASTERRORMSG**
- **PUT**
- **RUN**
- **VALID**
- [Implementing a library EXIT function](#)

Implementing a library EXIT function

You can develop a function in a library to be executed from an **EXIT** function.

- [EXIT function's library interface](#)
- [Using the EXITPARAM Structure](#)

EXIT function's library interface

Library functions are used within an **EXIT** function using information contained in the EXITPARAM structure. This method provides great flexibility for data passed to and from a map. For example, the map can pass binary data containing nulls, and there is no limitation on the length of the returned data. The method also allows functions to report additional information by providing a return code and error message.

Using the EXITPARAM Structure

Function prototype

The function to be executed must be a function in a library with the following prototype:

```
void MyFunc (LPEXITPARAM lpep);
```

Definition of the EXITPARAM structure

The definition of the EXITPARAM structure is as follows:

```
struct tagExitParamStruct
{
    DWORD      dwSize;
    DWORD      dwToLen;
    DWORD      dwFromLen;
    DWORD      dwMapInstance;
    void FAR *  lpv;
    LPSTR      lpszCmdLine;
    BYTE HUGE * lpDataToApp;
    BYTE HUGE * lpDataFromApp;
    UINT       uRetryCount;
```

```

    UINT          uRetryInterval;
    BOOL          bRollback;
    BOOL          bCleanup;
    int           nReturn;
    char          szErrMsg[100];
    char          szFile[260];
    void FAR *   lpMapHandle;
    void FAR *   lpInternal;
    void FAR *   lpCmdStruct;
    void FAR *   lpAdaptParms;
    void FAR *   lpContext;
    void FAR *   lpWildcard;
    void FAR *   lpfnMS;
    void FAR *   lpMS;
    DWORD         dwWildcardSize;
    LPSTR         lpszMapDirectory;
    WORD          wCardNum;
    WORD          wCleanupAction;
    WORD          wScope;
    WORD          uUnitSize;
    BOOL          bBurst;
    BOOL          bFromRule;
    BOOL          bSource;
    DWORD         dwRecords;
};

typedef struct tagExitParamStruct EXITPARAM;
typedef struct tagExitParamStruct FAR * LPEXITPARAM;

```

The engine environment sets up the EXITPARAM structure and the function should fill in the result. The engine will allocate and free the memory associated with **lpDataToApp**. The function must allocate the memory for **lpDataFromApp**. For all Windows operating systems, use the Windows macro **GlobalAllocPtr** defined in **windowsx.h**. For all other operating systems, use the C-runtime **malloc** function. The engine will free this memory.

Table 1. Components of EXITPARAM as used with the EXIT function.

Component	Used as	Usage
dwSize	Input	Size (in bytes) of EXITPARAM to assure correct compatibility
dwToLen	Input	Length (size in bytes) of lpDataToApp
dwFromLen	Output	Length (size in bytes) of lpDataFromApp
dwMapInstance		Not used
lpv		Not used
LpszCmdLine		Not used
lpDataToApp	Input	Data sent to the function. This is the third parameter of the EXIT function
lpDataFromApp	Output	Data sent back to the server from the function
uRetryCount		Not used
uRetryInterval		Not used
bRollback		Not Used
bCleanup		Not used
nReturn	Output	Return code based on the outcome of the function
szErrMsg	Output	String message based on nReturn
szFile		Not used
lpInternal		Not used
lpCmdStruct		Not used
lpAdaptParms		Not used
lpContext		Not used
lpWildcard		Not used
dwWildcardSize		Not used
lpszMapDirectory		Not used
wCardNum		Not used
wCleanupAction		Not used
wScope		Not used
uUnitSize		Not used
bBurst		Not used
lpfnMS		Not used.
lpMS		Not used
dwRecords		Not used

There is no interaction with the **nReturn** or **szErrMsg** fields. However, this might change in a future release.

GET

You can use the **GET** function to retrieve data using one of the source adapters, such as a messaging system, a database, a file, and so forth, within the course of your map.

When the **GET** function is used in a map, the default **OnSuccess** action is adapter specific. The default **OnFailure** action is to rollback any changes made during map processing. The default **Scope** will be integral unless the map is defined to run in bursts (which is the case when one or more inputs have the **FetchAs** property set to **Burst**).

GET can also be used for adapters that support request and reply, such as Socket.

Syntax:

GET (single-text-expression , single-text-expression
[, single-text-expression])

Meaning:

GET (adapter_alias, adapter_commands
[, data_request_to_send_to_adapter])

Returns:

A single character text item

GET returns the data that is returned by the source adapter. The adapter identified by *adapter_alias* is called using the specified *adapter_commands* and passing *data_request_to_send_to_adapter* as data to the adapter. See the Resource Adapters documentation.

You cannot use the **GET** function to retrieve a file that was built by an earlier output card within the same map. Instead, map the output of the earlier card to the later card.

To identify whether the function was successful, you can generally use the **VALID** function with the **GET** function. However, for certain adapters such as E-mail and FTP, the success state is not known until after map completion and using the **VALID** function in such cases might consistently return "success".

Examples

- Reply (s) = **GET** ("SOCKET", "-HOST localhost -PORT 8015 -EOF -LSN 10 -T", **PACKAGE** (Request Object..:Input))

In this example, the **GET** function would connect to the socket-based server on localhost using port 8015. The Socket Adapter would submit the "Input" data to the server, and then wait up to 10 seconds for a reply to that message.

- Acct# = **GET** ("DB", "-dbtype ORACLE -connect shasta -user rjc -pw vm70" + "SELECT Acct# FROM CustMaster WHERE CustID = " + SenderID Field:Identification Segment:Msg + "")

In this example, the **GET** function could be used instead of a **DBLOOKUP** or **DBQUERY** function to retrieve data from a database from within in a map rule.

- LASTERRORMSG**
- PUT**
- VALID**

JEXIT

The JEXIT function provides a means to interface with a method in an external Java class. Using this function, you can manipulate simple primitive types, simple objects, and complex objects.

There are two required text parameters for a JEXIT function. The first text parameter is the class name or key, depending on which meaning you use. The second text parameter is the method name. There are two optional text parameters for the data.

The first use of the JEXIT function creates an object that is based on the specified class name. Then, it invokes the named Java method, with any specified parameters, on that object. After the Java object's method is invoked, then JEXIT automatically destroys the Java object. If multiple invocations on the same Java object are required, then the predefined "<init>" function can be used in the second parameter of Meaning 1. The returned key from the "<init>" function now references a specific Java object and can then be used multiple times as the first parameter in Meaning 2 function calls.

The second use of the JEXIT function invokes the named Java method, with any specified parameters, on a specific Java object. The method is invoked by using the specified key. This method allows Java objects to be manipulated throughout the map's execution cycle. These Java objects are stored in the IBM Transformation Extender object pool and are referenced during map execution by using the specified key. The specified key can be returned from either a JEXIT meaning 1 or meaning 2 invocation, particularly when a non-scalar, complex Java object must be returned.

JEXIT is not supported on CICS, Batch, or MVS.

Prerequisites

To use JEXIT, do the following configuration steps, depending on the IBM Transformation Extender product you are using.

For IBM Transformation Extender with Command Server or IBM Transformation Extender with Launcher, either add the Java classes to your system class path or add the JAR files to the config.yaml file.

Add the JAR files to the **jar** statements under the /runtime/External Jar Files path of the config.yaml file. For each JAR file, uncomment a **jar** statement and add the fully qualified path and JAR file name, including the file extension. If a **jar** statement is already set to a value, add the JAR file to the next **jar** statement in the sequence. As an example, if the **jar1** statement is set to a value, and the **jar2** statement is not set to a value, add your JAR file to the **jar2** statement.

For IBM Transformation Extender for IBM Integration Bus, on Windows operating systems, copy the JAR file to the classes folder in the path where your version of IBM Integration Bus is installed. As an example, copy the JAR file to %MQSI_WORKPATH%\shared-classes. On UNIX operating systems, copy the JAR file to the \$MQSI_WORKPATH/shared-classes.

If you are using Meaning 1, a public default constructor must be declared in the external Java class. If the default constructor is not available or needed, you can use the "<init>" method to instantiate the Java object, but only when there is a class constructor that is defined with one or two string-type parameters.

Syntax

```
JEXIT ("single-text-expression" , "single-text-expression" ,  
["single-text-expression"] , ["single-text-expression"])
```

Returns

A single text item.

Meaning 1

```
JEXIT (class_name, method_name,  
[input_to_the_function_or_key], [input_to_the_function_or_key])
```

Using this approach, you provide a Java class and method name, and two optional inputs to the function.

When JEXIT is used in a map rule, at run time this function instantiates a Java virtual machine (JVM). The JVM reads your .class or .jar file and creates an object that is based on the defined Java class. The method, along with any specified parameters, is then invoked on the object.

When the returned object is a complex object, a unique identifier (key) is created that can be used to reference the object in the object pool.

All JEXIT parameters are text strings. Class name and method name are the two required parameters. The two optional parameters are generally input data. At run time, the strings are converted to UTF-8 and passed to the Java method, and the output from Java method is a UTF-8 text string.

The following simple Java class objects are internally converted to strings and returned to the map:

```
java.lang.Void  
java.lang.Short  
java.lang.Number  
java.lang.Long  
java.lang.Integer  
java.lang.Float  
java.lang.Double  
java.lang.Byte  
java.lang.Boolean  
java.lang.String  
java.lang.Character
```

Meaning 2

```
JEXIT (key, method_name, [input_to_the_function_or_key],  
[input_to_the_function_or_key])
```

The second use of JEXIT is similar to Meaning 1. The difference is that it assumes that you already have a key that references an object in the object pool. In this scenario, you use JEXIT to invoke a method on an object by using the key as the first required parameter instead of the class name.

Whenever the JEXIT function returns a key, the associated Java object must be deleted before the map completes processing. The object can be deleted by using the predefined JEXIT "<destroy>" method. Failure to invoke the "<destroy>" method results in a JVM memory leak. To prevent the JVM heap from getting fragmented, exhausted, or both, make sure that all object references returned from the JEXIT function are deleted. To delete those object references, use the JEXIT function in the following way:

```
JEXIT("key", "<destroy>")
```

Troubleshooting

To retrieve error messages for JEXIT, you can use the VALID and FAIL functions in your map rule. For example:

```
=VALID(JEXIT("key", "method_name", "data"), FAIL(LASTERROREMSG( ) ) )
```

- [JEXIT Examples](#)

JEXIT Examples

The JEXIT examples are based on the following defined Java classes.

```
class :  
package com.ibm.websphere.dtx.test;  
public class TestJExit {  
    Person person = new Person();  
    public TestJExit() {}  
    public String toUpper(String test) {  
        return test.toUpperCase();  
    }  
    public String concat(String test1, String test2) {  
        return test1 + test2;  
    }  
    public Integer toNumber(String test1) {  
        return new Integer(test1);  
    }  
    public Double toDouble(String test1) {  
        return new Double(test1);  
    }  
    public void toNothing() {}  
    public int returnInt() {  
        return 9;  
    }  
    public byte returnByte() {  
        return 8;  
    }
```

```

        public Person getPerson() {
            return person;
        }

    class :
package com.ibm.websphere.dtx.test;
public class Person{
    private String ext = new String("DTX");
    private String name = new String("Websphere");
    public Person() {
    }
    public String getName() {
        return name;
    }
    public String getExt() {
        return ext;
    }
}

```

Simple primitive types and simple objects

- JEXIT ("com.ibm.websphere.dtx.test.TestJExit", "toUpperCase", "IBM")

Returns IBM
- JEXIT ("com.ibm.websphere.dtx.test.TestJExit", "Concat", "IBM Transformation", "Extender")

Returns IBM Transformation Extender
- JEXIT ("com.ibm.websphere.dtx.test.TestJExit", "toDouble", "12")

Returns 12.0
- JEXIT ("com.ibm.websphere.dtx.test.TestJExit", "toNumber", "12")

Returns 12
- JEXIT ("com.ibm.websphere.dtx.test.TestJExit", "returnint")

Returns 9
- JEXIT ("com.ibm.websphere.dtx.test.TestJExit", "returnbyte")

Returns 8

Complex objects

When the function is returning a complex object, the returning object is added to the object pool and the key is returned to the map rule.

- JEXIT ("com.ibm.websphere.dtx.test.TestJExit", "getPerson")

Returns a key (as a string)
- JEXIT ("key", "getName")

Returns Websphere
- JEXIT ("key", "<destroy>")

Deletes the Person object from the JVM memory. The "**<destroy>**" method must be invoked before the map completes processing.

PUT

The **PUT** function passes data to a target adapter.

Use **PUT** to route data within your map using one of the target adapters such as to a messaging system, a database, a file, and so forth.

When the **PUT** function is used in a map, the default **OnSuccess** action is adapter specific. The default **OnFailure** action is to rollback any changes made during map processing. The default **Scope** will be integral unless the map is defined to run in bursts (which is the case when one or more inputs have the **FetchAs** property set to **Burst**).

Syntax:

PUT (single-text-expression, single-text-expression, single-text-expression)

Meaning:

PUT (adapter_alias, adapter_commands, data_to_send_to_adapter)

Returns:

"None"

The adapter identified by *adapter_alias* is called using the specified *adapter_commands* and passing *data_to_send_to_adapter* as data to the adapter.

The **PUT** function is not processed if the third argument is zero-sized data or NONE.

To identify whether the function was successful, you can generally use the **VALID** function with the **PUT** function. However, for certain adapters such as E-mail and FTP, the success state is not known until after map completion and using the **VALID** function in such cases might consistently return "success".

Examples

This example illustrates a mapping situation in which a set of messages is being produced in the output (output card #1). However, the ultimate target for these messages is a message queue and the messages need to be placed on the queue one at a time.

To accomplish this, the first output card builds the set of messages and its **Target** is defined as **Sink**. So, this set of messages is constructed in memory, but is discarded after the map completes. A second output card, uses the following **PUT** function to put each output message (from output card# 1), individually, on the output queue.

Message(s) = **PUT** ("MQS", "-QM myqueuemgr -QN chips_queue -T", **PACKAGE** (PaymentMessage:CHIPS_Payment_Message))

- The first argument, MQS, identifies that the data is to be routed using the IBM WebSphere MQ (server) adapter.
- The second argument, "-QM myqueuemgr -QN chips_queue -T", provides the adapter commands needed by the adapter to put the message on the queue.
- The third argument, **PACKAGE**, passes the data that is to be sent as the body of the message.

Related functions

- **FAIL**
 - **GET**
 - **LASTERRORCODE**
 - **LASTERRORMSG**
 - **VALID**
-

RUN

The **RUN** function allows you to execute another compiled map from a component or map rule.

You can use **RUN** to dynamically name source or destination files, or both, or to dynamically pass data to a map. You can also use the **RUN** function to split the output data into separate files based on some value in the input.

Syntax:

RUN (single-text-expression [, single-text-expression])

Meaning:

RUN (map_to_run [, command_option_list])

Returns:

A single text item

The first argument, *map_to_run*, is an expression identifying the name of the compiled map (.mmc) to be run.

The *command_option_list* argument is an optional argument that you can use to specify execution commands applicable to the map to be run. *Command_option_list* is a text item containing a series of execution commands separated by a space. Any execution command can be used as part of the *command_option_list* argument. For example, you can send data to another map by using the echo command option (-IE).

See the Execution Commands documentation for a list of command options.

The result of the **RUN** function depends on the command options in *command_option_list*.

Echo command option

- If you use the Echo command option for an output card, the data from that card will be passed back as a text item to the object in the map from which it was run.
- If you use the Echo command option for more than one output card, the data from all echoed cards will be concatenated together and passed back as a text-item to the object in the map from which it was run.
- If you do not use the Echo command option, the return code indicating the status of the map that was run will be passed back to the object in the map from which it was run.

Examples

- **RUN** ("MyMap", "-IE1s502 " + Invoice:File + "-OF1 install_dir\\" + CustomerID:Invoice)

This example runs the **MyMap** map, sending 502-byte fixed-size **Invoice** data as the data source for input card **1**, overriding the filename of output card **1** based on **Customer** data and returns the map return code as the result.

- **RUN** ("GetDbOpt" , " ")

This example runs the **GetDbOpt** map (with no command options specified) and returns the map return code as the result.

- **RUN** ("DoOneSet" , "-A -GR" +
ECHOIN(1 , Set:InFile) +

" -OF1 OUT_SET." + **NUMBERTOTEXT** (INDEX (\$)) +
" -OE2")

This example runs the **DoOneSet** map. Command options include the following choices:

- "-A -GR"

The **DoOneSet** map will produce no **Audit Log** and restrictions will be ignored.

- **ECHOIN**(1 , Set:InFile)

The **ECHOIN** function creates the -IE command option for echoing the data represented by Set:InFile to input **1** of the RUN map.

- " -OF1 OUT_SET." + **NUMBERTOTEXT** (INDEX (\$))

The output file for card **1** of the **DoOneSet** map will be called "OUT_SET." plus a sequence number based on the index of the Set in **InFile**. For example, the first output set will be OUT_SET.1, and so forth.

- " -OE2"

Using the output echo command option, the data built for output card **2** of the **DoOneSet** map will be returned as the result of the **RUN** function.

An alternative to using the **ECHOIN** function shown above is using the long version. For example, replace **ECHOIN**(1 , Set:InFile) with:

" -IE1S" + **NUMBERTOTEXT** (**SIZE** (**Set:InFile**) + " " + **TEXT** (**Set:InFile**)

Using the Echo input command option (**-IE**) with the sizing method (**Sn**) or the **ECHOIN** function, one **Set** object of **InFile** is passed to input card **1** for the **DoOneSet** map.

Related functions

- [DDEQUERY](#)
-

RENAMEFILE

The **RENAMEFILE** function renames the source file to that of the destination file. If the operation succeeds, the returned value is 0; if it fails, then an operating system-specific error number is returned.

Syntax:

RENAMEFILE (*single-text-expression*, *single-text-expression*, *single-text-expression*, *single-text-expression*)

Meaning:

RENAMEFILE (source, destination, number_of_retries (max 100), pause_between_retries_in_ms (max 100000))

Returns:

A single number

Related reference

- [COPYFILE](#)
-

HARDLINKFILE

A hard link points or references to a specific space on the hard drive. Multiple files can be hard linked to the same space in the hard drive. If some data is changed on one of the hard linked files, all the other files reflect that change. The **HARDLINKFILE** function returns the hard link file's command status. On successful execution of this function: 0 is returned; on failure: an operating system-specific error code is returned.

Syntax:

HARDLINKFILE (*single-text-expression*, *single-text-expression*, *single-text-expression*, *single-text-expression*)

Meaning:

HARDLINKFILE [oldpath, newpath, number_of_retries (max 100), pause_between_retries_in_ms (max 100000)]

Returns:

A single number

Related reference

- [SOFTLINKFILE](#)
-

SOFTLINKFILE

A soft link points to a specific file, which in turn, references to a particular location on the hard drive. The soft link, also known as symbolic link is a second file that exists independently of its target. The **SOFTLINKFILE** function returns the soft (symbolic) link file's command status. On successful execution of this function: 0 is returned; on failure: an operating system-specific error code is returned.

Syntax:

SOFTLINKFILE (*single-text-expression*, *single-text-expression*, *single-text-expression*, *single-text-expression*)

Meaning:

SOFTLINKFILE [(oldpath, newpath, number_of_retries (max 100), pause_between_retries_in_ms (max 100000))]

Returns:

A single number

Related reference

- [HARDLINKFILE](#)
-

COPYFILE

The **COPYFILE** function copies the source file to the destination file. It returns the copy file command status. On successful execution of this function: 0 is returned; on failure: an operating system-specific error code is returned.

Syntax:

COPYFILE (*single-text-expression*, *single-text-expression*, *single-text-expression*, *single-text-expression*)

Meaning:

COPYFILE [source, destination, number_of_retries (max 100), pause_between_retries_in_ms (max 100000)]
Returns:
A single number

Related reference

- [RENAMEFILE](#)
-

SLEEP

The **SLEEP** function suspends the execution of the current map until the time-out interval elapses. The time-out or sleep interval is represented in milliseconds. On successful execution of this function: 0 is returned; on failure: -1 is returned.

Syntax:

SLEEP(*single-number-expression*)

Meaning:

SLEEP (the sleep time is in milliseconds)

Returns:

A single number

Flow functions

Use Flow functions to specify a value for each of the flow variables defined for a flow, and additionally, to alter an already specified value for a flow variable.

Flow variables act as an alternative means to pass information throughout a flow instance without requiring the use of data links.

Flow variables are name value pairs that persist until the flow instance completes execution. Flow variables are case-sensitive. Flow variables are also instance-specific. Instance-specific means that no two flow-instances that are running simultaneously can share the same set of variables.

Flow functions return the output in UTF-8 character encoding format. The flow variable name and value are converted to UTF-8 character encoding before a flow function is executed.

- [DECVARIABLE](#)
 - [DELETEVARIABLE](#)
 - [GETVARIABLE](#)
 - [INCVARIABLE](#)
 - [RESOLVEVARIABLE](#)
 - [SETVARIABLE](#)
-

DECVARIABLE

The **DECVARIABLE** function decrements the numeric value a flow variable.

This function defines a new flow variable if one does not exist already and sets the specified decrement value as the initial value for the new flow variable. If the decrement value is not specified, it defaults to 1, and returns the set value in text format.

If the flow variable exists already and holds a numeric value, this function decrements by the specified increment value. If the decrement value is not specified, it decrements the numeric value associated to a flow variable by 1 and returns the set value in text format to the map. The value associated to a flow variable is non-numeric, then this function skips performing decrement operation on the value of the flow variable, leaves the non-numeric value intact.

Syntax:

DECVARIABLE (*single-text-expression* [, *single-text-expression*])

Meaning:

DECVARIABLE (*variable_name* [, *decrement_by*])

Returns:

A single text item.

Examples

- **flowlib DECVARIABLE ("interest.rate")**
Decrements the value of flow variable, interest.rate, by 1 and returns the decremented value in text format. If the flow variable, interest.rate, does not exist already, creates one by that name, assigns 1 and returns "1".
- **flowlib DECVARIABLE "interest.rate", 10**
Decrements the value of flow variable, interest.rate, by 10 and returns the decremented value in text format. If the flow variable, interest.rate, does not exist already, creates one by that name, assigns 10 and returns "10".
- **flowlib DECVARIABLE ("city")**
Returns empty value, if the flow variable, city, holds a non-numeric text value as 'New York'. Decrement operation is not performed and retains the value of the flow variable intact as 'New York'. If the flow variable, city, does not exist already, then a new flow variable, city, is created and set with value 1, returns "1" to the map.

DELETEVARIABLE

The **DELETEVARIABLE**

This function deletes a flow variable defined for a flow. Special (reserved or internal) flow variables cannot be deleted with this function. All flow variables, custom and special, are deleted by default when flow instance finishes its execution. Use this function when a flow variable must be removed from the visible scope of nodes in a flow execution. A flow variable has to be deleted as setting empty value does not affect the value or existence of the flow variable.

Syntax:

DELETEVARIABLE (single-text-expression)

Meaning:

DELETEVARIABLE (variable_name)

Returns:

NONE

Examples

- `flowlib DELETEVARIABLE ("interest.rate")`
Deletes flow variable, interest.rate, and returns empty (NONE)

GETVARIABLE

The **GETVARIABLE** function retrieves the value associated to a flow variable.

This function returns an empty value if the flow variable has not been defined, or if it has been deleted prior to making this function invocation. Otherwise, it returns the associated value of the flow variable to the map in text format. The value associated to a special (reserved or internal) flow variable can be retrieved with this function for further transformation purposes.

Syntax:

GETVARIABLE GETVARIABLE (single-text-expression)

Meaning:

GETVARIABLE GETVARIABLE (variable_name)

Returns:

A single text item

Examples

- `flowlib GETVARIABLE "interest.rate", "10"`
Returns the current value of custom flow variable, interest.rate, to the map.
- `flowlib GETVARIABLE(" _FLOWINSTANCE_ ")`
Special flow variables start and end with underscore. Returns the value of the special (reserved or internal) flow variable, _FLOWINSTANCE_ to the map.

INCVARIABLE

The **INCVARIABLE** function increments the numeric value for a flow variable.

This function defines a new flow variable if it does not exist already and sets the specified increment value as the initial value for the new flow variable. If the increment value is not specified, it defaults to 1, and returns the set value in text format.

If the flow variable exists already and holds a numeric value, this function increments by the specified increment value. If the increment value is not specified, it increments the numeric value associated to a flow variable by 1, and returns the set value in text format to the map. The value associated to a flow variable is non-numeric, then this function skips performing increment operation on the value of the flow variable, leaves the non-numeric value intact.

Syntax:

INCVARIABLE (single-text-expression [, single-text-expression])

Meaning:

INCVARIABLE (variable_name [, increment_by])

Returns:

A single text item

Examples

- `flowlib >INCVARIABLE ("interest.rate")`
Increments the value of flow variable, interest.rate, by 1 and returns the incremented value in text format. If the flow variable, interest.rate, does not exist already, creates one by that name, assigns 1 and returns "1".
- `flowlib >INCVARIABLE ("interest.rate", 10)`
Increments the value of flow variable, interest.rate, by 10 and returns the incremented value in text format. If the flow variable, interest.rate, does not exist already, creates one by that name, assigns 10 and returns "10".
- `flowlib >INCVARIABLE ("city")`

Returns empty value, if the flow variable, city, holds a non-numeric text value as 'New York'. Increment operation is not performed and retains the value of the flow variable intact as 'New York'. If the flow variable, city, does not exist already, then a new flow variable, city, is created and set with value 1, returns "1" to the map.

RESOLVEVARIABLE

The **RESOLVEVARIABLE** function resolves all flow variables in a given text.

A flow variable to resolve in the text is specified in the format %variable_name%. The value associated with a flow variable is a text expression that is substituted for the variable name in a given text, if defined for the flow.

A text input can have more than one flow variable to resolve, and each flow variable can occur any number of times within the text. Any variable name that cannot be resolved is returned unchanged in the text. Special flow variables (reserved or internal) are also resolved for further transformation purposes.

Syntax:

RESOLVEVARIABLE (single-text-expression)

Meaning:

RESOLVEVARIABLE (text_to_resolve)

Returns:

A single text expression.

Examples

- `flowlib->RESOLVEVARIABLE ("greeting% World!")`

If the greeting flow variable has been previously defined as 'Hello', then the text is resolved and it is returned as 'Hello World!'. If the greeting flow variable is not defined, then the function returns '%greeting% World!'.

- `flowlib->RESOLVEVARIABLE ("Flow instance number is %_FLOWINSTANCE_% and UUID is %_FLOWUUID_%)`

Each flow instance being run is associated with an instance number and UUID. Special variables `_FLOWINSTANCE_` and `_FLOWUUID_` are resolved to their values and resolved text is returned.

For example, if `_FLOWINSTANCE_` is 12345 and `_FLOWUUID_` is abcxyz1234ABCxyz, the resolved text is as follows:

'Flow instance number is 12345 and UUID is abcxyz1234ABCxyz.'

- `flowlib->RESOLVEVARIABLE ("A total of %recordcount% X12 transactions for ANSI version %version% have been processed")`

If recordcount and version flow variables have been defined as 100 and 4050 respectively, then the resolved text returned is as follows:

'A total of 100 X 12 transactions for ANSI version 4050 have been processed'.

SETVARIABLE

The **SETVARIABLE** function sets a new, or updates an existing flow variable. This function specifies the name of a flow variable if one does not already exist. Otherwise, it updates the value of an existing flow variable with the new value.

The value associated to a flow variable is a text expression and returns the new value to the map. Empty value skips creating or updating of a flow variable. Flow variables that are considered special (reserved or internal) cannot be set with this function.

Syntax:

SETVARIABLE (single-text-expression, single-text-expression)

Meaning:

SETVARIABLE (variable_name, variable_value)

Returns:

A single text item

Examples

- `flowlib SETVARIABLE "interest.rate", "10")`

Sets flow variable, interest.rate, with a value 10. Creates a new flow variable if interest.rate does not exist already, otherwise updates and returns the new value 10

- `flowlib SETVARIABLE ("message.id", "IDXYZ123")`

Sets or updates flow variable, message.id, with IDXYZ123 and returns IDXYZ123

Inspection functions

- **ABSENT**
- **CONTAINSERRORS**
- **DELETEFILE**

The **DELETEFILE** function returns the status of a file deletion command as a single number. **DELETEFILE** returns 0 for successful file deletion or the appropriate error code if file deletion was not successful.

 - [OR](#)
 - [PARTITION](#)
 - [PRESENT](#)
 - [SIZE](#)
 - [TESTOFF](#)
 - [TESTON](#)
 - [VALID](#)
-

ABSENT

The **ABSENT** function tests for the absence of an object.

Syntax:

ABSENT (single-object-expression)

Meaning:

ABSENT (object_to_test)

Returns:

True or false

ABSENT returns "true" if the object_to_test evaluates to "none". If the object_to_test does not evaluate to "none", the function returns "false".

Examples

- You can use this function to map an object only if another object is absent. For example, you might want to map **BillTo** information to the **ShipTo** fields if the **ShipToName** is absent.
- **ABSENT** (AreaCode:Phone)
This example evaluates to "true" when **AreaCode:Phone** evaluates to "none" or evaluates to "false" when **AreaCode:Phone** does not evaluate to "none".

Related Functions

- [PRESENT](#)
-

CONTAINSERRORS

The **CONTAINSERRORS** function tests a valid object to see whether it contains any objects in error.

Syntax:

CONTAINSERRORS (single-object-expression)

Meaning:

CONTAINSERRORS (object_to_test)

Returns:

True or false

The **CONTAINSERRORS** function returns "true" if any object contained in *object_to_test* is in error; it returns "false" if the *object_to_test* is completely valid.

The input object, itself, is a *valid* input object. This function does *not* evaluate for invalid objects. Therefore, if you have map rule:

CONTAINSERRORS (Invoice:InputFile)

and **Invoice[1]** is valid, **Invoice[2]** is invalid, and **Invoice[3]** is valid, then **CONTAINSERRORS** evaluates only twice-once for each *valid* instance of **Invoice**.

Examples

- `Msg (s) = IF (CONTAINSERRORS (Msg:MailBag) &`
`Type:Msg:MailBag = "PRIORITY" ,`
`Msg:MailBag ,`
`"none")`

In this example, if **Msg:MailBag** contains any object in error and **Type:Msg:MailBag** has a value of "PRIORITY", **Msg:MailBag** is mapped; otherwise, "none" is returned for this occurrence of **Msg**. This map rule returns all valid messages (**Msg**) that contain errors with a **Type** of "PRIORITY".

Related functions

- [ISERROR](#)
 - [REFORMAT](#)
-

DELETEFILE

The **DELETEFILE** function returns the status of a file deletion command as a single number. **DELETEFILE** returns 0 for successful file deletion or the appropriate error code if file deletion was not successful.

Syntax:

resourcelib->**DELETEFILE** (single-text-expression, single-text-expression, single-text-expression)

Meaning:

DELETEFILE (*filename, number_of_retries, pause_between_retries*)

Returns:

A single number

number_of_retries

The number of times the **DELETEFILE** function is to check for the deleted file. The maximum is 100 retries.

pause_between_retries

The amount of time, in milliseconds, that the function waits between checking for the deleted file. The maximum is 100,000.

Example

```
(resourcelib->DELETEFILE (GETDIRECTORY () + "myfile1.txt", "10", "1000"))
```

ISALPHA

You can use **ISALPHA** when you need to know whether a text string is all alphabetic characters.

Syntax:

ISALPHA (single-text-expression)

Meaning:

ISALPHA (*text_to_test*)

Returns:

This function evaluates to a Boolean "true" or "false" and should only be used as a conditional expression within a logical function.

The **ISALPHA** function tests a text object to see if it contains all alphabetic characters.

If *text_to_test* contains only alphabetic characters (for example, A-Z and a-z), **ISALPHA** evaluates to "true".

If *text_to_test* contains other than just alphabetic characters, **ISALPHA** returns "false".

Examples

- **IF(ISALPHA ("AnywhereUSA"))**
Returns "true"
- **IF(ISALPHA ("Anywhere USA"))**
Returns "false"
- **IF(ISALPHA ("Mr. Brown"))**
Returns "false"

Related functions

• ISLOWER	• LEAVEALPHANUM
• ISNUMBER	• LEAVENUM
• ISUPPER	• LEAVEPRINT
• LEAVEALPHA	

ISERROR

The **ISERROR** function tests an object to see if it is in error

You can use **ISERROR** to output your data in exactly the same order as it occurs in your input, both the valid data and the data in error. You can also use **ISERROR** to produce error messages for bad data in the same file in which you map your good data.

Syntax:

ISERROR (single-object-name)

Meaning:

ISERROR (*object_to_test*)

Returns:

"True" or "false"

ISERROR returns "true" when *object_to_test* is in error and returns "false" when *object_to_test* is completely valid.

Examples

- InfoRec (s) = IF (**ISERROR** (Record:SomeFile), "Bad --> " + **REJECT** (Record:SomeFile), "Ok --> " + TEXT (Record:SomeFile))

In this example, **ISERROR** is used to produce a report for *all* Record objects in **SomeFile**. If the record is in error, the **InfoRec** will have the text Bad --> followed by the data from the input **Record**. If the record is valid, the **InfoRec** will have the text Ok --> followed by the data from the input **Record**, such as:

```
Ok --> SZ-68839,486 Upgrade Microprocessor,186.86,100,W200
Bad --> MK-19309,,369.43,417,W100

Related functions

- CONTAINERRORS**

ISLOWER

The **ISLOWER** function tests a text object to see if it contains all lowercase alphabetic characters.

Syntax:

ISLOWER (series-text-expression)

Meaning:

ISLOWER (text_to_test)

Returns:

This function evaluates to a Boolean "true" or "false" and should only be used as a conditional expression within a logical function.

If *text_to_test* contains only lowercase alphabetic characters (for example, a-z), **ISLOWER** evaluates to "true".

If *text_to_test* contains other than lowercase alphabetic characters, **ISLOWER** returns "false".

Examples

- IF(**ISLOWER** ("company"))

Returns "true"
- IF(**ISLOWER** ("pots and pans"))

Returns "false"
- IF(**ISLOWER** ("Andrew"))

Returns "false"

Related functions

<ul style="list-style-type: none"> • LEAVEALPHA 	

ISNUMBER

The **ISNUMBER** function tests a text object to determine whether it contains all numeric characters.

Syntax:

ISNUMBER (single-text-expression)

Meaning:

ISNUMBER (text_to_test)

Returns:

This function evaluates to a Boolean "true" or "false" and should only be used as a conditional expression within a logical function.

If *text_to_test* contains only digits (for example, 0-9), **ISNUMBER** evaluates to "true".

If *text_to_test* contains other than digits, **ISNUMBER** evaluates to "false".

Examples

- IF(**ISNUMBER** ("1"))

Returns "true"

Related functions

<ul style="list-style-type: none"> • ISALPHA 	<ul style="list-style-type: none"> • LEAVEALPHANUM
--	--

• ISLOWER	• LEAVENUM
• ISUPPER	• LEAVEPRINT
• LEAVEALPHA	

ISUPPER

The **ISUPPER** function tests a text object to determine whether it contains all uppercase alphabetic characters.

Syntax:

ISUPPER (series-text-expression)

Meaning:

ISUPPER (text_to_test)

Returns:

This function evaluates to a Boolean "true" or "false" and should only be used as a conditional expression within a logical function.

If *text_to_test* contains only uppercase alphabetic characters (for example, A-Z), ISUPPER evaluates to "true".

If *text_to_test* contains other than uppercase alphabetic characters, ISUPPER returns "false".

Examples

- **IF(ISUPPER ("BOMBAY"))**
Returns "true"
- **IF(ISUPPER ("CD-ROM"))**
Returns "false"
- **IF(ISUPPER ("Map Designer"))**
Returns "false"

Related functions

• ISALPHA	• LEAVEALPHANUM
• ISLOWER	• LEAVENUM
• ISNUMBER	• LEAVEPRINT
• LEAVEALPHA	

MEMBER

Use **MEMBER** when you need to know whether an object occurs within a series.

The **MEMBER** function searches a series, looking for a single specified object in the series. If any object in the series matches the specified object, **MEMBER** returns "true". If there is no match, **MEMBER** returns "false".

Syntax:

MEMBER (single-object-expression , series-object-expression)
MEMBER (single-object-expression , { literal, literal ... })

Meaning:

MEMBER (object_to_look_for , series_of_objects_to_look_at)

Returns:

"True" or "false"

MEMBER returns "true" if *object_to_look_for* matches one of the values in *series_of_objects_to_look_at*.

It returns "false" if *object_to_look_for* does not match at least one of the values in *series_of_objects_to_look_at*.

The two arguments, *object_to_look_for* and *series_of_objects_to_look_at*, must be objects of the same item interpretation or the same group type. For example, if *object_to_look_for* is a date/time item, *series_of_objects_to_look_at* must be a series of date/time items.

Examples

- **MEMBER** (EntityIDCode:Name, {"BT", "ST"})
This example tests whether **EntityIDCode** has one of a particular set of literal values.
- **MEMBER** (Store# , EntityIDCode:Name)
This example tests whether **Store#** has the same value as any **EntityIDCode:Name**.

Related functions

- **EXTRACT**
 - **LOOKUP**
-

NOT

Use the **NOT** function to test a condition and have it return the inverse of its "true" or "false" result. For example, you want the function to return "true" if the condition results in "false".

Syntax:

NOT (single-condition-expression)

Meaning:

NOT (condition_to_evaluate)

Returns:

"True" or "false"

NOT returns "true" if the condition evaluates to "false" and returns "false" if the condition evaluates to "true".

Examples

- **NOT** (Qty::InputFile = 0)

This example returns "false" if the **Qty** equals 0 (the condition is true) and returns "true" if **Qty** does not equal 0 (the condition is false).

- **IF (NOT (PRESENT (StartDate)), "Unknown", "none")**

This example returns "unknown" if **StartDate** is not present and returns "none" if **StartDate** is present.

Another way to test that an object is not present is to use the **ABSENT** function.

OFFSET

Use the **OFFSET** function when you need to know the position of a particular data object within its card object.

OFFSET returns an integer representing the offset of the specified object within the data.

Syntax:

OFFSET (single-object-expression)

Meaning:

OFFSET (object_whose_offset_is_needed)

Returns:

A single integer

OFFSET returns the offset, in bytes, of the specified object within its card object, beginning at offset 0. For an object that has an initiator, the offset will apply to the first byte of the data. For an object that is right-justified with pad characters, **OFFSET** will return the offset of the first byte of data.

The **OFFSET** function works the same for output objects as it does for input objects.

Examples

- **OFFSET** (Application:LoanData)

In this example, if the first character of the first occurrence of the object **Application** occurs 210 bytes from offset 0 within **LoanData**, the **OFFSET** function returns 210.

Related function

- **SIZE**
-

OR

Use the **OR** function to test whether one of a series of conditions is true.

OR evaluates a series of conditions and returns "true" if at least one evaluates to "true"; otherwise returns "false".

Syntax:

OR (series-condition-expression)

Meaning:

OR (conditions_to_evaluate)

Returns:

"True" or "false"

OR evaluates to "true" if *any* member of the argument evaluates to "true" and evaluates to "false" if *all* members of the argument evaluate to "false".

Examples

- Order(s)=IF (OR (Store:Table = Store#:Order:Input), Order:Input)
This example produces an **Order** if the **Store#** of an **Order** in Input matches any **Store** in **Table**.

Related function

- **ALL**

PARTITION

The **PARTITION** function checks to see if an occurrence of an object belongs to a certain partition. If the object is that partition, "true" is returned. Otherwise, "false" is returned.

Syntax:

PARTITION (single-object-expression, single-simple-object-name)

Meaning:

PARTITION (partitioned_object, simple_name_of_partition_to_check_for)

Returns:

"True" or "false"

PARTITION returns "true" if the data object of *partitioned_object* belongs to the partition represented by *simple_name_of_partition_to_check_for*. Otherwise, **PARTITION** returns "false".

Examples

- Assume that **Transaction** has been partitioned into three partitioned subtypes: **Invoice**, **Order**, and **Remittance**, as shown.
The following rule could be used to detect whether a given **Transaction** is an **Invoice**:

PARTITION (Transaction::Batch, Invoice)

If the **Transaction** is an **Invoice**, **PARTITION** returns "true". If the **Transaction** is not an **Invoice** (for example, it is an **Order** or a **Remittance**), **PARTITION** returns "false" for that **Transaction**.

Related function

- **GETPARTITIONNAME**

PRESENT

The **PRESENT** function tests for the presence of an object.

PRESENT is commonly used with the **IF** function in a map rule to provide conditional logic. For example, if the object is present, do this; otherwise, do something else.

Similarly, **PRESENT** is commonly used with the **WHEN** function in component rules to provide conditional validation logic.

Syntax:

PRESENT (single-object-expression)

Meaning:

PRESENT (object_to_look_for)

Returns:

"True" or "false"

PRESENT returns "true" if the input argument does *not* evaluate to "none"; the object is present. It returns "false" if the input argument evaluates to "none"; the object is not present.

Examples

- **PRESENT** (Trailer:File)
This example returns "true" if **Trailer** is present and returns "false" if **Trailer** is absent.
- **IF (PRESENT(MiddleInitial::Input), MiddleInitial::Input, "***")**
This example in a map rule maps **MiddleInitial** if it is present. If **MiddleInitial** is not present, three asterisks are mapped.
- **WHEN (PRESENT (AreaCode Field), PRESENT (PhoneNo Field))**
In this example, **PRESENT** is being used in conjunction with the **WHEN** function in a component rule to determine whether a particular object is valid.

Related functions

- **ABSENT**
- **IF**
- **WHEN**

SIZE

The **SIZE** function returns an integer representing the size of a specified object, exclusive of any pad characters.

Syntax:

SIZE (single-object-expression)

Meaning:

SIZE (object_whose_size_is_needed)

Returns:

A single integer

The **SIZE** function returns the size, in bytes, of *object_whose_size_is_needed*. The byte size returned does not include any pad characters that might be in the object, but does include separators and signs.

The size of a group is the size, beginning with the first character of the first component and ending with the last character of the last component, of the group. If the group has delimiters, the infix delimiters are included in the size.

Examples

- **SIZE** (Transaction)
Returns 8000 if the size of **Transaction** (without pad characters) is 8000 bytes

Using SIZE with NORMXML

If the **SIZE** function is used with the **NORMXML** function to determine the size of the specified object after **NORMXML** has removed the XML formatting from the input XML fragment, the **SIZE** operation calculates the size of the data in Unicode, since the **NORMXML** function converts the input data to Unicode before it removes the XML formatting. The returned size does not match the size that would have been calculated if the data remained in its original character set, unless the original character set was Unicode.

TESTOFF

The **TESTOFF** function tests a specified bit in a binary number item to see whether it is off.

Syntax:

TESTOFF (single-binary-number-expression, single-integer-expression)

Meaning:

TESTOFF (binary_number_to_test, bit_to_test)

Returns:

"True" or "false"

The value of *bit_to_test* specifies which bit of *binary_number_to_test* should be tested for the value 0. If *bit_to_test* has the value 1, it refers to the leftmost bit of *binary_number_to_test*.

The **TESTOFF** function returns "true" if the specified bit is off and returns "false" if the specified bit is on.

If *bit_to_test* is less than one or greater than the number of bits of *binary_number_to_test*, **TESTOFF** returns "false".

Examples

- **TESTOFF** (A, 16)
Assume **A** is the two-byte binary value of "1", which is all zeros except for bit **16**. The binary representation of the value in **A** is 0001.
This example returns "false".
- **TESTOFF** (A, 20)
Returns "false" because bit **20** does not exist.

TESTON

The **TESTON** function tests a specified bit in a binary number to see if it is on.

Syntax:

TESTON (single-binary-number-expression, single-integer-expression)

Meaning:

TESTON (binary_number_to_test, bit_to_test)

Returns:

"True" or "false"

The value of *bit_to_test* specifies the bit of *binary_number_to_test* to test for the value 1. If *bit_to_test* has the value 1, it refers to the leftmost bit of *binary_number_to_test*.

The function returns "true" if the specified bit is on; it has the value 1. It returns "false" if the specified bit is off; it has the value 0.

If *bit_to_test* is less than one or greater than the number of bits of *binary_number_to_test*, **TESTON** returns "false".

Examples

- **TESTON (A , 16)**
Assume **A** is the two-byte binary value of "1", which is all zeros except for bit **16**. The binary representation of the value in **A** is 0001.
This example returns "true".
 - **TESTON (A , 20)**
Returns "false" because bit **20** does not exist in a two-byte value.
-

VALID

You can use the **VALID** function to perform conditional processing based on whether an external interface function executes successfully.

VALID returns the result of the first argument if it is valid; otherwise, returns the second argument.

Syntax:

VALID (single-text-expressions , single-general-expression)

Meaning:

VALID (function_that_can_fail , return_value_if_function_fails)

Returns:

A single text expression

VALID returns the result of the evaluation of *function_that_can_fail* if it is valid. If the function fails, **VALID** returns *return_value_if_function_fails*.

The following functions can fail:

• DBLOOKUP	• GET
• DBQUERY	• PUT
• DDEQUERY	• RUN
• EXIT	

Examples

- **SomeObject = VALID (RUN (**
"mymap.mmc" , "-OF1 mydata.txt") ,
FAIL ("My RUN failed!")

If the **RUN** function returns an error return code, the **VALID** function returns **none**, the map aborts, and the message **My RUN failed!** is reported under Execution Summary in the execution audit log.

-

ALL

The **ALL** function evaluates a series of conditions and returns "true" if they all evaluate to "true"; otherwise returns "false".

Syntax:

ALL (series-condition-expression)

Meaning:

ALL (conditions_to_evaluate)
Returns:
True or false
The **ALL** function evaluates to "true" if *all* members of the input argument evaluate to "true"; it evaluates to "false" if *any* member of the input argument is "false".

Examples

- You can use **ALL** when you want to test whether all conditions of a series are true.
- PO(s)=IF (ALL(PO#:Line:Order = PO#:Line:Order[1]), Order, "none")
If each and every **PO#** matches the **PO#** of the first **Order**, **ALL** evaluates to "true". Otherwise, **ALL** evaluates to "false".

Related functions

- **NOT**
 - **OR**
-

BINDABS

Use this function in a component rule for the implementation of binding and iterative evaluation. The implementation of binding ensures that when there are multiple references to a component in a rule, all references are to the same instance of that component. The implementation of iterative evaluation ensures that the rule is evaluated using all possible combinations of type references.

Do not use this function unless you have a clear understanding of the behavior.

Syntax:
BINDABS (Boolean_expression)

Meaning:
BINDABS (component rule)
Returns:
A Boolean "true" or "false"

Note: It is not necessary to use the **BINDABS** function for iterative behavior with the following functions because these functions already iterate: COUNT, COUNTABS, INDEX, MEMBER, MAX, MIN, SUM, and SERIESTOTEXT.

How it works

When the evaluation starts and the **BINDABS** function is encountered at the beginning of the component rule, binding is enforced and the rule is iterated across all valid combinations of objects specified in the rule.

BINDABS must be positioned first in the component rule and the entire component rule must be enclosed. Any other use of this function will have no effect.

When using **BINDABS**, the evaluation order is the same as mapping. Rules that contain both a normal instance and a last instance for the first instance of the type are not evaluated.

Example

```
BINDABS (Qty:LineItem:Order
* Price:LineItem:Order = ExtendedPrice:LineItem:Order)
```

As a result of binding, the Qty, Price, and ExtendedPrice elements in this example are all in the same LineItem of the same Order. As a result of iteration, all line items of all orders are checked.

EITHER

The **EITHER** function returns the result of the first argument that does not evaluate to "none".

Syntax:
EITHER (single-general-expression { , single-general-expression })
Meaning:
EITHER (try_this { , if_none_try_this })
Returns:
A single object

The **EITHER** return methods work in the following ways:

Returns...
When...
try_this
try_this does not evaluate to "none"
if_none_try_this
try_this evaluates to "none"
the next *if_none_try_this*
the first *if_none_try_this* evaluates to "none"

Note: The Design Studio compiler does not validate the second argument or subsequent arguments against the type tree.

Examples

- **EITHER** (OrderDate Field , **CURRENTDATE** ())
If **OrderDate Field** does not evaluate to "none", it is returned. If **OrderDate Field** evaluates to "none", the current system date (using **CURRENTDATE**) is returned.
- **EITHER** (LOOKUP (PriorityCd:Msg , CustID:Msg = "93X") , 8)
This example returns the result of the LOOKUP if that result does not evaluate to "none"; otherwise, it returns the second argument of 8.
- **EITHER** (IF (SomeCode = "C" , CustomerID:Input) ,
IF (SomeCode = "S" , SupplierID:Input) ,
IF (SomeCode = "O" , Reference#:Input) ,
"#####")
If **SomeCode** is **C** and **CustomerID:Input** has a value, **EITHER** returns the value of **CustomerID**. Otherwise, if **SomeCode** is **S** and **CustomerID:Input** has a value, **EITHER** returns the value of **SupplierID**. Otherwise, if **SomeCode** is **O** and **Reference#:Input** has a value, **EITHER** returns the value of **Reference#**. If none of those conditions result in a value, **EITHER** returns "#####".
- You can use **EITHER** when you want a default value when an expression evaluates to "none" and the expression might cause common arguments to produce an unintended result. For example, use:
EITHER (LOOKUP (PriorityCd:Msg , CustID:Msg = "93X") , 8)
-instead of-
IF (PRESENT (LOOKUP (PriorityCd:Msg , CustID:Msg = "93X")) ,
LOOKUP (PriorityCd:Msg , CustID:Msg = "93X") , 8)

IF

You can use the **IF** function for conditional logic. For example, to return one of two objects depending on the evaluation of a condition.

IF evaluates a conditional expression, returning one value if true, another if false.

Syntax:

IF (single-condition-expression , single-general-expression
[, single-general-expression])

Meaning:

IF (test_this , result_if_true [, result_if_false])

Returns:

A single item or single group

If *test_this* evaluates to "true", the result is *result_if_true*.

Otherwise, if *test_this* evaluates to "false", the result is *result_if_false*. If no *result_if_false* is specified, this evaluates to "none".

The *result_if_true* and *result_if_false* arguments must correspond to the same item interpretation or the same group type or either can be "none". For example, if *result_if_true* evaluates to a number, *result_if_false* must also evaluate to a number. If *result_if_true* evaluates to a **LineItem** group, *result_if_false* must also evaluate to a **LineItem** group.

Examples

- **IF** (Quantity:LineItem:PO > 500 , "PRIORITY" , "REGULAR")
This example tests the **Quantity** value. If that **Quantity** is > 500, the **IF** function evaluates to the value PRIORITY. If that **Quantity** is <= 500, the **IF** function evaluates to the value, REGULAR.
- **IF** (Status:Order = "Special" , "SPCL")
This example tests the **Status** value. If the **Status** is Special, the **IF** function evaluates to the value, SPCL. Otherwise, it evaluates to "none". Notice that this rule is equivalent to
IF (Status:Order = "Special" , "SPCL" , "none")

ISALPHA

You can use **ISALPHA** when you need to know whether a text string is all alphabetic characters.

Syntax:

ISALPHA (single-text-expression)

Meaning:

ISALPHA (text_to_test)

Returns:

This function evaluates to a Boolean "true" or "false" and should only be used as a conditional expression within a logical function.

The **ISALPHA** function tests a text object to see if it contains all alphabetic characters.

If *text_to_test* contains only alphabetic characters (for example, A-Z and a-z), **ISALPHA** evaluates to "true".

If *text_to_test* contains other than just alphabetic characters, **ISALPHA** returns "false".

Examples

- **IF(ISALPHA ("AnywhereUSA"))**
Returns "true"
- **IF(ISALPHA ("Anywhere USA"))**
Returns "false"
- **IF(ISALPHA ("Mr. Brown"))**
Returns "false"

Related functions

• ISLOWER	• LEAVEALPHANUM
• ISNUMBER	• LEAVENUM
• ISUPPER	• LEAVEPRINT
• LEAVEALPHA	

ISLOWER

The **ISLOWER** function tests a text object to see if it contains all lowercase alphabetic characters.

Syntax:

ISLOWER (series-text-expression)

Meaning:

ISLOWER (text_to_test)

Returns:

This function evaluates to a Boolean "true" or "false" and should only be used as a conditional expression within a logical function.

If *text_to_test* contains only lowercase alphabetic characters (for example, a-z), **ISLOWER** evaluates to "true".

If *text_to_test* contains other than lowercase alphabetic characters, **ISLOWER** returns "false".

Examples

- **IF(ISLOWER ("company"))**
Returns "true"
- **IF(ISLOWER ("pots and pans"))**
Returns "false"
- **IF(ISLOWER ("Andrew"))**
Returns "false"

Related functions

• ISALPHA	• LEAVEALPHANUM
• ISNUMBER	• LEAVENUM
• ISUPPER	• LEAVEPRINT
• LEAVEALPHA	

ISNUMBER

The ISNUMBER function tests a text object to determine whether it contains all numeric characters.

Syntax:

ISNUMBER (single-text-expression)

Meaning:

ISNUMBER (text_to_test)

Returns:

This function evaluates to a Boolean "true" or "false" and should only be used as a conditional expression within a logical function.

If *text_to_test* contains only digits (for example, 0-9), **ISNUMBER** evaluates to "true".

If *text_to_test* contains other than digits, **ISNUMBER** evaluates to "false".

Examples

- **IF(ISNUMBER("1"))**
Returns "true"

Related functions

• ISALPHA	• LEAVEALPHANUM
• ISLOWER	• LEAVENUM
• ISUPPER	• LEAVEPRINT
• LEAVEALPHA	

ISUPPER

The **ISUPPER** function tests a text object to determine whether it contains all uppercase alphabetic characters.

Syntax:

ISUPPER (series-text-expression)

Meaning:

ISUPPER (text_to_test)

Returns:

This function evaluates to a Boolean "true" or "false" and should only be used as a conditional expression within a logical function.

If *text_to_test* contains only uppercase alphabetic characters (for example, A-Z), ISUPPER evaluates to "true".

If *text_to_test* contains other than uppercase alphabetic characters, ISUPPER returns "false".

Examples

- **IF(ISUPPER ("BOMBAY"))**
Returns "true"
- **IF(ISUPPER ("CD-ROM"))**
Returns "false"
- **IF(ISUPPER ("Map Designer"))**
Returns "false"

Related functions

• ISALPHA	• LEAVEALPHANUM
• ISLOWER	• LEAVENUM
• ISNUMBER	• LEAVEPRINT
• LEAVEALPHA	

NOT

Use the **NOT** function to test a condition and have it return the inverse of its "true" or "false" result. For example, you want the function to return "true" if the condition results in "false".

Syntax:

NOT (single-condition-expression)

Meaning:

NOT (condition_to_evaluate)

Returns:

"True" or "false"

NOT returns "true" if the condition evaluates to "false" and returns "false" if the condition evaluates to "true".

Examples

- **NOT (Qty::InputFile = 0)**
This example returns "false" if the **Qty** equals 0 (the condition is true) and returns "true" if **Qty** does not equal 0 (the condition is false).
- **IF (NOT (PRESENT (StartDate))), "Unknown", "none")**
This example returns "unknown" if **StartDate** is not present and returns "none" if **StartDate** is present.

Another way to test that an object is not present is to use the **ABSENT** function.

OR

Use the **OR** function to test whether one of a series of conditions is true.

OR evaluates a series of conditions and returns "true" if at least one evaluates to "true"; otherwise returns "false".

Syntax:

OR (series-condition-expression)

Meaning:

OR (conditions_to_evaluate)

Returns:

"True" or "false"

OR evaluates to "true" if *any* member of the argument evaluates to "true" and evaluates to "false" if *all* members of the argument evaluate to "false".

Examples

- Order(s)=IF (**OR** (Store:Table = Store#:Order:Input), Order:Input)
This example produces an **Order** if the **Store#** of an **Order** in Input matches any **Store** in **Table**.

Related function

- **ALL**

WHEN

You can use the **WHEN** function in a component rule to test for the validity of one object based on another object.

WHEN evaluates a condition. Then, based on that evaluation, evaluates another condition and returns "true" or "false".

Syntax:

WHEN (single-condition-expression , single-condition-expression [, single-condition-expression])

Meaning:

WHEN (condition1 , condition2 [, condition3])

Returns:

"True" or "false"

The following statements summarize how the **WHEN** function works:

- Returns "true" if *condition1* and *condition2* both evaluate to "true".
- Returns "true" if *condition1* evaluates to "false" and there is no *condition3* or if *condition1* evaluates to "false" and *condition3* evaluates to "true".
- Returns "false" if *condition1* evaluates to "true" and *condition2* evaluates to "false".
- Returns "false" if both *condition1* and *condition3* evaluate to "false".

Evaluation of the three arguments:

Condition 1	Condition 2	Condition 3	WHEN returns:
True	True		True
False			True
False		True	True
True	False		False
False		False	False

Examples

- **WHEN (ABSENT(CatalogueField), ABSENT (QuantityField))**
Returns "true" when **CatalogueField** and **QuantityField** are both absent
- **WHEN (PRESENT(ShipDate), PRESENT(InStock), PRESENT(BackOrderDate))**
Returns "false" when **ShipDate** and **BackOrderDate** are both absent

CHOOSE

The **CHOOSE** function returns the object within a series whose position in the series corresponds to a specified number.

Syntax:

CHOOSE (series-object-name , single-integer-expression)

Meaning:

CHOOSE (from_these_objects , pick_the_nth_one)

Returns:

A single object whose index within the from_these_objects series matches the number specified by pick_the_nth_one. If that member of the series does not exist, **CHOOSE** returns "none".

You can use **CHOOSE** to use a variable value to specify the index for a particular object from a series. The CHOOSE function does not operate on a series object that was returned by another function, such as EXTRACT.

Examples

- **CHOOSE** (Row:DBSelect , 2)
Returns the second **Row**
- **CHOOSE** (Set:Claim , **INDEX** (Row:Header))
Returns the **Set** within the **Claim** that corresponds to the index of the **Row** of **Header**.

Related function

- **LOOKUP**

DBLOOKUP

The **DBLOOKUP** function executes an SQL statement against a database. The SQL statement can be any permitted by your database management system or ODBC driver.

When the **DBLOOKUP** function is used in a map, the default **OnSuccess** action is adapter specific. The default **OnFailure** action is to rollback any changes made during map processing. The default **Scope** will be integral unless the map is defined to run in bursts (which is the case when one or more inputs have the **FetchAs** property set to **Burst**).

There are two ways to specify arguments for **DBLOOKUP**.

You can use **DBLOOKUP** to execute an SQL statement when you want to execute a **SELECT** statement to retrieve a specific column value in a large table in a database using the value of another input, rather than defining the entire table as an input card and using the **LOOKUP**, **SEARCHDOWN**, or **SEARCHUP** functions.

You can use DBLOOKUP to execute an SQL statement when you want to execute a SELECT statement to retrieve a specific column value from a table or database that might vary based on a parameter file. Using Meaning 2 of the **DBLOOKUP** function allows these parameters to be dynamically specified at run time.

Syntax:

DBLOOKUP (single-text-expression , single-text-expression , [single-text-literal])

Meaning:

1. **DBLOOKUP** (SQL_statement , mdq_filename , database_name)
2. **DBLOOKUP** (SQL_statement , parameters)

Returns:

A single text item

The **DBLOOKUP** function returns the results of the query in the same format as a query specified for a map input card, except that it does not include the last carriage return/linefeed. Because this information is removed, it is easier to make use of a single value extracted from a database.

Arguments for meaning 1

DBLOOKUP (SQL_statement , mdq_filename , database_name)

- **SQL_statement**

The first argument is an SQL statement as a text string. This can be any valid SQL statement permitted by your database management system and supported by your database-specific driver. In addition to a fixed SQL statement, this argument can be a concatenation of text literals and data objects, enabling the concatenation of data values into your SQL statement.

- **mdq_filename**

The second argument is the name of a database query file (**.mdq**) produced by the Database Interface Designer. It contains the definition of the database that the SQL statement is to be executed against. If the **.mdq** file is in a directory other than the directory of the map, the path must be specified.

Note: The **.mdq** file is accessed at map build time and is not needed at run time.

- **database_name**

The third argument is the name of a database in the database query file (**.mdq**) as defined in the Database Interface Designer.

If used in this way, both the **.mdq** filename and database name must be literals.

Arguments for meaning 2

DBLOOKUP (SQL_statement , parameters)

- **SQL_statement**

The first argument is an SQL statement as a text string. This can be any valid SQL statement permitted by your database management system and supported by your database-specific driver. In addition to a fixed SQL statement, this argument can be a concatenation of text literals and data objects, enabling the concatenation of data values into your SQL statement.

- **parameters**

The second argument is a set of parameters, either:

- -MDQ mdqfilename -DBNAME dbname
 - or-

- -DBTYPE database_type [database specific parameters]

The keyword -MDQ is followed by the name of the database query file (**.mdq**) produced by the Database Interface Designer. This **.mdq** file contains the definition of the database. If the **.mdq** file is in a directory other than the directory of the map, the path must be specified. The **.mdq** filename is followed by the keyword -DBNAME and the database name as specified in the Database Interface Designer.

Using this syntax, the **.mdq** file is accessed at run time and must be present.

The keyword -DBTYPE is followed by a keyword specifying the database type (for example, ODBC or ORACLE) followed, optionally, by database-specific parameters.

This syntax does not use an **.mdq** file, because the database-specific parameters provide the information required to connect to the database. See the Resource Adapters documentation for detailed information about the database-specific parameters that can be specified.

When used with Meaning 2, **DBLOOKUP** must conform to these rules:

- All keywords (for example, -DBTYPE) can be upper or lowercase, but not mixed.
- A space is required between the keyword and its value (for example, -DBTYPE ODBC).
- The order of the keywords is not important.

All database-specific parameters are optional.

Examples

Assume that you have a table named "PARTS" that contains the following data:

PART_NUMBER	PART_NAME
1	1/4" x 3" Bolt
2	1/4" x 4" Bolt

Assume that this database has been defined using the Database Interface Designer in a file named **mytest.mdq** and that the name of the database, as specified in the **.mdq** file, is **PartsDB**.

- **DBLOOKUP** ("SELECT PART_NAME from PARTS where PART_NUMBER =1", "mytest.mdq", "PartsDB")
Returns: 1/4" x 3" Bolt

Using Meaning 2, you can specify the **DBLOOKUP** this way:

- **DBLOOKUP**("SELECT PART_NAME from PARTS where PART_NUMBER =1",
"-MDQ mytest.mdq -DBNAME PartsDB")
where both the **.mdq** file name and database name is specified.

Using Meaning 2, you can also specify the database type and the appropriate database-specific parameters:

- **DBLOOKUP**("SELECT PART_NAME from PARTS where PART_NUMBER =1",
"-DBTYPE ORACLE -CONNECT MyDB -USER janes")

Related functions

- **DBQUERY**
- **EXTRACT**
- **FAIL**
- **LASTERRORCODE**
- **LASTERRORMSG**
- **LOOKUP**
- **SEARCHDOWN**
- **SEARCHUP**
- **VALID**

For more examples using the **DBLOOKUP** function, see the Database Interface Designer documentation.

DBQUERY

The **DBQUERY** function executes an SQL statement against a database. The SQL statement can be any permitted by your database management system or ODBC driver.

When the **DBQUERY** function is used in a map, the default **OnSuccess** action is adapter specific. The default **OnFailure** action is to rollback any changes made during map processing. The default **Scope** will be integral unless the map is defined to run in bursts (which is the case when one or more inputs have the **FetchAs** property set to **Burst**).

There are two ways to specify the arguments for **DBQUERY**. You can use **DBQUERY** [Meaning 1] to execute an SQL statement when you want to look up information in a database using a parameterized query that is based on another value in your data. If your SQL statement is a SELECT statement, the **DBQUERY** function might be used in conjunction with the **RUN** function to issue dynamic SELECT statements whose results can be used as input to another map.

You can also use the **DBQUERY** function [Meaning 2] to execute an SQL statement when the database, table, or other database parameters might vary; perhaps being supplied by a parameter file.

Syntax:

```
DBQUERY (single-text-expression , single-text-expression ,
[ single-text-literal ])
```

Meaning:

1. **DBQUERY** (SQL_statement , mdq_filename , database_name)
2. **DBQUERY** (SQL_statement , parameters)

Returns:

A single text item

If your SQL statement is a SELECT statement, the results of the query in the same format as a query specified as a map input card, including row delimiters and terminators, and so on.

If your SQL statement is anything other than a SELECT statement, "none".

Arguments for meaning 1

DBQUERY (SQL_statement , mdq_filename , database_name)

- **SQL_statement**

The first argument is an SQL statement as a text string. This can be any valid SQL statement that is permitted by your database management system and supported by your database-specific driver. In addition to a fixed SQL statement, this argument can be a concatenation of text literals and data objects, enabling the concatenation of data values into your SQL statement.

- **mdq_filename**

The second argument is the name of a database query file (**.mdq**) produced by the Database Interface Designer. It contains the definition of the database that the SQL statement is to be executed against. If the **.mdq** file is in a directory other than the directory of the map, the path must be specified.

Note: The **.mdq** file is accessed at map build time and is not needed at run time.

- **database_name**

The third argument is the name of a database in the database query file (**.mdq**) as defined in the Database Interface Designer.

If used in this way, both the **.mdq** filename and database name must be literals.

Arguments for meaning 2

DBQUERY (SQL_statement , parameters)

- The first argument is an SQL statement as a text string. This can be any valid SQL statement that is permitted by your database management system and supported by your database-specific driver. In addition to a fixed SQL statement, this argument can be a concatenation of text literals and data objects, enabling the

- concatenation of data values into your SQL statement.
- The second argument is a set of parameters, either:
 - MDQ mdqfilename -DBNAME dbname
 - or-
 - DBTYPE database_type [database specific parameters]
 The keyword -MDQ is followed by the name of the database query file (**.mdq**) produced by the Database Interface Designer. This **.mdq** file contains the definition of the database. If the **.mdq** file is in a directory other than the directory of the map, the path must be specified. The **.mdq** filename is followed by the keyword -DBNAME and the database name as specified in the Database Interface Designer.
- Note: Using this syntax, the **.mdq** file is accessed at run time and must be present.
- The keyword -DBTYPE is followed by a keyword specifying the database type (for example, ODBC or ORACLE) followed, optionally, by database-specific parameters.
- Note: This syntax does not use an **.mdq** file, because the database-specific parameters provide the information required to connect to the database. See the appropriate database adapter documentation for detailed information about database-specific parameters.

When used with Meaning 2, **DBQUERY** must conform to these rules:

- All keywords (for example, -DBTYPE) can be upper or lower case, but not mixed.
 - A space is required between the keyword and its value (for example, -DBTYPE ODBC).
 - The order of the keywords is not important.
- All database-specific parameters are optional.

Examples

Assume that you have a table named "PARTS" that contains the following data:

PART_NUMBER	PART_NAME
1	1/4" x 3" Bolt
2	1/4" x 4" Bolt

Also assume that this database has been defined using the Database Interface Designer in a file named **mytest.mdq** and that the name of the database, as specified in the **.mdq** file, is **PartsDB**.

```
DBQUERY ( "SELECT * from
PARTS" , "mytest.mdq" , "PartsDB" )
Returns 1|¼" x 3" Bolt<cr><lf>2|¼" x 4" Bolt<cr><lf>
```

where <cr><lf> is a carriage return followed by a line feed.

Using Meaning 2, you can also specify the DBQUERY this way:

```
DBQUERY ( "SELECT * from PARTS" , "-MDQ mytest.mdq -DBNAME PartsDB"
)
where both the .mdq file name and database name are specified.
```

Or, specify it this way, using Meaning 2 by specifying the database type and the appropriate database-specific parameters:

```
DBQUERY ( "SELECT * from PARTS" , "-DBTYPE ORACLE -CONNECT MyDB -USER janes"
)
```

Assume that you have an input file containing one order record. To map that order to another proprietary format, you also have a parts table with pricing information for every part for every customer, a very large table. Rather than using the entire parts table as the input to your map, you might use the **RUN** function with a **DBQUERY** to dynamically select only those rows from the parts table corresponding to the customer in the order file, as follows:

```
RUN ( "MapOrder.MMC" ,
"IE2" + DBQUERY ( "SELECT * FROM Parts WHERE CustID = "
+ CustomerNo:OrderRecord:OrderFile + " ORDER BY PartNo" ,
"PartsDB.MDQ" , "PartsDatabase" ) )
```

DDEQUERY

The **DDEQUERY** function allows you to interface to other Windows applications such as Trading Partner PC, Excel, and so forth, provided that certain criteria are met. For example, if you receive an Excel spreadsheet file, you must have the appropriate version of the Excel application installed (that is compatible with the file received) and the application must be open.

Syntax:

```
DDEQUERY (single-text-expression , single-text-expression , single-text-expression)
```

Meaning:

```
DDEQUERY (application_name , topic , text)
```

Returns:

A single text item from an application

Examples

- **DDEQUERY** ("excel", "[MKTPRICE.XLS]Sheet1", "R8C1:R14C3")

In this example, **DDEQUERY** is used to get data from an Excel spreadsheet. The third argument, **R8C1:R14C3**, specifies the location of the data in the spreadsheet. (In Excel, the 8th row, 1st column to the 14th row, 3rd column is A8:C14.) The content of this spreadsheet range is returned as a single text item.

This example assumes that the application, the map, and the spreadsheet all reside in the same directory. If they are not in the same directory you must add the path. For example:

```
DDEQUERY ("excel", "c:\spreadsheet[MKTPRICE.XLS]Sheet1", "R8C1:R14C3")
```

- **DDEQYUERY** ("tppc","PartnerX","BGyourEDIode")

In this example, **DDEQUERY** is used as a request to Trading Partner PC.

Related functions

- **FAIL**
- **GET**
- **LASTERRORCODE**
- **LASTERRORMSG**
- **PUT**
- **RUN**
- **VALID**

EXTRACT

Use **EXTRACT** whenever you need only particular members of a series returned-those that meet a certain condition. An example might be only POs that contain back-ordered items.

The **EXTRACT** function can only be used in a map rule. It cannot be used in a component rule.

The **EXTRACT** function returns all members of a series for which a specified condition is true.

Syntax:

```
EXTRACT (series-object-expression, single-condition-expression)
```

Meaning:

```
EXTRACT (objects_to_extract, condition_to_evaluate)
```

Returns:

A series object.

The result is each member of *series_to_search* for which the condition specified by *condition_to_evaluate* evaluates to "true". **EXTRACT** returns "none", if no member of *series_to_search* has a corresponding *condition_to_evaluate* that evaluates to "true".

Examples

- **EXTRACT** (PO:Transaction , Store# = Location:PO:Transaction)
This example returns all **POs**, individually, whose **Location** is a particular **Store#**.
- **EXTRACT** (Row:DBSelect , ProcessFlag Column:Row:DBSelect = "Y")
This example returns all **Rows** that have a **ProcessFlag Column** value of "Y".

Related Functions

- **CHOOSE**
- **LOOKUP**
- **SEARCHDOWN**
- **SEARCHUP**

GETANDSET

You can use **GETANDSET** when you have an input file that keeps track of control information that serves as an input to your map and the control information in the file needs to be updated based on processing that occurs in your map.

The **GETANDSET** function gets a fixed length value from the input data stream, updates that value in the input data stream, and returns either the original or updated value.

Syntax:

```
GETANDSET (single-fixed-size-item-object-name, single-item-expression,  
           single-integer-expression)
```

Meaning:

GETANDSET (original_value ,new_value, integer_that_determines_which_value_to_return)

Returns:

A single-fixed-size-item and replaces the original value in the input data stream.

This function does not support decrementing integers past 0 into negative numbers.

GETANDSET updates an input by finding the object represented by *original_value* and replacing it with the value represented by the *new_value*. The function returns either the *original_value* or the *new_value*, depending on the value of the *integer_that_determines_which_value_to_return*. For example,

- If *integer_that_determines_which_value_to_return* has the value 1, *original_value* is returned.
- If *integer_that_determines_which_value_to_return* has the value 2, *new_value* is returned.
- If *integer_that_determines_which_value_to_return* has any other value, *original_value* is returned.
- If one of the input arguments evaluates to "none", **GETANDSET** returns "none".

The original value specified for *new_value* must be a fixed size item. During map execution, the original value is updated to reflect the evaluation of **GETANDSET**.

When the source is a file, that file will be updated after map completion. However, if the source is a database, message, or application, the content of the source is in memory and the source, itself, is not updated.

Examples

- New Tracking# = **GETANDSET** (Tracking#:Card, Tracking#:Card + 3, 1)

This rule finds the object **Tracking#:Card** (assume that it has the value 6), adds 3 to it, giving 9, and replaces the 6 with the 9 in the data location of **Tracking#:Card**. Subsequent references to **Tracking#:Card** will find its value to be 9. If **Card** is an input card whose source is a file, the file is rewritten with the new value.

Because the third input argument (*integer_that_determines_which_value_to_return*) is 1, the returned value is the original value of 6.

GETDIRECTORY

The **GETDIRECTORY** function returns the full path (directory) for the compiled map file or the source or destination associated with a specified card object.You can use **GETDIRECTORY** in a map rule or component rule when you need the full path (directory) of either the compiled map or of a data source or destination.

Syntax:

GETDIRECTORY ([single-simple-object-name])

Meaning:

GETDIRECTORY ([card_or_object_for_which_directory_is_needed])

Returns:

A single text item

Without an argument, **GETDIRECTORY** returns the full path associated with the compiled map.

With an argument, the following occurs:

- From a map rule, the function returns the full path of the source or destination that is associated with the card. In a map rule, the argument must be the name of the card for which to get the directory.
 - From a component rule, the function returns the full path of the source or destination that is associated with the active source or destination.
- The **GETDIRECTORY** command without arguments will return the directory of the compiled map, regardless of whether it is used in a map rule or in a component rule.

Examples

- **GETDIRECTORY** (OrderFile)

If the card **OrderFile** is associated with the data file, *install_dir\order.txt*, **GETDIRECTORY** returns *\install_dir*.

- **GETDIRECTORY** ()

If the compiled map on the HP-UX is */maps/prod/mymap.mmc*, **GETDIRECTORY** returns */maps/prod/*.

Suppose you want to run the map, **MyMap**, from a component rule on **Record** in your input to determine whether input customer names are valid. **MyMap** has two inputs and one output. The first input is the customer name to look up. The second input is a lookup file. The output is a text item whose value is "valid" or "error".

The name of the lookup file is constant; it is always **XREF_TBL.TXT**. However, its location might vary; it will always be in the same directory as the data file used as the source you are trying to validate. For example, if the name of the data file used as the source is **C:\SHR\ABC\INPUT.TXT**, the lookup file name is **C:\SHR\ABC\XREF_TBL.TXT**. If the data file name is **/local/data/somefile**, the lookup file name is **/local/data/XREF_TBL.TXT**, and so forth.

You could use this component rule on **Record** to determine whether the customer name is valid:

```
RUN ("MyMap.mmc", "-IE1S10" + CustomerName:$ + "-IF2" + GETDIRECTORY () + "XREF_TBL.TXT" + "-OE1") = "VALID"
```

Related functions

- **GETFILENAME**
- **GETRESOURCENAME**

GETITXUID

The **GETITXUID** function returns a universally unique identifier (UUID).

Syntax:
resourceLib->**GETITXUID** ()

Meaning:
GETITXUID ()

Returns:
A unique string of 36 single-digit hexadecimal numbers

This function has no arguments but requires parentheses (). This function is valid on all Transformation Extender platforms.

GETLOCALE

The GETLOCALE function returns the locale setting of the computer.

Syntax:
resourceLib->**GETLOCALE** ()

Meaning:
GETLOCALE ()

Returns:
A single text item

The GETLOCALE function returns the locale setting of the computer where the map runs. The locale is returned in the format specified by the operating system. Generally, the return format is an ISO Language Code (as defined by ISO-639) in combination with an ISO Country Code (as defined by ISO-3166) when applicable. The language codes are two lowercase letters and the country codes are two uppercase letters. For example, **en_US** is the code for English (United States).

This function has no arguments but requires parentheses.

Table 1. Examples

System locale	Returns
French	fr
Korean	ko
Brazilian Portuguese	pt_BR
Taiwanese Chinese	zh-TW

GETFILENAME

The **GETFILENAME** function returns the file name for a file adapter source or target of a specified card object. Without an argument, it returns the adapter command associated with the active source or destination.

You can use **GETFILENAME** in a map rule or component rule when you need the data file name.

Syntax:
GETFILENAME ([single-simple-object-name])

Meaning:
GETFILENAME ([card_for_which_resource_info_is_needed])

Returns:
A single text item

With an argument, **GETFILENAME** returns the file name for a file source or target of a specified card object. Without an argument, the function returns the source or destination name associated with the active source or destination.

Examples

- **GETFILENAME** (OrderFile)

If the card **OrderFile** is associated with the data file, *install_dir\order.txt*, **GETFILENAME** returns *install_dir\order.txt*.

Suppose you want to run the map **MyMap** from a component rule on **Record** in your input to determine if input customer names are valid. **MyMap** has two inputs and one output. The first input is the customer name to be looked up. The second input is a lookup file. The output is a text item whose value is "valid" or "error".

The name of the lookup file can vary; it must correspond to the name of the data file used as the source you are trying to validate. For example, if the data file name is **c:\DATA.AAA**, the lookup file name is **c:\LOOKUP.AAA**. If the data file name is **c:\DATA.XYZ**, the lookup file name is **c:\LOOKUP.XYZ**, and so on.

You could use this component rule on **Record** to determine whether the customer name is valid:

```
RUN ( "MyMap.mmc" , "-IE1S10" + CustomerName:$ + " -IF2 LOOKUP." + RIGHT ( GETFILENAME () , 3 ) + " -OE1" ) = "VALID"
```

Related functions

- **GETDIRECTORY**
- **GETRESOURCENAME**

GETPARTITIONNAME

You can use **GETPARTITIONNAME** when you need to know the name of the partition to which the data for the given object belongs.

Syntax:

GETPARTITIONNAME (single-partitioned-object-expression)

Meaning:

GETPARTITIONNAME (partitioned_object)

Returns:

A single simple object name

GETPARTITIONNAME returns a text item that represents the name of the partition to which the data for *partitioned_object* belongs.

Examples

- **GETPARTITIONNAME** (Transaction:File)

The type defined by **Transaction** is a partitioned object that has three partitions: **Add**, **Delete**, and **Modify**. In this example, if the input data for **Transaction** belongs to the **Delete** partition, the **GETPARTITIONNAME** function returns "delete".

Related functions

- **PARTITION**

GETRESOURCEALIAS

The **GETRESOURCEALIAS** function returns the resource alias value specified in a Resource Registry resource name file (.mrn).

Syntax:

resourcelib->GETRESOURCEALIAS (single-text-expression, single-text-expression)

Meaning:

GETRESOURCEALIAS (single-text-expression, single-text-expression)

Returns:

A single text item

The **GETRESOURCEALIAS** function loads a Resource Registry resource configuration file and retrieves the specified alias value. The values are defined as part of the Global object in the .mrc file.

In the below example the resource configuration file is defined as:

```
<?xml version="1.0" encoding="UTF-8"?>
<ResourceCfg>

    <Global>
        <ResourceFile ActiveVirtualServer="test">Company.mrn</ResourceFile>
    </Global>
</ResourceCfg>
```

The resource name file is defined as:

```
<?xml version="1.0" encoding="UTF-8"?>
<MRN>
    <VirtualServerSet>
        <VirtualServer>test</VirtualServer>
    </VirtualServerSet>
    <Resource>
        <Name>company</Name>
        <Value Server="test" encrypt="OFF">ABC</Value>
    </Resource>
</MRN>
```

..when used as a part of this rule:

```
=resourcelib->GETRESOURCEALIAS ("company.mrc", "%company%")
```

In this scenario, the return value is "ABC".

When an absolute path is not defined in the location, the default location is the map directory.

GETRESOURCENAME

The **GETRESOURCENAME** function returns the adapter source or target command of a specified card object. Without an argument, it returns the adapter command associated with the active source or destination.

You can use **GETRESOURCENAME** in a component or map rule when you need to know the name of a source or destination.

Syntax:

GETRESOURCENAME ([single-simple-object-name])

Meaning:

GETRESOURCENAME ([card_for_which_resource_info_is_needed])

Returns:

A single text item

With an argument, the source or destination name that is associated with the card. Without an argument, returns the source or destination name associated with the active source or destination.

Examples

- **GETRESOURCENAME** (OrderFile)

If the card **OrderFile** is associated with the data file, *install_dir\order.txt*, the **GETRESOURCENAME** function returns *install_dir\order.txt*.

Related functions

- **GETDIRECTORY**
 - **GETFILENAME**
-

GETTXINSTALLDIRECTORY

The **GETTXINSTALLDIRECTORY** function returns the IBM Transformation Extender product installation directory.

Syntax:

```
resourceLib->GETTXINSTALLDIRECTORY ()
```

Meaning:

```
GETTXINSTALLDIRECTORY ()
```

Returns:

A single text item

GETTXINSTALLDIRECTORY returns the product installation directory. For example, a Windows operating system might return C:\Program Files\IBM\TransformationExtender_11.0.0, or a UNIX operating system would return the DTX_HOME_DIR value in the setup script.

This function has no arguments but requires parentheses.

This function cannot be used in a z/OS environment.

GETDATADIRECTORY

The **GETDATADIRECTORY** function returns the data directory chosen by the user during installation.

INDEX

You can use the **INDEX** function when you need to select or test particular objects based on their occurrence, or to add a sequence number to output objects.

INDEX returns an integer that represents the index of an object relative to its nearest contained object, counting only valid objects.

INDEX cannot be used in a component rule.

Syntax:

```
INDEX (single-object-name)
```

Meaning:

```
INDEX (object_for_which_to_get_index)
```

Returns:

A single integer

The *object_for_which_to_get_index* variable must be a type name. The result is the index of *object_for_which_to_get_index*.

- If *object_for_which_to_get_index* is an input, this will be the index within all valid objects.
- If *object_for_which_to_get_index* is an output, this will be the index within all objects (valid and invalid).
- Returns 0 if the input argument is "none".

The difference between **INDEXABS** and **INDEX** is that **INDEXABS** counts both valid and invalid instances, whereas **INDEX** counts only valid instances.

Examples

- Message (s) = IF (**INDEX** (Message:Input) > 3, Message:Input, "none")

For example, there are five **Messages** in **Input**. The first three evaluations of this rule return "none". The fourth evaluation returns **Message[4]**. The fifth evaluation returns **Message[5]**.

- Invoice (s) = MyMap (Invoice Segment:Input, INDEX (\$))

For the first evaluation of **MyMap**, **INDEX(\$)** is 1. For the second evaluation of **MyMap**, **INDEX(\$)** is 2.

Related functions

- **CHOOSE**
- **COUNT**
- **COUNTABS**

- **INDEXABS**

INDEXABS

You can use **INDEXABS** when you need the absolute occurrence of a particular object across all occurrences, rather than across only valid occurrences.

The **INDEXABS** function returns an integer that represents the index of an object relative to its nearest contained object, counting both valid and invalid instances of the object.

Syntax:

INDEXABS (single-object-name)

Meaning:

INDEXABS (object_for_which_to_get_index)

Returns:

A single integer

INDEXABS returns an integer that represents the absolute index of *object_for_which_to_get_index*. The integer indicates the instance this object that is in the set of *all* instances of the object, including both valid and invalid occurrences. Returns 0 if the input argument is "none".

- If *object_for_which_to_get_index* is an input, this will be the index within all members of the series, including valid objects, invalid objects, and existing "none"s.
 - If *object_for_which_to_get_index* is an output, this will be the index within all existing members of the series, including existing "none"s.
- The difference between **INDEXABS** and **INDEX** is that **INDEXABS** counts both valid and invalid instances, as well as existing "none"s, whereas **INDEX** counts only valid instances.

Examples

- **INDEXABS** (Message Record:Order:PO_File)

For this example, that **Order** contains the following **Messages**:

Message Record[1] Valid

Message Record[2] Error

Message Record[3] Valid

In a map rule, **INDEXABS** (MessageRecord[3]:Order:PO_File) would evaluate to 3.

If the **INDEX** function was used, **INDEX** (Message Record[3]:Order:PO) would evaluate to 2.

Related function

- **INDEX**

LASTERRORCODE

The **LASTERRORCODE** function returns a text item whose value is the last error code returned by one of a specified set of functions during map execution.

You can use **LASTERRORCODE** to interrogate or report the error code returned by one of the external interface functions.

Syntax:

LASTERRORCODE ()

Meaning:

LASTERRORCODE ()

Returns:

A single text item

LASTERRORCODE has no arguments but it requires parentheses.

LASTERRORCODE returns a text item whose value is the last error code returned by one of a specified set of functions during map execution.

The following functions can fail:

- **DBLOOKUP**
- **DBQUERY**
- **DDEQUERY**
- **EXIT**
- **GET**
- **PUT**
- **RUN**

Examples

- Message = VALID (RUN ("Map1Msg.mmc" , "-AE -OMMSMQ1B ` -QN .\aqeue -CID 2001"), FAIL ("Failure on RUN (" + TEXT (LASTERRORCODE ()) + ")" + LASTERRORMSG ()))

In this example, the **LASTERRORCODE** and **LASTERRORMSG** functions are being used in conjunction with the **FAIL** and **VALID** functions to fail (abort) the map if the map executed by the **RUN** function (**Map1Msg.mmc**) fails. In this example, the map fails and returns the error code and error message reported by the **RUN**

function using the **LASTERRORCODE** and **LASTERRORMSG** functions.

If **Map1Msg** fails because one or more of its inputs was invalid, **Message** is assigned a value of "none". The map aborts and the following message is reported in the execution audit log:

Failure on RUN (8): One or more inputs was invalid.

Related functions

- **DBLOOKUP**
 - **DBQUERY**
 - **DDEQUERY**
-

LASTERRORMSG

The **LASTERRORMSG** function returns a text item whose value is the message corresponding to the last error code returned by one of a specified set of functions during map execution.

Syntax:

LASTERRORMSG ()

Meaning:

LASTERRORMSG ()

Returns:

A single text item

Although **LASTERRORMSG** has no arguments, it does require parentheses.

LASTERRORMSG returns a text item whose value is the message corresponding to the last error code returned by one of a specified set of functions during map execution.

The following is the list of functions that can fail:

• DBLOOKUP	• GET
• DBQUERY	• PUT
• DDEQUERY	• RUN
• EXIT	

Examples

```
• Message = VALID ( RUN (  
"Map1Msg.mmc" , "-AE -OMMSMQ1B ` -QN .\aqueue -CID 2001'" ) , FAIL ( "Failure on RUN (" + TEXT  
(LASTERRORCODE ( ) ) + ")" + LASTERRORMSG ( ) ) )
```

In this example, the **LASTERRORCODE** and **LASTERRORMSG** functions are being used in conjunction with the FAIL and VALID functions to fail (abort) the map if the map executed by the RUN function (**Map1Msg.mmc**) fails. In this example, the map fails and returns the error code and error message reported by the RUN function using the **LASTERRORCODE** and **LASTERRORMSG** functions.

If **Map1Msg** fails because one or more of its inputs was invalid, **Message** is assigned a value of "none". The map aborts and the following message is reported in the execution audit log:

Failure on RUN (8): One or more inputs was invalid.

Related functions

- **DBLOOKUP**
 - **DBQUERY**

LOOKDOWN

The **LOOKDOWN** function sequentially searches a series beginning at the end of the series, returning the last member of the series that meets a specified condition.

Syntax:

LOOKDOWN (series-object-expression , single-condition-expression)

Meaning:

LOOKDOWN (series_to_search , condition_to_evaluate)

Returns:

A single object

LOOKDOWN returns the last member of *series_to_search* for which *condition_to_evaluate* evaluates to "true"; it returns "none" if no member of *series_to_search* meets the condition specified by *condition_to_evaluate*.

Examples

- **LOOKDOWN** (Account#:Customer , Company Name:Customer = "ACME")
This example returns the **Account#** of **Customer** whose **Company Name** is ACME.
- **LOOKDOWN** (Part#:Row:DBSelect , Model#:Row:DBSelect = ModelCode:Legacy & Serial#:Row:DBSelect > "123")
This example returns the **Part#** of **DBSelect** where the **Model#** in that row matches the **ModelCode** of **Legacy** and the **Serial#** is greater than 123.

Related functions

- CHOOSE
- EXTRACT
- LOOKUP

Note: **LOOKDOWN** differs from **LOOKUP** in that **LOOKDOWN** returns the last member of *series_to_search* that meets the *condition_to_evaluate*, while **LOOKUP** returns the first member of *series_to_search* that meets the *condition_to_evaluate*.

- SEARCHUP
- SEARCHDOWN

The **LOOKDOWN** function performs a sequential search on an unsorted series, starting from the end of the series. The **SEARCHUP** and **SEARCHDOWN** functions perform a binary search on a series that is sorted in ascending or descending code-page byte-order. The **SEARCHUP** and **SEARCHDOWN** functions are efficient for performing multiple searches on a large series. The **LOOKDOWN** function can be more efficient for performing fewer searches. Note that **LOOKDOWN** returns a different instance from the one returned by **SEARCHUP** and **SEARCHDOWN** if multiple instances in the series match the condition.

LOOKUP

The **LOOKUP** function sequentially searches a series, returning the first member of the series that meets a specified condition.

Syntax:

LOOKUP (series-object-expression , single-condition-expression)

Meaning:

LOOKUP (*series_to_search* , *condition_to_evaluate*)

Returns:

A single object

LOOKUP returns the first member of *series_to_search* for which *condition_to_evaluate* evaluates to "true"; it returns "none" if no member of *series_to_search* meets the condition specified by *condition_to_evaluate*.

Examples

- **LOOKUP** (Account#:Customer , Company Name:Customer = "ACME")
This example returns the **Account#** of **Customer** whose **Company Name** is ACME.
- **LOOKUP** (Part#:Row:DBSelect , Model#:Row:DBSelect = ModelCode:Legacy & Serial#:Row:DBSelect > "123")
This example returns the **Part#** of **DBSelect** where the **Model#** in that row matches the **ModelCode** of **Legacy** and the **Serial#** is greater than 123.

Related functions

- CHOOSE
- EXTRACT

Note: **LOOKUP** differs from **EXTRACT** in that **LOOKUP** returns the first member of *series_to_search* that meets the *condition_to_evaluate*, while **EXTRACT** returns all members (one at a time) of *series_to_search* that meet the *condition_to_evaluate*.

- LOOKDOWN

Note: **LOOKUP** differs from **LOOKDOWN** in that **LOOKUP** returns the first member of *series_to_search* that meets the *condition_to_evaluate*, while **LOOKDOWN** returns the last member of *series_to_search* that meets the *condition_to_evaluate*.

- SEARCHUP
- SEARCHDOWN

The **LOOKUP** function performs a sequential search on an unsorted series, starting from the beginning of the series. The **SEARCHUP** and **SEARCHDOWN** functions perform a binary search on a series that is sorted in ascending or descending code-page byte-order. The **SEARCHUP** and **SEARCHDOWN** functions are efficient for performing multiple searches on a large series. The **LOOKUP** function can be more efficient for performing fewer searches.

MEMBER

Use **MEMBER** when you need to know whether an object occurs within a series.

The **MEMBER** function searches a series, looking for a single specified object in the series. If any object in the series matches the specified object, **MEMBER** returns "true". If there is no match, **MEMBER** returns "false".

Syntax:

MEMBER (single-object-expression , series-object-expression)

MEMBER (single-object-expression , { literal, literal ... })

Meaning:

MEMBER (*object_to_look_for* , *series_of_objects_to_look_at*)

Returns:

"True" or "false"

MEMBER returns "true" if *object_to_look_for* matches one of the values in *series_of_objects_to_look_at*.

It returns "false" if *object_to_look_for* does not match at least one of the values in *series_of_objects_to_look_at*.

The two arguments, *object_to_look_for* and *series_of_objects_to_look_at*, must be objects of the same item interpretation or the same group type. For example, if *object_to_look_for* is a date/time item, *series_of_objects_to_look_at* must be a series of date/time items.

Examples

- **MEMBER** (EntityIDCode:Name, {"BT", "ST"})

This example tests whether **EntityIDCode** has one of a particular set of literal values.

- **MEMBER** (Store#, EntityIDCode:Name)

This example tests whether **Store#** has the same value as any **EntityIDCode:Name**.

Related functions

- **EXTRACT**
 - **LOOKUP**
-

SEARCHDOWN

Use the **SEARCHDOWN** function to look up data within a series of data that is sorted in descending code-page byte-order. **SEARCHDOWN** performs a binary search on the sorted series and returns a related object that corresponds to the item found.

The byte-order of characters varies by code page. For example, because the ASCII **A** character (0x41) has a higher numeric value than the ASCII **O** character (0x30), the **SEARCHDOWN** function requires the **O** character to be sorted after the ASCII **A** character in the series. The EBCDIC **A** character (0xC1) has a lower numeric value than the EBCDIC **O** character, so the **SEARCHDOWN** function requires the EBCDIC **A** character to be sorted be after the EBCDIC **O** character in the series.

The IBM Transformation Extender Data Language property values change the collation order of some characters. For example, the German National Language property value is arranged in byte order, with the exception of certain characters: æ is ordered after a, e is ordered before ä, and so forth. There are particular collation rules for other National Language property values. However, there is no collation order for "Western" and "Japanese" property values, and the deprecated Data Language property values are always in byte order.

Syntax:

SEARCHDOWN (series-object-expression , series-item-object-expression , single-item-expression)

Meaning:

SEARCHDOWN (corresponding_object_to_return , descending_items_to_search , item_to_match)

Returns:

A single object

SEARCHDOWN performs a binary search on the item series of *descending_items_to_search*. The *descending_items_to_search* must be sorted in descending code page byte-order. The value to search for is specified as the *item_to_match*. The object returned (*corresponding_object_to_return*) must be related to *descending_items_to_search* by a common object name.

If no match is found, **SEARCHDOWN** returns "none".

Examples

- **SEARCHDOWN** (Age Column:Row:DBSelect ,
SSN Column:Row:DBSelect ,
SSN_Value:Message)

If there are ten rows in **DBSelect**, the search starts by comparing the first **SSN Column** of the fifth row with the **SSN_Value** in **Message**. If the result matches, **SEARCHDOWN** returns the first **Age Column** of that **Row**. If the value of **SSN Column** is less than the **SSN_Value** in **Message**, the search continues with the third **Row**. If the value of **SSN Column** is greater than the **SSN_Value** in **Message**, the search continues with the seventh Row in **DBSelect**. The search continues in this fashion until either a match is found or until one **Row** is selected. If there is more than one **SSN Column** for the selected **Row**, a similar search is initiated for all **SSN Column**'s for the selected **Row** in **DBSelect**.

SEARCHDOWN returns the first **Age Column** for the selected **Row** of **DBSelect**.

Related functions

- **EXTRACT**
 - **LOOKUP**
 - **SEARCHUP**
-

SEARCHUP

Use the **SEARCHUP** function to look up data within a series of data that is sorted in ascending code-page byte-order. The **SEARCHUP** function performs a binary search on the sorted series and returns a related object that corresponds to the item found.

The byte-order of characters varies by code page. For example, because the ASCII **A** character (0x41) has a higher numeric value than the ASCII **0** character (0x30), the **SEARCHUP** function requires the **0** character to be sorted before the ASCII **A** character in the series. The EBCDIC **A** character (0xC1) has a lower numeric value than the EBCDIC **0** character, so the **SEARCHUP** function requires the EBCDIC **A** character to be sorted before the EBCDIC **0** character in the series.

The IBM Transformation Extender Data Language property values change the collation order of some characters. For example, the German National Language property value is arranged in byte order, with the exception of certain characters: æ is ordered after a, e is ordered before ä, and so forth. There are particular collation rules for other National Language property values. However, there is no collation order for "Western" and "Japanese" property values, and the deprecated Data Language property values are always in byte order.

Syntax:

SEARCHUP (series-object-expression, series-item-object-expression, single-item-expression)

Meaning:

SEARCHUP (corresponding_object_to_return, ascending_items_to_search, item_to_match)

Returns:

A single object

SEARCHUP performs a binary search on the item series of *ascending_items_to_search*. The *ascending_items_to_search* must be sorted in ascending code page byte-order. The value to search for is specified as the *item_to_match* and must be of the same type as the *ascending_item_to_search*.

The object returned (*corresponding_object_to_return*) must be related to *ascending_items_to_search* by a common object name. If no match is found, **SEARCHUP** returns "none".

Examples

- **SEARCHUP** (Age Column:Row:DBSelect, SSN Column:Row:DBSelect, SSN_Value:Message)

If there are ten rows in **DBSelect**, the search starts by comparing the first **SSN Column** of the fifth **Row** with the **SSN_Value** in **Message**. If the result matches, **SEARCHUP** returns the first **Age Column** of that **Row**. If the value of **SSN Column** is greater than the **SSN_Value** in **Message**, the search continues with the third **Row**. If the value of **SSN Column** is less than the **SSN_Value** in **Message**, the search continues with the seventh **Row** in **DBSelect**. The search continues in this fashion until either a match is found or until one **Row** is selected. If there is more than one **SSN Column** for the selected **Row**, a similar search is initiated for all **SSN Column's** for the selected **Row** in **DBSelect**.

SEARCHUP returns the first **Age Column** for the selected **Row** of **DBSelect**.

Related functions

SORTDOWN

Use the **SORTDOWN** function to sort objects in a series in descending sequence. The function returns a series containing the values from the input series in descending order.

- When the character set of the data is ASCII, the objects are sorted in ASCII descending order.
- For all other character sets, the objects are sorted in binary descending order.

Syntax:

SORTDOWN (series-item-expression)

Meaning:

SORTDOWN (item_series_to_sort)

Returns:

A series object

Returns the values in *item_series_to_sort* in descending order.

Examples

- **SORTDOWN** (Abbr:File)

In this example, if **Abbr** has these ASCII values:

ABC, GHI, DEF

SORTDOWN returns these values as a series as:

GHI, DEF, ABC

- The following table displays the results of using the **SORTDOWN** and **SORTUP** functions for a typical series of ASCII text items.

Original Input Series	Result using SORTDOWN	Result using SORTUP
Clams Casino	shrimps	1 Shrimp
Grouper	raw oysters	22 Shrimp
groupers	oysters	A
Shrimp	lobster tails	A 1 A shrimp
shrimps	lobster	A1A Shrimp
lobster	groupers	AA
lobster tails	clams	AAAAA

Original Input Series	Result using SORTDOWN	Result using SORTUP
oysters	aaaaa	Clams Casino
raw oysters	aa	Grouper
clams	a	Rock Lobster
SHRIMP	Snapper	SHRIMP
1 Shrimp	Snapper	Shark Fin Soup
22 Shrimp	Shrimp	Shrimp
A 1 A shrimp	Shark Fin Soup	Snapper
A1A Shrimp	SHRIMP	Snapper
AAAAAA	Rock Lobster	a
aaaaa	Grouper	aa
aa	Clams Casino	aaaaa
AA	AAAAA	clams

- [UNIQUE](#)

SORTDOWNBY

Use **SORTDOWNBY** to sort the objects of a series based on a component that the objects contain. The **SORTDOWNBY** function returns the input series, sorted in descending order by the value of the specified component.

- When the character set of the data is ASCII, the objects are sorted in ASCII descending order.
- For all other character sets, the objects are sorted in binary descending order.

The **SORTDOWNBY** function does not sort the output of the **EXTRACT**, **REJECT**, or **UNIQUE** functions.

Syntax:

SORTDOWNBY (series-item-expression, single-item-expression)

Meaning:

SORTDOWNBY (group_series_to_sort, group_component_to_sort_by)

Returns:

A series object

SORTDOWNBY returns a series of instances of a group, sorted in descending order by the value of an item that the group contains.

Example

In this example, the group **Soldier** contains the items:

- Name
- Rank
- Serial number

The following command returns the instances of Soldier, sorted in descending order by Rank:

```
SORTDOWNBY (Soldier:Army, Rank:Soldier:Army)
```

Related functions

- [SORTUP](#)
- [SORTUPBY](#)

SORTUP

Use **SORTUP** to sort the objects of a series in ascending sequence. The **SORTUP** function returns a series containing the values from an input series in ascending order.

- When the character set of the data is ASCII, the objects are sorted in ASCII ascending order.

- For all other character sets, the objects are sorted in binary ascending order.

Syntax:

SORTUP (series-item-expression)

Meaning:

SORTUP (item_series_to_sort)

Returns:

A series object

SORTUP returns the values in *item_series_to_sort* in ascending order.

Examples

- SORTUP** (Abbr:File)

In this example, if **Abbr** had the ASCII values ABC, GHI, DEF, the **SORTUP** function would return these values as a series: ABC, DEF, GHI.

Related functions

- SEARCHDOWN**
- SEARCHUP**
- SORTDOWN**
- UNIQUE**

SORTUPBY

Use **SORTUPBY** to sort the objects of a series based on a component that the objects contain. The **SORTUPBY** function returns the input series, sorted in ascending order by the value of the specified component.

- When the character set of the data is ASCII, the objects are sorted in ASCII ascending order.
- For all other character sets, the objects are sorted in binary ascending order.

The **SORTUPBY** function does not sort the output of the **EXTRACT**, **REJECT**, or **UNIQUE** functions.

Syntax:

SORTUPBY (series-item-expression, single-item-expression)

Meaning:

SORTUPBY (group_series_to_sort, group_component_to_sort_by)

Returns:

A series object

SORTUPBY returns a series of instances of a group, sorted in ascending order by the value of an item that the group contains.

Example

In this example, the group **Soldier** contains the items:

- Name
- Rank
- Serial number

The following command returns the instances of Soldier, sorted in ascending order by Rank:

```
SORTUPBY (Soldier:Army, Rank:Soldier:Army)
```

Related functions

- SEARCHDOWN**
- SEARCHUP**
- SORTUP**
- SORTDOWN**
- SORTDOWNBY**

UNIQUE

The **UNIQUE** function returns a series containing all "unique" members of a series.

UNIQUE can only be used in a map rule, not in a component rule.

Syntax:

UNIQUE (series-object-expression)

Meaning:

UNIQUE (series_to_evaluate)

Returns:

A series object

UNIQUE evaluates to a series containing all unique members of *series_to_evaluate* and evaluates to "none" if *series_to_evaluate* evaluates to "none".

Examples

- **UNIQUE** (PartNumber:Inventory:File)
Returns the unique **PartNumbers** in **Inventory:File**
- **COUNT** (**UNIQUE** (Customer:Order:File))
Returns the number of unique **Customers** in **Order:File**

Related functions

- **SORTDOWN**
- **SORTUP**

GETENV

The **GETENV** function returns the value of the environment variable. If no variable exists, an empty string is returned.

Syntax:

GETENV(*single-text-expression*)

Meaning:

GETENV (the environment variable name)

Returns:

 A single-text-item

Related reference

- [GETOSNAME](#)

GETOSNAME

The **GETOSNAME** function returns the name of the operating system.

The returned values can be:

- Windows for any version of Microsoft Windows operating system
- zLinux for Linux operating system on z/OS hardware
- Linux for Linux operating system on Intel hardware
- AIX for AIX operating system on PowerPC hardware
- OS/390 for native z/OS operating system

Syntax:

GETOSNAME()

Meaning:

GETOSNAME ()

Returns:

 A single-text-item

ABS

The **ABS** function returns the absolute value of a number.

Syntax:

ABS (single-number-expression)

Meaning:

ABS (number)

Returns:

A single number; the absolute value of a number

Examples

- **ABS** (-3)
Returns 3
 - **ABS** (3)
Returns 3
 - AvailableCredit has a value of -69.42
ABS (AvailableCredit) returns 69.42
 - FlexDollars has a value of 50
ABS ((100 - FlexDollars)/2) returns 25
-

ACOSINE

Use the ACOSINE function to calculate the arccosine of a value.

Syntax:

`mathlib->ACOSINE (single-number-expression)`

Meaning:

`mathlib->ACOSINE (number_to_convert)`

Returns:

A single number item

The result is the arccosine of the converted value.

ASIN

Use the ASIN function to calculate the arcsine of a value.

Syntax:

```
mathlib->ASIN (single-number-expression)
```

Meaning:

```
mathlib->ASIN (number_to_convert)
```

Returns:

A single number item

The result is the arcsine of the converted value.

ATAN

The ATAN function calculates the arctangent of a value.

Syntax:

```
mathlib->ATAN (single-number-expression)
```

Meaning:

```
mathlib->ATAN (number_to_convert)
```

Returns:

A single number item

ATAN2

The ATAN2 function calculates the arctangent of y,x.

Syntax:

```
mathlib->ATAN2 (single-number-expression, single-number-expression)
```

Meaning:

```
mathlib->ATAN2 (number_to_convert)
```

Returns:

A single number item

COSINE

The COSINE function calculates the cosine of a value.

Syntax:

```
mathlib->COSINE (single-number-expression)
```

Meaning:

```
mathlib->COSINE (number_to_convert)
```

Returns:

A single number item

COSINEH

The COSINEH function calculates the hyperbolic cosine of a value.

Syntax:

```
mathlib->COSINEH (single-number-expression)
```

Meaning:

```
mathlib->COSINEH (number_to_convert)
```

Returns:

A single number item

COUNT

You can use the COUNT function to return an integer representing the number of valid input or output objects in a series.

Syntax:

```
COUNT (series-object-expression)
```

Meaning:

```
COUNT (valid_objects_to_count)
```

Returns:

A single integer

The result is the number of *valid_objects_to_count*. If the input argument evaluates to "none", **COUNT** returns 0.

COUNT does not count existing "none's unless its group was defined as an explicit format with a **Track** setting of **Places**.

Examples

- **COUNT** (Claim Record:Patient File)
This example returns the number of valid **Claim Record** objects in **Patient File**.
- **COUNT** (Class IN Transcript)
This example returns the number of valid **Class** objects in **Transcript**.
- **COUNT (UNIQUE** (Class IN Transcript))
This example returns the number of valid **Unique Class** objects in **Transcript**.

Related functions

- **COUNTABS**

COUNTABS

You can use **COUNTABS** to count the input or output objects in a series, regardless of the validity of the object.

Unlike **COUNT**, **COUNTABS** includes both valid and invalid objects in a series.

Syntax:

COUNTABS (series-object-expression)

Meaning:

COUNTABS (objects_to_count)

Returns:

A single-integer

The result is the number of *objects_to_count*. If the input argument evaluates to "none", **COUNTABS** returns 0.

COUNTABS does not count existing "none's unless its group was defined as an explicit format with a **Track** setting of **Places**.

Examples

- **COUNTABS** (Claim Record:Patient File)
This example returns the number of **Claim Record** objects in **Patient File**.
- **COUNTABS** (Class IN Transcript)
This example returns the number of **Class** objects in **Transcript**.

Related functions

- **COUNT**

EXP

The EXP function calculates the exponential of a value.

Syntax:

`mathlib->EXP (single-number-expression)`

Meaning:

`mathlib->EXP (number_to_convert)`

Returns:

A single number item

FACTORIAL

The FACTORIAL function calculates the factorial of a value.

Syntax:

`mathlib->FACTORIAL (single-number-expression)`

Meaning:

`mathlib->FACTORIAL (number_to_convert)`

Returns:

A single number item

FROMBaseten

You can use **FROMBaseten** when you need to convert numbers to a base other than 10.

The **FROMBaseten** function converts an integer to a text item that can be interpreted as a number, using positional notation of the base specified.

Syntax:

FROMBaseten (single-integer-expression, single-integer-expression)

Meaning:

FROMBaseten (positive_integer_to_convert, base_to_convert_to)

Returns:

 A single text item

FROMBaseten returns a text item that results from converting *positive_integer_to_convert* to a text item that can be interpreted as a number using positional notation of the base specified by *base_to_convert_to*.

If *base_to_convert_to* is less than 2 or greater than 36, **FROMBaseten** evaluates to "none". Resulting text item characters A-Z are interpreted as digits having decimal values from 10-35, respectively. The characters returned are uppercase.

Example

- **FROMBaseten** (18, 2)
Returns the value 10010
- **FROMBaseten** (123, 8)
Returns the value 173

Related function

- **TOBaseten**

INT

You can use the **INT** function when you need only the integer portion of a number.

Syntax:

INT (single-number-expression)

Meaning:

INT (number_to_convert)

Returns:

 A single integer

INT returns the integer portion of a number. The result is the integer part of *number_to_convert*. Any fractional part after the decimal point is dropped.

Examples

- **INT** (1.45)
Returns 1
- **INT** (3.6)
Returns 3
- **INT** (Purchase:Amt - Discount:Amt)
Subtracts **Discount:Amt** from **Purchase:Amt** and returns the result as a whole number.

Related functions

- **MOD**
- **ROUND**
- **TRUNCATE**

LOG

The **LOG** function calculates the logarithms of a value.

Syntax:

 mathlib->**LOG** (single-number-expression)

Meaning:

 mathlib->**LOG** (number_to_convert)

Returns:

 A single number item

LOG10

The LOG10 function calculates the logarithms for base 10 of a value.

Syntax:

```
mathlib->LOG10 (single-number-expression)
```

Meaning:

```
mathlib->LOG10 (number_to_convert)
```

Returns:

A single number item

MAX

The **MAX** function returns the maximum value from a series of number, date, time, or text values.

Syntax:

```
MAX (series-item-expression)
```

Meaning:

```
MAX (series_of_which_to_find_max)
```

Returns:

A single number

The result is the maximum value in the input argument series: number, text, or date/time.

Examples

- **MAX (UnitPrice:Input)**
If the values for **UnitPrice** are {20, 10, 100}, MAX returns 100.
- **MAX(EXTRACT(DueDate:Book:Library, CheckedOut:Book:Library = "Y"))**
Returns the maximum (latest) **DueDate** for a book that is checked out from the library.

Related functions

- MIN

MIN

Use MIN when you need the minimum value from a series of number, date, time, or text values.

The MIN function returns the minimum value from a series.

Syntax:

```
MIN (series-item-expression)
```

Meaning:

```
MIN (series_of_which_to_find_min)
```

Returns:

A single number

The result is the minimum value of the input series: number, text, or date/time.

Examples

- **MIN (UnitPrice:Input)**
If the values for **UnitPrice** are {20,10,100}, MIN returns 10.
- **MIN (StartTime:::Schedule)**
Returns the minimum (earliest) **StartTime** in **Schedule**.

Related functions

- MAX

MOD

Use MOD when you need the modulus of an integer and a number.

The MOD function returns the modulus that remains after a number is divided by an integer.

Syntax:
MOD (single-number-expression, single-integer-expression)

Meaning:
MOD (dividend , divisor)

Returns:
A single integer

The result is the remainder (modulus) after *dividend* is divided by *divisor*. The result has the same sign as *divisor*.

The *dividend* is first divided by the integer *divisor*, resulting in a quotient. The modulus is calculated by multiplying the integer portion of the quotient by *divisor* and then subtracting that product from *dividend*.

If *divisor* is 0, MOD returns "none".

Examples

- MOD (3, 2) or MOD (-3, 2)
Returns 1
 - MOD (3, -2) or MOD (-3, -2)
Returns -1
 - MOD (-3, 2) or MOD (-3, -2)
Returns 1
 - MOD (-3, -2) or MOD (-3, -2)
Returns -1
-

POWER

The POWER function calculates x raised to the power of y.

Syntax:
mathlib->POWER (single-number-expression, single-number-expression)

Meaning:
mathlib->POWER (base_number, exponent_number)

Returns:
A single number item

RAND

The RAND function returns a pseudorandom number.

Syntax:
RAND ()
Meaning:
RAND ()
Returns:
A single number item

RAND takes no parameters. If the SEED function is called prior to RAND, RAND will return the same value based on the value to SEED.

Related functions

- RANDDATA
 - SEED
-

ROUND

The **ROUND** function rounds a number to a specified number of decimal places. If the number of decimal places is not specified, the number is rounded to a whole number. The result is in character number format.

Syntax:
ROUND (single-number-expression [, single-integer-expression])
Meaning:
ROUND (number_to_round [, number_of_decimal_places])
Returns:
A single number

ROUND converts *number_to_round* to character format, if necessary, and then produces the value of *number_to_round* rounded to the number of decimal places specified by *number_of_decimal_places*. If *number_of_decimal_places* is not specified, *number_to_round* is rounded to the nearest whole number.

Examples

- **ROUND** (1.46, 1)
Returns 1.5
- **ROUND** (1.46)
Returns 1

Related functions

- TRUNCATE
-

SEED

The SEED function primes the RAND and RANDDATA functions so they produce repeated results.

Syntax:

SEED(*single-number-expression*)

Meaning:

SEED(*number_for_seed*)

Returns:

NONE

Related functions

- **RAND**
 - **RANDDATA**
-

SIN

The SIN function calculates the sine of a value.

Syntax:

mathlib->SIN (*single-number-expression*)

Meaning:

mathlib->SIN (*number_to_convert*)

Returns:

The value of a number

SINH

The SINH function calculates the hyperbolic sine of a value.

Syntax:

mathlib->SINH (*single-number-expression*)

Meaning:

mathlib->SINH (*number_to_convert*)

Returns:

A single number item

SQRT

The **SQRT** function returns the square root of a number.

Syntax:

SQRT (*single-number-expression*)

Meaning:

SQRT (*number*)

Returns:

A single number

SQRT returns the square root of *number*.

Examples

- **SQRT** (4)
Returns 2

SUM

The **SUM** function calculates the sum of a series of numbers.

Syntax:

SUM (series-number-expression)

Meaning:

SUM (series_to_sum)

Returns:

A single number

SUM returns the sum of all members in *series_to_sum*.

Examples

- **SUM** (Quantity:LineItem)

This example calculates the sum of all the **Quantity** objects of **LineItem**.

TAN

The TAN function calculates the tangent of a value.

Syntax:

mathlib->TAN (single-number-expression)

Meaning:

mathlib->TAN (number_to_convert)

Returns:

A single number item

TANH

The TANH function calculates the hyperbolic tangent of a value.

Syntax:

mathlib->TANH (single-number-expression)

Meaning:

mathlib->TANH (number_to_convert)

Returns:

A single number item

TOBASETEN

The **TOBASETEN** function converts a text item that can be interpreted as a number, using positional notation of the base specified, to a base 10 number.

Syntax:

TOBASETEN (single-text-expression, single-integer-expression)

Meaning:

TOBASETEN (text_to_convert, base_to_convert_from)

Returns:

A single integer

TOBASETEN returns a number that results from converting *text_to_convert* that can be interpreted as a number, using positional notation of the base specified by *base_to_convert_from*, to its base 10 representation. Text item characters A-Z are interpreted as digits having decimal values from 10-35, respectively.

If *base_to_convert_from* is less than 2 or greater than 36, **TOBASETEN** evaluates to "none". If *text_to_convert* contains a character that is not alphanumeric or is not in the range specified by *base_to_convert_from*, **TOBASETEN** returns "none".

Examples

- **TOBASETEN** ("A", 16)

Returns the value 10

- **TOBASETEN** ("10", 36)

Returns the value 36

- **TOBASETEN** ("A0", 15)

Returns the value 150

- **TOBASETEN** ("A0", 5)

Returns the value "none"

Related functions

- [FROMBASESETEN](#)

TRUNCATE

The **TRUNCATE** function removes decimal places from a number, leaving a specified number of decimal places.

You can use **TRUNCATE** with a second argument to truncate a number to a specified number of decimal places or without a second argument to reduce a number to an integer by removing all decimal places.

Syntax:

TRUNCATE (single-number-expression[, single-integer-expression])

Meaning:

TRUNCATE (number_to_truncate[, number_of_decimal_places])

Returns:

A single number

TRUNCATE first converts *number_to_truncate* to character format, if necessary. It then truncates that number by removing decimal places to the right of *number_of_decimal_places*. If *number_of_decimal_places* is not used, the number is truncated to an integer.

Examples

- **TRUNCATE** (3.9292, 2)
Returns 3.92
- **TRUNCATE** (3.9292)
Returns 3

The **REGEXMATCH** function tests whether a piece of text matches the regular expression.

- [REGEXPARSE](#)

The **REGEXPARSE** function breaks a text based on regular expression into its capture groups, delimiting them using the provided delimiter.

- [REGEXPOSITION](#)

The **REGEXPOSITION** function returns the first position of a match of the regular expression in the text.

- [REGEXREPLACE](#)

The **REGEXREPLACE** function replaces the first occurrence of the regular expression with the replacement text in the input text.

- [REGEXREPLACEALL](#)

The **REGEXREPLACEALL** function replaces all occurrences of the regular expression with the replacement text in the input text.

- [RANDDATA](#)

The **RANDDATA** function returns random text based on the properties of the output type. The **RAND** function returns a pseudo-random integer between 0 and RAND_MAX (guaranteed to be at least 32,767). The **RANDDATA** function generates a valid random value of the item type that is being built when it is invoked. In

other words, if the rule were "A:Card = RandData()", the random value would be valid data for type "A"—where that type "A" is a component of the specified "Card". The type "A" can be text, a date/time object, or a number.

BCDTOTEXT

The **BCDTOTEXT** function converts the digits in a BCD (Binary Coded Decimal) item to a text item containing the digits of the BCD-encoded item as a string of characters.

Syntax:

BCDTOTEXT (single-text-expression)

Meaning:

BCDTOTEXT (BCD_item_to_convert)

Returns:

A single text item

BCD_item_to_convert is converted from BCD format to a text string containing the digits of the BCD-encoded value as a string of characters.

Numbers in BCD format have two decimal digits in each byte. Each half-byte, therefore, can contain a binary value from 0000 (which represents the digit 0) through 1001, which represents the digit 9). Based on this definition, the following behavior applies:

- If any half-byte of the BCD number contains the binary value 1101 or 1111, that half-byte is ignored.
- If the BCD item contains the binary value 1010, 1011, 1100, or 1110, the output of the function is "none".

Examples

- **BCDTOTEXT** (Qty:Item)
If **Qty** is x'1234', the result is 1234.
- **BCDTOTEXT** (DiscountAmt)
If **DiscountAmt** is x'0123', the result is 0123.
- **BCDTOTEXT** (TotalDollars)
If **Total** is x'F123', the result is 123.

Related functions

- [BCDTOHEX](#)
 - [BCDToInt](#)
 - [TEXTTOBCD](#)
-

COUNTSTRING

You can use the **COUNTSTRING** function when you need to know the number of times a specific text string appears within another text string. The function begins to look for the character string from the first position of the first string, and proceeds forward one byte at a time.

Syntax:

COUNTSTRING (single-text-expression , single-text-expression)

Meaning:

COUNTSTRING (text_to_search , text_to_find_and_count)

Returns:

A single-integer

COUNTSTRING returns an integer that represents the number of times that a specified character string appears in another character string.

The result is a number representing the number of times *text_to_find_and_count* appears within *text_to_search*. If either *text_to_search* or *text_to_find_and_count* evaluates to "none", COUNTSTRING returns 0.

Examples

- **COUNTSTRING** ("banana" , "a")
Returns a value of 3.
- **COUNTSTRING** ("aaaa" , "aa")
Returns a value of 3.

Related functions

- FIND
- LEFT
- MID
- RIGHT

CPACKAGE

CPACKAGE specifies the character set of the output of the function. From that point onward, the data is treated as if it were in that character set. If the data is not in the specified character set, you get the wrong answer.

The character set is required to be specified in this function. If you choose not to specify a character set, you should use the original version of the PACKAGE function.

Syntax:

CPACKAGE (single-object-expression , "character-set-of-object-content")

Meaning:

CPACKAGE (object_to_convert, object_character_set)

Returns:

A single text item

The second argument, *object_character_set*, represents the character set of the resulting object. Character set codes are listed in [Character set codes](#).

Examples

In this example, the group **Record** has an initiator of "#", a terminator of "@" and a delimiter of ";" with the following data:

"#1339X10A,491.38,Green,42x54@"

- **CPACKAGE** (Record:Card, "ASCII")
Returns: #1339X10A,491.38,Green,42x54@

CSERIESTOTEXT

CSERIESTOTEXT specifies the character set of the output of the function. From that point onward, the data is treated as if it were in that character set. If the data is not in the specified character set, you get the wrong answer.

The character set is required to be specified in this function. If you choose not to specify a character set, you should use the original version of the SERIESTOTEXT function.

Syntax:

CSERIESTOTEXT (series-object-expression , "character-set-of-object-content")

Meaning:

CSERIESTOTEXT (series_to_convert, object_character_set)

Returns:

A single text item

The *series_to_convert* argument concatenates the series of the input argument, including nested delimiters but excluding initiators and terminators.

The second argument, *object_character_set*, represents the character set of the resulting object.

Examples

In this example, you have the following data that represents bowler information for a bowling league:

Andrews, Jessica:980206:JBC:145:138:177:159

Little, Randy:980116:BBK:175:168

Wayne, Richard:980102:JBC:185:204:179:164:212

Each record consists of the bowler's name, the date of their last game played, a team code and one or more bowling scores. **Record** is defined as a group that is infix delimited by a colon.

Using the following rule produces results of the concatenation of all scores for all of the bowlers, even though the scores are not all contiguous within the data.

- = **CSERIESTOTEXT** (Score Field:Bowler:Input, "ASCII")
Returns: 145138177159175168185204179164212

You can change the rule to concatenate the list of scores to the bowler's name using the following rule:

- = BowlerName Field:Bowler:Input + " ->" +
CSERIESTOTEXT (Score Field:Bowler:Input, "ASCII")

Returns:

Andrews, Jessica -> 145138177159

Little, Randy -> 175168

Wayne, Richard -> 185204179164212

In this example, you have an input number that is of variable size, followed by a name. There is no syntax that separates the number from the name. You can define the number as a group with **Byte(s)** as a component and provide a component rule for **Byte(s)**, such as:

ISNUMBER (\$)

CSIZE

The **CSIZE** function returns an integer representing the size of a specified object in characters, exclusive of any pad characters.

Syntax:

CSIZE (single object expression)

Meaning:

CSIZE (object whose size is needed)

Returns:

A single integer

Example

This example shows how the CSIZE function differs from the SIZE function.

The SIZE function returns the number of bytes used to represent those symbolic characters in a particular code page.

The CSIZE function returns the number of symbolic characters.

Symbolic text: Mañana

UTF-8 hexadecimal representation : 0x4D 0x61 0xC3 0xA3 0x61 0x6E 0x61

SIZE (Mañana)

Returns 7 bytes

CSIZE (Mañana)

Returns 6 characters

CTEXT

CTEXT specifies the character set of the output of the function. From that point onward, the data is treated as if it were in that character set. If the data is not in the specified character set, you get the wrong answer.

The character set is required to be specified in this function. If you choose not to specify a character set, you should use the original version of the TEXT function.

Syntax:

CTEXT (single-object-expression , "character-set-of-object-content")

Meaning:

CTEXT (object_to_convert , object_character_set)

Returns:

A single text item

The first argument, *object_to_convert*, represents the object that is converted to a text item, excluding the initiator and terminator of the input object.

The second argument, *object_character_set*, represents the character set of the resulting object.

Example

In this example, the group **Record** has an initiator of the pound sign (#), a terminator of the at sign (@), and a delimiter of a comma (,), and uses the following data:

#1339X10A,491.38,Green,42x54@

- **CTEXT** (Record:card, "ASCII")
Returns: 1339X10A,491.38,Green,42x54

The initiator and terminator are not included because only the content of the object is converted to text.

DATETOTEXT

The **DATETOTEXT** function converts a date object or expression to a text item.

Syntax:

DATETOTEXT (single-date-expression)

Meaning:

DATETOTEXT (date_to_convert)

Returns:

A single text item

If *date_to_convert* is a date object name, this returns the date as a text item formatted according to the presentation of the date object.

If *date_to_convert* is a date expression produced by a function, this returns the date as a text item formatted according to the presentation of the output argument of that function.

Examples

- **DATETOTEXT** (ShipDate)

In this example, **ShipDate** is converted from a date to text. If **ShipDate** has a CCYYMMDD presentation, the resulting text item will have that presentation, as well.

- **DATETOTEXT** (**CURRENTDATETIME** ("{MM/DD/CCYY}"))

In this example, **CURRENTDATETIME** evaluates and returns a date in MM/DD/CCYY format. Then **DATETOTEXT** evaluates and returns a text string that is that date in MM/DD/CCYY format.

For example, use **DATETOTEXT**, to do text concatenation. The **FROMDATETIME** function provides greater flexibility in specifying the format of the resulting text item.

Related Functions

- **FROMDATETIME**
 - **NUMBERTOTEXT**
 - **TEXT**
 - **TEXTTODATE**
 - **TEXTTONUMBER**
 - **TEXTTOTIME**
 - **TIMETOTEXT**
 - **TODATETIME**
-

FILLELEFT

The **FILLELEFT** function returns a text item of the length specified. In the output, the text item is preceded with the specified pad value.

You can use **FILLELEFT** when you have a value that needs to be of a fixed size with a variable number of leading characters with a specified value.

Syntax:

FILLELEFT (single-text-expression , single-text-expression , single-integer-expression)

Meaning:

FILLELEFT (text_to_fill , pad_character , pad_to_length)

Returns:

A single text item

The **FILLELEFT** function returns the text string that results from padding out *text_to_fill* by preceding it with the *pad_character* up to *pad_to_length* bytes.

If the *pad-length* argument is less than the number of bytes in the text to fill, no padding will appear.

Examples

- **FILLELEFT** (AcctID:Transaction , "0" , 5)

If **AcctID** has the value 14, **FILLELEFT** returns 00014

- **FILLELEFT** (**NUMBERTOTEXT** (InvoiceAmt) , "*" , 10)

If **InvoiceAmt** has the value 24.75, **FILLELEFT** returns ****24.75

Related functions

 - **LEAVEALPHA**
 - **LEAVEALPHANUM**
 - **LEAVENUM**
 - **LEAVEPRINT**
 - **SQUEEZE**
 - **SUBSTITUTE**
 - **TRIMLEFT**
 - **TRIMRIGHT**
-

FILLRIGHT

The **FILLRIGHT** function returns a text item of the length specified. In the output, the text item is appended with the specified pad value.

You can use **FILLRIGHT** when you have a value that needs to be of a fixed size with a variable number of trailing characters of a specified value.

Syntax:

FILLRIGHT (single-text-expression , single-text-expression , single-integer-expression)

Meaning:

FILLRIGHT (text_to_fill , pad_character , pad_to_length)

Returns:

A single text item

FILLRIGHT returns the text string that results from padding out *text_to_fill* by appending the *pad_character* up to *pad_to_length* bytes.

If the *pad-length* argument is less than the number of bytes in the text to fill, no padding will appear.

Examples

- **FILLRIGHT** (LastName>Contact, " ", 25)

If *Lastname* has the value Peterson, **FILLRIGHT** returns Peterson followed by 17 spaces.

Related functions

- **FILLEFT**
- **LEAVEALPHA**
- **LEAVEALPHANUM**

- **LEAVEPRINT**
- **SQUEEZE**
- **SUBSTITUTE**
- **TRIMLEFT**
- **TRIMRIGHT**

FIND

The **FIND** function looks for one text string within another text string and returns to its starting position, if found.

Syntax:

FIND (single-text-expression , single-text-expression
[, single-number-expression])

Meaning:

FIND (text_to_find, where_to_look[, position_to_start_the_search])

Returns:

A single integer

FIND returns the starting position of the text item specified by *text_to_find* within the text item specified by *where_to_look*. A third argument (*position_to_start_the_search*) can be used to specify the location in *where_to_look* for the **FIND** to begin. Bytes in the text are numbered from left to right, with the leftmost byte being position 1.

If *text_to_find* is "none", **FIND** evaluates to "none".

If a third argument is not used or *position_to_start_the_search* evaluates to a negative number, it is assumed to be 1. If *position_to_start_the_search* evaluates to a number greater than the size of *where_to_look*, **FIND** evaluates to "none".

If *text_to_find* is not found in the *where_to_look* string, **FIND** evaluates to 0.

Examples

- **FIND** ("id", "Florida")
Returns the value 5
- **FIND** ("id", "Florida", 8)
Returns 0 because the 8 (*position_to_start_the_search*) is greater than the size of *where_to_look*
- **FIND** ("\", "mypath",2)
Returns 0 because the string "\" was not found in argument 2

Related functions

- **LEFT**
- **MID**
- **RIGHT**

HEXTXTTOSTREAM

HEXTXTTOSTREAM is the reverse of **STREAMTOHEXTXT**. You can use the **HEXTXTTOSTREAM** function to assign a binary text value to a character text item represented by hexadecimal pairs.

HEXTXTTOSTREAM returns a binary text stream whose value is the evaluation of input character text represented by hexadecimal pairs.

Syntax:

HEXTEXTTOSTREAM (single-text-expression)

Meaning:

HEXTEXTTOSTREAM (series_of_hex_pairs)

Returns:

A single byte stream item

This function returns a binary text stream item whose value is the evaluation of input character text in *series_of_hex_pairs*, ignoring <WSP> characters between the hexadecimal pairs. White space characters include space, horizontal tab, carriage return, and line feed characters.

Input formats

The following table shows an example of input in its character text representation as viewed through the character editor, and in its ASCII code representation (binary text stream) as viewed through the hex editor. Each pair of binary text in the hex view represents one character in the character view of the character text.

Input ("41 42 43 44")	Editor View	Value
Character text (hex pairs)	Character	"41 42 43 44"
ASCII code representation (binary text stream)	Hex	0x3431203432203433203434

Examples

- **HEXTEXTTOSTREAM** ("41 42 43 44")
Returns the evaluated value of the input (ASCII) character text string "41 42 43 44" as the output (ASCII) character text string "ABCD" as viewed in the character editor. (The hex view of the input is 0x3431203432203433203434. The hex view of the output is 0x41424344.)
- **HEXTEXTTOSTREAM** ("0D 0A 00")
Returns the evaluated value of the input (ASCII) character text string "0D 0A 00" as the output (ASCII) character text string "<CR><LF><NULL>" as viewed in the character editor. (The hex view of the input is 0x3044203041203030. The hex view of the output is 0xD0A00.)

See Design Studio Introduction documentation for a list of special symbols.

LEAVEALPHA

The **LEAVEALPHA** function removes all non-alphabetic characters from a specified text item.

You can use **LEAVEALPHA** to remove non-alphabetic characters such as symbols or numbers from a text item.

Syntax:

LEAVEALPHA (single-text-expression)

Meaning:

LEAVEALPHA (*text_to_change*)

Returns:

A single text item

LEAVEALPHA returns a string containing only the alphabetic characters (for example, A-Z and a-z) in *text_to_change*.

Examples

- **LEAVEALPHA** ("A-b-C-1\$3")
Returns: AbC

Related functions

- **ISALPHA**
- **ISLOWER**

- **LEAVEALPHANUM**
- **LEAVENUM**
- **LEAVEPRINT**

LEAVEALPHANUM

The **LEAVEALPHANUM** function removes all non-alphanumeric characters (such as symbols) from a specified text item.

Syntax:

LEAVEALPHANUM (single-text-expression)

Meaning:

LEAVEALPHANUM (*text_to_change*)

Returns:

A single text item

LEAVEALPHANUM returns a string containing only the alphanumeric characters (for example, A-Z, a-z and 0-9) in *text_to_change*.

Examples

- **LEAVEALPHANUM** ("A-b-C-1\$3")

Returns: AbC13

Related functions

• ISALPHA	• LEAVEALPHA
• ISLOWER	• LEAVENUM
• ISNUMBER	• LEAVEPRINT
• ISUPPER	

LEAVENUM

The **LEAVENUM** function removes all non-numeric characters from a text item. For example, you can use **LEAVENUM** when you want to remove all alphabetic characters and symbols from a text string.

Syntax:

LEAVENUM (*single-text-expression*)

Meaning:

LEAVENUM (*text_to_change*)

Returns:

A single text item

LEAVENUM returns a string containing only the numeric characters (for example, 0-9) in *text_to_change*.

Examples

- **LEAVENUM** ("A-b-C-1\$3")

Returns: 13

Related functions

• ISALPHA	• LEAVEALPHA
• ISLOWER	• LEAVEALPHANUM

LEAVEPRINT

The **LEAVEPRINT** function removes all non-printable characters from a text item.

Syntax:

LEAVEPRINT (*single-text-expression*)

Meaning:

LEAVEPRINT (*text_to_change*)

Returns:

A single text item

LEAVEPRINT returns a string containing only printable characters in *text_to_change*.

Examples

- **LEAVEPRINT** ("A-b<SP>C-1\$3<CR><LF>")

Returns: A-b C-1\$3

Related functions

• ISALPHA	• LEAVEALPHA
• ISLOWER	• LEAVEALPHANUM

LEFT

The **LEFT** function returns a specified number of characters from a text expression beginning with the leftmost byte of a text item.

You can use **LEFT** when you need a specific part of a text item. For example, a customer number might have several uses and sometimes only the first 10 characters are needed. Therefore, **LEFT** can be used to return only the leftmost 10 characters.

Syntax:

LEFT (single-text-expression , single-integer-expression)

Meaning:

LEFT (text_to_extract_from , number_of_characters_to_extract)

Returns:

A single text item

LEFT returns the leftmost *number_of_characters_to_extract* characters from *text_to_extract_from* starting at the first (the leftmost) character in *text_to_extract_from*.

If *number_of_characters_to_extract* evaluates to an integer whose value is less than 1, **LEFT** evaluates to "none". If *number_of_characters_to_extract* evaluates to an integer whose value is greater than the size of *text_to_extract_from*, **LEFT** evaluates to the entire value of *text_to_extract_from*.

Examples

- **LEFT** ("Abcd", 2)
Returns Ab
- **LEFT** ("Abcd", 6)
Returns Abcd
- **LEFT** (LastName + " " + FirstName, 25)
Returns the leftmost 25 characters of the text string resulting from the concatenation of **LastName** and **FirstName** (separated by a comma and a space).

Related functions

- **RIGHT**
- **MID**
- **FIND**

LOWERCASE

The **LOWERCASE** function converts an alphabetic text item to all lowercase characters.

Syntax:

LOWERCASE (single-text-expression)

Meaning:

LOWERCASE (text_to_convert)

Returns:

A single text item

LOWERCASE produces a text item in which each byte from the input has been converted to lowercase. Any numeric or symbol characters in the text item remain unchanged.

Examples

- **LOWERCASE** ("A1b2C!")
Returns: a1b2c!

Related functions

- **ISLOWER**
- **ISUPPER**
- **UPPERCASE**

MAX

The **MAX** function returns the maximum value from a series of number, date, time, or text values.

Syntax:

MAX (series-item-expression)

Meaning:

MAX (series_of_which_to_find_max)

Returns:

A single number

The result is the maximum value in the input argument series: number, text, or date/time.

Examples

- **MAX** (UnitPrice:Input)
If the values for **UnitPrice** are {20, 10, 100}, MAX returns 100.
- **MAX(EXTRACT**(DueDate:Book:Library, CheckedOut:Book:Library = "Y"))
Returns the maximum (latest) **DueDate** for a book that is checked out from the library.

Related functions

- **MIN**

MID

You can use the **MID** function when you need specific characters from a text item. **MID** returns one or more characters from a text item.

Syntax:

MID (single-text-expression, single-number-expression,
single-number-expression)

Meaning:

MID (source_text, position_to_start_the_search, number_of_characters)

Returns:

A single text item

MID extracts one or more characters from *source_text* where *position_to_start_the_search* is the position of the first character to extract and *number_of_characters* specifies the number of characters to extract. The first character (leftmost) of *source_text* has a starting position of 1.

If *position_to_start_the_search* is greater than the length of *source_text*, **MID** returns "none". If *position_to_start_the_search* or *number_of_characters* is less than one, **MID** returns "none". If the rightmost number of characters of *source_text*, starting at *position_to_start_the_search*, is less than *number_of_characters*, **MID** returns the rightmost characters starting at the position specified in *position_to_start_the_search*.

Examples

- **MID** ("abc123", 5, 3)
Returns 23
- **MID** ("abc123", 7, 1)
Returns "none" because argument2 is larger than the number of characters in argument1
- **MID** ("abc123", -1, 3)
Returns "none" because argument2 is a negative number
- **MID** ("abc123", 2, -2)
Returns "none" because argument3 is a negative number

Related functions

- **FIND**
- **LEFT**
- **RIGHT**

MIN

Use MIN when you need the minimum value from a series of number, date, time, or text values.

The MIN function returns the minimum value from a series.

Syntax:

MIN (series-item-expression)

Meaning:

MIN (series_of_which_to_find_min)

Returns:

A single number

The result is the minimum value of the input series: number, text, or date/time.

Examples

- MIN (UnitPrice:Input)
If the values for **UnitPrice** are {20,10,100}, MIN returns 10.
- MIN (StartTime::Schedule)
Returns the minimum (earliest) **StartTime** in **Schedule**.

Related functions

- MAX

NORMXML

Use this function to remove XML formatting from an input XML fragment. The function accepts text items only.

Syntax:

NORMXML (single-text-expression)

Meaning:

NORMXML (XML fragment)

Returns:

A single text item

This function removes any XML whitespaces from between a (parent) start tag and the start tag of the first child element; and from between the end tag of the child element and the (parent) end tag. *XML whitespace* pertains to carriage returns, line feeds, tabs, and spaces.

For example, all carriage returns, line feeds, tabs, and spaces in between parent tags `<A>` and `` are removed, excluding any that are inside of child element tags `<a>` and ``.

In the following example, there is a carriage return after `<A>`, ``, and ``. There are also three spaces before `<a>` and three spaces before ``.

```
<A>
  <a>This is sample text</a>
  <b>More   sample text</b>
</A>
```

The **NORMXML** function removes the three carriage returns and the six spaces. As a result, there is one line instead of four lines:

```
<A><a>This is sample text</a><b>More   sample text</b></A>
```

Limitation

When a type has mixed content, the function removes any XML whitespaces from the character data sections. Here is the previous example, but with mixed content added:

```
<A>My first example
  <a>This is sample text</a>
  <b>More   sample text</b>
</A>
```

This is the result of using the **NORMXML** function:

```
<A>Myfirstexample<a>This is sample text</a><b>More   sample text</b></A>
```

The XML whitespaces in **My first example** are removed because they are not enclosed within child element tags.

Using SIZE with NORMXML

The **NORMXML** function converts the input data to Unicode, and then removes the XML formatting from the input XML fragment. The conversion to Unicode is transparent because the normal processing automatically converts the data from Unicode to the character set that was assigned to the output object.

If the **SIZE** function is used with the **NORMXML** function to determine the size of the specified object after **NORMXML** removes the XML formatting from the input XML fragment, the **SIZE** operation calculates the size of the data as it exists at that time, in the Unicode character set. The returned size does not match the size that would have been calculated if the data remained in its original character set, unless the original character set was Unicode.

Using CSIZE with NORMXML

If the **CSIZE** function is used with the **NORMXML** function, the **CSIZE** operation returns the size in characters, regardless of the character set.

NUMBERTOTEXT

The **NUMBERTOTEXT** function converts a character number to a text item that looks like the original object.

You can use **NUMBERTOTEXT** when you need an object that is defined as a number converted to an object defined as text. This is useful when you need to concatenate text, however, the **FROMNUMBER** function provides greater flexibility in specifying the format of the resulting text item.

Syntax:

NUMBERTOTEXT (single-number-expression)

Meaning:

NUMBERTOTEXT (number_to_convert)

Returns:

A single text item

The resulting text looks like the input argument. The result is truncated, if necessary.

Examples

- **NUMBERTOTEXT** (ROUND (1000 - 24.75, 3))

This example converts the result of the calculation (rounded to 3 decimal places) to text, resulting in 975.250.

- **NUMBERTOTEXT** (PurchaseNumber)

This example converts **PurchaseNumber** from a number to text.

Related functions

- **FROMNUMBER**
 - **TEXTTONUMBER**
 - **TODATETIME**
 - **TONUMBER**
-

PACKAGE

The **PACKAGE** function converts a group or item object to a text item, including its initiator, terminator, and any delimiters it contains.

Syntax:

PACKAGE (single-object-expression)

Meaning:

PACKAGE (object_to_convert)

Returns:

A single text item

The **PACKAGE** function converts *object_to_convert*, which must be a type reference to a text item, including the type reference's initiator, terminator, and all delimiters. **PACKAGE** differs from **TEXT** in that it includes the initiator and terminator of the specified type reference.

Examples

- **PACKAGE** (Record:Card)

Returns: #1339X10A,491.38,Green,42x54@

For this example, the group **Record** has an initiator of "#", a terminator of "@" and a delimiter of ",". The data looks like this: "#1339X10A,491.38,Green,42x54@".

Related functions

- **DATETOTEXT**
- **NUMBERTOTEXT**
- **SERIESTOTEXT**
- **TIMETOTEXT**
- **TEXT**

PACKAGE differs from **TEXT** because it includes the initiator and terminator of the input object.

JSON native schema package

JSON schema fields with _V following the name and fields starting with oneOf, allOf and anyOf are the virtual fields.

Virtual JSON fields do not appear in the data and have no syntax. Syntax is controlled by real fields above these virtual fields.

Real fields are fields that appear in the JSON data.

Using a virtual field in a package command will give incomplete syntax. Use a real field either above or below the virtual fields for complete syntax.

PROPERCASE

Use **PROPERCASE** to convert the first alphabetic character in each word to uppercase and all remaining characters to lowercase.

Syntax:

PROPERCASE (single-text-item-expression)

Meaning:

PROPERCASE (text_item_to_convert)

Returns:

A single text item

The **PROPERCASE** function views the text string as containing a series of "words" where the delimiter between words is the space character. For each "word" in *text_item_to_convert*, **PROPERCASE** converts the first alphabetic character (for example, A-Z and a-z) found to uppercase and all other characters are converted to lowercase.

Example

PROPERCASE ("sally jo BRADLEY")

Returns: Sally Jo Bradley

Related functions

- **ISALPHA**
 - **ISLOWER**
 - **ISUPPER**
 - **LOWERCASE**
 - **UPPERCASE**
-

REGEXMATCH

The **REGEXMATCH** function tests whether a piece of text matches the regular expression.

Syntax:

REGEXMATCH (single-text-expression, single-text-expression)

Meaning:

REGEXMATCH (input_text, regular_expression)

Returns:

A single boolean

Examples

- **REGEXMATCH** ("abcdXYZ", "([a-zA-Z]+)")
Returns: True
 - **REGEXMATCH** ("ABCDXYZ", "([0-9]+)")
Returns: False
-

REGEXPARSE

The **REGEXPARSE** function breaks a text based on regular expression into its capture groups, delimiting them using the provided delimiter.

Syntax:

REGEXPARSE (single-text-expression, single-text-expression, single-text-expression)

Meaning:

REGEXPARSE (input_text, regular_expression, delimiter)

Returns:

A single text item

Examples

- **REGEXPARSE** ("44034AAA",
"^(4)([0-9] | [aAbBcC])\s*([0-9]{2})\s?(?:[A-Z]{3})\$", " | ")
Returns: 44|0|34
 - **REGEXPARSE** ("1011XYZ",
"^(10)([0-9] | [aAbBcC])\s*([0-9]{1})\s?(?:[A-Z]{3})\$", ".")
Returns: 10.1.1
-

REGEXPOSITION

The **REGEXPOSITION** function returns the first position of a match of the regular expression in the text.

Syntax:

REGEXPOSITION (single-text-expression, single-text-expression)

Meaning:

REGEXPOSITION (input_text, regular_expression)

Returns:
A single integer

Examples

- **REGEXPOSITION** ("ABC6EF", "(\d+)")
Returns: 4
 - **REGEXPOSITION** ("1234A3456", "(A-Z)+")
Returns: 5
-

REGEXREPLACE

The **REGEXREPLACE** function replaces the first occurrence of the regular expression with the replacement text in the input text.

Syntax:
REGEXREPLACE (single-text-expression, single-text-expression, single-text-expression)
Meaning:
REGEXREPLACE (input_text, regular_expression, replacement_text)
Returns:
A single text item

Examples

- **REGEXREPLACE** ("ABC 7 DEF 8 GHI", "\d+", "###")
Returns: ABC ### DEF 8 GHI
 - **REGEXREPLACE** ("ABC_DEF_GHI", "_", " ")
Returns: ABC DEF_GHI
-

REGEXREPLACEALL

The **REGEXREPLACEALL** function replaces all occurrences of the regular expression with the replacement text in the input text.

Syntax:
REGEXREPLACEALL (single-text-expression, single-text-expression, single-text-expression)
Meaning:
REGEXREPLACEALL (input_text, regular_expression, replacement_text)
Returns:
A single text item

Examples

- **REGEXREPLACEALL** ("ABC 7 DEF 8 GHI", "\d+", "###")
Returns: ABC ### DEF ### GHI
 - **REGEXREPLACEALL** ("10 1 1 1", " ", ".")
Returns: 10.1.1.1
-

RANDDATA

The **RANDDATA** function returns random text based on the properties of the output type. The **RAND** function returns a pseudo-random integer between 0 and RAND_MAX (guaranteed to be at least 32,767). The **RANDDATA** function generates a valid random value of the item type that is being built when it is invoked. In other words, if the rule were "A:Card = RandData()", the random value would be valid data for type "A"—where that type "A" is a component of the specified "Card". The type "A" can be text, a date/time object, or a number.

Syntax:
RANDDATA ()
Meaning:
RANDDATA ()
Returns:
A single object (text, a date/time object, or a number)

RANDDATA takes no parameters. If the SEED function is called prior to RANDDATA, RANDDATA will return the same value for the same item properties it is returning to, based on the value to SEED.

Related functions

- **RAND**
- **SEED**

REVERSEBYTE

Use the **REVERSEBYTE** function when you need the bytes in the opposite sequence. **REVERSEBYTE** reverses the byte order of an item.

Syntax:

REVERSEBYTE (single-item-expression)

Meaning:

REVERSEBYTE (item_to_reverse)

Returns:

A single item

This function reverses the byte order of *item_to_reverse*.

Examples

- **REVERSEBYTE** ("HI MOM!")

Returns "IMOM IH"

- **RIGHT** (FullName, FIND(" ", **REVERSEBYTE** (FullName)) - 1)

If **FullName** is "Alyce N. Wunderland", the above example uses **REVERSEBYTE** to reverse the characters in **FullName** (resulting in "dnalrednuW .N ecylA"). Then, the **FIND** function is evaluated to locate the first space in the resultant string (between the "W" and the ".") that would result in a value of 11. Finally, the **RIGHT** function is evaluated to take the rightmost 10 (11-1) characters of **FullName**; providing the final result of "Wunderland".

Note: The examples are used for illustration only. Do not use this function with string literals.

RIGHT

You can use **RIGHT** when you need a specific part of a text item. For example, a customer number might have several uses and sometimes only the last three characters are needed. **RIGHT** can be used to return only the rightmost three characters.

The **RIGHT** function returns a specified number of characters from a text expression beginning with the rightmost byte of a text item.

Syntax:

RIGHT (single-text-expression , single-integer-expression)

Meaning:

RIGHT (text_to_extract_from , number_of_characters_to_extract)

Returns:

A single text item

RIGHT returns the rightmost *number_of_characters_to_extract* characters from *text_to_extract_from* starting at the last (the rightmost) character in *text_to_extract_from*.

If *number_of_characters_to_extract* evaluates to an integer whose value is less than 1, **RIGHT** evaluates to "none". If *number_of_characters_to_extract* evaluates to an integer whose value is greater than the size of *text_to_extract_from*, **RIGHT** evaluates to the entire value of *text_to_extract_from*.

Examples

- **RIGHT** ("Abcd" , 2)

Returns cd

- **RIGHT** ("Abcd" , 6)

Returns Abcd

- **RIGHT** ("000000" + **NUMBERTOTEXT** (TransactionNum) , 6)

If **TransactionNum** contains 123, this example returns 000123. If **TransactionNum** contains 123456789, this example returns 456789.

Related functions

- **FIND**
- **LEFT**
- **MID**

SEED

The **SEED** function primes the **RAND** and **RANDDATA** functions so they produce repeated results.

Syntax:

SEED(single-number-expression)

Meaning:

SEED(number_for_seed)

Returns:

NONE

Related functions

- **RAND**
- **RANDDATA**

SERIESTOTEXT

You can use the **SERIESTOTEXT** function to project your input data as a series and to interpret it as a text item for output.

SERIESTOTEXT converts a contiguous or non-contiguous series to a text item.

Syntax:

SERIESTOTEXT (series-object-expression)

Meaning:

SERIESTOTEXT (series_to_convert)

Returns:

A single text item

SERIESTOTEXT returns a text item containing the concatenation of the series of the input argument, including nested delimiters but excluding initiators and terminators.

Examples

In this example, you have the following data that represents bowler information for a bowling league:

Andrews, Jessica:980206:JBC:145:138:177:159

Little, Randy:980116:BBK:175:168

Wayne, Richard:980102:JBC:185:204:179:164:212

Each record consists of the bowler's name, the date of their last game played, a team code and one or more bowling scores. **Record** is defined as a group that is infix-delimited by a colon.

Using the rule:

= **SERIESTOTEXT** (Score Field:Bowler:Input)

the following results are produced, which is the concatenation of all of the scores for all of the bowlers, even though the scores are not all contiguous within the data:

145138177159175168185204179164212

However, if the rule was changed, for instance, to concatenate the list of scores to the bowler's name:

= BowlerName Field:Bowler:Input + "-" +
SERIESTOTEXT (Score Field:Bowler:Input)

the following output would be produced:

Andrews, Jessica -> 145138177159

Little, Randy -> 175168

Wayne, Richard -> 185204179164212

In this example, you have an input number that is of variable size, followed by a name. There is no syntax that separates the number from the name. You can define the number as a group with **Byte(s)** as a component and provide a component rule for **Byte(s)**, such as:

ISNUMBER (\$)

Related functions

- **PACKAGE**
- **TEXT**

SQUEEZE

The **SQUEEZE** function removes consecutive duplicate occurrences of a specified character or characters from a text item.

Syntax:

SQUEEZE (single-text-item , single-text-item)

Meaning:

SQUEEZE (text_to_squeeze , duplicate_characters_to_remove)

Returns:

A single text item

SQUEEZE returns a text item with all the consecutive duplicates of *duplicate_characters_to_remove* removed from *text_to_squeeze*.

Examples

- **SQUEEZE** ("AB CDE F", " ")
Returns: AB CDE F
- **SQUEEZE** ("Connolly", "n")
Returns: Conolly

Related functions

- LEAVEALPHA
- LEAVEALPHANUM
- LEAVENUM
- LEAVEPRINT
- SUBSTITUTE

SUBSTITUTE

You can use the **SUBSTITUTE** function to replace or remove a character. You can also use this function for multiple pairs.

Syntax:

SUBSTITUTE (single-text-expression { , single-text-expression , single-text-expression })

Meaning:

SUBSTITUTE (item_to_convert, one-or-more-text-substitution-pairs)

Where each one-or-more-text substitution-pair is

text_to_change , substitute_text

Returns:

A single text item

SUBSTITUTE returns the text string that results from replacing all instances of the first *text_to_change* with *substitute_text* in *item_to_convert*, then replaces all instances of the second *text_to_change* with the *substitute_text* in the result of the first substitution, and so forth.

Examples

- **SUBSTITUTE** ("123*456*7" , "*" , "/")
Finds 123*456*7 and returns 123/456/7
- **SUBSTITUTE** ("120-45-6789" , "-" , "")
Finds 120-45-6789 and returns 120456789
- **=SUBSTITUTE** ("ABBA" , "B" , "A" , "A" , "B")
This example illustrates multiple searches for the **SUBSTITUTE** function.

The first search-and-replace finds all "B"s and returns "A"s: AAAA

The next search-and-replace finds all "A"s and returns "B"s: BBBB

The end result is a return of: BBBB

Related functions

- LEAVEALPHA
- LEAVEALPHANUM
- LEAVENUM
- LEAVEPRINT
- SQUEEZE

TEXT

You can use the **TEXT** function to convert an object to a text item or when echoing entire data objects to another map.

TEXT converts the content of a group or item object to a text item.

Syntax:

TEXT (single-object-expression)

Meaning:

TEXT (object_to_convert)

Returns:

A single text item

The **TEXT** function converts *object_to_convert* to a text-item, excluding the initiator and terminator of the input object.

Examples

- **TEXT** (Record:card)

Data: #1339X10A,491.38,Green,42x54@

Returns: 1339X10A,491.38,Green,42x54

In this example, the group **Record** has an initiator of the pound sign (#), a terminator of the at-sign (@), and a delimiter of a comma (,).

The initiator and terminator are not included because only the content of the object is converted to text.

Related functions

- **DATETOTEXT**
 - **FROMDATETIME**
 - **FROMNUMBER**
 - **NUMBERTOTEXT**
 - **PACKAGE**
Note: **TEXT** differs from **PACKAGE** in that it does not include the initiator and terminator of the input object.
 - **SERIESTOTEXT**
 - **TIMETOTEXT**
-

TEXTTOBCD

The **TEXTTOBCD** function converts a text item from decimal digits to BCD (Binary Coded Decimal) format.

Syntax:

TEXTTOBCD (single-integer-text-expression)

Meaning:

TEXTTOBCD (text_to_be_converted)

Returns:

A single BCD-formatted text item

TEXTTOBCD converts *text_to_be_converted* (which consists of decimal digits) to BCD format. In this format, each byte contains two decimal digits represented as binary numbers. If there is an odd number of decimal digits in the input, the high-order half-byte of the leftmost output byte will contain the decimal value 15 (hex "F").

If anything other than a decimal digit is encountered in the input, **TEXTTOBCD** returns "none".

Examples

- **TEXTTOBCD** ("1234")
Returns the hexadecimal value x'1234'
- **TEXTTOBCD** ("123A")
Returns "none"
- **TEXTTOBCD** ("123")
Returns the hexadecimal value x'F123'

In this example, the values shown as input ("123") are meant to represent character items in the native character set to the machine on which the map is running. On a personal computer, "123" would contain the ASCII characters for the digits that have the hexadecimal values "31", "32", and "33". The output, described as "the hexadecimal value 'F123'", consists of the two binary bytes "F1" and "23".

On an IBM mainframe the input string would contain EBCDIC characters for the digits that have the hexadecimal values "F1", "F2", "F3", Âº, but the output would be the same as the personal computer output.

- **BCDTOHEX**
 - **BCDToint**
 - **BCDTOTEXT**
-

TEXTTONUMBER

Use **TEXTTONUMBER** to convert text to a number.

The **TONUMBER** function provides greater flexibility for specifying the format of the text item that is to be converted to a number.

Syntax:

TEXTTONUMBER (single-text-expression)

Meaning:

TEXTTONUMBER (text_to_convert_to_number)

Returns:

A single character number

The *text_to_convert_to_number* must be in integer or ANSI-formatted (floating point) presentation. The resulting number looks like the input argument, however, nonsignificant zeroes to the right of the decimal separator will be truncated. If the input argument is in error (for example, it is not a recognizable as a valid number), the

result is "none".

When specified as in ANSI-formatted presentation, the text string must meet the following requirements:

- The decimal point can be a period, a comma, or "none".
- The leading sign can be a plus sign, a minus sign, or "none".
- No thousands separator is allowed.

Examples

- **TEXTT tonumber** (OrderQty)
Returns **OrderQty** as a character number item

Related functions

- DATETOTEXT
- FROMNUMBER
- NUMBERTOTEXT
- TEXTTODATE
- TEXTTOTIME
- TIMETOTEXT

TEXTTOTIME

Use **TEXTTOTIME** when you want to convert an object defined as text that is in HHMM or HHMMSS presentation, to an item defined as time. For greater flexibility, use the **TODATETIME** function for specifying the format of the text item that is to be converted to a date/time.

Syntax:

TEXTTOTIME (single-text-expression)

Meaning:

TEXTTOTIME (text_to_convert_to_time)

Returns:

A single time

The *text_to_convert_to_time* must be in HHMM or HHMMSS presentation. HH is a two-digit hour in a 24-hour format. If the result is being assigned to a time object, the resulting time looks like the output object. Otherwise, the resulting time looks like the input argument. If the input argument is in error (for example, it is not a valid time), the result is "none".

Examples

- **TEXTTOTIME** (CallTime)
Returns **CallTime** as a time item

Related functions

• DATETOTEXT	• TEXTT tonumber
• FROMDATETIME	• TIMETOTEXT
• NUMBERTOTEXT	• TODATETIME
• TEXTTODATE	

TIMETOTEXT

You can use the **TIMETOTEXT** function to perform text concatenation. For greater flexibility, use the **FROMDATETIME** function for specifying the format of the resulting text item.

TIMETOTEX converts a time object or expression to a text item.

Syntax:

TIMETOTEXT (single-time-expression)

Meaning:

TIMETOTEXT (time_to_convert_to_text)

Returns:

A single text item

If *time_to_convert_to_text* is a time object name, this returns the time as a text item formatted according to the presentation of the input date object.

If *time_to_convert_to_text* is a time expression produced by a function, this returns the time as a text item formatted according to the presentation of the output argument of that function.

Examples

- **TIMETOTEXT** (LeadTime)
In this example, **LeadTime** is converted from a time to text. If **LeadTime** has an HH:MM presentation, the resulting text item will be of that presentation.
- **TIMETOTEXT (CURRENTDATETIME ("{HH:MM:SS}"))**
Here, **CURRENTDATETIME** evaluates and returns a time in HH:MM:SS format. Then, **TIMETOTEXT** evaluates and returns a text string that is that time in HH:MM:SS format.

Related functions

- **DATETOTEXT**
- **FROMDATETIME**
- **NUMBERTOTEXT**
- **TEXTTODATE**
- **TEXTTONUMBER**
- **TEXTTOTIME**
- **TODATETIME**

TODATETIME

The **TODATETIME** function converts a text string of a specified format to a date-time item.

Syntax:

```
TODATETIME ( single-character-text-expression  
[ , single-text-expression ] )
```

Meaning:

```
TODATETIME ( text_to_convert [ , date_time_format_string ] )
```

Returns:

A single character date item

TODATETIME returns the date-time that corresponds to the value specified by *text_to_convert*, which is in the format specified by *date_time_format_string*. If *date_time_format_string* is not specified, it will be assumed that *text_to_convert* is in [CCYYMMDDHH24MMSS] format.

The *date_time_format_string* must conform to the date-time format strings as described in "Format strings".

Examples

- **TODATETIME ("05/14/1999@10:14pm", "[MM/DD/CCYY]@{HH12:MMAM/PM}")**
In this example, a text string containing a date and time is converted to a date-time item.
- **RptDate = TODATETIME (RIGHT (GETRESOURCENAME() , 8) , "CCYYMMDD")**
Assume that you receive a file that contains historical data. The name of the file identifies the date of the historical data. For example, a filename of **19960424** indicates that the data was produced on April 24, 1996. To map this date to **RptDate**, the **TODATETIME** function could be used with the **RIGHT** and **GETRESOURCENAME** functions.

Related functions

- **CURRENTDATE**
- **CURRENTDATETIME**
- **CURRENTTIME**
- **TEXTTODATE**
- **TEXTTOTIME**

TONUMBER

The **TONUMBER** function converts a text string of a specified format to a number.

Syntax:

```
TONUMBER ( single-character-text-expression  
[ , single-text-expression ] )
```

Meaning:

```
TONUMBER ( text_to_convert [ , number_format_string ] )
```

Returns:

A single character number item

TONUMBER returns the number that corresponds to the value specified by *text_to_convert*, which is in the format specified by *number_format_string*. If *number_format_string* is not specified, it will be assumed that *text_to_convert* is in ANSI decimal format (for example, "[L-#####[.'##]")).

The *number_format_string* must conform to the number format strings as described in the "Format strings" topic.

Examples

- **TONUMBER(text_to_convert, "[L+'\$'##]##")**
L+\$ indicates the leading dollar sign is positive. That leading sign and the comma separators are removed when the text is converted to a number.

Input String: \$123,000,000

Output: 123000000

- **TONUMBER(text_to_convert, "####T-")**
Four number signs are required for each whole number, regardless of the actual number of digits in the number.

Input string:	Output:	Note:
12345-	-12345	The output becomes a negative number.
67890	67890	No change occurs.
345-	-345	The output becomes a negative number.

- **TONUMBER(text_to_convert, "####T+'K'-")**
If an invalid character, such as an X, is encountered, nothing is returned.

If a K is encountered, it is treated as a positive indicator.

Input string:	Output:	Note:
11212-	-11212	The output becomes a negative number.
67890X		The X is an invalid character. No number is returned.
54354	54354	No change occurs.
34567K	34567	The K is recognized as a positive sign. The character is removed and the number is returned as a positive.
345-	-345	The output becomes a negative number.

- **TONUMBER(text_to_convert, "[L-'#','##]T')")**
The parentheses indicating a negative number are removed and replaced with a negative sign.

Comma separators are removed when the text is converted to a number.

Input string:	Output:	Note:
(12,345)	-12345	The output becomes a negative number. The comma separator is removed.
67,890	67890	The comma separator is removed.
(345)	-345	The output becomes a negative number.

- **TONUMBER(text_to_convert, "#['']##[.'##5]T+'K'-")**
The optional comma separators are removed, but the decimal points and decimal values are retained.

Input string:	Output:	Note:
54,345.098	54354.098	The comma separator is removed.
67890.0X		The X is an invalid character. No number is returned.
11213-	-11213	The output becomes a negative number.
34567K	34567	The K is recognized as a positive sign. The character is removed and the number is returned as a positive.
345.1-	-345.1	The output becomes a negative number.

- **NUMBERTODATE**
- **NUMBERTOTEXT**

TRIMLEFT

You can use the **TRIMLEFT** function to remove spaces or a text string at the beginning of some text.

TRIMLEFT removes leading characters from a text item.

Syntax:

TRIMLEFT (single-text-expression [, single-text-expression])

Meaning:

TRIMLEFT (item_to_trim [, text_to_trim])

Returns:

A single text item

TRIMLEFT removes leading characters that match *text_to_trim* from *item_to_trim* and returns the result as a single text item. If *text_to_trim* is not specified, leading spaces are removed from *item_to_trim*.

Examples

- **TRIMLEFT (" abc")**
Returns: abc
- **TRIMLEFT ("000345" , "0")**
Returns: 345
- **TRIMLEFT (LastName Column:Row , "<WSP>")**

Returns the content of **LastColumn** after removing all leading whitespace characters (space, horizontal tab, carriage return, or line feed characters).

Related functions

• FILLEFTP	• LEAVEPRINT
• FILLRIGHT	• SQUEEZE
• LEAVEALPHA	• SUBSTITUTE
• LEAVEALPHANUM	• TRIMRIGHT
• LEAVENUM	

TRIMRIGHT

You can use the **TRIMRIGHT** function to remove spaces or a text string at the end of text.

TRIMRIGHT removes trailing characters from a text item.

Syntax:

TRIMRIGHT (single-text-expression [, single-text-expression])

Meaning:

TRIMRIGHT (item_to_trim [, text_to_trim])

Returns:

A single text item

TRIMRIGHT removes trailing characters that match *text_to_trim* from *item_to_trim* and returns the result as a single text item. If *text_to_trim* is not specified, trailing spaces are removed from *item_to_trim*.

Example

- **TRIMRIGHT** ("abc ")
Returns: abc
- **TRIMRIGHT** ("Cat in the Hat!?!?!" , "!")
Returns: Cat in the Hat
- **TRIMRIGHT** (**LastColumn:Row**)
Returns the content of **LastColumn** after removing all trailing spaces.

Related functions

• FILLEFTP	• LEAVEPRINT
• FILLRIGHT	• SQUEEZE
• LEAVEALPHA	• SUBSTITUTE
• LEAVEALPHANUM	• TRIMLEFT
• LEAVENUM	

UPPERCASE

The **UPPERCASE** function converts text to all uppercase characters.

Syntax:

UPPERCASE (single-text-expression)

Meaning:

UPPERCASE (text_to_convert)

Returns:

A single text item

UPPERCASE produces a text item in which each byte in *text_to_convert* has been converted to uppercase. Any numeric or symbolic characters in *text_to_convert* remain unchanged.

Examples

- **UPPERCASE** ("abC123!")
Returns ABC123!

Related functions

- [ISLOWER](#)
- [ISUPPER](#)
- [LOWERCASE](#)

WORD

You can use the **WORD** function to parse a text item that is delimited by some character, such as a space or a comma.

WORD returns the characters between two user-defined separators within a text item. The separators are counted from left to right when the third argument is positive, and from right to left when the third argument is negative, enabling the function to search from either end of the item.

Syntax:

WORD (single-text-expression , single-text-expression ,
single-integer-expression)

Meaning:

WORD (text_to_search , word_separator , number_of_word_to_get)

Returns:

A single text item

WORD returns the characters (word) between the *n*th-1 and *n*th *word_separator*, where *n* corresponds to *number_of_word_to_get*.

Define the separator (*word_separator*) and specify the number of the occurrence of that separator. The **WORD** function returns the characters between the *n*th-1 and *n*th separators in the delimited text item.

The separator is case sensitive.

Examples

The following examples assume that a file exists named **Letter** with two text objects named **Line1** and **Line2**:

```
Line1:Congratulations, Mr Brown! You're a winner!  
Line2:You may have already won 1 million dollars!;
```

- **WORD** (Line1:Letter , " ", 3)
Returns: **Brown!**

The exclamation point is returned because it is read as a character within the word before the separator (a space).

- **WORD** (Line1:Letter , " ", 6)
Returns: **winner!**

If the *n*th separator is missing and the *n*th-1 separator exists, the function returns the characters between the last separator and the end of the delimited text item. The separator is a space; "**winner!**" (including the exclamation point) is the sixth word.

- **WORD** (Line2:Letter , "!", 3)
Returns "none"

Both *n*th and *n*th-1 separators are missing. In this example, there is only one separator, located at the end of the text object. As a result, there is no third word because the function sees everything before "!" as the first word.

- **WORD** (Line1:Letter , " ", 1)
Returns: **Congratulations,**

If *n*-1 = 0, the function returns the characters between the beginning of the delimited text item and the first separator.

- **WORD** (Line1:Letter , " ", -1)
Returns: **winner!**

If *n*+1 = 0, then the function returns the characters between the end of the text item and the last separator.

XML functions

There are several XML functions that you can call from component rules and map rules to process input XML data. They fall under two different categories. The XML functions in one category are called through the XMLLIB library. They are the XPATH (used with XMLLIB), VALIDATEEX, VALIDATE, XPATHEX, XSLT (used with XMLLIB), and XSLTEX functions. The XML functions in the other category are called directly, without using the XMLLIB library. They are the XPATH, XVALIDATE, and XSLT functions.

- [**VALIDATE**](#)
The VALIDATE function validates the XML input by using the XMLLIB library.

- **VALIDATEEX**
The VALIDATEEX function validates the XML input, and logs the function processing in the directory where the map runs by using the XMLLIB library.
 - **XVALIDATE**
The XVALIDATE function validates the XML input.
 - **XPATH functions**
 - **XPATHEX**
The XPATHEX function queries the XML input by using the XMLLIB library, and logs function processing in the directory where the map runs.
 - **XSLT functions**
 - **XSLTEX**
The XSLTEX function applies an XSLT transformation to the XML input, and logs the function processing in the directory where the map runs by using the XMLLIB library.
-

VALIDATE

The VALIDATE function validates the XML input by using the XMLLIB library.

This function validates XML input, which is provided as a text stream or URL, against the provided XML Schema, returning 0 if the validation succeeded or -1 otherwise.

Syntax:

```
VALIDATE (single-text-expression, single-text-expression)
```

Meaning:

```
VALIDATE (xml_url_or_xml_fragment, target_namespace XML_schemaname)
```

Returns:

A single number

Examples

- NUMBERTOTEXT(xmllib->VALIDATE("ipo.in.xml", "urn:h17-org:v3 http://www.example.com/IPO ipo.xsd"))
Returns 0 when validation of the ipo.in.xml file succeeds and returns -1 otherwise.
 - VALID(NUMBERTOTEXT(xmllib->VALIDATE(PACKAGE(source), "ipo.xsd")), LASTERRORMSG())
Returns 0 when validation of the input XML fragment succeeds or returns a validation error message otherwise.
-

VALIDATEEX

The VALIDATEEX function validates the XML input, and logs the function processing in the directory where the map runs by using the XMLLIB library.

This function validates XML input, which is provided as a text stream or URL, against the provided XML Schema. The VALIDATEEX function returns 0 if the validation succeeded or -1 if validation failed, and generates the specified trace log file in the directory where the IBM Transformation Extender map runs.

Syntax:

```
VALIDATEEX (single-text-expression, single-text-expression, tracelog)
```

Meaning:

```
VALIDATEEX (xml_url_or_xml_fragment, target_namespace XML_schemaname, trace_file_name.extension)
```

Returns:

A single number

Example

- NUMBERTOTEXT(xmllib->VALIDATEEX("ipo.in.xml", "urn:h17-org:v3 http://www.example.com/IPO ipo.xsd", "numtotext.log"))
Returns 0 when validation of the ipo.in.xml file succeeds or returns -1 when validation fails, and generates a trace log of function processing.
-

XVALIDATE

The XVALIDATE function validates the XML input.

This function validates XML input, provided as a text stream or URL, against the provided XML Schema.

The default encoding type for a literal string in the Map rule is UTF-16LE.

Syntax:

```
XVALIDATE (single-text-expression, single-text-expression)
```

Meaning:

```
XVALIDATE (xml_url_or_xml_fragment, target_namespace XML_schemaname)
```

Returns:

This function evaluates to a Boolean "true" or "false".

Examples

- IF(XVALIDATE("ipo.in.xml", "http://www.example.com/IP ipo.xsd"), "VALIDATION SUCCESS", LASTERRORMSG())

Returns the message VALIDATION SUCCESS when the validation of the ipo.in.xml file succeeds and returns a message that explains the validation error otherwise.

XPATH functions

- **XPATH**
The XPATH function queries the XML input.
- **XPATH used with XMLLIB**
The XPATH function that is used with XMLLIB queries the XML input.

XPATH

The XPATH function queries the XML input.

This function queries the XML input, which is provided as a text stream or URL, by using the specified XPATH expression and context, returning the result of the evaluation.

Syntax:

XPATH (single-text-expression, single-text-expression, single-text-expression)

Meaning:

XPATH (xml_url_or_xml_fragment, xpath_expression, context_expression)

Returns:

A single text item

Examples

- XPATH("current://ipo.in.xml", "/ipo:purchaseOrders/order/items/item[1]/shipDate", "ipo http://www.example.com/IPO")
Returns the content of the shipDate element from the ipo.in.xml file.
- XPATH(PACKAGE(source), "/ipo:purchaseOrders/order/items/item[1]/shipDate", "ipo http://www.example.com/IPO")
Returns the content of the shipDate element from the input XML fragment.

XPATH used with XMLLIB

The XPATH function that is used with XMLLIB queries the XML input.

This function queries the XML input, which is provided as a text stream or URL, by using the specified XPATH expression and context, returning the result of the evaluation.

Syntax:

XPATH (single-text-expression, single-text-expression, single-text-expression)

Meaning:

XPATH (xml_url_or_xml_fragment, xpath_expression, context_expression)

Returns:

A single text item

Examples

- xmllib->XPATH("ipo.in.xml", "./order//item[1]/shipDate", "/ipo:purchaseOrders")
Returns the content of the shipDate element from the ipo.in.xml file.
- xmllib->XPATH(PACKAGE(source), "/ipo:purchaseOrders/order/items/item[1]/shipDate", "/")
Returns the content of the shipDate element from the input XML fragment.

XPATHEX

The XPATHEX function queries the XML input by using the XMLLIB library, and logs function processing in the directory where the map runs.

This function queries the XML input, provided as a text stream or URL, by using the specified XPath expression and context. The XPATHEX function returns the result of the evaluation and generates the specified trace log file in the directory where the map runs.

Syntax:

XPATHEX (single-text-expression, single-text-expression, single-text-expression, tracelog)

Meaning:

XPATHEX (xml_url_or_xml_fragment, xpath_expression, context_expression, trace_file_name.extension)

Returns:

A single text item

Example

- xmllib->XPATHEX("ipo.in.xml", "./order//item[1]/shipDate", "/ipo:purchaseOrders", "xpathlog.txt")
Returns the content of the shipDate element from the ipo.in.xml file and generates a trace log of function processing.

XSLT functions

- **XSLT**
The XSLT function applies an XSLT transformation.
- **XSLT used with XMLLIB**
The XSLT function that is used with XMLLIB applies an XSLT transformation.

XSLT

The XSLT function applies an XSLT transformation.

This function applies an XSLT transformation, expressed as a text stream or URL, to the provided XML input, returning the result of the transformation.

Syntax:

XSLT (single-text-expression, single-text-expression)

Meaning:

XSLT (xml_url_or_xml_fragment, xslt_url_or_xslt_fragment)

Returns:

A single text item

Examples

- XSLT("current://ipo.in.xml", "current://ipo.xsl")
Applies the XSLT transformation that is defined in the ipo.xsl file to the ipo.in.xml file.
- XSLT(PACKAGE(source), "current://ipo.xsl")
Applies the XSLT transformation that is defined in the ipo.xsl file to the input XML fragment.

XSLT used with XMLLIB

The XSLT function that is used with XMLLIB applies an XSLT transformation.

This function applies an XSLT transformation, expressed as a text stream or URL, to the provided XML input, returning the result of the transformation.

Syntax:

XSLT (single-text-expression, single-text-expression)

Meaning:

XSLT (xml_url_or_xml_fragment, xslt_url_or_xslt_fragment)

Returns:

A single text item

Examples

- xmllib->XMLLIB XSLT("ipo.in.xml", "ipo.xsl")
Applies the XSLT transformation that is defined in the ipo.xsl file to the ipo.in.xml file.
- xmllib->XMLLIB XSLT(PACKAGE(source), "ipo.xsl")
Applies the XSLT transformation that is defined in the ipo.xsl file to the input XML fragment.

XSLTEX

The XSLTEX function applies an XSLT transformation to the XML input, and logs the function processing in the directory where the map runs by using the XMLLIB library.

This function applies an XSLT transformation, expressed as a text stream or URL, to the provided XML input. The XSLTEX function returns the result of the transformation and generates the specified trace log file in the directory where the IBM Transformation Extender map runs.

Syntax:

XSLTEX (single-text-expression, single-text-expression, tracelog)

Meaning:

XSLTEX (xml_url_or_xml_fragment, xslt_url_or_xslt_fragment, trace_file_name.extension)

Returns:

A single text item

Example

- xmllib->XSLTEX("ipo.in.xml", "ipo.xsl", "transform.log")
Applies the XSLT transformation that is defined in the ipo.xsl file to the ipo.in.xml file, and generates a trace log of function processing

Custom functions

From the Type Designer or Map Designer, you can create custom functions to call external libraries.

While the EXIT function is often used to call external libraries, the EXIT function is limited to support only text objects and is operating system dependent. When you create a custom function to use in a map rule, the function is operating system independent and supports text, number, and date-time objects.

Similar to the regular functions that are shipped with the product, a maximum of four parameters are supported per argument.

- [Creating a custom function](#)

To create your own functions, a C or C++ development tool is required, or the Java Native Interface (JNI) if you are working in a Java environment.

Creating a custom function

To create your own functions, a C or C++ development tool is required, or the Java Native Interface (JNI) if you are working in a Java environment.

1. From a component rule in the Type Designer or from a map rule in the Map Designer, right-click and select the Insert Function option.
(Additionally in the Map Designer, if you are not in a map rule, you can create a new function by selecting Rules>New Function.)
2. From the Insert Function window, select Design.
The Custom Function Modules window is displayed.
3. In the Path field, enter the path of where to create the external library.
This should always be in the *install_dir/function_libs* directory.
4. In the Name field, enter a name for the library.
5. Click Add to add a function to the library.
The Function Specifics window is displayed.
6. In the Name field, enter a name for the function.
7. For Return Type, select the function return type from the drop-down list.
You can select up to four function parameters from the respective drop-down list. Choices include Boolean, date, number, text, time, and byte stream.
8. In the space provided, enter a description for your function.
This information will be displayed in the Insert Function window of both Designers.
9. Click OK to validate the selected parameters and close the Function Specifics window.
10. Click Generate.
The Designer generates a collection of operating system specific makefiles and definition files that provide the framework for the function you are creating.
11. Go to the *install_dir/function_libs* directory to view the results.
As a result of the generation process, framework files are created for each operating system that IBM Transformation Extender supports. You can find the operating system-specific makefiles and definition files in the *install_dir/function_libs/your_new_lib* directory.
12. Now you must modify the framework that was generated by the Designer.
The following functions with the parameter information that you selected were exported to the .c file:
 - GetFunctionCount
 - GetFunctionName
 - GetInputParameter
 - GetReturnType
 - GetParameterCount
 - GetFunctionDesc

To complete the new function, open the .c file and add your programming code for the applicable function or functions provided.

Use the .c file to build your dynamic link library (DLL) and then place the DLL in the *install_dir/function_libs/your_new_lib* directory. (All custom designed libraries and functions must be placed in the *install_dir/function_libs* directory.)

The new library name is listed under Category in the Insert Function window, and the new function that you created is placed in the list of functions and will remain available for future use from both the Type Designer and Map Designer applications.

The following example displays how to implement a custom function called SIN.

```
void ConvertToBytes(double returnValue, LPEXITPARAM lpep)
{
    double value = 0.0;
    int decimal = 2, sign = 0, j = 0, k = 0;
    char byString[100];
    char* lpbyData = fcvt(returnValue, 7, &decimal, &sign );
    memset(byString, 0, sizeof(byString));

    if (sign)
        byString[j++] = '-';

    if (decimal <= 0)
    {
        byString[j++] = '0';
        byString[j++] = '.';
        while (decimal != 0)
        {
            byString[j++] = '0'; decimal++;
        }
    }
    else if (decimal > 0)
    {
        while (decimal != 0)
        {
            byString[j++] = lpbyData[k++]; decimal--;
        }
        byString[j++] = '.';
    }
}
```

```

    }
    while (lpbyData[k]) byString[j++] = lpbyData[k++];
    byString[j] = '\0';

    if (NULL == (lpep->lpDataFromApp = GlobalAllocPtr
        (GHND, j + 1)))
    {
        lpep->nReturn = -1;
        lstrcpy(lpep->szErrMsg, "Memory allocation failed in Alternate");
        return;
    }

    memcpy(lpep->lpDataFromApp, byString, j);
    lpep->dwFromLen = j;
    lpep->lpDataFromApp[j++] = '\0';
}

```

```

void CALLBACK EXPORT SIN(LPEXITPARAM lpep)
{
    double value = 0.0;
    double returnValue = 0.0;
    LPEXITPARAMEXTENDED lpExtended = NULL;

    if (lpep->dwSize != sizeof(EXITPARAM))
    {
        return;
    }

    lpExtended = (LPEXITPARAMEXTENDED)lpep->lpv;
    value = atof(lpExtended->lpFirstInputParameter);

    returnValue = sin(value);
    ConvertToBytes(returnValue, lpep);
    lpep->wCleanupAction = GetReturnType("SIN");
    lstrcpy(lpep->szErrMsg, "SIN function was successful");

    return;
}

```

At run time, all custom designed libraries and functions that your maps use must be in the *install_dir/function_libs* directory. When you deploy a map that uses a custom function to a remote host, the library is not transferred. Therefore you must manually copy the custom function library to the *install_dir/function_libs* directory on the remote host.

Date and time format strings

You can use the listed format strings for numbers, dates and times in functions such as the CURRENTDATETIME, FROMNUMBER, TONUMBER, FROMDATETIME, and TODATETIME.

Create custom date and time formats by using the symbols based on the given format strings.

- [Time units](#)
- [Date units](#)
- [Binary date and time format strings](#)
- [Japanese date and time format strings](#)
- [Western date and time format strings](#)

Time units

Symbol	Description
HH24	Hour (based on a 24-hour clock) in two digits (00 to 24)
H24	Hour (based on a 24-hour clock) in one or two digits as needed (0 to 24)
HH12	Hour (based on a 12-hour clock) in two digits (1-12)
H12	Hour (based on a 12-hour clock) in one or two digits as needed (1 to 12)
MM	Minute in two digits (00 to 59)
M	Minute in one or two digits as needed (0 to 59)
SS	Seconds in two digits (00 to 59)
S	Second in one or two digits as needed (0 to 59)
AM/PM	Meridian (AM/PM)
ZZZ	Three character abbreviation for time zone (EST, and so on)

+/-ZZZ
 Hours and minutes before or after Greenwich Mean Time (GMT), also known as Coordinated Universal Time (UTC)

+/-ZZ:ZZ
 4-digit time where the format is a 2-digit hour and 2-digit minute, separated by a colon.

+/-ZZ[ZZ]
 4-digit time where the format is a 2-digit hour and an optional 2-digit minute, separated by colon.

+/-ZZ[ZZ]
 4-digit time where the format is a 2-digit hour and an optional 2-digit minute.

TZD
 4-digit time where the format is a 2-digit hour and 2-digit minute, separated by a colon. Z on output, if value is +/−00:00.

Date units

Symbol	Description
CCYY	Full year including century (2001)
YY	Last two digits of the year (00-99)
MM	Month of the year in two numeric digits (01-12)
M	Month of the year in one or two numeric digits as needed (1 to 12)
MON	First three letters of the month (Jan to Dec)
MONTH	Full name of the month (January to December)
DDD	Day of the year in three numeric digits (001 to 366)
DD	Day of the month in two numeric digits (01 to 31)
D	Day of the month in one or two numeric digits as needed (1 to 31)
DY	First three letters of the weekday (Sun to Sat)
DAY	Full name of the weekday (Sunday to Saturday)
WW	Week of year (1-52)
Qn	Quarter of the year (Q1-Q4)
EEYY	Emperor's year, long form
EY	Emperor's year, short form

Binary date and time format strings

Sub-String Name	Sub-String Value
Binary DateTime	["{" + Date + "}"] + ["{" + Time + "}"]
Date	CCYYMMDD YYMMDD
	CCYYDDD
	YYDDD
Time	HH24MMSS HH24MM

Japanese date and time format strings

Sub-String Name	Sub-String Value
Japanese DateTime	"{" + DateTime + "}"
	"{" + DateTime + "}" + Separator(1) + "{" + DateTime + "}"

```

"{" + DateTime + "}" + "[" + Separator(1) + "{" + DateTime + "}" + "]"

```

DateTime
 Date
 Time

Separator
 Separator is optional. If specified, it can be up to 120 bytes, composed of non-alphabetic characters. Symbol table values, such as <CR>, can be used to indicate non-printable characters.
 The Separator is required if the second DateTime option is used and the format string of the first DateTime ends in a variable sized specification - EY, M, or D for Date or H24, H12, M, or S for Time.

- [Japanese date format strings](#)

Japanese date format strings

Sub-String Name	Sub-String Value
Japanese Date	Year + MonthSet(1)
Year	CCYY YY EEYY EY
MonthSet	Separator(1) + "MM" + DayOfMonth(1) "[" + Separator(1) + "MM" + DayOfMonth(1) +] Separator(1) + M + DayOfMonth(1) [+ Separator(1) + M + DayOfMonth(1) +]
DayOfMonth	Separator(1) + "DD" + WeekDay(1) "[" + Separator(1) + "DD" + WeekDay(1) + "]" Separator(1) + "D" + WeekDay(1) "[" + Separator(1) + "D" + WeekDay(1) + "]"
WeekDay	Separator(1) + "DY" "[" + Separator(1) + "DY" + "]" Separator(1) + "DAY" "[" + Separator(1) + "DAY" + "]"
Separator	Separator is optional. If specified, it can be up to 120 bytes composed of non-alphabetic characters. Symbol table values, such as <CR>, can be used to indicate non-printable characters. MonthSet Separator required if Year is EY DayOfMonth Separator required if MonthSet is M WeekDay Separator required if DayOfMonth is D

Japanese time format strings

Sub-String Name	Sub-String Value
Japanese Time	Meridian(1) + HMS
Meridian	"AM/PM"
HMS	"HH24" + MinuteSet(1) "H24" + MinuteSet(1) "HH12" + MinuteSet(1) "H12" + MinuteSet(1)
MinuteSet	

```

Separator(1) + "MM" + SecondSet(1)
"[ " + Separator(1) + "MM" + SecondSet(1) + "]"

Separator(1) + "M" + SecondSet(1)
"[ " + Separator(1) + "M" + SecondSet(1) + "]"

SecondSet
Separator(1) + "SS"
"[ " + Separator(1) + "SS" + "]"

Separator(1) + "S"
"[ " + Separator(1) + "S" + "]"

Separator
Separator is optional. If specified, it can be up to 120 bytes, composed of non-alphabetic characters. Symbol table values, such as <CR> can be used to indicate non-printable characters.
MinuteSet Separator required if HMS is H24 or H12
SecondSet Separator required if MinuteSet is M

Western DateTime

```

"{" +DateTime + "}"
"{" +DateTime + "}" + Separator(1) + "{" + DateTime + "}"

"{" +DateTime + "}" + "[" + Separator(1) + "{" + DateTime + "}" + "]"

```

DateTime

Date

Time

Separator

Separator is optional. If specified, it can be up to 120 bytes, composed of non-alphabetic characters. Symbol table values, such as <CR>, can be used to indicate non-printable characters.

The Separator is required if the second DateTime option is used and the format string of the first DateTime ends in a variable sized specification - M, MONTH, D, or DAY for Date or H24, H12, M, or S for Time.

Number format strings

You can create custom number formats by using the given format strings.

Decimal
"{" + Leading-Sign(1) + Whole# + Fraction + Trailing-Sign(1) + "}"
Integer
"{" + Leading-Sign(1) + Whole# + Trailing-Sign(1) + "}"

- [Leading sign format strings](#)
- [Trailing sign format strings](#)
- [Substring format strings](#)
- [Whole number and fraction format strings](#)

Leading sign format strings

Sub-String Name	Sub-String Value	Positive	Negative
Leading-Sign	"L" + Positive + Negative + Zero(1) -or-	Req	Req
	"L" + "[" + Positive + "]" + Negative + Zero(1) -or-	Opt	Req
	"L" + Positive + "[" + Negative + "]" + Zero(1) -or-	Req	Opt
	"L" + Positive + Zero(1) -or-	Req	-
	"L" + Negative + Zero(1)	-	Req

Trailing sign format strings

Sub-String Name	Sub-String Value	Positive	Negative
Trailing-Sign	"T" + Positive + Negative + Zero(1)	Req	Req
	"T" + "[" + Positive + "]" + Negative + Zero(1)	Opt	Req
	"T" + Positive + "[" + Negative + "]" + Zero(1)	Req	Opt
	"T" + Positive + Zero(1)	Req	-
	"T" + Negative + Zero(1)	-	Req

Substring format strings

Substring Name	Substring Value	Meaning
Positive	"+ Value(1)	
Negative	"-" + Value(1)	
Value	A text-string enclosed in single quotation marks '. Value has a release character of / if the text contains any single quotation mark ' or forward slash / characters.	The sign value of the previous sign-indicator. If Value is not used, the default is + for positive numbers and - for negative numbers.
Zero	"Z" + Value "[" + "Z" + Value + "]"	Specifies the required leading sign value if the number is zero. If Zero is not used, there is no sign associated with a zero. Specifies the optional leading sign value if the number is zero. If Zero is not used, there is no sign associated with a zero.

Whole number and fraction format strings

Whole# substring name

Substring value
Meaning
`MinDigits(1) + "#" + Value(1) + "##" + MaxDigits(1)`
`MinDigits(1) + "#" + "[" + Value(1) + "]" + "##" + MaxDigits(1)`
 Specifies the thousands separator and the range of whole number digits. If min-digits is not used, the default is zero. If max-digits is not used, the default is "S". If a ThousandsItem is specified, a Value must be present as the default for the syntax item.

Fraction substring name

Substring value
Meaning
`"V" + ImpliedPlaces`
 Specifies the decimal to be in an explicit place, and ImpliedPlaces determines where the intended decimal separator is to be placed.
`Value + MinDigits(1) + "##" + MaxDigits(1)`
 Specifies the value of the decimal separator to be required and the range of fraction digits. If min-digits is not used, default is zero. If max-digits is not used, default is "S"
`"[" + Value + MinDigits(1) + "##" + MaxDigits(1) + "]"`
 Specifies the value of the decimal separator to be optional if there is no fractional portion of the number. It also specifies the range of fraction digits. If min-digits is not used, default is zero. If max-digits is not used, default is "S"

RUN function return codes

The **RUN** function return codes and messages might result when using the **RUN** function. Return codes and messages are returned when the particular activity completes. Return codes and messages might also be recorded as specified in the audit logs, trace files, execution summary files, and so forth.

The following table lists the return codes and messages that can result when using the **RUN** function.

Return Code	Message
50	<i>Memory allocation failure</i> Occurs when memory fails.
51	<i>Card override failure</i> Occurs when memory fails.
52	<i>I/O initialization failure</i> Occurs when memory fails.
53	<i>Open audit failure</i> The audit log file is not accessible.
54	<i>No command line</i> There is nothing to process.
55	<i>Recursive command files</i> More than one command file is included in the command line.
56	<i>Invalid command line option -x</i> The option is invalid for the command.
57	<i>Invalid 'W' command line option</i> The Work file option is invalid.
58	<i>Invalid 'B' command line option</i> The Batch (close) file option is invalid.
59	<i>Invalid 'R' command line option</i> The Refresh Rate option is invalid.
60	<i>Invalid 'A' command line option</i> The Audit option is invalid.
61	<i>Invalid 'P' command line option</i> The Paging option is invalid
62	<i>Invalid 'Y' command line option</i> The General I/O Retry option is invalid.
63	<i>Invalid 'T' command line option</i> The Trace option is invalid.
64	<i>Invalid 'G' command line option</i> The Ignore option is invalid
65	<i>Invalid 'I' command line option for input x</i> The Source option is invalid for the identified input.
66	<i>Invalid size in echo command line for input x</i> The size specified using the Size option is greater than memory allowed.
67	<i>Invalid adapter type in command line for input x</i> The adapter is not of a known adapter type. Includes -IMxxx where xxx is an unknown adapter alias.
68	<i>Invalid 'O' command line option for output x</i> The target option is invalid for output x. The number of characters between the single quotation marks that represent the options for an adapter exceed 258 characters in the adapter override.
69	Invalid adapter type in command line for output x

The adapter is not of a known adapter type. Includes -OMxxx where xxx is an unknown adapter alias.

70

Command line memory failure

Occurs when memory is exceeded during echo or override card commands.

71

Invalid 'D' command line option

The Date option is invalid.

72

Invalid 'F' command line option

The Failure option is invalid.

73

Resource manager failure

(Launcher only) The resource manager is not used, possibly a memory failure.

74

Invalid 'Z' command line option

The Ignore option is invalid.

75

Adapter failed to get data on input

Enable the adapter trace to record the adapter activity to discover the cause of the error.

76

Adapter failed to put data on output

Enable the adapter trace to record the adapter activity to discover the cause of the error.

77

Invalid map name

This message can occur in two different cases. First, this message occurs when the map name specified on the command line is more than 32 bytes long in UTF-8 encoding. Also, this message can occur when there is an error in the command line such that text for another execution command is erroneously being interpreted as the map name. For example, in the command line below, the number representing the size of the echoed data is missing.

`mymap mmc -IE1S HereIsMyDataButIForgotToSpecifyTheSize -AED`

Because the size is missing, it is interpreted to be 0, such that there is no echoed data. The next string encountered on the command line

`(HereIsMyData...)`

Because it does not start with a hyphen (-), it is assumed to be the name of the next map to execute. Because the text is longer than 32 bytes in UTF-8 encoding, the *Invalid Map Name* message is returned.

Character set codes for CPACKAGE, CSERIESTOTEXT, and CTEXT

The second argument of the **CPACKAGE**, **CSERIESTOTEXT**, and **CTEXT** functions specifies the character set of the output of the function. The value of the second argument (the character set of the object content), must be a valid character set code.

All actions done that use the text string that results from one of these functions (**CPACKAGE**, **CSERIESTOTEXT**, or **CTEXT**) treat the text string as being of the specified character set—it is not automatically treated as Native.

After you tested the running of IBM Transformation Extender maps in the Design Server, you can deploy them from Design Server to a Sterling B2B Integrator server map repository.

Sterling B2B Integrator in Design Server overview

The Design Server provides the functionality to create and test maps that you can run on a Sterling B2B Integrator server and deploy to a Sterling B2B Integrator server map repository.

The Sterling B2B Integrator functions can be used for various processes such as validation, running as a step in a Business Process, translation, or transformation, and for generating reports.

To read about the benefits of using Sterling B2B Integrator, see the product page on the IBM website: <http://www.ibm.com/software/commerce>.

See additional information in the IBM Transformation Extender for Sterling B2B Integrator documentation.

Supported Transformation Extender map functionality on Sterling B2B Integrator

Sterling B2B Integrator supports all mapping functions in IBM Transformation Extender maps.

All adapters are available on the target platform and specified in the map and card rules.

In addition to IBM Transformation Extender mapping functions, there are extensions to IBM Transformation Extender maps with the Sterling adapter so that the map can share information with the Sterling B2B Integrator services and other Sterling B2B Integrator processes. The adapter calls the data harness to provide access to Sterling B2B Integrator tables for maps to read data from, and write data to, these tables. Through calls to the data harness from the Sterling adapter in map rules, maps can store information about the data for tracking purposes and retrieve information from these tables.

If the maps use **GET** and **PUT** calls to the Sterling adapter to get and set certain values that are maintained in the Sterling B2B Integrator database tables, those maps can only run within the Sterling B2B Integrator environment.

Differences when running Transformation Extender maps on Sterling B2B Integrator

On Sterling B2B Integrator, IBM Transformation Extender maps run through different services that are called by business processes.

There is a set of Sterling B2B Integrator services that run IBM Transformation Extender maps with some restrictions. There is also a WTX Map service that can run any IBM Transformation Extender map with no restrictions. Through the Design Server, you can test running maps on a Sterling B2B Integrator server inside this WTX Map service.

Although map functions and all adapters are supported by Sterling B2B Integrator, running IBM Transformation Extender maps on Sterling B2B Integrator is different in the following ways:

- For maps to run inside Sterling B2B Integrator services other than the WTX Map service, these services require that maps meet certain requirements to be considered "[well behaved](#)" maps.
- If the map is not checked into the Sterling B2B Integrator map repository, the map runs in the same way as any other IBM Transformation Extender map runs.
- The map can include the Sterling adapter in **PUT** and **GET** rules in the following locations:
 - On the map
 - Through the command line on an input or output card

The Sterling adapter calls the [data harness](#) to provide access to Sterling B2B Integrator tables. These maps can only run within the Sterling B2B Integrator.

- You must configure the Design Server settings, such as connection properties, the Check In Map service options, and the troubleshooting options, for Sterling B2B Integrator services.
- The map must be built for a platform that the Sterling B2B Integrator server supports.
- For troubleshooting problems, you must configure the Save service request and response, Save service session log messages options in the Design Server.

You can test the map in the Design Server to verify that you configured the map to run correctly on Sterling B2B Integrator. After you completed test running the map, you can then [deploy](#) the map from Design Server to a Sterling B2B Integrator server map repository.

- [Well-behaved map](#)

There are several Sterling B2B Integrator services that can run IBM Transformation Extender maps. When a IBM Transformation Extender map runs from those services, except of the WTX Map service, it must operate according to a certain set of requirements. A map that meets these requirements is well-behaved map.

- [Data harness](#)

IBM Transformation Extender maps share information with the Sterling B2B Integrator services and other Sterling B2B Integrator processes through the data harness interface.

Well-behaved map

There are several Sterling B2B Integrator services that can run IBM Transformation Extender maps. When a IBM Transformation Extender map runs from those services, except of the WTX Map service, it must operate according to a certain set of requirements. A map that meets these requirements is well-behaved map.

A well-behaved map has the following characteristics:

- The map is an executable IBM Transformation Extender map. If at runtime the map is provided with the required input, it can be run.
- The map is designed to be called from within a specific Sterling B2B Integrator service. If the service is set up to process incoming X12 data, for example, the first input card of the map accepts X12 data. If the service is expecting the map to generate an XML message, then the last output card of the map creates an XML message.
- You define the restart and burst settings in the map as the service requires, and as stipulated in the Sterling B2B Integrator exhaust input setting.
- If the map requires table data information or settings from Sterling B2B Integrator, such as delimiter settings for outbound EDI, or extract information while parsing the data that is to be sent back to Sterling B2B Integrator, such as correlations, then the map has been designed to meet these requirements.
- The map design follows published Sterling B2B Integrator and IBM Transformation Extender integration best practices including being a thread-safe map. In Sterling B2B Integrator, Sterling B2B Integrator maps are run in a multi-threaded environment.
- The service passes the Primary Document to the first input card and reads it from the last output card. For more information about the Primary Document, see the IBM Transformation Extender for Sterling B2B Integrator documentation.

Data harness

IBM Transformation Extender maps share information with the Sterling B2B Integrator services and other Sterling B2B Integrator processes through the data harness interface.

The data harness uses the basic service framework, or harness model, that Sterling B2B Integrator uses to view all services in the same way. It is invoked by the IBM Transformation Extender map through the Sterling adapter to provide access to database tables.

IBM Transformation Extender maps can read information, such as trading partner information or code list table data, from Sterling B2B Integrator tables. They can also write information about the data, such as a document ID or other key field, that Sterling B2B Integrator can use to track the data.

Some of the examples that are included in the IBM Transformation Extender for Sterling B2B Integrator use the data harness to set values in Sterling B2B Integrator database tables. These values and any other values that maps set or read are included in the map description.

Access the data harness through maps with **PUT** and **GET** rules in the following locations:

- On the map
- Through the Sterling adapter command line on an input or output card

For details about accessing the data harness from maps, see the IBM Transformation Extender for Sterling B2B Integrator documentation.

For more information about the Sterling B2B Integrator harness model and how it operates with external systems, see the IBM Sterling B2B Integrator documentation that you can access through the IBM Sterling B2B Integrator Support website (<http://www.ibm.com/software/commerce/support>).

Getting started with Sterling B2B Integrator

To get started using the Design Server with the Sterling B2B Integrator runtime, use the following high-level task list in a preproduction phase.

- Add a Sterling B2B Integrator server in the Design Server.
- Test run the IBM Transformation Extender map.
- Deploy the IBM Transformation Extender maps to a Sterling B2B Integrator server map repository.

Adding a Sterling B2B Integrator server

Specify the Design Server settings for the connection properties in the Sterling B2B Integrator services. You must enter values for the Sterling B2B Integrator server name, port number for the Sterling B2B Integrator Dashboard, and the user name and password.

1. Login to Design Server.
2. Go to Deploy and select Servers from the list.
The Servers page opens.
3. Click on Add button.
An Add a Server window opens.
4. In the Add a Server window, do the following:
 - a. In the Name field, type the name of the server.
 - b. In the Description field, add the description of the server.
 - c. From the Type drop down list, select Sterling B2B Integrator.
 - d. From the Platform drop-down list, select the required platform.
 - e. Enter the host name or IP address of the Sterling B2B Integrator in the Login server field.
 - f. Enter the port number of the Dashboard Port field.
 - g. Enter the User name and Password.
5. Click on Test button to test the connection with the Sterling B2B Integrator server.
You will get the **Successfully Connected** message when the server is up and running.
6. Click on Add button to add the Sterling B2B Integrator server in the Design Server.
You can see the added server in the Servers page.

- [Configuring an HTTPS connection to the Sterling B2B Integrator server](#)
You can configure a secure connection to the Sterling B2B Integrator server.

Configuring an HTTPS connection to the Sterling B2B Integrator server

You can configure a secure connection to the Sterling B2B Integrator server.

The Design Server establishes a HyperText Transfer Protocol (HTTP) connection with a Sterling B2B Integrator server, which is the default connection type, using the server and Sterling B2B Integrator Dashboard port number connection properties specified in the options for IBM Transformation Extender maps.

To configure a secure connection with the Sterling B2B Integrator server using HTTPS in the Design Server:

1. Go to Design Server...Deploy...Servers.
2. Select the added Sterling B2B Integrator server from the Servers page and click on Edit button to open the Edit server window.
3. Enter the port number in the Dashboard port field.
If you configured the Map Test HTTP Server Adapter for a secure connection, use that same port number for the Dashboard port field.
4. Select the Secure Transport check box.
5. To specify direct trust, select the Trust all hosts check box.
At run time when the map run or deploy operations are attempting to establish a connection to a Sterling B2B Integrator server, the following results occur depending on how Trust all hosts is set:
 - If Trust all hosts is selected, the connection verification step that checks the host passes even if the machine host name does not match the host name in the certificate.
 - If Trust all hosts is cleared, the connection verification step that checks the host fails if the machine host name does not match the host name in the certificate.
6. Click Save to save changes.

Configuring the Check In Map service options

To run the services on a Sterling B2B Integrator server, you must configure the Check In Map service options in the Design Server.

You can change Design Server settings pertaining to the Check In Map service options for IBM Transformation Extender maps in the Sterling B2B Integrator service, under Check In Map Service.

1. Go to Design Server...Deploy...Servers.
2. Select the added Sterling B2B Integrator server from the Servers page and click on Edit button to open the Edit server window.
3. Select the options under Check In Map service.
4. Select one of the following choices about which version of the map you want to specify as the default in the Sterling B2B Integrator map repository:
 - To make the version of the map that you deploy from the Design Server the default map in the Sterling B2B Integrator map repository, select the Make checked in map the default check box.

- To keep the version of the same map that is already in the Sterling B2B Integrator map repository, as the default map, clear the Make checked in map the default check box.
5. Select one of the following choices about whether you want the service to check if the map is thread-safe to run on the Sterling B2B Integrator server:
 - If you do not want the Check In Map service to check if the map is thread-safe to run on the Sterling B2B Integrator server, select the Ignore map thread-safe check check box.
 - If you do want the Check In Map service to check if the map is thread-safe to run on the Sterling B2B Integrator server, clear the Ignore map thread-safe check check box.
 6. Click Save to save changes.
- **[Configuring troubleshooting options](#)**
- To help you troubleshoot problems when test running IBM Transformation Extender maps on a Sterling B2B Integrator server and deploying the maps to a Sterling B2B Integrator server map repository, you must configure the Service request and response messages option in the Design Server.
-

Configuring troubleshooting options

To help you troubleshoot problems when test running IBM Transformation Extender maps on a Sterling B2B Integrator server and deploying the maps to a Sterling B2B Integrator server map repository, you must configure the Service request and response messages option in the Design Server.

You can change Design Server settings pertaining to the Service request and response messages option for IBM Transformation Extender maps in the Sterling B2B Integrator preferences, under Save Messages.

To configure troubleshooting options:

1. Select the added Sterling B2B Integrator server from the Servers page and click on Edit button to open the Add a server window.
2. In the Add a server window, under Save Messages, select the Service request and response messages check box to save request and response messages. These files are generated when you run a map from the Design Server with the Test Map service, or deploy a map from the Design Server to the Sterling B2B Integrator map repository with the Check In Map service.
3. Select Service session log check box to see the session log. These files are generated when you run or deploy a map.
You can see the files in Design>Files.
4. Click Save to save changes.

Building Transformation Extender map

Go to Design>Maps tab to use the build and run on process to generate a compiled map to use on a Sterling B2B Integrator server.

You can build a map for the Sterling B2B Integrator server using Build button.

You can use Run On button to select the available Sterling B2B Integrator server to run a map.

After a successful build, you can test the map on the Sterling B2B Integrator server. When you run on Sterling B2B Integrator server the IBM Transformation Extender map, the compiled map, and input files are sent to the Sterling B2B Integrator for processing. The map audit, map trace and results are returned to the Design Server.

Deploying Transformation Extender maps

After you tested the running of IBM Transformation Extender maps in the Design Server, you can deploy them from Design Server to a Sterling B2B Integrator server map repository.

To deploy a IBM Transformation Extender map or maps to a Sterling B2B Integrator server map repository:

1. Configure the Design Server connection properties for IBM Transformation Extender maps deployed on a Sterling B2B Integrator server.
 2. Configure the Design Server Check In Map service options for IBM Transformation Extender maps deployed on a Sterling B2B Integrator server.
 3. Make the selections to deploy your map on a Sterling B2B Integrator server in either one of the two following ways:
 - Deploy a single map.
 - Deploy multiple maps or projects by creating a package.
You can select multiple compiled IBM Transformation Extender maps to deploy at the same time by selecting the created packages.
 4. Click Deploy button from the Packages page.
The Deploy window opens.
 5. Select one or more packages to deploy and one or more Sterling B2B Integrator Servers to deploy to.
 6. Click Deploy.
This starts the map deploy operation. Once done, you get the message **Deployed Successfully** in the Deploy window.
 7. Click View Log to see the detailed information of deploy operation.
The **View deploy log** is generated with detailed information.
- **[Making the checked-in map the default](#)**
Select the Make checked in map default check box to make the version of the map that you deploy from the Design Server the default map in the Sterling B2B Integrator map repository.

Making the checked-in map the default

Select the Make checked in map default check box to make the version of the map that you deploy from the Design Server the default map in the Sterling B2B Integrator map repository.

If there already is a version of the same map in the Sterling B2B Integrator map repository that is the default, this version of the map is made the default map instead.

When this version of the map is made the default map in the Sterling B2B Integrator map repository, this is the version that Sterling B2B Integrator uses for various processes such as validation, running as a step in a Business Process, translation or transformation, and for generating reports.

To keep the version of the same map that is already in the Sterling B2B Integrator map repository, as the default map, clear the Make checked in map default check box.

Sterling B2B Integrator in the Design Studio

Sterling B2B Integrator functions are available for you to use from the Design Studio.

- [Sterling B2B Integrator in Design Studio overview](#)

Sterling B2B Integrator functions are available for you to use from the Design Studio.

Sterling B2B Integrator in Design Studio overview

Sterling B2B Integrator functions are available for you to use from the Design Studio.

The Design Studio provides the functionality to create and test maps that you can run on a Sterling B2B Integrator server, and deploy to a Sterling B2B Integrator server map repository.

The Sterling B2B Integrator functions can be used for various processes such as validation, running as a step in a Business Process, translation or transformation, and for generating reports.

You need to install IBM Transformation Extender for Integration Servers on both the machine where the Design Studio is installed, and on the machine where the Sterling B2B Integrator server is installed. For specific product installation and configuration information, see the [release notes](#).

To read about the benefits of using Sterling B2B Integrator, see the product page on the IBM website: <http://www.ibm.com/software/commerce>.

See additional information in the IBM Transformation Extender for Sterling B2B Integrator documentation.

- [Supported Transformation Extender map functionality on Sterling B2B Integrator](#)

Sterling B2B Integrator supports all mapping functions in IBM Transformation Extender maps.

- [Differences when running Transformation Extender maps on Sterling B2B Integrator](#)

On Sterling B2B Integrator, IBM Transformation Extender maps run through different services that are called by business processes.

- [Well-behaved map](#)

There are several Sterling B2B Integrator services that can run IBM Transformation Extender maps. When a IBM Transformation Extender map runs from those services, with the exception of the WTX Map service, it must operate according to a certain set of requirements. A map that meets these requirements is considered to be well-behaved.

- [Data harness](#)

IBM Transformation Extender maps share information with the Sterling B2B Integrator services and other Sterling B2B Integrator processes through the data harness interface.

Supported Transformation Extender map functionality on Sterling B2B Integrator

Sterling B2B Integrator supports all mapping functions in IBM Transformation Extender maps.

All adapters are available on the target platform and specified in the map and card rules.

In addition to IBM Transformation Extender mapping functions, there are extensions to IBM Transformation Extender maps with the Sterling adapter so that the map can share information with the Sterling B2B Integrator services and other Sterling B2B Integrator processes. The adapter calls the data harness to provide access to Sterling B2B Integrator tables for maps to read data from, and write data to, these tables. Through calls to the data harness from the Sterling adapter in map rules, maps can store information about the data for tracking purposes and retrieve information from these tables.

If the maps use **GET** and **PUT** calls to the Sterling adapter to get and set certain values that are maintained in the Sterling B2B Integrator database tables, those maps can only run within the Sterling B2B Integrator environment.

Differences when running Transformation Extender maps on Sterling B2B Integrator

On Sterling B2B Integrator, IBM Transformation Extender maps run through different services that are called by business processes.

There is a set of Sterling B2B Integrator services that run IBM Transformation Extender maps with some restrictions. There is also a WTX Map service that can run any IBM Transformation Extender map with no restrictions. Through the Design Studio, you can test running maps on a Sterling B2B Integrator server inside this WTX Map service.

Although map functions and all adapters are supported by Sterling B2B Integrator, running IBM Transformation Extender maps on Sterling B2B Integrator is different in the following ways:

- For maps to run inside Sterling B2B Integrator services other than the WTX Map service, these services require that maps meet certain requirements to be considered "[well behaved](#)" maps.
- If the map is checked into the Sterling B2B Integrator map repository, the IBM Transformation Extender map working directory is *SI_install_dir\logs*.
 - If a map uses the **RUN** function in a rule, the map that is referenced must be located either in the Sterling B2B Integrator map repository, or relative to the parent map location on the server.
 - If the Schema *>_Type_>* Metadata card setting specifies an XML schema, the schema should be checked into the Sterling B2B Integrator schema repository. However, if the schema is not in the repository, it should be placed relative to the *SI_install_dir\logs* directory.

All IBM Transformation Extender maps, including validation and translation maps, and maps run through the WTX Map service, first attempt to load the schema from the repository. If the schema is not in the repository, the maps then attempt to load the schema from the map location on the server.

If the map is not checked into the Sterling B2B Integrator map repository, the map runs in the same way as any other IBM Transformation Extender map runs.

- The map can include the Sterling adapter in **PUT** and **GET** rules in the following locations:
 - on the map
 - on component rules in schemas
 - through the command line on an input or output card

The Sterling adapter calls the [data harness](#) to provide access to Sterling B2B Integrator tables. These maps can only run within the Sterling B2B Integrator environment.

To see how to use the Sterling adapter in a map rule to access Sterling B2B Integrator tables, see the translation example in the *install_dir\examples\integrations\SterlingB2B\Engine* directory, where *install_dir* refers to the path where IBM Transformation Extender is installed.

See [Supported Transformation Extender map functionality on Sterling B2B Integrator](#).

- You must [configure](#) the Design Studio settings, such as connection properties, the Check In Map service options, and the troubleshooting options, for Sterling B2B Integrator services.

To test that IBM Transformation Extender for Sterling B2B Integrator is installed correctly, and that Design Studio and Sterling B2B Integrator are configured and are running properly, run the Installation Verification Test (IVT) example under *install_dir\examples\integrations\SterlingB2B*.

- The map must be built on a platform that the Sterling B2B Integrator server supports.
- When you run maps from the Design Studio on the Sterling B2B Integrator server, the map server location is the *install_dir\logs* directory.
- For troubleshooting problems, you must [configure](#) the Save service request and response messages option in the Design Studio.

You can [test](#) the map in the Design Studio to verify that you configured the map to run correctly on Sterling B2B Integrator. After you completed test running the map, you can then [deploy](#) the map from Design Studio to a Sterling B2B Integrator server map repository.

Well-behaved map

There are several Sterling B2B Integrator services that can run IBM Transformation Extender maps. When a IBM Transformation Extender map runs from those services, with the exception of the WTX Map service, it must operate according to a certain set of requirements. A map that meets these requirements is considered to be well-behaved.

A well-behaved map has the following characteristics:

- The map is an executable IBM Transformation Extender map. If at run time the map is provided with the required input, it can be run.
- The map is designed to be called from within a specific Sterling B2B Integrator service. If the service is set up to process incoming X12 data, for example, the first input card of the map accepts X12 data. If the service is expecting the map to generate an XML message, then the last output card of the map creates an XML message.
- You define the restart and burst settings in the map as the service requires, and as stipulated in the Sterling B2B Integrator exhaust input setting.
- If the map requires table data information or settings from Sterling B2B Integrator, such as delimiter settings for outbound EDI, or extract information while parsing the data that is to be sent back to Sterling B2B Integrator, such as correlations, then the map has been designed to meet these requirements.
- The map design follows published Sterling B2B Integrator and IBM Transformation Extender integration best practices including being a thread-safe map. In Sterling B2B Integrator, Sterling B2B Integrator maps are run in a multi-threaded environment.
- The service passes the Primary Document to the first input card and reads it from the last output card. For more information about the Primary Document, see the IBM Transformation Extender for Sterling B2B Integrator documentation.

Data harness

IBM Transformation Extender maps share information with the Sterling B2B Integrator services and other Sterling B2B Integrator processes through the data harness interface.

The data harness uses the basic service framework, or harness model, that Sterling B2B Integrator uses to view all services in the same way. It is invoked by the IBM Transformation Extender map through the Sterling adapter to provide access to database tables.

IBM Transformation Extender maps can read information, such as trading partner information or code list table data, from Sterling B2B Integrator tables. They can also write information about the data, such as a document ID or other key field, that Sterling B2B Integrator can use to track the data.

Some of the examples that are included in the IBM Transformation Extender for Sterling B2B Integrator use the data harness to set values in Sterling B2B Integrator database tables. These values and any other values that maps set or read are included in the map description.

Access the data harness through maps with **PUT** and **GET** rules in the following locations:

- on the map
- on component rules in schemas
- through the Sterling adapter command line on an input or output card

For details about accessing the data harness from maps, see the IBM Transformation Extender for Sterling B2B Integrator documentation.

For more information about the Sterling B2B Integrator harness model and how it operates with external systems, see the IBM Sterling B2B Integrator documentation that you can access through the IBM Sterling B2B Integrator Support website (<http://www.ibm.com/software/commerce/support>).

Getting started with Sterling B2B Integrator

To get started using the Design Studio with the Sterling B2B Integrator runtime option, use the following high-level task list in a preproduction phase.

- [Configure](#) Design Studio for Sterling B2B Integrator.
- [Build](#) the IBM Transformation Extender maps in the Design Studio.
- [Test](#) run the IBM Transformation Extender maps from the Design Studio to a Sterling B2B Integrator server.
- [Deploy](#) the IBM Transformation Extender maps to a Sterling B2B Integrator server map repository.
When your maps are ready for production, after you deploy the maps to a Sterling B2B Integrator server map repository, there are additional tasks to complete using the Sterling B2B Integrator Graphical Process Modeler (GPM) user interface. For information about running maps in a production environment, see the [IBM Sterling B2B Integrator documentation](#).

Configuring Design Studio for Sterling B2B Integrator

You have to configure the Design Studio settings for Sterling B2B Integrator services.

Configure the Test Map service and the Check In Map service to test run IBM Transformation Extender maps on a Sterling B2B Integrator server, and deploy the maps to a Sterling B2B Integrator map repository. In the Sterling B2B Integrator preferences pane, configure the connection properties that are under Connectivity, and the options that are under Check In Map Service and Save Messages.

- [Configuring the connection properties](#)
To test run a IBM Transformation Extender map on a Sterling B2B Integrator server and deploy it to a Sterling B2B Integrator map repository, you must configure the connectivity properties for the services in the Design Studio.
- [Configuring the Check In Map service options](#)
To run the services on a Sterling B2B Integrator server, you must configure the Check In Map service options in the Design Studio.
- [Configuring troubleshooting options](#)
To help you troubleshoot problems when test running IBM Transformation Extender maps on a Sterling B2B Integrator server, and deploying the maps to a Sterling B2B Integrator server map repository, you must configure the Save service request and response messages option in the Design Studio.

Configuring the connection properties

To test run a IBM Transformation Extender map on a Sterling B2B Integrator server and deploy it to a Sterling B2B Integrator map repository, you must configure the connectivity properties for the services in the Design Studio.

Specify the Design Studio settings for the connection properties in the Sterling B2B Integrator preferences under Connectivity. You must enter values for the Sterling B2B Integrator server name, port number for the Sterling B2B Integrator Dashboard, and the user name and password Dashboard authentication information; these are required fields. The connection is established using HyperText Transport Protocol (HTTP), which is the default connection type, or HyperText Transport Protocol Secure (HTTPS).

To configure a connection to the server in the Design Studio:

1. In the Design Studio, click Window > Preferences > Transformation Extender > Map > Sterling B2B Integrator.
The Sterling B2B Integrator preferences pane opens. Enter values and select options under the Connectivity section.
 2. Select one of the following options to specify how you want to set the connection properties for the services:
 - To specify that the same set of connection properties be used for the Sterling B2B Integrator services, select the Use the same server connection properties for 'Test Map' and 'Check In Map' services check box. The preferences pane displays the Connection Properties tab.
 - To specify that a different set of connection properties be used for the Sterling B2B Integrator services, clear the Use the same server connection properties for 'Test Map' and 'Check In Map' services check box. The preferences pane displays the Test Map Service and the Check In Map Service tabs.
- Under the tab that the preference pane displays based on your selection, enter values in the fields and select the required options for the connection properties.
3. Enter the host name or IP address of the Sterling B2B Integrator server in the Login server field.
 4. Enter a number for the Dashboard port field.
If you are using HTTPS, see the topic about [configuring an HTTPS connection](#).
 5. Enter the name of the user in the User name field.

6. Enter the password in the Password field.
7. Click OK to save changes.

- **Configuring an HTTPS connection to the Sterling B2B Integrator server**

You can configure a secure connection to the Sterling B2B Integrator server.

You can configure a secure connection to the Sterling B2B Integrator server.

The Design Studio establishes a HyperText Transfer Protocol (HTTP) connection with a Sterling B2B Integrator server, which is the default connection type, using the server and Sterling B2B Integrator Dashboard port number connection properties specified in the options for IBM Transformation Extender maps.

However, to have a secure connection to the Sterling B2B Integrator server, you can use HyperText Transfer Protocol Secure (HTTPS) access through the Secure Socket Layer (SSL) with the Test Map and Check In Map services. You must configure the Map Test HTTP Server Adapter using SSL in the Sterling B2B Integrator Dashboard. To read about how to do this, see the topic about configuring the HTTP Server adapter in the IBM Sterling B2B Integrator documentation that you can access through the IBM Sterling B2B Integrator Support website (<http://www.ibm.com/software/commerce/support>).

There are additional options under the Connectivity section of the Sterling B2B Integrator server preferences pane in the Design Studio where you specify a secure connection.

To configure a secure connection with the Sterling B2B Integrator server using HTTPS in the Design Studio:

1. Enter the port number in the Dashboard port field.

If you configured the Map Test HTTP Server Adapter for a secure connection, use that same port number for the Dashboard port field.

2. Select the Secure Transport check box.

3. To specify direct trust, select the Trust all hosts check box.

At run time when the map run or deploy operations are attempting to establish a connection to a Sterling B2B Integrator server, the following results occur depending on how Trust all hosts is set:

- If Trust all hosts is selected, the connection verification step that checks the host passes even if the machine host name does not match the host name in the certificate.
- If Trust all hosts is cleared, the connection verification step that checks the host fails if the machine host name does not match the host name in the certificate.

4. Click OK to save changes.

Configuring the Check In Map service options

To run the services on a Sterling B2B Integrator server, you must configure the Check In Map service options in the Design Studio.

You can change Map Designer settings pertaining to the Check In Map service options for IBM Transformation Extender maps in the Sterling B2B Integrator preferences, under Check In Map Service.

To configure the options for running the services:

1. In the Design Studio, click Window > Preferences > Transformation Extender > Map > Sterling B2B Integrator.

The Sterling B2B Integrator preferences pane opens. Select the options under Check In Map Service.

2. Select one of the following choices about which version of the map you want to specify as the default in the Sterling B2B Integrator map repository:

- To make the version of the map that you deploy from the Design Studio the default map in the Sterling B2B Integrator map repository, select the Make checked in map the default check box.
- To keep the version of the same map that is already in the Sterling B2B Integrator map repository, as the default map, clear the Make checked in map the default check box.

3. Select one of the following choices about whether or not you want the service to check if the map is thread-safe to run on the Sterling B2B Integrator server:

- If you do not want the Check In Map service to check if the map is thread-safe to run on the Sterling B2B Integrator server, select the Ignore map thread-safe check check box.
- If you do want the Check In Map service to check if the map is thread-safe to run on the Sterling B2B Integrator server, clear the Ignore map thread-safe check check box.

4. Click OK to save changes.

Configuring troubleshooting options

To help you troubleshoot problems when test running IBM Transformation Extender maps on a Sterling B2B Integrator server, and deploying the maps to a Sterling B2B Integrator server map repository, you must configure the Save service request and response messages option in the Design Studio.

You can change Design Studio settings pertaining to the Save service request and response messages option for IBM Transformation Extender maps in the Sterling B2B Integrator preferences, under Save Messages.

To configure troubleshooting options:

1. In the Design Studio, click Window > Preferences > Transformation Extender > Map > Sterling B2B Integrator.

The Sterling B2B Integrator preferences pane opens.

2. Under Save Messages, select the Save service request and response messages check box to save request and response messages. These files are generated when you run a map from the Design Studio with the Test Map service, or deploy a map from the Design Studio to the Sterling B2B Integrator map repository with the Check In Map service.

3. Click OK to save changes.

Building Transformation Extender maps

Use the build process in the Map Designer to generate a compiled map to use on a Sterling B2B Integrator server.

The build process generates a compiled map with a file name extension that is specific to the target platform of the server, which you specified in the Sterling B2B Integrator preferences window.

You can test run a map from the Design Studio or deploy a map from the Design Studio to the Sterling B2B Integrator server in either the Outline view or Composition view. When you select the map in either of these views, the test run map and deploy map functions automatically build the IBM Transformation Extender map for the target platform of the server, which you specified in the Sterling B2B Integrator preferences window.

You can also deploy a map from the Design Studio to the Sterling B2B Integrator server in either the Navigator view or the Extender Navigator view. When you select an executable map in either of these views, you must first manually build the IBM Transformation Extender map for the target platform of the server by selecting one of the build map options.

After a successful build, you can test the map on the Sterling B2B Integrator server. When you run a IBM Transformation Extender map, the compiled map, and input files are sent to the Sterling B2B Integrator for processing. The results are returned to the Design Studio.

This is a pre-production phase. When your maps are ready for production, after you deployed the maps to a Sterling B2B Integrator server map repository, there are additional tasks to complete using the Sterling B2B Integrator Graphical Process Modeler (GPM) user interface. For information about running maps in a production environment, see the [IBM Sterling B2B Integrator documentation](#).

Testing Transformation Extender maps

You can test running an IBM Transformation Extender map on a Sterling B2B Integrator server.

When you run an IBM Transformation Extender map, the map run operation attaches the compiled map and input files to a request message and sends it to the Sterling B2B Integrator server. After processing has completed successfully, the Sterling B2B Integrator server returns a response message with the status of the map run, any error messages, and audit log file if available to the Design Studio.

To test running an IBM Transformation Extender map on a Sterling B2B Integrator server:

1. Configure the Design Studio connection properties for IBM Transformation Extender maps in the Sterling B2B Integrator preferences pane.
2. Complete any additional prerequisite steps depending on the map's functionality and settings.

Examples:

- You need to make sure that any maps that will be run by the **RUN** function are either checked into the Sterling B2B Integrator map repository, or located relative to the parent map location on the server.
 - If the Schema...Type...Metadata card setting specifies an XML schema, you need to check the schema into the Sterling B2B Integrator schema repository from the Sterling B2B Integrator Dashboard. For information about resolving XML entries, read the related topic in the IBM Transformation Extender for Sterling B2B Integrator documentation.
3. In the Outline view or Composition view, select one or more executable maps, and right-click the maps.
You can select multiple compiled IBM Transformation Extender maps to test run at the same time using the standard selection operations. Press Shift and click a range of maps, or press Ctrl and click individual maps.
 4. Click Run on Sterling B2B Integrator.
This starts the map run operation. For more details about what occurs during the map run operation, see [Run operation details](#).
 5. To run the maps in the background, from the Run on Sterling B2B Integrator: *host_URL* window, click Run in Background.
 6. You can monitor the operation's progress in the Progress view, and view the progress indicator. If you did not open the Progress view before you clicked Run on Sterling B2B Integrator, you can open it in either one of the following ways:
 - Click the progress icon.
 - Click Window...Show View...Other, and under General in the Show View window, click Progress.The Progress view opens.

You can also cancel the map run operation in this view.

The map run operation completes. For more details about the run results from testing an IBM Transformation Extender map on a Sterling B2B Integrator server, see [Result details from test running maps](#).

When you have completed testing your maps so that they run without errors and are ready for production, there are additional tasks to complete. You can deploy the maps to the production environment using the Deploy map to Sterling B2B Integrator option in the context menu of the selected maps. For information about running maps in a production environment, see the [IBM Sterling B2B Integrator documentation](#).

- **[Run operation details](#)**

When the operation to test running a IBM Transformation Extender map on a Sterling B2B Integrator server starts, several things occur.

- **[Result details from test running maps](#)**

These are the result details from test running IBM Transformation Extender maps on a Sterling B2B Integrator server.

Run operation details

When the operation to test running a IBM Transformation Extender map on a Sterling B2B Integrator server starts, several things occur.

The map run operation first verifies that the required connection properties in the Sterling B2B Integrator preferences pane contain values.

If you did not configure the required connection properties in the Sterling B2B Integrator preferences pane before doing this step and so the properties do not contain values, the verification process fails and the Error connecting window opens. The window has a link to the Sterling B2B Integrator preferences pane. You can click the Open preference page to update connection properties link, and in the Sterling B2B Integrator preferences pane, configure the connection properties. If you do not click the link, or you click the link but do not configure the connection properties in the Sterling B2B Integrator preferences pane, and then click OK, the map run operation ends and returns the presentation focus to the Design Studio.

You might be prompted to enter your Sterling B2B Integrator password depending on various scenarios. To learn more about the various scenarios, see [Setting password when test running or deploying map](#).

If the verification process passes, the Run on Sterling B2B Integrator: *host_URL* window opens and displays the progress of the map run operation. The window remains open and the progress of the map run operation continues to display until the operation completes. There is an option available for the maps to run in the background so that you can continue to access the Design Studio graphical user interface (GUI). You might want to select this option for long-running maps.

Result details from test running maps

These are the result details from test running IBM Transformation Extender maps on a Sterling B2B Integrator server.

If the operation ended successfully, the Request Status window opens and displays the `Processing completed successfully` message. The Sterling B2B Integrator server returns a response message with the status of the map or maps run.

If the Test Map service detects a problem, such as a problem connecting to the Sterling B2B Integrator server, or with the running of the map, the Problem Occurred window opens and displays the `Run on Sterling B2B Integrator: host_URL has encountered a problem` message, along with a summary of the problem. You can click Details to view the details about the problem.

If the Progress view was opened before you clicked Run on Sterling B2B Integrator, the status of the map run operation appears there. The Progress view displays the `Processing completed successfully` link. When you click the link, the Test Map Results window opens and lists the names of those map files that ran successfully. In the Test Map Results window, you can click the Show Sterling B2B Integrator Dashboard link to open the Sterling B2B Integrator Dashboard and verify the processes.

If the Progress view was not opened before you clicked Run on Sterling B2B Integrator, you can open the Progress view now. The status of the map run operation appears there. The Test Map Results window opens as if you clicked the `Processing completed successfully` link in the Progress view.

The status in the Progress view includes information such as the host and port name, and the time the process finished. The status indicates the progress of the map or maps run while the data is being mapped.

If you selected the Save service request and response messages option in the Sterling B2B Integrator preferences pane before you clicked Run on Sterling B2B Integrator, at run time, the map run operation saves the response files in the directory where the compiled map is located.

After running the map on Sterling B2B Integrator the output files are saved in the directories that the map's output card with File adapter specified.

The test runs under the MapTest business process. View additional details about the MapTest business process through the Sterling B2B Integrator Dashboard.

If you enabled the Map Audit function in the map's output card and specified `File` for the `MapAudit>.AuditLocation` map setting, the map run operation saves the audit log file in the file location that you specified. If you specified `Memory` for the `MapAudit>.AuditLocation` map setting, the map run operation saves the audit log file in the same working directory where the map is located.

Trace and backup files are not returned to the Design Studio. They are saved on the Sterling B2B Integrator server in the logs directory if map settings are set to map directory, or in custom directory, if custom directory is present.

The map run operation also creates a session log file as `map_name.sil`, which you can view through a text editor.

Deploying Transformation Extender maps

After you tested the running of IBM Transformation Extender maps in the Design Studio, you can deploy them from Design Studio to a Sterling B2B Integrator server map repository.

To deploy a IBM Transformation Extender map or maps to a Sterling B2B Integrator server map repository:

1. Configure the Design Studio connection properties for IBM Transformation Extender maps in the Sterling B2B Integrator preferences pane.
2. Configure the Design Studio Check In Map Service options for IBM Transformation Extender maps in the Sterling B2B Integrator preferences pane.

To make the version of the map that you deploy from the Design Studio the default map in the Sterling B2B Integrator map repository, see [Making the checked-in map the default](#).

3. Make the selections to deploy your map on a Sterling B2B Integrator server in either one of the two following ways, based on the view you use:
 - In the Navigator view or Extender Navigator view, select one or more compiled map files that you built manually for the Sterling B2B Integrator server platform, and right-click the map executable file.
 - In the Outline view or Composition view, select one or more maps, and right-click the maps.
You can select multiple compiled and executable IBM Transformation Extender maps to deploy at the same time using the standard selection operations. Press Shift and click a range of maps, or press Ctrl and click individual maps.
4. Click Deploy to Sterling B2B Integrator.
This starts the map deploy operation. For more details about what occurs during the map deploy operation, see [Deploy operation details](#).
5. To deploy the maps in the background, from the Deploy to Sterling B2B Integrator: *host_URL* window, click Run in Background.
6. You can monitor the operation's progress in the Progress view, and view the progress indicator. If you did not open the Progress view before you clicked Deploy to Sterling B2B Integrator, you can open it in either one of the following ways:
 - Click the green progress icon.
 - Click Window>Show View>Other, and under General in the Show View window, click Progress.The Progress view opens.

You can also cancel the map deploy operation in this view.

The map deploy operation completes. For more details about the run results from deploying IBM Transformation Extender maps from Design Studio to a Sterling B2B Integrator server map repository, see [Result details from deploying maps](#).

- **Making the checked-in map the default**

Select the Make checked in map default check box to make the version of the map that you deploy from the Design Studio the default map in the Sterling B2B Integrator map repository.

- **Deploy operation details**

This is what occurs when the operation to deploy a IBM Transformation Extender map to a Sterling B2B Integrator server map repository starts.

- **Result details from deploying maps**

These are the result details from deploying IBM Transformation Extender maps to a Sterling B2B Integrator server map repository.

Making the checked-in map the default

Select the Make checked in map default check box to make the version of the map that you deploy from the Design Studio the default map in the Sterling B2B Integrator map repository.

If there already is a version of the same map in the Sterling B2B Integrator map repository that is the default, this version of the map is made the default map instead.

When this version of the map is made the default map in the Sterling B2B Integrator map repository, this is the version that Sterling B2B Integrator uses for various processes such as validation, running as a step in a Business Process, translation or transformation, and for generating reports.

To keep the version of the same map that is already in the Sterling B2B Integrator map repository, as the default map, clear the Make checked in map the default check box.

Deploy operation details

This is what occurs when the operation to deploy a IBM Transformation Extender map to a Sterling B2B Integrator server map repository starts.

The map deploy operation first verifies that the required connection properties in the Sterling B2B Integrator preferences pane contain values.

If you did not configure the required connection properties in the Sterling B2B Integrator preferences pane before doing this step and so the properties do not contain values, the verification process fails and the Error connecting window opens. The window has a link to the Sterling B2B Integrator preferences pane. You can click the Open preference page to update connection properties link, and in the Sterling B2B Integrator preferences pane, configure the connection properties. If you do not click the link, or you click the link but do not configure the connection properties in the Sterling B2B Integrator preferences pane, and then click OK, the map deploy operation ends and returns the presentation focus to the Design Studio.

You might be prompted to enter your Sterling B2B Integrator password depending on various scenarios. To learn more about these scenarios, see the Setting password when test running or deploying map topic.

If the verification process passes, the Deploy to Sterling B2B Integrator: *host_URL* window opens and displays the progress of the map deploy operation. The window remains open and the progress of the map deploy operation continues to display until the operation completes. There is an option available for the maps to run in the background so that you can continue to access the Design Studio graphical user interface (GUI). You might want to select this option for long-running maps.

Result details from deploying maps

These are the result details from deploying IBM Transformation Extender maps to a Sterling B2B Integrator server map repository.

If the operation ended successfully, the Request Status window opens and displays the Processing completed successfully message. The IBM Transformation Extender map or maps are deployed to a Sterling B2B Integrator server map repository.

If the Checked In Map service detects a problem, such as a problem connecting to the Sterling B2B Integrator server, or with the deployment of the map, the Problem Occurred window opens and displays the Deploy to Sterling B2B Integrator: *host_URL* has encountered a problem message, along with a summary of the problem. You can click Details to view the details about the problem.

If the Progress view was opened before you clicked Deploy to Sterling B2B Integrator, the status of the map deploy operation appears there. The Progress view displays the Processing completed successfully link. When you click the link, the Check In Map Results window opens and lists the names of those map files that successfully finished being checked into a Sterling B2B Integrator server map repository. In the Check In Map Results window, you can click the Show Sterling B2B Integrator Dashboard link to open the Sterling B2B Integrator Dashboard and verify the checked-in files.

If the Progress view was not opened before you clicked Deploy to Sterling B2B Integrator, you can open the Progress view now. The status of the map deploy operation appears there. Alternatively, you can click the progress icon. The Check In Map Results window opens as if you clicked the Processing completed successfully link in the Progress view.

The status in the Progress view includes information such as the host and port name, and the time the process finished. The status indicates the progress of the map deploy operation while the map or maps are deployed to a Sterling B2B Integrator server map repository.

If you selected the Save service request and response messages option in the Sterling B2B Integrator preferences pane before you clicked Deploy to Sterling B2B Integrator, at run time, the map deploy operation saves the response files in the directory where the compiled map is located.

The map deploy operation also creates a session log file as *map_name.sil*, which you can view through a text editor.

Troubleshooting Transformation Extender maps

If you are testing running or deploying a IBM Transformation Extender map on a Sterling B2B Integrator server for the Test Map service or Check In Map service, and the map fails, follow these troubleshooting tips.

Verify that IBM Transformation Extender for Sterling B2B Integrator is installed correctly, and that Design Studio and Sterling B2B Integrator are configured and are running properly. To do this verification, run the Installation Verification Test (IVT) example that is under *install_dir\examples\integrations\SterlingB2B*, where *install_dir* refers to the path where IBM Transformation Extender is installed.

- [Troubleshooting for the Test Map service](#)
 - [Troubleshooting for the Check In Map service](#)
-

Troubleshooting for the Test Map service

To troubleshoot IBM Transformation Extender maps running on a Sterling B2B Integrator server using the Test Map service, you reference the error return codes, and the session and audit log files.

Error messages

When a map fails to run, it displays the error status in the Run window of the Design Studio. The following topics contain the error codes and messages that can be returned when your IBM Transformation Extender map fails.

- [Map execution error and warning messages](#)
- [Error messages in Design Studio for Sterling B2B Integrator services](#)

Log files for Transformation Extender maps

The following files are created automatically when running a IBM Transformation Extender map from the Design Studio:

- [Sterling B2B Integrator session log file](#)
- [Sterling B2B Integrator audit log file](#)

Each file is viewable with a text editor or from the Map Designer Organizer.

Trace and backup files are not returned to the Design Studio. They are saved on the Sterling B2B Integrator server in the logs directory if map settings are set to map directory, or in custom directory, if custom directory is present.

- [Sterling B2B Integrator session log file](#)
The Sterling B2B Integrator session log (.sil) file contains test session and execution status messages when running a IBM Transformation Extender map from the Design Studio to a Sterling B2B Integrator server.
 - [Sterling B2B Integrator audit log file](#)
The Sterling B2B Integrator audit log (.log) file is generated automatically at run time.
-

Sterling B2B Integrator session log file

The Sterling B2B Integrator session log (.sil) file contains test session and execution status messages when running a IBM Transformation Extender map from the Design Studio to a Sterling B2B Integrator server.

This log file also contains exceptions that occur during the session. The file is generated in the map directory, and is named after the executable map. The contents of this file can be viewed in a text editor.

Sterling B2B Integrator audit log file

The Sterling B2B Integrator audit log (.log) file is generated automatically at run time.

It is generated regardless of the Switch setting for MapAudit. If the map audit log is enabled on a Sterling B2B Integrator server, the map audit log that the server generates contains the same content as the audit log file that the map running locally generates.

The audit log file generally has content, regardless of a successful execution. It is named after the executable map (*map_name.log*) and is generated in the map directory. The contents of this file can also be viewed in the Audit Log view.

Troubleshooting for the Check In Map service

To troubleshoot IBM Transformation Extender maps deploying to a Sterling B2B Integrator server map repository using the Check In Map service, for specific Sterling B2B Integrator information, view the Sterling B2B Integrator log files. This is in addition to viewing the WebSphere Transformation Extender Design Studio log (.log) file located in the *your_workspace/.metadata* folder.

If the Check In Map service detects an error, the Problem Occurred window opens. Click OK to close the window, or Details to expand the window and view the error message.

For more information about the Sterling B2B Integrator log files and how to view them, see the [IBM Sterling B2B Integrator documentation](#).

WebSphere DataPower SOA Appliances

IBM DataPower SOA Appliances are network devices that can help secure and accelerate your XML and Web services deployments.

The Map Designer provides the features to build and test maps that you can run on, and deploy to IBM DataPower SOA Appliances.

See [DataPower appliance](#) to read about the benefits of using a DataPower appliance.

How the Map Designer works with DataPower appliances

Using the Map Designer, you can create maps that ultimately serve as executable programs designed to transform and route data. From the Map Designer, you test the maps on, and deploy them to the DataPower appliance, the appliance runs the executable maps, and then returns the results back to the Map Designer.

Getting started with DataPower appliances

To get started using the Map Designer with the WebSphere DataPower runtime option, use the following high-level task list in a preproduction phase.

- [Configure](#) your project to create DataPower maps by default, and enable the functions that are supported for IBM DataPower SOA Appliances.
- [Configure](#) the Map Designer for an WebSphere DataPower SOA Appliance.
- Define the structure of your data using the Type Designer and use the resulting schemas to create your DataPower maps.
- [Build](#) the DataPower maps with the map run time set to WebSphere DataPower.
- [Test](#) the DataPower maps in the Map Designer.
- [Deploy](#) the DataPower maps to be processed to an WebSphere DataPower SOA Appliance.

When your maps are ready for production, after you deployed the maps to an WebSphere DataPower SOA Appliance, there are additional tasks to complete using the DataPower appliance user interface. For information about running maps in a production environment, see the *IBM WebSphere DataPower SOA Appliances: Integrating with Transformation Extender* documentation that is published on the IBM DataPower Support website (<http://www.ibm.com/software/integration/datapower/support>).

- [Limitations of DataPower SOA appliances](#)
- [Project settings for DataPower maps](#)
- [Configuring for WebSphere DataPower SOA Appliance services](#)
- [Generating WebSphere DataPower maps](#)
- [Testing DataPower maps](#)
- [Deploying WebSphere DataPower maps](#)
- [Troubleshooting DataPower maps](#)

Limitations of DataPower SOA appliances

DataPower SOA appliances do not support all of the features of Map Designer. Some features are not available and the ability to use map and card settings is limited. The limitations on DataPower maps are listed here. For limitations on DataPower SOA appliances, see the [DataPower release notes](#).

Map settings

DataPower SOA appliances support all map settings except [MapTrace](#). For the [WorkSpace](#) setting, they support only the [Memory](#) value.

The mapping process sets the [Switch](#) setting for MapTrace to OFF, and the WorkSpace setting to Memory, and then runs the map by using those values. It also overrides the MapAudit and Warnings settings that are based on the settings on the WebSphere DataPower SOA Appliance.

If the ITX Audit Log map audit setting is enabled on the WebSphere DataPower SOA Appliance, that setting overrides the Switch setting for MapAudit to ON and the AuditLocation setting to Memory. If the map audit setting is not enabled on the Appliance, the mapping process sets the Switch setting for MapAudit to OFF. The mapping process generates the map audit log based on the map audit setting on the Appliance.

If the Support ITX Warnings map warning option is selected on the WebSphere DataPower SOA Appliance, the mapping process uses the values that you set for the Warnings property in the map settings. If the warning setting is not selected on the Appliance, the mapping process on the Appliance handles all map warnings as failures, unless the Warnings>Return setting is specified as Ignore. When you specify Warning>Custom, the mapping process on the Appliance handles those map warnings that are set as Warn or Fail as failures, while those map warnings set as Ignore, are ignored. To be able to use the Restart attribute and the REJECT function, the map warnings setting must be specified as Ignore. At run time, when the map detects invalid objects, it ignores them and continues processing.

To read about how to enable or disable map audit and warning settings on DataPower SOA appliances, see the DataPower documentation. For information about how to run a DataPower map locally, see [Running locally](#).

Card settings

DataPower SOA appliances support all card settings except the Backup setting. The mapping process sets the Switch setting for Backup to OFF for all of the input and output cards of a map. Then, the mapping process runs the map with that setting turned off. For information about how to run a DataPower map locally, see [Running locally](#).

The mapping process sets the DocumentVerification setting to Well Formed for all input cards of the map and then runs the map with that setting. It calls the external parser for document verification only for the well-formed document. So there is no external schema validation for DataPower maps.

Map Designer features

The following Map Designer features are not available for use with DataPower maps:

- [Debugger](#)
- [Profiler](#)

For information about how to run a DataPower map locally, see [Running locally](#).

Functions

Custom functions cannot be used in DataPower maps. In addition, DataPower SOA appliances do not support the following functions:

- **DBLOOKUP**
- **DBQUERY**
- **DDEQUERY**
- **EXIT**
- **GET**
- **GETANDSET**
- **GETDIRECTORY**
- **GETFILENAME**
- **GETRESOURCENAME**
- **JEXIT**
- **PUT**

The unsupported functions that are listed previously are applicable to both map and component rules.

XML functions

DataPower SOA appliances support the use of the following XML functions in map rules in DataPower maps:

- XPATH
- XSLT
- XVALIDATE

The above XML functions may need access to resources located either on the appliance or that are remotely accessible to the appliance. The resources referenced in the functions include XML, XSL, or XSD files. DataPower SOA appliances use their own methods to process these functions in the map rules.

Absolute resource paths can have only Uniform Resource Locators (URLs) that start with **local:///**, **store://**, **http://**, or **https://**. Resources that are on the DataPower SOA appliances can be accessed by the appliances through URL paths that start with **local:///** or **store://**. Resources that are located remotely can be accessed through URL paths that start with **http://** or **https://**.

Relative resource paths are resolved by the mapping process, which appends the relative path to the absolute path of its parent map. Relative resource paths of the top-level map are resolved based on the working directory that is set by the DataPower SOA appliance for the top-level map. If you specify relative paths that contain the parent directory (..) notation, which is not valid for DataPower SOA appliances, the mapping process returns an error.

DataPower maps also support paths that start with **current://**. Resource paths starting with **current://** are run like the relative resource paths defined above. Therefore, **current://** equates to the . (current directory) notation in relative paths and is substituted with the parent map path during transformation. DataPower maps do not support **file://** URL paths in the XML functions.

Since DataPower SOA Appliances use their own methods to process these XML functions, map runtime behavior differences may occur when running DataPower maps on an appliance against running them locally on the system. Errors reported with the **LASTERRORMSG** function may differ for appliance and local runs of DataPower maps.

For information about how to run a DataPower map locally, see [Running locally](#). To read about the functions, see the related topics in the *Functions and Expressions* documentation.

Resource adapters

DataPower SOA appliances support the following IBM Transformation Extender resource adapters:

- ECHO
- FILE
- SINK
- STATIC FILE

The FILE and SINK adapters are the only target options available for output. The ECHO, FILE, and STATIC FILE adapters are the only source options available for input. IBM DataPower SOA Appliances do not support the other IBM Transformation Extender resource adapters.

RUN maps

DataPower SOA appliances support the use of the **RUN** function in map and component rules in DataPower maps, but with specific limitations.

All of the limitations that are described in this *Limitations* topic apply as well to **RUN** maps. Here are more limitations that apply only to **RUN** maps.

- If the map input source and output target cards specify adapters other than ECHO, SINK, or STATIC FILE, you must use the **-IE**, **-OE**, or **-OASINK** command-line options to override the adapters. You can use the **ECHOIN** or **HANDLEIN** functions to override the adapters in the map input source cards. If you do not override the input source or output target adapters that are not supported for **RUN** maps, for example, the FILE adapter, the mapping process returns **Source not available (12)** or **Target not available (9)** errors.
- The following commands and command options are ignored:
 - **-T (MapTrace)** command
 - **-W (WorkSpace)** command
 - **K (Backup)** option with **-OASINK** command
 - **EN, EA, EF, ES** (DocumentVerification) options with **-IE**, **-OE**, or **-OASINK** commands
 - **U, +, !+, ={file|dir}** options with **-A (MapAudit)** command
- The map audit log is generated only when both of the following settings are specified:
 - The MapAudit setting is set to ON, either with the **MapAudit** switch map setting that is set to ON or with the **-A (MapAudit)** command line that is specified along with options.
 - The ITX Audit Log map audit setting is set on the DataPower SOA appliances.
- Absolute map paths can have only Uniform Resource Locators (URLs) that start with **local:///**, **store://**, **http://**, or **https://**. Maps that are on the DataPower SOA appliances can be accessed by the appliances through URL paths that start with **local:///** or **store://**. Maps that are located remotely can be accessed through URL paths that start with **http://** or **https://**.
- Relative map paths are resolved by the mapping process, which appends the relative path to the absolute path of its parent map. Relative **RUN** map paths of the top-level map are resolved based on the working directory that is set by the DataPower SOA appliances for the top-level map. If you specify relative paths that contain the parent directory (..) notation, which is not valid on DataPower SOA appliances, the mapping process returns **Could not open map(3)** error.

For information about how to run a DataPower map locally, see [Running locally](#). To read about the execution commands, and the command availability, which lists the commands that are valid with the **RUN** function, see the related topics in the *Execution Commands* documentation.

The Database Interface Designer is only available for use with IBM Transformation Extender maps. DataPower SOA appliances do not support IBM Transformation Extender database adapters.

Integration Flow Designer

The Integration Flow Designer is only available for use with IBM Transformation Extender maps. DataPower maps within a map source file are not visible in the Integration Flow Designer.

Resource Registry

The Resource Registry is only available for use with IBM Transformation Extender maps. DataPower maps do not support resource aliases in map settings, card settings, and map rules. Resource configuration (.mrc) files and Resource name (.mrn) files created by using the Resource Registry are not supported on DataPower SOA appliances.

Enterprise Application Packs and Industry Packs

DataPower SOA appliances do not support the IBM Transformation Extender Enterprise Application Packs.

For the latest information, see [DataPower SOA appliances support of IBM Transformation Extender Industry Packs](#).

For information about a specific release of the Industry Packs, see the IBM Transformation Extender [release notes](#).

WSDL Importer

DataPower SOA appliances do not support the Transformation Extender Web Services Description Language (WSDL) Importer.

Map runtime behavior differences

Maps that are run on a WebSphere DataPower SOA Appliance behave differently from maps that are run on other platforms on which IBM Transformation Extender maps run. The mapping process behaves differently in the following ways:

- Processes the NULL value in a character text item for XML types, which are specified in the schema with the Intent property set to XML, as an invalid character.
- Processes the year 0000 value in the Date & Time item as an invalid date.
- Overrides map and card settings before it runs the WebSphere DataPower maps. See [Map settings](#) and [Card settings](#).
- Processes some of the XML functions with its own methods. For more information, see [XML functions](#).

Tip: If you abide by these limitations, you can initially create your maps by using the standard IBM Transformation Extender run time to take advantage of features such as the Map Debugger and Profiler. When your map unit testing is successful, you can then change the runtime setting to WebSphere DataPower and proceed to build and run the maps. For information about how to run a DataPower map locally, see [Running locally](#).

Project settings for DataPower maps

You can configure settings for your project for DataPower maps.

There are two project settings that you can configure:

- Default Map Runtime
- Update Map Runtime

You configure the project settings in the Map Designer under Project > Properties > Transformation Extender. These project settings are used to set and update the MapRuntime setting to indicate the map runtime environment in source map (.mms) files.

Use the Default Map Runtime setting with the DataPower check box selected to create DataPower maps by default. This selection sets the MapRuntime setting to DataPower in source map (.mms) files that you create. If you clear the DataPower check box, it sets the MapRuntime setting to Integration Platform in source map (.mms) files that you create. You might want to use this setting when most of the maps you create are to be deployed to an WebSphere DataPower SOA Appliance.

Use the Update Map Runtime setting to update the MapRuntime setting with a value that you select in the MapRuntime list, in all of the executable maps in all of the map source (.mms) files in the project. Select one of the values in the MapRuntime list: DataPower or Integration Platform. Click Update and toggle between updating the MapRuntime setting to the selected value in all of the executable maps in all of the map source (.mms) files in the project. You might want to use this project setting when you need to compile all executable maps for IBM DataPower SOA Appliances, or environments other than IBM DataPower SOA Appliances, with one set of source maps.

- [Configuring your project to create DataPower maps by default](#)

You can configure your project to create DataPower maps by default.

- [Configuring your project to update the MapRuntime setting in all of the executable maps](#)

You can configure your project to update the MapRuntime setting in all of the executable maps in all of the map source (.mms) files in the project.

Configuring your project to create DataPower maps by default

You can configure your project to create DataPower maps by default.

If most of the maps you create are to be deployed to an WebSphere DataPower SOA Appliance, before you begin creating your DataPower maps, you can change the Default Map Runtime setting on your project to DataPower. All new maps that you create are DataPower maps by default. This setting makes all Map Designer functions that IBM DataPower SOA Appliances support available to you as you design your DataPower maps.

To configure the Default Map Runtime setting:

1. In the Map Designer, select the project in the Extender Navigator view, and click Project > Properties > Transformation Extender.
2. In the Default Map Runtime pane, select the DataPower check box.
3. Click OK to save the change.

When you create a map, DataPower is the value set in the MapRuntime setting by default. You can view this value in the MapRuntime setting in the Map Settings window.

Configuring your project to update the MapRuntime setting in all of the executable maps

You can configure your project to update the MapRuntime setting in all of the executable maps in all of the map source (.mms) files in the project.

When you need all of the executable maps in all of the map source (.mms) files in your project to have the same MapRuntime setting, you can use the MapRuntime setting that is in the Update Map Runtime pane. It updates the MapRuntime setting to indicate the map runtime environment in all of the source maps.

To configure your project to update the MapRuntime setting in all of the executable maps in all of the map source (.mms) files in your project:

1. In the Map Designer, select the project in the Extender Navigator view, and click Project > Properties > Transformation Extender.
2. In the Update Map Runtime pane, select from the MapRuntime list, either Integration Platform or DataPower.
3. Click Update.

All of the executable maps in all of the map source (.mms) files in your project are updated with the value that you selected from the MapRuntime list for the MapRuntime setting. If you selected DataPower, only those maps that use the functions and adapters that DataPower supports, are updated. If the source map is open, maps that were updated are listed in the Outline view or Composition view with their respective map icon.

You can click OK or Cancel to close the Properties window.

Configuring for WebSphere DataPower SOA Appliance services

You have to configure the Map Designer settings for the Interoperability Test Service and the XML Management Interface service to test and deploy DataPower maps on an WebSphere DataPower SOA Appliance.

- [Configuring for the Interoperability Test Service](#)
- [Configuring for the XML Management Interface service](#)

Configuring for the Interoperability Test Service

To test a DataPower map on an WebSphere DataPower SOA Appliance from the Map Designer, you must configure the connectivity settings for the Interoperability Test Service in the Map Designer. The host name or IP address, and a port number for the DataPower appliance are required. The connection is established using HyperText Transport Protocol (HTTP), which is the default connection type, or HyperText Transport Protocol Secure (HTTPS).

You can change default Map Designer settings pertaining to connectivity for the Interoperability Test Service in the DataPower preferences.

To configure a connection to the appliance for the Interoperability Test Service using HTTP in the Map Designer:

1. In the Map Designer, click Window > Preferences > Transformation Extender > Map > DataPower.
The DataPower preferences pane opens.
 2. Under Connectivity, enter the IP address or the host name for the DataPower appliance in the Host field. (For IPv6, enclose the IP address in brackets.)
The default value is `localhost`.
 3. Click the Interoperability Test Service tab.
 4. Enter a value for the Port field.
The default port for the HTTP Service is 9990. If you are using HTTPS, you must enter a different value for the Port field. See the topic about [configuring an HTTPS connection](#).
 5. Click OK to save changes.
- [Configuring an HTTPS connection](#)
 - [Save Messages options](#)
 - [Appliance Configuration options](#)
 - [Working Directory option](#)
 - [Retry map setting](#)

Configuring an HTTPS connection

The Map Designer establishes an HTTP connection with an WebSphere DataPower SOA Appliance, which is the default connection type, using the host and port parameters specified in the options for the Interoperability Test Service. To have a secure connection with the DataPower appliance, you can use Hypertext Transfer Protocol Secure. (HTTPS).

To establish a secure connection using HTTPS, you must first enable the security option in the Map Designer. When you run a DataPower map from Map Designer on the IBM DataPower SOA Appliances, you are prompted through a standard Certificate window to dynamically select the option to trust the certificate from the appliance, and add it to the certificate store (`install_dir\java\lib\security\cacerts`, where `install_dir` refers to the path where IBM Transformation Extender is installed). The server certificate and private key must be set up on the DataPower appliance. For information about how to set up the server certificate and private key on the DataPower appliance, see the related topics in the *IBM WebSphere DataPower SOA Appliances: Integrating with Transformation Extender* documentation that is published on the IBM WebSphere DataPower Support website (<http://www.ibm.com/software/integration/datapower/support>).

To configure a secure connection to the appliance for the Interoperability Test Service using HTTPS in the Map Designer:

1. In the Map Designer, click Window > Preferences > Transformation Extender > Map > DataPower.
The DataPower preferences pane opens.
2. Under Connectivity, enter the IP address or the host name for the DataPower appliance in the Host field. (For IPv6, enclose the IP address in brackets.)

The default value is localhost.

3. Click the Interoperability Test Service tab.
4. Enter a value for the Port field.
The default port for the HTTPS Service is 9991.
5. Select the Secure Transport check box.
6. Click OK to save changes.

Save Messages options

The Save Messages options for the Interoperability Test Service pertain to the request and response messages, and the session log file.

Use the files that are generated when you select the Save Messages options to debug the problems that your map might encounter while running on a DataPower appliance. You can view these files using a text editor. By default, the options are not selected.

To access these settings, click Window > Preferences > Transformation Extender > Map > DataPower, and under Connectivity, click the Interoperability Test Service tab.

Request option

Select the Request option to save a copy of the request message (*map_name_Request.msg*) in the map directory.

The request message is the initial communication passed from the Map Designer to the DataPower appliance. It contains information about the compiled map, input files, as well as information about the Appliance configuration options, and mapping information pertaining to the input and output cards.

Response option

Select the Response option to save a copy of the response message (*map_name_Response.msg*) in the map directory.

The response message is a message generated by the DataPower appliance that passes the output and audit log files back to the Map Designer.

Session option

Select the Session option to generate the DataPower session log (*map_name.dpl*) file in the map directory.

The DataPower session log file contains test session information about a DataPower map running on a DataPower appliance from the Map Designer. It logs exception, informational, and execution messages.

Appliance Configuration options

The Appliance Configuration options pertain to the ITX Audit Log map audit setting, and the Support ITX Warnings setting for the Interoperability Test Service, and for the DataPower maps running locally.

To access the Appliance Configuration options, click Window > Preferences > Transformation Extender > Map > DataPower, and under Connectivity, click the Interoperability Test Service tab.

ITX Audit Log

Specify the audit context name for the Interoperability Test Service that the WebSphere DataPower SOA Appliance references to generate and save the map audit log. If you do not specify the audit context name, the audit log is not generated, and therefore it is not saved. By default, the audit context name is not specified; the field is blank.

If the ITX Audit Log map audit setting is set on the WebSphere DataPower SOA Appliance for the Interoperability Test Service from the Map Designer, the audit log is generated regardless of the MapAudit->Switch map setting.

You must specify the ITX Audit Log map audit setting for DataPower maps running locally to generate the map audit log regardless of the MapAudit->Switch map setting. This specification is required to generate the map audit log even if you run the compiled DataPower map from the Extender Navigator view using the Map Settings option.

Support ITX Warnings

Select the Support ITX Warnings check box to support map warnings on the WebSphere DataPower SOA Appliance from the Map Designer for the Interoperability Test Service, when running DataPower maps locally. The Support ITX Warnings check box option is not selected by default.

If the Support ITX Warnings map warning option is selected on the WebSphere DataPower SOA Appliance for the Interoperability Test Service from the Map Designer, the mapping process uses the values that you set for the Warnings property in the map settings. If the warning setting is not selected on the Appliance, the mapping process on the Appliance handles all map warnings as failures, unless the Warnings->Return setting is specified as Ignore. When you specify Warning->Custom, the mapping process on the Appliance handles those map warnings set as Warn or Fail as failures, while those map warnings set as Ignore, are ignored.

You must specify the Support ITX Warnings map warning option for DataPower maps running locally to support map warnings. This option is required to support map warnings even if you run the compiled DataPower map from the Extender Navigator view using the Map Settings option.

Working Directory option

The Working Directory option for the Interoperability Test Service pertains to specifying the Uniform Resource Locator (URL). The Interoperability Test Service uses the working directory URL to resolve the relative **RUN** map paths of the DataPower map being tested on the WebSphere DataPower SOA Appliance from the Map Designer. This option is not used by the DataPower maps running locally.

To specify the working directory URL, click Window > Preferences > Transformation Extender > Map > DataPower, and under Connectivity, click the Interoperability Test Service tab.

URL

Select the Uniform Resource Locator (URL) from the URL list. The default URL is local:///{{project_name}}/.

Custom

If the URL you need is not in the URL list, you can create a custom URL by clicking Custom. After you click Custom, the Custom URL window is displayed.

In the Custom URL window, you can specify the URL to resolve the relative **RUN** map paths. The default is local:/// . You can define custom URL paths that start with local:///, store:///, http:// and https://.

Retry map setting

The Retry map setting can be used to request additional connection attempts to the DataPower appliance when a failure occurs. After you set the `RetryAttempts` setting to ON, you can enter maximum number of attempts and interval values. The `MaxAttempts` value is the maximum number of connection attempts to make. The default value for this setting is 10.

The Interval value determines the amount of time (in seconds) to allow between connection attempts. The default value for this setting is 5.

Configuring for the XML Management Interface service

To deploy a map on a WebSphere DataPower SOA Appliance, you must configure the connectivity settings for the XML Management Interface service in the Map Designer.

The host name or IP address, password, port number, domain, and file options for the DataPower appliance are required. The connection is established using HTTPS.

You can change default Map Designer settings pertaining to connectivity for DataPower maps in the DataPower preferences.

When you deploy a DataPower map from Map Designer on the IBM DataPower SOA Appliances, you are prompted to establish a secure connection using HTTPS, through a standard Certificate window, to dynamically select the option to trust the certificate from the appliance, and add it to the certificate store (`install_dir\java\lib\security\cacerts`, where `install_dir` refers to the path where IBM Transformation Extender is installed). The server certificate and private key must be set up on the DataPower appliance. For information about how to set up the server certificate and private key on the DataPower appliance, see the related topics in the *IBM WebSphere DataPower SOA Appliances: Integrating with Transformation Extender* documentation that is published on the [IBM DataPower Support website](#).

To configure a secure connection to the appliance using HTTPS in the Map Designer:

1. In the Map Designer, click Window > Preferences > Transformation Extender > Map > DataPower.
The DataPower preferences pane opens.
2. Under Connectivity, enter the IP address or the host name for the DataPower appliance in the Host field. (For IPv6, enclose the IP address in brackets.)
The default value is `localhost`.
3. Click the XML Management Interface Service tab.
4. Enter your DataPower user name and password for the User and Password fields.
These fields are the credentials to log on to the DataPower File Manager.
5. Enter a value for the Port field.
The default port for the XML Management Interface service is 5550.
6. Enter the DataPower deploy domain for the Domain field.
7. Under File Options, select the target location of the file being deployed by using one of the following file options:
 - Default file - Select one of the predefined location variables from the Default file list. The default predefined location value is `local:///{{project_name}}/{{map_name}}`.
 - Custom - Define your own custom target location other than the predefined locations in the Default file list.
 - Overwrite file without asking - Select to overwrite a file that was previously deployed to an WebSphere DataPower SOA Appliance without asking for permission.
8. Click OK to save changes.

- [Setting Custom File name](#)

Setting Custom File name

Use the Custom File window to define where the file is to be deployed if it is to a location other than the predefined locations in the Default file list.

To define the custom target location of the file being deployed:

1. In the Map Designer, click Window > Preferences > Transformation Extender > Map > DataPower.
The DataPower preferences pane opens.
2. Under Connectivity, click the XML Management Interface Service tab.
3. Under File Options, click Custom.
The Custom File window opens.
4. Select the custom file name from the list under Enter the custom file name.
The default value is `local://`.
5. Define your own location by specifying either the actual path or variables, or a combination of both path and variables.
6. Click OK.
This returns you to the Connectivity window with your location in the Default file field.

Generating WebSphere DataPower maps

Before building a DataPower map, the `MapRuntime` setting must be set to DataPower.

To set the map runtime setting:

1. In the Outline view or Composition view, select the map and do one of the following choices:
 - On the Map menu, click Map Settings.
 - On the toolbar, click the Map Settings icon.
 - Right-click the map and on the menu, click Map Settings.
2. In the Map Settings window, locate the `MapRuntime` setting.

3. Display the list, and select DataPower.

4. Click OK.

In the Outline view or Composition view, a DataPower map is represented by a distinct icon.

The next step is to build the map. After a successful build, you can run the map. When you run a DataPower map, the compiled map, and input files are sent to the WebSphere DataPower SOA Appliance for processing. The results are returned to the Map Designer.

This is a preproduction phase. When your maps are ready for production, there are additional tasks to complete using the WebSphere DataPower SOA Appliance user interface. For information about running maps in a production environment, see the DataPower documentation.

- [Building a WebSphere DataPower map](#)

Building a WebSphere DataPower map

Use the build process in the Map Designer to generate a compiled map with the DataPower appliance (.dpa) extension.

To build a DataPower map:

1. In the Outline view or Composition view, select the map and do one of the following choices:

- On the Map menu, click Build.
- On the toolbar, click the Build icon.
- Right-click the map and on the menu, click Build.

2. From the menu bar, click Map > Build.

A window opens that displays the build status and then closes.

To verify that the map was built without errors, open the Organizer folder and double-click the Build Results element. The Build Results view opens. A blank Build Results view indicates that there were no build errors.

The build results can also be viewed using a text editor. The file (*map_name.mme*) is located in the map directory.

If you are building multiple DataPower maps, select the map in the Outline view or Composition view, and from the menu bar, click Map > Build All.

During the build process, the Map Designer generates a compiled map with the DataPower appliance (.dpa) extension.

Testing DataPower maps

You can test a DataPower map by running it on an WebSphere DataPower SOA Appliance from the Map Designer, or by running it locally.

- [Running on a WebSphere DataPower SOA Appliance](#)
- [Running locally](#)

Running on a WebSphere DataPower SOA Appliance

When you run a DataPower map, the compiled map, and input files are attached to a request message that is sent to the WebSphere DataPower SOA Appliance. All RUN maps referenced by the DataPower map that is run on the appliance, must be in the specified RUN map URL paths. RUN maps are not packaged and sent to the appliance in the request message for the Interoperability Test Service. After processing completes, a response message is returned with the output and audit log files.

If you built a map to be run on an WebSphere DataPower SOA Appliance, to test it from the Map Designer, the Interoperability Test Service must be running on the appliance.

To run a DataPower map on an WebSphere DataPower SOA Appliance:

1. In the Outline view or Composition view, select the map and do one of the following choices:

- On the Map menu, click Run.
- On the toolbar, click the Run icon.
- Right-click the map and on the menu, click Run.

If you configured the Interoperability Test Service using HTTPS in the Map Designer, after you click Run to test the DataPower map, you are prompted through a standard Certificate window to dynamically select the option to trust the certificate from the appliance, and add it to the certificate store.

2. Click Cancel to close the IBM DataPower SOA Appliances window.

3. To view results, right-click the map and click Run Results on the menu.

The Run Results window opens.

4. Select the items you want to view and click OK.

The results are displayed.

The IBM DataPower SOA Appliances window opens and displays the executable map name, host and port information, status, and elapsed time. These statistics indicate the progress of the map run while the data is being mapped. After the mapping process completes, the outputs are saved as specified in the settings of the output cards, and the map audit log file is saved as specified in the map settings.

When you completed testing your maps so that they run without errors and are ready for production, there are additional tasks to complete. You can deploy the maps to the production environment using the Deploy to DataPower option in the menu of the selected maps. For information about running maps in a production environment, see the [IBM DataPower SOA Appliances: Integrating with Transformation Extender](#) documentation that is published on the [IBM DataPower Support website](#).

Running locally

The Run Locally command that is on the menu for the map, is enabled for DataPower maps.

- The command is used to run DataPower maps locally on the system, instead of on IBM DataPower SOA Appliances.
- All of the map settings, MapAudit in File, MapTrace, and WorkSpace in File, in addition to the Backup card setting that IBM DataPower SOA Appliances do not support, are supported when you run DataPower maps locally.
- To troubleshoot and debug your map, you can specify the following options to generate the map audit and trace log files:
 - Set the Switch setting for the MapTrace map setting to ON in the Map Settings window.
 - Specify the audit context name in the ITX Audit Log map audit setting in the Appliance Configuration options in the DataPower preferences window. When you run maps locally, you must specify the HIP Audit Log map audit setting to generate the map audit log. You specify this setting in this same way whether you are testing DataPower maps by running them on a WebSphere DataPower SOA Appliance, or locally, or whether you are running them on an WebSphere DataPower SOA Appliance from the Map Designer.

If the MapAudit.`_AuditLocation` setting on the DataPower map is set to Memory, the map audit log is saved in the map directory and named after the executable map (`map_name.log`).

- To support map warnings, select Support ITX Warnings option under Appliance Configuration options for DataPower. The mapping process uses the values that you set for the Warnings property in the map settings. If the warning setting is not selected, the mapping process handles all map warnings as failures, unless the Warnings.`_Return` setting is specified as Ignore. When you specify Warning.`_Custom`, the mapping process handles those map warnings that are set as Warn or Fail as failures, while those map warnings set as Ignore, are ignored. To be able to use the **Restart** attribute and the **REJECT** function, the map warnings setting must be specified as Ignore. At run time, when the map detects invalid objects, it ignores them and continues processing.
- The mapping process sets the DocumentVerification setting to Well Formed for all input cards of the map and then runs the map with that setting. It calls the external parser for document verification only for the well-formed document. So there is no external schema validation for DataPower maps.
- When you locally run a DataPower map that is compiled with a static input file, the mapping process validates the static input file in the compiled map only once, when the map loads, and creates a trace file in the map directory only if the static file input fails validation.
- If the map input source and output target cards specify adapters other than ECHO, SINK, or STATIC FILE, you must use the **-IE**, **-OE**, or **-OASINK** command-line options to override the adapters. You can use the **ECHOIN** or **HANDLEIN** functions to override the adapters in the map input source cards. If you do not override the input source or output target adapters that are not supported for **RUN** maps, for example, the FILE adapter, the mapping process returns `Source not available (12) or Target not available (9)` errors.
- The following commands and command options are supported when you run DataPower maps locally even though they are not supported on IBM DataPower SOA Appliances:
 - **-T (MapTrace)** command
 - **-W (WorkSpace)** command
 - **K (Backup)** option with **-OASINK** command
 - **U, +, !+, ={file|dir}** options with **-A (MapAudit)** command
- The **EN**, **EA**, **EF**, **ES** (DocumentVerification) options with **-IE**, **-OE**, or **-OASINK** commands are ignored.
- When you run DataPower maps locally, the mapping process ignores the absolute map URL path that references a **RUN** map. Instead, the mapping process searches for the **RUN** map in the map directory. Absolute map URL paths start with `local:///`, `store://`, `http://`, or `https://`.
- Relative paths that contain the parent directory (..) notation, are not valid on IBM DataPower SOA Appliances and when you run the DataPower map locally. If you specify relative paths in this way, the mapping process returns `Could not open map(3)` error. The mapping process resolves the relative **RUN** map paths that are based on the map directory of the parent map.
- When you run DataPower maps locally, the mapping process ignores the absolute resource URL path that references a resource located either on the appliance or that is remotely accessible to the appliance when specified for the XML functions (such as XPATH, XSLT, or XVALIDATE). Instead, the mapping process searches for the resource in the map directory. Absolute map URL paths start with `local:///`, `store://`, `http://`, or `https://`.
- Relative resource paths that contain the parent directory (..) notation are not valid on DataPower appliances when you run the DataPower map locally. If you specify relative resource paths in this manner for the XML functions, the mapping process returns an error. The mapping process resolves the relative resource paths that are based on the map directory of the parent map.
- DataPower maps that are run locally also support paths that start with `current://`. Resource paths starting with `current://` are run like the relative resource paths defined above. In this scenario, `current://` equates to the .. (current directory) notation in relative paths and is substituted for the parent map path during transformation. DataPower maps do not support `file://` URL paths in the XML functions.
- DataPower appliances use their own methods to process some XML functions (such as XPATH, XSLT, or XVALIDATE), and map runtime behavior differences may occur when running DataPower maps on an appliance against running them locally on the system. Errors reported with the LASTERRORMSG function might differ between appliance and local runs of DataPower maps.

Default map settings are set in the Run Options window that you open from Window > Preferences > Transformation Extender > Map > Run Options. After a map is created, select Map Settings from the Map menu to change the settings for the selected map.

You can override the original map and card settings of the DataPower map in the Map Designer. In the Extender Navigator view, right-click the DataPower (.dpa) map in the Map Executables folder, and on the menu, click Map Settings. Use this feature to test different combinations of map and card settings dynamically with the same DataPower (.dpa) map without recompiling the source map.

To run a DataPower map locally:

1. Run the DataPower map locally by using one of the following menu options:
 - In the Extender Navigator view, right-click the compiled DataPower (.dpa) map in the Map Executables folder, and click Run Locally.
 - In the Outline view or Composition view, right-click the executable DataPower, and on the menu, click Run Locally.
2. Click Cancel to close the window.
3. To view results, right-click the map and click Run Results on the menu.
The Run Results window opens.
4. Select the items that you want to view and click OK.
The results are displayed.

The Command Server window opens. It displays the executable map name, status, total number of input objects that are found, total number of output objects that are built, and elapsed time. These statistics indicate the progress of the map that is run, while the data is being mapped. After the mapping process completes, the outputs are saved as specified in the settings of the output cards. The map audit log and trace files are saved as specified in the map settings.

Deploying WebSphere DataPower maps

After you tested the DataPower maps in the Map Designer, you can deploy them from Map Designer to an WebSphere DataPower SOA Appliance.

To deploy a DataPower map or maps:

1. Configure the Map Designer deployment settings for DataPower maps using the DataPower preferences.
2. From the Map Designer, deploy the DataPower map using one of the following menu options:
 - In the Extender Navigator view, right-click the compiled DataPower (.dpa) map in the Map Executables folder, and select Deploy to DataPower.
 - In the Outline view or Composition view, right-click the executable DataPower map, and on the menu, click Deploy to DataPower.

You can select multiple compiled and executable DataPower maps to deploy at the same time using the standard selection operations. Press **Shift** and click a range of maps, or press **Ctrl** and click individual maps; then right-click and select Deploy to DataPower.

If you configured the XML Management Interface service in the Map Designer, after you click Deploy to DataPower to deploy the DataPower map from Map Designer to an WebSphere DataPower SOA Appliance, you are prompted through a standard Certificate window to dynamically select the option to trust the certificate from the appliance, and add it to the certificate store.

3. If the Overwrite file without asking checkbox in the XML Management Interface tab under Connectivity in the DataPower preferences pane is clear, that is, not selected, the Overwrite File window opens, and you can select one of several overwrite options for the deployment process.

The DataPower map or maps are deployed to an WebSphere DataPower SOA Appliance.

If the XML Management Interface service detects an error, the Problem Occurred window opens. Click OK to close the window, or Details to expand the window and view the error message.

- [Setting password for XML Management Interface service](#)
- [Overwriting a deployed file](#)

Setting password for XML Management Interface service

When you select Deploy to DataPower to deploy a DataPower map from the Map Designer to an WebSphere DataPower SOA Appliance, you might or might not be prompted to enter your DataPower password in the Enter Password window.

If the Enter Password window does open, it is because one of the following scenarios occurred:

- You did not enter a password under Connectivity, in the XML Management Interface Service tab of the DataPower preferences pane that opens from Window > Preferences > Transformation Extender > Map > DataPower.
- You entered a password in the DataPower preferences pane, but you subsequently closed the Map Designer application before deploying the DataPower map. When you enter your password, it is saved only in memory, and therefore, available to the deploy process until you exit the Map Designer. After you exit the Map Designer application, your password is no longer available when you restart Map Designer and attempt to deploy a DataPower map.

To set password:

1. Enter a password in the Enter Password window.
2. Click OK.
The Enter Password window closes.

The XML Management Interface service validates your DataPower user name, password and domain.

If the authentication is successful, the deployment process continues.

If the authentication fails, the Problem Occurred window opens. Click OK to close the window, or Details to expand the window and view the error message.

Overwriting a deployed file

Use the Overwrite File window to overwrite a file that was previously deployed to an WebSphere DataPower SOA Appliance without asking for permission. This window opens if the Overwrite file without asking check box in the XML Management Interface Service tab under Connectivity in the DataPower preferences pane is clear, that is, not selected. There are three file overwrite options for the deployment process.

To overwrite a file:

1. Click one of the following file overwrite options for the deployment process:
 - Overwrite the current file, which overwrites the same file that was previously deployed.
 - Deploy the file with a different name, which overwrites the file with the absolute path location where the file is to be deployed that you enter in the File field.
 - Cancel the deployment, which cancels the deployment process.
2. Select Remember my decision if you want subsequent deployments to use the settings you selected in this Overwrite File window.
When you select Remember my decision, Map Designer selects the Overwrite file without asking check box in the DataPower preferences pane. The next time you deploy a DataPower map to an WebSphere DataPower SOA Appliance, the deployment process does not open the Overwrite File window.
3. Click Proceed.

If you specified a new file name, the DataPower map is deployed to an WebSphere DataPower SOA Appliance with the new file name.

If the XML Management Interface service detects an error, the Problem Occurred window opens. Click OK to close the window, or Details to expand the window and view the error message.

Troubleshooting DataPower maps

If you are testing or deploying a DataPower map on a DataPower appliance for the Interoperability Test Service or XML Management Interface service, and the map fails to run on or deploy to the DataPower appliance, follow the troubleshooting tips listed here.

To troubleshoot DataPower environment-specific issues while you are testing or deploying a DataPower map on the appliance, see the troubleshooting tips in the DataPower documentation that is published on the [IBM DataPower Support website](#). Read about the DataPower logs on the appliance, to help you troubleshoot these issues, in the *IBM DataPower SOA Appliances: Problem Determination Guide* documentation that is published on the [IBM DataPower Support website](#).

- [Troubleshooting for the Interoperability Test Service](#)
- [Troubleshooting for the XML Management Interface service](#)

Troubleshooting for the Interoperability Test Service

To troubleshoot DataPower maps running on a WebSphere DataPower appliance using the Interoperability Test Service, you reference the error return codes, and the session and audit log files.

Error messages

When a map fails to run, it displays the error status in the Run dialog box of Map Designer. The following topics contain the error codes and messages that can be returned when your DataPower map fails.

- [Map execution error and warning messages](#)
- [Error messages for maps](#)

Log files for DataPower maps

The following files can be used for troubleshooting the errors when running a DataPower map from the Map Designer:

- DataPower session log file
- DataPower audit log file

Each file is viewable with a text editor or from the Organizer in the Map Designer.

- [DataPower session log file](#)
- [DataPower audit log file](#)

DataPower session log file

The DataPower session log (.dpl) file contains test session and execution status messages when running a DataPower map from the Map Designer. This log file also contains exceptions that occur during the session. The file is generated in the map directory, and is named after the executable map. The contents of this file can be viewed in the Session view as well as in a text editor.

- [Viewing the DataPower session log file](#)

Viewing the DataPower session log file

Use the Session view to examine the contents of the DataPower session log.

To view the DataPower session log:

1. Expand the map in the Outline view, and expand the Organizer folder.
2. Double-click the Session element.

The Session view opens, and you can view the contents of the DataPower session log file. The *map_name.dpl* is generated in the map directory and can also be viewed using a text editor.

DataPower audit log file

The DataPower audit log is generated at run time, regardless of the Switch setting for MapAudit. If the ITX Audit Log map audit setting is enabled on the WebSphere DataPower SOA Appliance for Interoperability Test Service, the audit log that the Appliance generates contains the same content as the map audit log file that the map running locally generates. If a problem occurs with the Interoperability Test Service that prevents DataPower map from running, and the ITX Audit Log map audit setting is enabled on the WebSphere DataPower SOA Appliance, the audit log that the Appliance generates contains different content, with dummy data, than the audit log that the map running locally generates.

The DataPower audit log that the WebSphere DataPower SOA Appliance generates is saved as you specified in the *MapAudit->AuditLocation* setting on the DataPower map. If the *MapAudit->AuditLocation* setting on the DataPower map is set to Memory, the DataPower audit log is saved in the map directory and named after the executable map (*map_name.log*).

The audit log file generally has content, regardless of a successful execution. The contents of this file can be viewed in the Audit Log view, as well as in a text editor.

Troubleshooting for the XML Management Interface service

To troubleshoot DataPower maps deploying to a DataPower appliance using the XML Management Interface service, in addition to viewing the WebSphere Transformation Extender Design Studio log (.log) file located in the *your_workspace/.metadata* folder, for specific DataPower information, view the DataPower log files.

If the XML Management Interface service detects an error, the Problem Occurred window opens. Click OK to close the window, or Details to expand the window and view the error message.

For more information about the DataPower log files and how to view them, see the *IBM WebSphere DataPower SOA Appliances: Problem Determination Guide* documentation that is published on the [IBM DataPower Support website](#).

Standards Processing Engine

When Standards Processing Engine (SPE) is installed on IBM Transformation Extender, you can use IBM Transformation Extender maps to de-envelope, transform, and envelope documents and to validate document compliance with data standards.

You install SPE on Design Studio to test and deploy IBM Transformation Extender maps, IBM Sterling B2B Integrator maps, XSLT maps, XML schemas, and DTDs on SPE.

- **[Configuring Map Designer for SPE](#)**

To configure Map Designer to work with the Standards Processing Engine (SPE), set up the connection to the SPE database and configure the test and deployment options.

- **[Testing a map on SPE and displaying results](#)**

To test-run a map on Standards Processing Engine, right-click the map in the appropriate view and click Run on Standards Processing Engine. To display the test results of XSLT and IBM Sterling B2B Integrator maps, right-click the map in the appropriate view and click View Run Results. IBM Transformation Extender map results display in the input and output cards as usual.

- **[Deploying a map to SPE](#)**

To deploy maps and other artifacts to Standards Processing Engine (SPE), right-click the artifact in the appropriate view and click Deploy to Standards Processing Engine Repository.

Configuring Map Designer for SPE

To configure Map Designer to work with the Standards Processing Engine (SPE), set up the connection to the SPE database and configure the test and deployment options.

- **[Creating a project and importing maps](#)**

A project organizes maps and artifacts in Design Studio. You can create a project for the maps and artifacts that run on the Standards Processing Engine (SPE). Import any maps that are not created by Design Studio (such as XSLT files and schemas) into the project.

- **[SPE database connection](#)**

The Standards Processing Engine (SPE) database stores maps and other artifacts. Design Studio supports a default database as well as other SPE databases.

- **[SPE database deployment options](#)**

Configure the Standards Processing Engine (SPE) deployment options to identify and organize the artifacts that you deploy from Design Studio to the SPE database.

- **[SPE test options](#)**

To run on the Standards Processing Engine (SPE), IBM Sterling B2B Integrator maps and XSLT maps require input and output files. You can configure default input and output files to avoid supplying the file names each time you test-run the map. You also can specify the name of a .properties file to use when you test-run a IBM Sterling B2B Integrator map.

- **[SPE Logging options](#)**

Use the Design Studio Standards Processing Engine preferences to configure the logging options that are in effect when you deploy an artifact to SPE or test-run a map on SPE.

Creating a project and importing maps

A project organizes maps and artifacts in Design Studio. You can create a project for the maps and artifacts that run on the Standards Processing Engine (SPE). Import any maps that are not created by Design Studio (such as XSLT files and schemas) into the project.

1. Start Design Studio.

2. Create a project:

- a. Select File > New > Extender Project.
- b. Specify a unique project name.
- c. Use the default path for the project, or clear the Use default location field and browse to another directory.
- d. Click Finish.

3. Import a map to the project:

- a. Click File > Import.
- b. Expand General.
- c. Click File System and click Next.
- d. Browse to the directory that contains the map or other artifact to import and click OK.
The source directory and its contents display.
- e. Select the maps and artifacts to import.
- f. Click Browse to select a folder in the current project to copy the artifacts into.
- g. Optional: Select the overwrite or folder structure options.
- h. Click Finish.

SPE database connection

The Standards Processing Engine (SPE) database stores maps and other artifacts. Design Studio supports a default database as well as other SPE databases.

To use Design Studio to test maps on SPE or deploy artifacts to SPE, you can configure a database in the Design Studio Preferences, or you can use the default database.

When you configure a database, you must supply the SPE database URL, user name, and password to connect Design Studio to the database. If you specify the user name and password in advance in the Manage Repository window, they are automatically in effect when you test on or deploy to the database on SPE. If you do not specify them in advance, you must supply the database user name and password each time you test on or deploy to the database on SPE.

You do not need to configure a URL, user name, or password to test or deploy maps to the SPE default database. The default database uses the values in the SPE dbprops.cfg file.

- [Configuring SPE database connections](#)

Design Studio can test-run maps and deploy artifacts to the Standards Processing Engine (SPE). Use the Design Studio preferences to configure the connection to an SPE database, or use the default SPE database.

Configuring SPE database connections

Design Studio can test-run maps and deploy artifacts to the Standards Processing Engine (SPE). Use the Design Studio preferences to configure the connection to an SPE database, or use the default SPE database.

These steps configure a connection to an SPE database other than the default SPE database. The default SPE database displays `DEFAULT` in the Name field, is always available, and requires no configuration.

1. Start Design Studio.
2. Click Window \rightarrow Preferences.
3. In the navigation pane, expand Transformation Extender and click Standards Processing Engine.
4. In the Repository section, click Manage to add, edit, or delete a database connection.
Note: You cannot edit or delete the default database connection.
5. In the Name field, enter a label for the database connection, for example, "Test" or "Production."
(The Name field displays `DEFAULT` when the SPE default database connection is in effect.)
6. In the URL field, enter either:
 - The URL of the SPE database in JDBC format. For example:

```
jdbc:derby://localhost:1527/spe  
jdbc:oracle:thin:@oracledb6.acme.com:1527:ora11  
jdbc:db2://db2db9.acme.com:50000/spetest
```

- The URL of a configuration file that contains the JDBC/OpenJPA connection parameters of the SPE database. For example:

```
file:///C:/oracledb.cfg  
file:///C:/SPEInstall/dbprops_SQLServer2012.txt
```

7. Specify the SPE database user name and password in one of the following ways:
 - Enter the information in the User Name and Password fields.
 - Include the user name and password in the URL for the SPE database. For example:

```
jdbc:derby://localhost:1527/spe;user=admin1;password=sec12cde
```

- Include the user name and password in the URL by specifying the `{dbuser}` and `{dbpswd}` variables. For example:

```
jdbc:derby://localhost:1527/spe;user={dbuser};password={dbpswd}
```

With this configuration, Design Studio prompts you to enter a user name and password each time you test-run a map or deploy an artifact to SPE.

- Specify the user name and password by specifying the `{dbuser}` and `{dbpswd}` variables in the User Name and Password fields. With this configuration, Design Studio prompts you to enter a user name and password each time you test-run a map or deploy an artifact to SPE.

8. In the Driver Name field, enter the name of the JDBC driver that connects to the SPE database.

9. Optional: In the Schema Name field, enter the name of the SPE database schema.

10. Click one of the following:

Update

To update an existing SPE database connection or add a new one.

Delete

To delete an existing SPE database connection.

Finish

To update or add an SPE database connection and close the Manage Repository window without a confirmation prompt.

Close

To cancel your changes and close the Manage Repository window.

SPE database deployment options

Configure the Standards Processing Engine (SPE) deployment options to identify and organize the artifacts that you deploy from Design Studio to the SPE database.

Tenant Identifier

Associates an identifier with the artifacts that you check in, and creates a segment in the database for the artifacts that are associated with the identifier. The tenant identifier is sometimes called the reference identifier.

Make checked in resource the default

You can store multiple versions of artifacts and maps in the SPE database. SPE uses the default version when you invoke the `ENVELOPE`, `DEENVELOPE`, or `TRANSFORM` command.

When you enable this option and deploy an artifact that already exists in the database, the new version becomes the default version in the database. If you do not enable the option and you deploy an artifact that already exists in the database, the new version is added to the database, but the current default remains the default version. If you do not enable the option and you deploy an artifact that does not exist in the database, the new artifact is added to the database and becomes the default version.

You can use the SPE trading partner user interface to change the default version of a map or artifact in the SPE database.

Use default comments

Enable this option to associate a pre-configured comment with an artifact that you deploy to the database. The comments display when you view the artifacts with SPE Trading Partner user interface.

Click Show Comments to display or edit the check-in comment. You can enter freehand comments, or you can use the variables in any order to dynamically create comments at check-in time. If the comment exceeds 255 characters when the variables are resolved, Design Studio truncates the comment.

For example, when you specify the following check-in comment as the default comment:

```
Test of {map_schema_dir} {map_schema_name} on {timestamp}
```

The check-in comment in the database looks similar to:

```
Test of install_dir 8.4.1 PreProcessEDI on  
Fri Oct 11 09:26:14 EDT 2013
```

{timestamp}

Adds the current time and date to the check-in comment.

{user_name}

Adds the system account user name to the check-in comment. The system account user name is configured in the Microsoft Windows system properties.

Note that this user name can be different from the SPE database user name.

{project_name}

Adds the name of the project from which the artifact is deployed to the SPE database.

{map_schema_dir}

Adds the directory of the map or schema on the local file system to the check-in comment.

{map_schema_name}

Adds the name of the map or schema that you are deploying to the check-in comment.

SPE test options

To run on the Standards Processing Engine (SPE), IBM Sterling B2B Integrator maps and XSLT maps require input and output files. You can configure default input and output files to avoid supplying the file names each time you test-run the map. You also can specify the name of a .properties file to use when you test-run a IBM Sterling B2B Integrator map.

- **Configuring default input and output files**

You can configure default input and output files to use each time you test-run XSLT and IBM Sterling B2B Integrator maps on the Standards Processing Engine. You can select default files from the Design Studio project or the file system, or generate the file names at run time. Without default file names, you must enter the name of the input and output file each time you run an XSLT or IBM Sterling B2B Integrator map on SPE.

- **Setting Sterling B2B Integrator translator properties**

You can specify the translator properties that are to be in effect when you test-run a IBM Sterling B2B Integrator map on the Standards Processing Engine (SPE). Use the Configuration file field to enter the .properties file name, or browse to the file in the project or on the file system. Design Studio passes the properties through SPE to the IBM Sterling B2B Integrator translator. The properties are available when the map runs.

Configuring default input and output files

You can configure default input and output files to use each time you test-run XSLT and IBM Sterling B2B Integrator maps on the Standards Processing Engine. You can select default files from the Design Studio project or the file system, or generate the file names at run time. Without default file names, you must enter the name of the input and output file each time you run an XSLT or IBM Sterling B2B Integrator map on SPE.

1. Start Design Studio.

2. Click Window> Preferences.

3. In the navigation pane, expand Transformation Extender and click Standards Processing Engine.

4. Click Use default input and output files for XSLT and Sterling B2B Integrator maps.

5. Specify the default file name:

- Generate the input and output file names at run time:

In each Default file field, use the down-arrow to select a predefined name-pattern or click Custom to enter your own pattern. You can use the following variables in the file name:

{map_dir}

Substitutes the directory of the map that uses the file as a source or a target.

{map_name}

Substitutes the name of the map that uses the file as a source or a target.

- Select an input or output file from the current project:

Click Custom and browse to the folder in the project where the default file is. Use the filter field to show only the folders that match the filter text.

- Select an input or output file from the local file system:

Click Custom>Browse and enter the name in the File field, or browse to the file on the file system.

Setting Sterling B2B Integrator translator properties

You can specify the translator properties that are to be in effect when you test-run a IBM Sterling B2B Integrator map on the Standards Processing Engine (SPE). Use the Configuration file field to enter the .properties file name, or browse to the file in the project or on the file system. Design Studio passes the properties through SPE to the IBM Sterling B2B Integrator translator. The properties are available when the map runs.

SPE Logging options

Use the Design Studio Standards Processing Engine preferences to configure the logging options that are in effect when you deploy an artifact to SPE or test-run a map on SPE.

Generate Session Log

Generates a log file when you test-run a map or deploy an artifact to SPE. The log file is created in the artifact directory on the file system with the name *artifact_name.slg*. If you do not enable this option, Design Studio does not produce a session log.

Append to an existing session log

Appends a new log to an existing log file, if one exists, or creates a new log. When this option is not enabled, the new log overwrites an existing log.

Logging Level

Controls the level of information that is logged. The Severe, Warning, and Information options correspond to Java™ logging levels and represent descending message severity and importance. The All option tracks all messages.

The Debug option logs exceptions and other information from both IBM Transformation Extender and SPE. The Debug option produces a log of Transformation Extender and SPE information even when no exceptions occur.

Click Project > Clean to delete session log files.

Testing a map on SPE and displaying results

To test-run a map on Standards Processing Engine, right-click the map in the appropriate view and click Run on Standards Processing Engine. To display the test results of XSLT and IBM Sterling B2B Integrator maps, right-click the map in the appropriate view and click View Run Results. IBM Transformation Extender map results display in the input and output cards as usual.

Table 1. Testing on SPE. Design Studio views for testing a map on SPE and displaying test results

Map type:	Test-run the map from:	Display the test results from:
Executable Transformation Extender map	<ul style="list-style-type: none">Outline viewComposition view	Map input and output cards
Compiled (for Microsoft Windows) Transformation Extender map	<ul style="list-style-type: none">Navigator viewExtender Navigator view	Map input and output cards
IBM Sterling B2B Integrator map	<ul style="list-style-type: none">Navigator viewExtender Navigator view	<ul style="list-style-type: none">Navigator viewExtender Navigator view

Global transaction management

Although this functionality is referred to as global transaction management, it can also be referred to as distributed transaction management or two-phase commit architecture.

Global transaction management is the monitoring of transactions that can include operations on two or more different data sources. This feature of transaction processing enables data resources to be returned to a pre-transaction state if some error occurs. Either all data resources are updated or none are. The advantage of this strategy is that data resources remain synchronized and data remains consistent.

- [Components](#)

Components

There are three components commonly found in global transaction management models:

- Client Application
- Transaction Manager
- one or more Resource Managers
- [Client application](#)
- [Transaction manager](#)
- [Resource managers](#)

Client application

The role of the client application in global transaction management is similar to what it was for local transaction management. It will initiate and complete transactions and perform standard data operations, as in getting messages and updating rows, upon data sources included in this transaction. However, with global transaction management being implemented, the main difference is when the transactions are either committed or rolled back as monitored by a transaction manager.

In this global transaction management model, client applications are those adapters that support this functionality. For more information about the adapters currently supported, refer to ["Supported Adapters"](#).

After the data operations have been successfully completed by the client applications, the transaction manager is notified to commit the transaction. For an example of the entire process, refer to ["Flow Example"](#).

Transaction manager

The role of the transaction manager is to serve as a coordinator for all of the components involved in the global transaction and to keep track of all of the steps involved in the transactions. The transaction manager works with all of the resource managers to reach a consistent decision as to whether to commit or cancel the transaction.

If all of the resource managers are ready and in unanimous agreement, the transaction manager instructs them all to commit their transactions. If any one of the resource managers involved in this global transaction is not ready or able to commit, or does not respond to the transaction manager request, *all* of the resource managers are instructed by the transaction manager to roll back their transactions.

In summary, there are three different results that the transaction manager may find on a local level:

- The client application either commits or cancels the transaction.
- One of the resource managers cancels the transaction.
- A failure occurs, for example, there is an interruption on the network.

In all of the situations, the transaction manager must signal the resource managers to either commit or roll back the entire transaction. If any failure in the system occurs, the transaction would be rolled back.

- [Transaction specification types](#)
- [Supported Third-party Transaction Managers](#)
- [Supported adapters](#)

Transaction specification types

The communication between the three components involved in global transaction has been defined in specifications. The two protocols supported in the IBM Transformation Extender implementation of the global transaction management functionality are:

- XA/TX protocol
- OLE transactions specification protocol

There are differences in the way that each of these protocols is used in the transaction management models.

XA/TX protocol

The XA/TX protocol consists of two X/Open specifications: XA and TX.

The XA interface is a bi-directional interface between a transaction manager and a resource manager. Both managers must implement some functions from this interface. These managers use functions from the XA interface to communicate during the transaction preparation and commit activities.

The TX interface is used by the client application to contact the transaction manager. Only the transaction manager can implement this interface. This is used by the client application to notify the transaction manager that the transaction has been successfully committed, or not. If there was an error in the commit, the transaction manager takes over the data recovery portion.

Most of the commonly used resource managers support the XA interface and can be called XA/TX-compliant resource managers. However, there are only a few XA/TX-compliant transaction managers that are widely accepted or acknowledged.

OLE transactions specification protocol

The OLE Transactions specification protocol is a protocol developed to support the COM model and must be used on Windows platforms.

Supported Third-party Transaction Managers

The third-party transaction managers currently supported are:

- **IBM® MQ Transaction Manager (MQS TM)**

This manager is installed as part of the IBM MQ product and supports the XA/TX protocol.

- **Microsoft Distributed Transaction Coordinator Transaction Manager (MSDTC TM)**

This manager is installed along with Microsoft Windows operating systems and supports the OLE Transactions specification protocol.

Supported adapters

The following adapters support¹ global transactions: These adapters are listed with the transaction manager required for each. For operating system and version-specific information, see the system requirements (www.ibm.com/software/integration/wdatastagtx/requirements/requirements.html). See also the [release notes](#).

Adapter

Transaction Manager

IBM® WebSphere® MQ
MQS TM

MSMQ
MSDTC TM

Oracle

MQS TM

MS SQL Server
MSDTC TM

Oracle AQ

MQS TM

There are special configuration requirements to implement global transaction management. For more information, see ["Configuration Requirements"](#). For specific information about these adapters, see the respective documentation.

¹Only the IBM WebSphere MQ and MS SQL Server adapters can initiate and participate in global transactions. The MSMQ, Oracle, and Oracle AQ adapters can participate only in global transactions initiated by the MS SQL Server or IBM WebSphere MQ adapters, respectively.

Resource managers

Resource managers are data source managers, such as database management systems (DBMSs), that participate in a global transaction. These resource managers track their activities at the local level in transaction log files. Additionally, they can prepare recovery information and acquire all of the necessary locks and resources to either commit or roll back transactions when instructed by the transaction manager. Often, the old and new data is saved in storage so that any commit or rollback instruction can be performed accurately, even after any failure in the system, including applications, the transaction manager, or the resource manager. The resource managers work in cooperation with the transaction manager to provide the client application with a guarantee of atomicity of the global transactions.

Configuration requirements

Before global transaction management can be implemented, the following requirements must be met:

- A transaction manager must be installed and running on the same machine as the IBM Transformation Extender products are installed.

- The transaction manager being used must be established in the TransManager setting of the **config.yaml** file under the /runtime/Resource Manager path. See "[TransManager Setting](#)".
 - Each input and output card in any map involved with the global transaction scenario must include the Global Transaction (-GTX) adapter command.
 - [Installing and running transaction managers](#)
 - [TransManager setting](#)
 - [Input and output card settings](#)
 - [Global transactions in multiple threads](#)
-

Installing and running transaction managers

Because the supported transaction managers, MQS TM and MSDTC TM,) are third-party applications, refer to the respective documentation for more information about how to install and run these services. However, make sure that the transaction manager is installed on the same machine where IBM Transformation Extender products are installed when you are ready to begin your processing.

TransManager setting

There is a new setting under the /runtime/Resource Manager path of the **config.yaml** file for the transaction manager. MQS is the default setting.

```
TransManager: {MQS[,qm_name][,trace_full_path]|
  MSDTC[,machine_name][,trace_full_path]}
```

Value

Value	Description
MQS	This indicates that the IBM® WebSphere® MQ Transaction Manager is the transaction manager for this machine.
<i>qm_name</i>	This indicates the name of the queue manager to which to connect. If not entered, the default queue manager is assumed.
<i>trace_full_path</i>	This indicates the fully qualified path name of the trace file to be used to track all of the activities surrounding this transaction. The reason to specify this trace file is because it captures information such as connections to and from the transaction manager, and the start of global transaction. This information is not included in the trace files generated at the adapter or card level.
MSDTC	This indicates that the Microsoft Distributed Transaction Coordinator Transaction Manager is the transaction manager for this machine.
<i>machine_name</i>	This indicates the name of the machine upon which the master MSDTC service is running. This master service controls resources and all of the slave MSDTCs. If not entered, the default is assumed to be the local machine.

Input and output card settings

The Global Transaction (-GTX) adapter command must be specified in all of the input and output cards involved in this transaction. If the command is missing from any card, the transaction will be processed as a local transaction, not as a global one. Again, only those [adapters](#) supporting this functionality can use this command.

Global transactions in multiple threads

When global transactions are run concurrently in multiple threads, additional steps are required to configure the environment.

A new setting, **ShareConnectionThreads**, has been added to the **config.yaml** file under /runtime/Connections Manager to enable data operations on different resources to be executed in the same thread. If you want to enable multi-threaded global transactions, you must configure this setting as follows:

```
ShareConnectionThreads:1
```

The value of 1 indicates that the connections from the cards with the -GTX adapter command belong to the same thread.

When the IBM® WebSphere® MQ, Oracle, and Oracle AQ adapters are participating in global transactions managed by the MQS TM, the XAResourceManager stanza for Oracle must be properly configured. For UNIX systems, this stanza is located in the **qm.ini** file of the queue manager that is being used as a transaction manager; for Windows systems, it is located in the Windows Registry. On UNIX systems, the **qm.ini** file must be manually edited. In Windows, you can use the graphical user interface (GUI) to configure this stanza.

The **ThreadOfControl** setting of this stanza must be set to THREAD, as indicated below:

```
ThreadOfControl=THREAD
```

Additionally, in the Oracle XA open string, the following setting must be added:

```
Threads=True
```

For more information about the settings in the **config.yaml** file, refer to the *Launcher documentation*.

Examples

This documentation contains the following examples:

- a global transaction between IBM® WebSphere® MQ and Oracle
- trace log files created by both the MSDTC and the MQS transaction managers
- [Flow example](#)
- [Trace log file examples](#)

Flow example

Refer to the information about the events that occur for each number in this example. Processes A and B must be run on the same machine. Process C can also run on the same machine or on another machine.

- [Legend for the example](#)

Legend for the example

1. The transformation server begins to run the map and detects the presence of the `-GTX` adapter command in the first input card.
2. The transformation server reads the value of the `TransManager` entry in the `config.yaml` file. In this example, the value is `MQS,qm_name` which indicates to the transformation server that this card is going to participate in an XA type of global transaction. The other option for the `TransManager` value would be `MSDTC,machine_name`, which would indicate the OLE Transactions type of the global transaction.
3. The transformation server calls the IBM® WebSphere® MQ adapter and the adapter receives a request to initiate a new XA global transaction.
The transformation server passes the `qm_name` value from the `config.yaml` file to the IBM WebSphere MQ adapter. This is so that the queue manager selected to serve as the XA transaction monitor recognizes the adapter.
4. The IBM WebSphere MQ adapter connects to the `qm_name` queue manager.
The IBM WebSphere MQ queue manager returns the connection handle to the adapter.
5. The IBM WebSphere MQ adapter requests that the IBM WebSphere MQ queue manager start a new global transaction. The IBM WebSphere MQ queue manager has already recognized the process context of the application that has requested to start the transaction (*Process A*).
6. The IBM WebSphere MQ queue manager searches to determine if there is any other XA resource manager registered with the `qm_name` queue manager. In this search, the Oracle entry is discovered.
The IBM WebSphere MQ queue manager then calls the Oracle resource manager to inform it about the new global transaction started on behalf of the *Process A* process.
- The Oracle resource manager acknowledges this and the IBM WebSphere MQ queue manager notifies the IBM WebSphere MQ adapter that a new global transaction started.
- The IBM WebSphere MQ adapter reports this to the transformation server.
7. The transformation server continues to run the map. The first input card is IBM WebSphere MQ.
The transformation server requests that the IBM WebSphere MQ adapter connect to the queue manager and queue specified in the adapter command of the card (`-QMN QMNAME -QN QUEUE1`).
8. The IBM WebSphere MQ adapter recognizes that this card belongs to a global transaction because the `-GTX` adapter command was specified. Because of this, instead of connecting again to the IBM WebSphere MQ queue manager, it uses the connection handle obtained in Step 4. Therefore, if the `-GTX` adapter command is used, the `-QMN` adapter command is irrelevant because the IBM WebSphere MQ adapter will use the `qm_name` queue manager.
9. The transformation server requests that the IBM WebSphere MQ adapter get a message.
10. The IBM WebSphere MQ adapter sends a `GET` request to the IBM WebSphere MQ queue manager.
The IBM WebSphere MQ queue manager checks the process context of the application and gets the message within the transaction started on behalf of this same process.
- The IBM WebSphere MQ queue manager returns the message to the adapter and the adapter passes it back to the transformation server.
11. The transformation server now examines the output card. It requests that the Oracle adapter connect to the Oracle resource manager.
12. The Oracle adapter recognizes that it is participating in a global transaction, because of the presence of the `-GTX` adapter command. Instead of using the regular connection mechanism, the Oracle adapter calls special Oracle XA functions to obtain the connection handles.
13. The Oracle resource manager checks the process context of the application and it recognizes that this application started the global transaction, as communicated by the IBM WebSphere MQ queue manager previously in Step 6.
The Oracle resource manager returns a special connection handle to the Oracle adapter. Operations performed on this connection will belong to the global transaction.
14. The transformation server passes data from the input card, an IBM WebSphere MQ message, to the output card.
15. The transformation server issues a request to the Oracle adapter to store this data in the database table.
16. The Oracle adapter calls the Oracle resource manager with the `INSERT` request, using the connection handle obtained in Step 13.
17. The Oracle resource manager stores data in the table and notifies the Oracle adapter, which then informs the transformation server that the database output operation was performed successfully.
18. The mapping was successful and the transformation server calls the IBM WebSphere MQ adapter to commit the global transaction.
19. The IBM WebSphere MQ adapter calls the IBM WebSphere MQ queue manager with the `COMMIT` request.
20. The IBM WebSphere MQ queue manager knows that this process started the global transaction and that it now should commit it.
The IBM WebSphere MQ queue manager and the Oracle resource manager now start working together to commit the transaction. They exchange information using the XA two-phase commit protocol to ensure that either everything is committed, message retrieved and data inserted in the table, or that everything is rolled back.

No partial outcome is possible. The XA protocol ensures this with its functions and the help of the transaction logs managed both by the IBM WebSphere MQ queue manager and the Oracle resource manager.

When the committing process is done, the IBM WebSphere MQ queue manager informs the IBM WebSphere MQ adapter about the successful commit and the IBM WebSphere MQ adapter passes this information to the transformation server.

21. The map has completed successfully.

Trace log file examples

There are two examples of trace log files:

- IBM® WebSphere® MQ (MQS TM)
- Microsoft Distributed Transaction Coordinator (MSDTC TM)
- [MQS TM trace file example](#)
- [MSDTC TM trace file example](#)

MQS TM trace file example

```
<2396-1852>: GLOBAL TX TRACE ON
<2396-1852>: [m4mqcConnectToTM]

Performance overview

This documentation contains general performance tips and recommendations to improve performance.

IBM® Transformation Extender offers the flexibility and power to solve integration needs. This flexibility provides a user with a variety of options to develop their transformation processes and the power to accomplish their objectives in the most optimum ways.

This documentation contains general performance tips and recommendations to improve performance. The purpose of this documentation is to present strategies for leveraging the flexibility and power of IBM Transformation Extender so that transformation needs can be met while achieving reasonable performance objectives.

Note that not all recommendation will apply to all platforms.

General performance overview

This documentation describes what takes place during product execution and presents performance tips and recommendations regardless of the platform on which a specific IBM® Transformation Extender product is running.

This information provides you with additional background to assist in defining performance objectives.

There are several platform-independent topics for which background information, performance tips, and recommendations are addressed:

- [Performance Factors](#)
- [Understanding Command Server Operation](#)
- [Understanding Launcher Operation](#)
- [Map Performance Tuning Tips](#)
- **Performance measurement factors**
When analyzing how well an application has performed, there are potentially a large number of measurements that can be used to gauge workload efficiency in terms of the specific resources the application used.
- [Command Server operation overview](#)
The first step in trying to achieve performance improvements running the Command Server in your environment is to understand Command Server operation.
- [Launcher operation overview](#)
The first step in trying to achieve performance improvements running the IBM Transformation Extender Launcher is to understand its operation.
- [Map performance and tuning best practices](#)
Many functions available to users for developing IBM Transformation Extender maps are very powerful and can perform difficult and complicated tasks. Some functions may sacrifice performance for powerful capabilities, and it is important to understand the implications of these.
- [Merging and Pruning Schemas and Type Trees](#)
You can merge and prune schemas and type trees. Always practice save file management. Copy the source type tree to another name before you make any modifications.

Performance measurement factors

When analyzing how well an application has performed, there are potentially a large number of measurements that can be used to gauge workload efficiency in terms of the specific resources the application used.

The most common resource used in measuring performance is time. Memory, disk space, and other resource usage are often used, too, because of their impact on performance.

Comparisons can be made between workload and the various resources that impact performance. In this documentation, when the word *performance* is used without a qualifier, it refers to workload/time comparisons. This shortcut is used since this general resource usage is the most common. Other types of comparisons will be explicitly noted by using a qualifier with the word *performance*. The phrase, *all types of performance*, will refer to any workload/resource usage comparison, such as memory and disk space comparisons to workload as well as execution-time comparisons.

For every different application execution, there are a wide variety of performance factors that influence all types of performance for the Command Server and Launcher. The significance of each factor varies for every application execution. Most of these factors are dependent on the performance of other factors; few of the factors are completely independent. Accounting for these inter-relationships among performance factors increases the difficulty in tuning the performance of an application.

Although there can be a wide variety of performance factors, the following list shows a subset of the more significant and commonly-encountered performance factors when running applications using IBM® Transformation Extender maps. They represent the specific potential areas that you can target for analysis when tuning the performance of your applications. They are listed below organized by logical groupings.

- Mapping
 - Type design
 - Map design
- Hardware
 - CPUs (ISA, MHz, #)
 - Memory architecture
 - Physical memory
- Load
 - Memory contention
 - CPU contention
 - I/O contention
- Compiler
 - C/C++ runtime
 - Code generation

- Input/Output
 - File size
 - File/Disk configuration
 - File system
- Map execution
 - Paging
 - Workspace options
 - Burst/Integral
- Operating system
 - Virtual memory
 - Context switching
 - Load time

Many application executions have a specific constraining factor that impacts performance more so than other factors. Reducing the impact of that factor can provide a more substantial performance improvement than committing time and effort in examining other factors. Often, identifying the constraining factor requires additional time and effort. That additional time is balanced by a more significant performance improvement, which might be sufficient to preclude further analysis of those other factors.

- **Load and performance measurements**

There are many factors that can impact system load and performance, and these can be measured with the goal of improving performance.

- **Throughput and CPU measurements**

There are many factors that can impact system throughput and CPU performance, and these can be measured with the goal of improving performance.

Load and performance measurements

There are many factors that can impact system load and performance, and these can be measured with the goal of improving performance.

When measuring performance, it is important to account for extraneous load. If a system has a significant amount of usage outside the process being measured, the elapsed time for the process is likely to be longer than when the system has less use. Even though the process has much of the same resource needs, such as memory or CPU processing power, in a busy or a quiet environment, heavy competition for those resources can stall execution. For this reason, elapsed time, or wall time as an example, is not the most appropriate measure of performance for a heavily used system.

Performance metrics should attempt to isolate the process being monitored. Better alternatives to elapsed time include user/system time or CPU time. When measuring CPU use, the proportion used by each application should be noted. Lastly, performance metrics should be done on a system with as little extraneous load as possible.

Occasionally, the combined user/system time or the CPU time of an execution will be acceptable, but the elapsed time is too high. In such cases, reducing the impact of extraneous load should reduce the gap between the two times. The impact results from a scarcity of one or more resources. Whether the scarce resource is CPU processing power or memory, reducing the impact of external load requires increasing the amount of the contested resources available.

Increasing the amount of a specific resource can usually be done in a number of ways.

For example, if a system is at 100% CPU use because of extraneous load, there are a number of options for reducing that load:

- Tune the application. On a system constrained by CPU power, tuning the application for CPU usage will reduce its overall run time.
- Tune other applications. Reducing the CPU needs of the applications making up the extraneous load will free up some computational power. You should tune the focal application before tuning the other applications. For best results, request assistance from your systems administrator.
- Reduce the application load. Reducing the number of applications running will free up CPU power for the focal application. Unfortunately, this is not an option in many cases.
- Obtain additional processors. Additional processors will increase the amount of CPU power available. Assuming that the extraneous load remains constant, this leaves more CPU power available for the focal application. The amount of improvement will depend on the applications running and the underlying operating system.
- Use faster processors. Replacing the existing processors with faster models will increase the amount of CPU power available.

Because every situation presents its own set of performance variables, each situation must be evaluated to determine the best option to use.

Throughput and CPU measurements

There are many factors that can impact system throughput and CPU performance, and these can be measured with the goal of improving performance.

The execution of a single map occurs in the context of a single thread. Therefore, additional processors will not improve the execution time of a single transformation. The Command Server executes a simple map in this fashion. Execution time measurements of a single transformation performed with the Command Server will only account for the computational power of a single processor.

The affect additional processors have on the Command Server contrasts with the affect additional processors might have on the Launcher. Depending on how event triggers occur, separate transformations can execute on multiple processors concurrently. Even in this situation, each transformation still runs in a single thread.

In gauging performance, it is important to choose a measure of performance appropriate to the architecture of the mapping process. The performance measurement should agree with the performance goal for the system as a whole. If the system includes a number of maps running in parallel on multi-processor hardware, transactional throughput is probably more important than the execution time of any single transformation.

For example, a given map might execute in 10 seconds. On a 4-processor box, 4 simultaneous executions of that same map might complete in 11 seconds. The transactional throughput is nearly four times that of the single execution scenario, but each of the 4 simultaneous executions still executed in 10 seconds.

Conversely, if the process involves a batch of data with a single map, map execution time might be the most appropriate primary measurement. Execution time is also quite appropriate when running a series of maps. In such cases, all of the work occurs in a single thread as previously mentioned.

Assuming that CPU processing power is the constraining factor in both cases, improving throughput and execution time require different approaches. Adding additional processors of the same type will not improve map execution time. Improving map execution time requires more computationally powerful (faster) processors. Conversely, additional processors with the same power can improve throughput. More processors of the same power can allow more maps to execute simultaneously.

This same principle applies when comparing map performance across hardware platforms. A hardware configuration might have more processors available, but if an individual processor lacks computational power, the execution time of a single map on that processor will suffer. However, even with weaker processors, this same configuration might provide better throughput. While computational power varies considerably among processors, clock cycle frequency is a loose predictor of relative computational strength.

Command Server operation overview

The first step in trying to achieve performance improvements running the Command Server in your environment is to understand Command Server operation.

- **[Command Server execution overview](#)**

When you want to achieve performance improvements when running the Command Server in your environment, you must understand Command Server execution.

- **[Command Server work and data files](#)**

Depending on the conditions of the transformation, such as input data file size and processing complexity, work and data files can significantly affect performance.

- **[Command Server paging settings](#)**

To minimize the memory footprint during transformation, IBM Transformation Extender keeps only a subset of the work and data file information in memory at a given time.

Command Server execution overview

When you want to achieve performance improvements when running the Command Server in your environment, you must understand Command Server execution.

After you have developed your map, you are ready to run it using the Command Server. During the map execution process, the transformation engine performs several operations. These operations generally fall under the following phases:

- Initialization
- Validation
- Transformation
- Finalization

- **[Command Server initialization](#)**

When you want to achieve performance improvements when running the Command Server in your environment, you must understand Command Server initialization.

- **[Command Server validation](#)**

When you want to achieve performance improvements when running the Command Server in your environment, you must understand Command Server validation.

- **[Command Server transformation](#)**

When you want to achieve performance improvements when running the Command Server in your environment, you must understand Command Server transformation.

- **[Command Server finalization steps](#)**

When you want to achieve performance improvements when running the Command Server in your environment, you must understand the steps that Command Server takes to finalize its processes after execution.

- **[Command Server execution time](#)**

When you want to achieve performance improvements when running the Command Server in your environment, you must understand the factors that can affect execution time.

Command Server initialization

When you want to achieve performance improvements when running the Command Server in your environment, you must understand Command Server initialization.

During initialization, the transformation engine loads maps and prepares data for validation. Adapters are loaded and initialized at this time. This phase of execution also includes allocation of memory for the paging subsystem.

Command Server validation

When you want to achieve performance improvements when running the Command Server in your environment, you must understand Command Server validation.

During validation, the transformation engine parses all the input data sources and identifies objects based on type definitions. The information about the objects within each input data source is stored in one or more temporary files called work files or in memory. Each work file locates and sets boundaries for objects within all input data sources.

Command Server transformation

When you want to achieve performance improvements when running the Command Server in your environment, you must understand Command Server transformation.

During transformation, the rules contained within the map are executed. If a map is designed to produce output, the result of this execution process is the expected output data. Map execution proceeds through the output cards, executing each contained rule.

Multiple input values or multiple combinations of data values might cause rules to be executed multiple times. If a rule calls a functional map, the rules contained within the functional map would be executed multiple times.

During transformation, both the workspace and the data sources are heavily used. Paging settings affect how much of these two information sources are available at any one time. You also have the option of creating the Burst and Data Audit Logs in this step.

Command Server finalization steps

When you want to achieve performance improvements when running the Command Server in your environment, you must understand the steps that Command Server takes to finalize its processes after execution.

During finalization, temporary work files used during transformation are deleted and other system clean-up tasks are performed. Optionally, the **Map Settings** and **Execution Audit** log creation also occur in this step.

Command Server execution time

When you want to achieve performance improvements when running the Command Server in your environment, you must understand the factors that can affect execution time.

Execution time can be affected by various factors. When most transformation processes are executed, the transformation itself consumes the bulk of execution times. Complex validation logic in type trees, especially restarts, can increase the proportion of execution time spent in validation.

The map execution process occurs in a single thread. By using a single thread of execution, the overhead of context switching is avoided in heavily-loaded systems. Excess context switching on heavily loaded systems can quickly dominate execution.

Command Server work and data files

Depending on the conditions of the transformation, such as input data file size and processing complexity, work and data files can significantly affect performance.

Work and data files are the two major sources of information used in the transformation phase of map execution. Data files are the input data specified at execution time. Work files created during validation contain data about the input and output data sources.

The data types defined by the transformation's type tree depend on the internal format of the data files and are ultimately determined by the business process. This internal format drives the validation phase. The storage characteristics of the data files also depend on the business process as well as the underlying operating system.

IBM® Transformation Extender offers a significant number of options for creating and using work files. Depending on the conditions of the transformation, such as input data file size and processing complexity, some of these options can significantly affect performance. [Reusing Work Files](#), [Paging](#) and [WorkSpace in Memory](#) present the performance impact of these options.

The size requirements for work files ultimately depend on the number of type instances found in the input data file and generated in the output data file. The number of type instances found in both cases depends greatly on the type definitions. To save work file space, type instances are only recorded in the workspace if needed later in the transformation process.

- [Reusing work files](#)

Depending on the conditions of the transformation, such as input data file size and processing complexity, work and data files can significantly affect performance. When possible, reusing work files can produce measurable performance gains.

Reusing work files

Depending on the conditions of the transformation, such as input data file size and processing complexity, work and data files can significantly affect performance. When possible, reusing work files can produce measurable performance gains.

Work files contain metadata about the various type objects found in each input data file. If the data content is static, this metadata can be reused in subsequent runs. Reusing work files allows the transformation engine to bypass the validation step for these sources. Reducing the number of steps results in a shorter overall execution time.

When possible, reusing work files can produce measurable performance gains, especially in input data files requiring complex validation logic. This option is ideal for map processes that make use of static data, such as lookup tables. Work file reuse is specified separately for each input card, either as an execution command or as an option in the Map Designer. Reusing work files with an execution command is done with the W option on the input card override (-I) execution command.

To reuse work files, you must generate a work file.

To generate a work file

1. Specify an input card override -I execution command for the corresponding input source for a compiled map with the (w) reuse option.
2. Execute the map.
A work file is generated.

Subsequent map executions with the same input override options will reuse the generated work file. As mentioned previously, this option is ideal if the data content is static. If the data content changes, the work file should be regenerated.

To regenerate a work file

1. Remove the old work file.

2. Specify an input card override `-I` execution command for the corresponding input source for a compiled map with the `(W)` reuse option.
3. Execute the map.
A work file is generated.

A generated work file can be used to determine the amount of workspace required for a given input source. This can be helpful when using workspace options such as `-WM`.

See the *Command Server* documentation and the *Execution Command* documentation for more information about work file reuse.

Command Server paging settings

To minimize the memory footprint during transformation, IBM® Transformation Extender keeps only a subset of the work and data file information in memory at a given time.

The total amount of memory available for storing data used in the transformation process is segmented into equal-sized portions called pages. Each page holds a contiguous section of either an input or a work file.

- **Paging and I/O usage**

Paging controls the amount of data available to the transformation portion of the map execution at any time. If a map rule requires a piece of data that is not in memory, the paging subsystem will fetch the appropriate data from disk. This can impact existing data in memory; if there are no unused pages, an existing page is swapped out of memory.

- **Scenario: configure paging by input file size**

The following test scenario was created to demonstrate how the input size might require a larger information window or page setting, so it does not impact performance.

- **Configuring optimal page subsystem settings**

The settings for the paging subsystem in IBM Transformation Extender can determine whether a transformation process runs bound by I/O bandwidth or by CPU capacity. These settings can impact system performance.

- **WorkSpace in Memory option**

The **WorkSpace in Memory** option can be a viable choice for reducing I/O usage during transformation if enough memory is available. With a smaller input data file, the transformation engine can attempt to process the work file entirely in memory.

Paging and I/O usage

Paging controls the amount of data available to the transformation portion of the map execution at any time. If a map rule requires a piece of data that is not in memory, the paging subsystem will fetch the appropriate data from disk. This can impact existing data in memory; if there are no unused pages, an existing page is swapped out of memory.

In situations where a great deal of information from various areas of the input are needed, increasing the number and size of pages available to the system can reduce I/O volume. Increasing the information window allows the map to process more information without loading pages from disk.

Paging portions of data files allow for processing a large transformation in a much smaller amount of memory. Choosing paging settings appropriate to the transformation can improve performance considerably.

The following paging-related activities affect performance:

- [Using the WorkSpace paging setting](#)
- [Setting information windows](#)
- [Knowing the size of the input](#)

Using the WorkSpace paging setting

In many maps, paging settings are explicitly specified in the maps themselves during design. If the designer of a map does not explicitly specify page settings, the page settings for the map will default to a page size of 64 KB and a page count of 8 KB. Optimal page size and count settings depend ultimately on the amount of workspace needed. Because the workspace requirements are not available at the beginning of execution, the estimated page size and count will not always result in an optimal execution time. In this situation or if the paging settings within a map are sub optimal, altering paging behavior at execution time might improve performance.

The primary method of altering runtime paging behavior during Command Server execution uses the **WorkSpace PageSize** (`-P`) execution command. With the `(-P)` command, the page size and count can be specified for a transformation. The page count determines the total number of pages available to the system for both data and work file usage. Half of the requested pages are allocated to each file usage. Page size determines the total amount of storage available on each page. Together, the two directly control the amount of information available at any given time, as an information window.

To determine the values for the page settings, you must understand how the transformation engine allocates memory.

When the **WorkArea** card setting on a map is set to **Memory**, the transformation engine will allocate memory as required for both data and workspace, with the page size controlled by the **PageSize** setting in the map.

When the **WorkArea** card setting on a map is set to **File**, the transformation engine will allocate memory to track the information written to file for both data and work space, with the page size controlled by the **PageSize** and **PageCount** settings.

As a result of how memory is allocated depending on the **WorkArea** card setting, if the **WorkArea** is set to **File**, and the **PageSize** and **PageCount** map settings are set to a high number, the transformation engine is more likely to exceed memory.

For most data transformations, a **PageSize** map setting of 1024 kilobytes is too large. Data transformations whose **PageSize** map settings are 64, 128, 256 or 384 kilobytes should be tested for performance results using sample data that mirrors the size and complexity of the data that will be used in your production environment. Performance will be impacted negatively if you use **PageSize** map settings that are lower or higher than these recommended settings.

When executing maps in the Launcher, the memory used at startup time includes the totals of all the maps included in the **.msl** files deployed, with the addition of the memory used by any cached maps.

Setting information windows

When specifying paging information, it is critical to understand the information requirements of the map. Certain usage patterns require a larger window into the data and the workspace than other usage patterns. If a paging setting does not provide a large enough window, the paging subsystem will generate additional I/O requests to meet the demands of the map.

Conversely, requesting too much memory through paging settings can have detrimental effects as well. If the amount of requested memory exceeds available physical memory, the underlying operating system will begin paging memory to disk. Selecting appropriate paging settings is a balance between the information needs of the map and the amount of available memory.

Setting an appropriate information window especially applies to series-consuming functions such as `EXTRACT()`, `LOOKUP()`, and `CHOOSE()`. Depending on context, series-consuming functions can require access to the entire data file to complete map execution. This contrasts with the much smaller requirements of simple sequential maps.

Knowing the size of the input

One significant factor in determining appropriate paging settings is the amount of data processed by a map. A larger amount of input might require more paging memory to attain optimal execution time. More paging memory results in a larger information window. The degree to which larger input might require a larger information window varies with the design of the map.

Scenario: configure paging by input file size

The following test scenario was created to demonstrate how the input size might require a larger information window or page setting, so it does not impact performance.

Two test cases were created and then executed using the same testing procedures.

- Maps: The same map is used in both tests.
- Inputs: There are two input data files.
 - Input 1 size: 3 MB
 - Input 2 size: 11 MB
- Process:
 - Map performed a number of operations such as a large number of `EXTRACT()` calls that spanned each of the input data files.
 - These requests mandated that a certain percentage of the input data be available at any given time for optimal performance.
- Objective:
 - Determine the page size to get the optimal execution time for each of the input data files.
- Test Case 1 Result:
 - Quantitative measurement of execution time at various page counts and sizes identified an optimal execution time at the following workpage settings for the 3 MB input data file: size 64 K and count 12. This is represented by `-P64:12`, where `-P` is **WorkSpace Paging**, 64 is the page size and 12 is the page count.
- Test Case 2 Result:
 - The same testing procedure found `-P64:53` to produce the optimal execution time for the 11 MB input data file.
- Conclusion:
 - Paging settings depend on input data size just as much as they do on the map rules. An optimal page setting for a given map and data file might not be optimal for the same map with a much larger or smaller data file.

Configuring optimal page subsystem settings

The settings for the paging subsystem in IBM® Transformation Extender can determine whether a transformation process runs bound by I/O bandwidth or by CPU capacity. These settings can impact system performance.

Behavior

The settings for the paging subsystem within IBM Transformation Extender can determine whether a transformation process runs bound by I/O bandwidth or by CPU capacity. A typical execution time/page count curve has two easily discernible parts, based on performance characteristics.

In a graph where the vertical coordinate measures execution time and the horizontal coordinate measures page count, at the low page count end of the graph, the execution time falls quickly as the page count increases. Here, the transformation is I/O bound. The data access patterns implicit in the map require more information than what is available in memory. Because of this, time spent driving I/O dominates execution time.

As page count increases, execution time decreases into a nearly flat portion of the graph. At that stage, the transformation is bound by the computational power of the executing processor. Increasing the amount of memory available through paging settings will probably not improve performance.

Tuning procedure

Finding the combination of page size and page count that optimizes performance is the goal of the following procedure. There are several steps to follow for tuning paging settings. The settings found for this procedure are specific to the behavior of the map and data used. Because of this, the data should represent future workloads as much as possible.

To tune page settings

1. Verify that the execution environment is stable. Execution times must be relatively repeatable. Run a few simple preliminary executions and time them to gauge the reproducibility of the timing procedure. If the resulting execution times are not similar to one another, then the execution environment is not stable enough for

- tuning paging settings. Improve reproducibility by reducing extraneous loads from other applications.
2. Select initial values for page size and count. The overall page size and count specify the total amount of memory available for paging data and workspace. This total amount of memory is allocated early in the execution process. A failure to allocate paging space will result in an early termination. Therefore, a memory request for C pages of S kilobytes should be expected to succeed, given available storage.

- Appropriate values for each setting vary highly on the data access patterns of the map and the design of the type tree. Not only is each setting a factor in execution time, but the overall amount of memory allocated also affects performance. The tuning procedure here will attempt to insulate page size from the effect of changing overall memory.
3. Execute the map and data to be tuned. Note the overall processing time and the processing time spent managing I/O during execution. Sub-optimal paging settings often result in an I/O bound transformation process.
4. Execute the map and data again with different paging settings. Vary the page size up or down. The page count should be adjusted so that the combined paging memory remains as constant as possible. For example, if you double the page size in the second run, the page count should be halved. Again, note the overall processing time and the processing time spent managing I/O during execution. The page count must still be small enough for the entire paging space to fit in the memory allocated to IBM Transformation Extender by the operating system.
5. Compare the collected times from both executions after the second execution completes.
6. Repeat this procedure with various page sizes to find the optimal page size for the map.
7. After an optimal page size is determined, a similar set of iterations to vary the page count should be performed, keeping the page size fixed.
If an increase in memory drastically reduces performance, it is likely that the overall amount of memory has started to throttle the operating system's virtual memory system. If this occurs, reduce the page count. The threshold at which throttling can occur depends heavily on the application load across the entire system. If a decrease in page count drastically reduces execution time, then the execution was probably I/O bound. Compare the difference in I/O usage between executions or the time used by the operating system. An increase indicates that the proportion of execution time devoted to handling I/O has increased. In this case, increase the page count.

Recent changes

Recent changes in the transformation engine altered the paging behavior of IBM Transformation Extender from release 6.7 onward. These recent changes simplify the tuning process by reducing the CPU overhead required to manage larger page counts. Previously, many maps had a single page count setting that would minimize execution time. Choosing a page count larger than this setting would require more CPU bandwidth. Choosing a smaller page count setting would require more I/O bandwidth, putting the execution into an I/O bound state.

WorkSpace in Memory option

The **WorkSpace in Memory** option can be a viable choice for reducing I/O usage during transformation if enough memory is available. With a smaller input data file, the transformation engine can attempt to process the work file entirely in memory.

Using this option:

- Significantly reduces the number of I/O requests issued across the execution.
- Produces optimal performance benefits when the work files do not exceed available physical memory. For more information about determining work file size, see the [Reusing Work Files](#).
- When producing work files that exceed the amount of available physical memory, will cause operating system level-memory management to simulate additional memory with disk storage. This will ultimately degrade performance.

Launcher operation overview

The first step in trying to achieve performance improvements running the IBM® Transformation Extender Launcher is to understand its operation.

- [Launcher and Command Server performance comparison](#)

The Launcher is similar to the Command Server in the way it executes maps. However, the Launcher offers multiple simultaneous transformations, each on its own execution thread.

Launcher and Command Server performance comparison

The Launcher is similar to the Command Server in the way it executes maps. However, the Launcher offers multiple simultaneous transformations, each on its own execution thread.

Triggering logic specified in the Launcher configuration determines the number of maps that can be executed at any one time.

Important:

The ability of the Launcher on a given platform to take advantage of multiple processors is dependant on the configuration of the underlying operating system. More information about Launcher configuration can be found in *Configuration Parameters* and *Launcher Settings* in the *Launcher* documentation.

By launching each transformation in its own thread, the Launcher can take advantage of multiple CPU resources concurrently. Using multiple CPU resources can increase the total throughput and transactional volume. While the transactional volume might increase, the execution time of a simple map, measured against how the Command Server would perform, will be unchanged or possibly longer. The improved throughput results from parallel execution of multiple maps and not faster execution of individual transformations.

Map performance and tuning best practices

Many functions available to users for developing IBM® Transformation Extender maps are very powerful and can perform difficult and complicated tasks. Some functions may sacrifice performance for powerful capabilities, and it is important to understand the implications of these.

It is important to understand when it is better to use one function over another that can perform the same task but does so differently. Each function has advantages and disadvantages and users have the flexibility to choose the function that best suits their specific transformation needs.

These are suggestions for tuning maps to achieve the best performance results through the various map functions. The functions fall under the following categories:

- [Data Searches](#)
- [Routing](#)

Also, the following utilities can be used to help you identify the areas in your maps that might be causing performance degradation and then you can make the appropriate changes to your maps to improve their performance:

- [Map Profiler \(dtxprof\)](#)
 - [Page Setting Assistant for Maps \(dtxpage\)](#)
 - [Data search performance best practices](#)
- There are many ways to develop IBM Transformation Extender maps that search through data. These different options provide varying balances between functionality and performance.
- [Routing](#)
 - [Map Profiler \(dtxprof\)](#)
 - [Page Setting Assistant for Maps \(dtxpage\)](#)

Data search performance best practices

There are many ways to develop IBM® Transformation Extender maps that search through data. These different options provide varying balances between functionality and performance.

The functions available to the map developer to do data searches are:

- EXTRACT()
- LOOKUP()
- SEARCHUP() or SEARCHDOWN()
- CHOOSE() - see POSITIONAL INDEXING in the table below

The following table contains the functions available to the map developer to do data searches.

Function	Use	Advantage	Disadvantage
EXTRACT()	When expected results are multiple objects.	One of the most powerful ways of searching through a data file.	Not the most efficient way to locate objects if the expected result set is only a single object.
LOOKUP()	Where expected results are a single object. Scans a data file object-by-object, looking for an object that matches the specified criteria.	More efficient than Extract().	The average amount of time required for search depends proportionally on the number of objects in the data file.
SEARCHUP() or SEARCHDOWN()	When the set of items to be searched is sorted.	Increased performance. Takes advantage of the sorted order of the data file by traversing the data file as a binary tree. Search time is proportional to $\log_2(N)$, where N is the number of data items.	Cannot be used for unsorted data files. The smaller the input data file, the less performance results benefit.
POSITIONAL INDEXING	When used with CHOOSE() and INDEX(), locates objects within a data file by position.	Executes repeated CHOOSE() requests and maintains a cache of position information for the indexed data file. The cache continues to be used as long as repeated calls to CHOOSE() reference the same type, and indexing is fast.	When repeated calls to CHOOSE() don't reference the same type, the cache isn't used, and indexing is not as fast.

- [Data search functions](#)

As you develop your IBM Transformation Extender maps to search through data, you should consider the input format and the requirements for the output. Based upon those considerations, you can make your decision on which search function to use to for optimum performance results.

- [Search functions reference](#)

This documentation contains quantitative comparisons of the data search functions. It presents results of comparing the LOOKUP() against the SEARCHUP() or SEARCHDOWN() functions.

Data search functions

As you develop your IBM® Transformation Extender maps to search through data, you should consider the input format and the requirements for the output. Based upon those considerations, you can make your decision on which search function to use to for optimum performance results.

The following table lists search usage scenarios with the recommended function that should give you the best performance results.

Usage

Search Function Recommendation

Single output data item is the expected result and the input data cannot be sorted.

LOOKUP ()
 Multiple output data items are expected result.
EXTRACT ()
 The set of items to be searched is or can be sorted.
SEARCHUP () OR SEARCHDOWN ()
 Same data type is being referenced (Positional Indexing).
 In cases where **CHOOSE ()** consistently references the same type, execution performance can exceed **SEARCHUP ()** and **SEARCHDOWN ()**.
CHOOSE ()

Search functions reference

This documentation contains quantitative comparisons of the data search functions. It presents results of comparing the **LOOKUP ()** against the **SEARCHUP ()** or **SEARCHDOWN ()** functions.

The primary difference between the functionality of **LOOKUP ()** and **SEARCHUP ()** or **SEARCHDOWN ()** is the ability to use a full logical expression in **LOOKUP ()**. For example, **LOOKUP ()** can be used to find the first item whose value is less than 3. **SEARCHUP ()** or **SEARCHDOWN ()** can only find an exact match.

Functionality aside, **LOOKUP ()** and **SEARCHUP ()** or **SEARCHDOWN ()** differ in their performance characteristics. A **LOOKUP ()** search operates by scanning the appropriate set of items in sequence, attempting to match the logical condition. On average, a **LOOKUP ()** search takes time proportional to the number of items in the set.

In contrast, **SEARCHUP ()** and **SEARCHDOWN ()** take advantage of sorted input to provide faster response. Searches with **SEARCHUP ()** or **SEARCHDOWN ()** use a binary search index on the items in the data series. This results in execution time proportional to the logarithm of the item count. In other words, doubling the number of items in the data series causes only an incremental increase in the execution time required for that search.

To achieve this response-time benefit, **SEARCHUP ()** and **SEARCHDOWN ()** require sorted input. Additionally, **SEARCHUP ()** and **SEARCHDOWN ()** can only be used to find an exact match. If these conditions are suitable for the map, then using **SEARCHUP ()** or **SEARCHDOWN ()** can provide significant execution-time benefits. These benefits are especially noticeable for larger data series.

The following table presents the example results.

This table compares map execution times of the **SEARCHUP()** and **LOOKUP()** functions, based on the size of the input data.

Map Functions	16 KB	128 KB	1 MB	2 MB
SEARCHUP ()	0.23	0.46	3.04	5.83
LOOKUP ()	0.28	4.84	288.40	1220.27

This table captures execution times in seconds for two maps that both attempt to match each data element from one input file with another. The two maps differ in the function that each uses to match data. The first map uses **SEARCHUP ()** to locate matches quickly. The second map uses **LOOKUP ()**.

For small series of data, the difference in execution time is not as noticeable. However, as the input series size grows, the execution time for the **SEARCHUP** map grows much more slowly than the execution time for the **LOOKUP** map.

A search is executed for every data element in the input file. As a result, the overall execution time grows with the data size *and* the search response time. In the case of the **LOOKUP** map, this yields a map execution time that grows exponentially with input size. A doubling of the input size requires an execution time four times as long for this map.

Routing

Routing is the splitting of output to separate files based on the data values. This is a common operation in many IBM® Transformation Extender mapping procedures. This documentation discusses differences between the **PUT ()** and **RUN ()** functions when used to route data. The behavior of each is broader than simply routing, and neither function is an exact replacement for the other.

The various functions available to the map developer to do data routing are:

- **PUT()**
- **RUN()**

For both the **PUT ()** and **RUN ()** functions, the best performance for routing style maps is generally obtained by mapping the largest available group object.

The following table contains the two functions available to the map developer to do data routing.

Function	Use	Advantage	Disadvantage
PUT ()	Routes an output item to an adapter.	Overhead is less than using RUN () .	I/O and CPU overhead from repeated opening and closing of routing targets can be great for large maps.
RUN ()	Allows a map that is currently running to execute another map.	Is versatile. Using a second map to process output allows for a great deal of flexibility in output generation.	Overhead is much greater than using PUT () . I/O and CPU overhead from repeated opening and closing of routing targets can be great for large maps.

- [Data routing usage](#)
- [Comparisons between the routing functions](#)

Data routing usage

As you develop your IBM® Transformation Extender maps to route input data and create output, you consider the format of the input and the requirements for the output. Based upon those considerations, you can make your decision on which routing function to use to derive optimum performance results. The following table lists the routing usage with the recommended function that should give you the best performance results.

Usage

Routing Function Recommendation

Avoid using additional maps to route data. Instead, try to use `PUT()` with the appropriate adapter whenever possible.

PUT

Additional processing with a secondary map is required.

RUN

As stated previously, the functionality of `PUT()` and the functionality of `RUN()` differ significantly. Because `RUN()` enables the map to execute a secondary map, there might be many routing situations where `PUT()` might not be a feasible choice. In cases where `PUT()` can be used, usually better performance results.

Comparisons between the routing functions

This documentation contains quantitative comparisons of the data routing functions. It presents results of comparing the `RUN()` against the `PUT()` functions.

In this example, two maps that attempt to route input to any one of twenty possible output targets are executed. The two maps differ in their use of `RUN()` or `PUT()` to route data items to an output target.

For each map, two scenarios were tested, each processing input of different sizes. Varying the input was intended to indicate relative scalability between the two functions in a routing context.

The following table presents the example results.

Map Functions	Input Size (Bytes)	
	128 KB	4 MB
<code>PUT()</code>	0.74	13.43
<code>RUN()</code>	2.14	62.22

This table captures execution times in seconds for the two example maps. Even for input that is smaller in size, `PUT()` executes faster. For input that is larger in size, the overhead of the additional maps in `RUN()` processing is far more noticeable. Execution of the `PUT` map completes in nearly one-fifth the time of the `RUN` map.

Comparing type sizes

Regardless of whether `PUT()` or `RUN()` is used to route data, there is an execution time overhead in each routing attempt. Minimizing the number of routings performed will improve execution time. Careful attention to map and type tree design can reduce the number of routings done.

This example demonstrates the benefit of minimizing routing attempts. Four maps were run with inputs of two different sizes. The maps differ in two primary ways. They use two different functions, `PUT()` and `RUN()`, and different type tree designs.

The two different type tree designs are used for the same input sources. In the first type tree design, **N1**, the input card type tree consists of a simple series of items (`0:s`). In the second type tree design, **N100**, the input card type tree consists of a series of groups of items. The groups themselves are series, (`0:100`). Therefore, the second type tree has two levels of series where the first, **N1**, has one.

The following table presents the example results.

This table compares the execution times of two type-tree designs, based on input data size and whether the map uses the `PUT` function or the `RUN` function.

Type Tree Design	PUT()		RUN()	
	128 KB	4 MB	128 KB	4 MB
N1	0.74	13.43	2.14	62.22
N100	0.36	0.75	0.41	1.83

This table captures execution times in seconds for the four example maps. The savings in execution time are significant, especially at larger input sizes. Whether the map uses `RUN()` or `PUT()`, reducing the number of routes can improve execution time.

Simply grouping input together to route larger amounts of data is not always possible in every map design effort. The degree to which map or type tree design can address route reduction depends on the needs of the business process. This example demonstrates the potential for improving execution time by reducing the number of routing attempts.

Map Profiler (dtxprof)

The map profiler is a user-configurable utility that captures and reports map execution statistics.

The resulting output highlights those areas in your maps, such as component and mapping rules, and the functions and types within those rules, with very long processing times, which might be adversely affecting performance. It might show that specific rules and functions are being executed for an unusual number of times. It also might show that type objects are being accessed too many times or that the nesting level of an object is too deep. With this information, you can then make the appropriate changes to your maps to achieve your performance objectives.

For example, you might have output from the map profiler that indicates that the processing time for a `LOOKUP` function in your map is significantly more than the processing time for other functions. If the data is sorted, you might see the processing time decrease by using the `SEARCHUP` function in your rule instead.

See [Data Search Usage](#).

- [Using the Map Profiler](#)

Using the Map Profiler

The profiler can be configured and started from the Performance interface using the Map Designer, or from the command line using the `dtxprof` utility command.

See the *Map Designer* documentation for information on how to use the map profiler in the Map Designer GUI.

See the *Utility Commands* documentation for information about how to use the map profiler from the command line, outside the Map Designer GUI.

The map profiler is an important tool to assist you in improving the performance of your maps and achieving your performance goals.

Page Setting Assistant for Maps (dtxpage)

The **Page Setting Assistant for Maps** application is used to calculate suggested settings for memory page size and count for work files used in maps. It is started by using the `dtxpage` utility command. The `.mmc` file is a required parameter and is the file name of the map for which the calculation is being performed.

The application will run iterations of the specified map and therefore you should expect that the overall run time will be longer than a typical run.

See the *Utility Commands* documentation for information about how to use the `dtxpage` utility command from the command line.

The **Page Setting Assistant for Maps** application invoked by the `dtxpage` utility command is an important tool to assist you in improving the performance of your maps and achieving your performance goals.

Merging and Pruning Schemas and Type Trees

You can merge and prune schemas and type trees. Always practice save file management. Copy the source type tree to another name before you make any modifications.

To prune a schema or type tree to contain only a sub-set of standard transactions, copy the source schema or type tree, for example, `hipaa_x12` or `ansi8020`, to a new name. Or copy the source schema to a new design server project.

Design Studio:

1. Copy the file using windows file system or you can open the type tree using Design Studio.
2. Save the file using a new name. For example, copy `hipaa_x12` to new type tree `hipaa_x12_5010x22a1.mtt`

Design Server:

1. Create a new project.
 2. Open the new project.
 3. Using the bar at the top where the project name is displayed and select copy into.
 4. Select the project that contains the schema you want to prune.
 5. Expand the schemas and select the schema you want to prune for example, `hipaa_x12` or `ansi8020` schema.
- [Prune transactions sets from a schema or type tree](#)
 - [Merge pruned schema or type tree to destination schema or type tree](#)
- At this step the unused messages or transactions have been removed. Merging the pruned schema or type tree will remove references to unused segments and elements within the destination schema or type tree.

Prune transactions sets from a schema or type tree

1. In the source schema or type tree, locate the ANSI Funct'lGroup Partner Inbound type.
2. Remove the unnecessary transaction sets under ANSI Funct'lGroup Partner Inbound type.
3. Remove the unnecessary transaction sets under ANSI Funct'lGroup Partner Outbound type.
4. Save changes and continue below.

Create a destination schema or type tree

Design Studio Only:

1. Create a new schema or type tree.
2. Rename root type to **EDI**.

Merge pruned schema or type tree to destination schema or type tree

At this step the unused messages or transactions have been removed. Merging the pruned schema or type tree will remove references to unused segments and elements within the destination schema or type tree.

Design Studio:

1. In the pruned source type tree, locate the Transmission type.
2. Right-click the Transmission type and select Merge from the menu.
The Merge Type dialog box opens.
3. Click on the new type tree window.
The To tree field in the Merge Type dialog box is populated with destination type tree.
4. Click Merge in the Merge Type dialog box.
The new type tree is created.
5. Copy the %_Type_Tree_Information type from the source type as a subtype of EDI (the root type) in the destination type tree.
6. Update the %_Type_Tree_Information type to reflect the changes made.
7. Analyse the new type tree.
8. Save the new type tree under the appropriate name.

Design Server:

1. In the pruned source type tree, locate the Transmission type.
2. Right-click the Transmission type and select Copy To Schema from the menu.
The Copy Type dialog box opens.
3. Enter the Schema Name and select Folder from the drop-down list.
4. Click OK.
5. Open the new type tree and copy the %_Type_Tree_Information type from the source type as a subtype of EDI (the root type) in the destination type tree using Copy To Schema.
6. Update the %_Type_Tree_Information type to reflect the changes made.
7. Analyse the new type tree.
8. Save the new type tree under the appropriate name.

Mainframe performance

This documentation explains mainframe performance, what takes place during IBM® Transformation Extender product execution, as well as performance tips and recommendations for the Batch and CICS® execution environments. This information will provide some additional background to assist in defining performance objectives.

- [Overview](#)
- [Understanding mainframe performance](#)
- [Batch execution environment](#)
- [CICS execution environment](#)
- [Troubleshooting](#)

Overview

General mainframe performance is discussed in the following topic:

- ["Understanding Mainframe Performance"](#)

Performance tips and recommendations for the two execution environments are discussed in the following topics:

- ["Batch Execution Environment"](#)
- ["CICS Execution Environment"](#)

The ["Command Server Troubleshooting"](#) information provides recommendations and references to identify potential performance areas when executing IBM® Transformation Extender under either Batch or CICS® environments. Troubleshooting information is available for ["Batch Troubleshooting"](#) and ["CICS Troubleshooting"](#).

Understanding mainframe performance

An important step in trying to achieve performance improvements running the IBM® Transformation Extender under Batch and CICS® on the z/OS® operating environment is to understand the IBM Transformation Extender execution characteristics specific to these environments.

["General Performance"](#) includes performance tips and information on what occurs during product execution when running the IBM Transformation Extender on all available platforms.

There are additional performance and execution characteristics specific to running the IBM Transformation Extender under Batch and CICS on z/OS environments that can greatly affect their overall performance, including:

- Hardware Expectations and MIPS/MSU Ratings
- File Formats
- Pre-allocating Work Files (Temporary Data Sets)
- Paging in Memory
- External Factors
- [Hardware expectations and MIPS/MSU ratings](#)

- [File formats](#)
 - [Pre-allocating work files \(temporary data sets\)](#)
 - [Paging in memory](#)
 - [External factors](#)
-

Hardware expectations and MIPS/MSU ratings

Hardware performance ratings such as MIPS or MSUs indicate machine-wide throughput, and not the speed of a single processor. As mentioned in [Throughput and CPU Expectations](#), a measurement of CPU throughput over multiple CPUs might not accurately estimate the execution time of a single transformation. This results from the single-threaded nature of map executions.

- [Performance case](#)
 - [Performance case after normalizing](#)
-

Performance case

MIPS and MSU ratings account for all active processors on a particular hardware configuration, yet the Command Server or a single transformation can only use a single processor at any given time. Therefore, comparing MIPS or MSU ratings between machines to estimate transformation speed will not produce reliable estimates if the number of processors differs. To derive MSU ratings that can provide valid estimates, the number of processors must be taken into account.

Here is a hypothetical case using fictitious configurations to illustrate how estimating performance results might be affected by various factors. The considered factors include hardware configurations, MSU ratings, and taking into account the number of processors on the machine (normalizing) used to run maps or perform transformations.

Comparing performance

Analyze the following table of the MSU ratings for two different hardware configurations:

Configuration	Number of Processors	Rating (MSUs)
Config-02	two	28
Config-01	one	13

Conclusion of comparison

The MSU ratings and estimated MIPS ratings of the higher rated configuration, **Config-02**, imply that it yields twice the execution speed. This is not the case when measuring the execution time of a single map.

Performance case after normalizing

Normalizing a machine-wide MIPS rating for the number of processors on the machine results in a more representative estimate for comparative transformation performance. It accounts for the number of processors on a box.

Comparing performance

Analyze the following table of the MSU ratings that have been normalized for two different hardware configurations to account for the number of processors on each box:

Configuration	Number of Processors	Rating (MSUs) before Normalization	Rating (MSUs) after Normalization
Config-02	two	28	14
Config-01	one	13	13

Conclusion of comparison after normalization

Because the **Config-01** configuration has only a single processor, the normalized rating and non-normalized ratings are the same. This similarity in normalized MSU ratings accounts for similarities in execution times. All other things being equal between the two configurations, the two different machines should execute a single transformation, X , in roughly the same time, T .

Parallel execution

Even though the transformation execution times for the two boxes are roughly the same, the **Config-02** configuration with two processors, could execute two instances of that same transformation X in parallel. This assumes that the input and output data sets have no interdependence. In this case, the execution time for each transformation is roughly the same.

If both transformations are initiated at the same time, however, they should complete in that same time interval, T . Because both transformations executed in parallel, the amount of transformation work for both is twice as much as it would be for a single execution.

Twice the amount of transformation work in the same amount of time yields double the throughput, which represents a significant performance improvement.

File formats

The z/OS® operating system traditionally processes data in a record-oriented fashion. On other platforms (UNIX and Windows) it is byte (stream) oriented.

The z/OS operating system offers many file format choices, including record sizes, block sizes and record types for record-oriented processing.

Some of the most common record types are: Fixed or Fixed Block, and Variable or Variable Blocked record formats.

The IBM® Transformation Extender run under Batch and CICS® environments provides an additional Record Separators execution command (/V) to enable special handling of data sets with *variable length* record formats, if required.

The special handling of record separators for variable length records occurs during initialization, finalization, or both depending upon your source, input data, and targets, output data.

- [Record separators \(/V\) execution command](#)

Record separators (/V) execution command

For more efficient access during the transformation and validation processes, input files with a variable-length format are copied to temporary work files with the /V execution command-specified separators inserted directly into the file. This operation is reversed, and record separators removed, on targets where the output record format type is variable length.

Though from the Command Server processing perspective this is generally more efficient, there is a slight overhead cost of the copy-insertion-deletion operation to take into account for variable-length records

If your requirements can be met using a fixed format, then the use of Record Separator execution command (/V) will not be required along with its slight increased overhead.

If a data set of variable-length records already contains the separators defined to the map embedded in the data, this option should not be used.

See [z/OS Batch](#) and [z/OS CICS](#) for more information about the /V Record Separators execution command.

Pre-allocating work files (temporary data sets)

There are guidelines you can follow for pre-allocating work files before you run the IBM® Transformation Extender under Batch and CICS® on z/OS® environments.

- [Batch](#)
- [CICS](#)

Batch

The Batch Command Server, by default, and without explicit pre-allocation of work files, will attempt to allocate the work files dynamically during map execution.

Dynamic allocations incur a significant penalty compared to static pre-allocation of work files. Dynamic allocation inherits the overhead associated with the operating systems' dynamic allocation mechanisms. Therefore, pre-allocating work files before execution provides overall better performance.

A good guideline to use when pre-allocating work files is to allocate two temporary work files for each map card, plus one additional file. One of the two temporary work files for each card is used to process data sets containing variable-length records. The other temporary work file and the additional file are used as general-use work files.

See [Temporary Data Sets \(Work Files\)](#) for more details about allocating work files.

CICS

The IBM® Transformation Extender running under CICS® uses a predefined VSAM workspace file for its work file processing requirements.

For more details about allocating work files, see [Temporary Data Sets \(Work Files\)](#).

Paging in memory

Processing work files in memory can improve some performance characteristics of a transformation execution. Introduced in the IBM® Transformation Extender for z/OS® v6.7.2 release, two methods of processing the work file in memory are provided. They incorporate the **Work Files in Memory** and **Work Files in Memory - Hiperspace™** execution commands.

- [WorkSpace Work Files in Memory](#)
- [WorkSpace Work Files in Memory - Hiperspace](#)

WorkSpace Work Files in Memory

The **Work Files in Memory** execution command requests that the transformation engine handle all work file pages in address-space memory. An advantage in using this command is that it significantly reduces the I/O request volume involved in the transformation and therefore decreases EXCPs. This EXCP count reduction comes at a small CPU usage penalty ranging from 10% to 15% for some maps.

WorkSpace Work Files in Memory - Hiperspace

The **Work Files in Memory - Hiperspace** execution command requests that the transformation engine handle all work file pages in Hiperspace memory. An advantage in using this command is that it significantly reduces the I/O request volume involved in the transformation and decreases EXCPs like the **Work Files in Memory** execution command, but at a lower cost of CPU usage.

Carefully consider using these execution commands to ensure that they do not monopolize your available operating system physical memory for both the **Work Files in Memory** and **Work Files in Memory - Hiperspace** execution commands.

Indiscriminate use of these execution commands *might* result in excessive operating system paging. Use these execution command options on a case-by-case basis after consulting with your systems administration staff.

Valid **Work Files in Memory** execution commands for each execution environment are:

- Batch:
 - [WorkSpace \(Work Files in Memory\) \(-WM\) or \(/WM\)](#)
 - [WorkSpace \(Work Files in Memory - Hiperspace\) \(-WH\) or \(/WH\)](#)
- CICS®
 - [WorkSpace \(Work Files in Memory\) \(-WM\) or \(/WM\)](#)

External factors

External factors can greatly affect the overall performance of the IBM® Transformation Extender running under Batch or CICS® on the z/OS® operating environment and should be taken into account when assessing overall throughput and performance.

The following factors should be considered:

- Configuration of the operating system
- Work loads / Queue depths
- Work Load Manager policies and goals
- Batch-oriented scheduling issues relating to resource contentions or collisions, or both
- Transaction priorities

Some of these factors can significantly impact overall performance of the IBM Transformation Extender running under Batch or CICS on the z/OS operating environment, thereby requiring a more in-depth analysis or real-time tools to gather resource statistics to isolate and take corrective action.

Tools such as RMF (Resource Measurement Facility), in conjunction with SMF (System Management Facilities) records, help in monitoring and identifying any performance problems within traditional batch-oriented processing. Additionally, the CICS Performance Monitor can be used to identify performance problems within CICS environments.

Batch execution environment

When executing the Batch Command Server, there are several areas where you might be able to improve performance results. These areas are:

- IBM® Language Environment® (LE) Runtimes
- Input Data Sets (Source)
- Output DataSets (Target)
- Temporary Data Sets (Work Files)
- Execution Command Settings
- Striped Data Sets
- [IBM Language Environment \(LE\) runtimes](#)
- [Input Data Sets \(Source\)](#)
- [Output data sets \(Target\)](#)
- [Temporary data sets \(work files\)](#)
- [Execution command settings](#)
- [Striped data sets](#)
- [XPLINK performance build](#)

IBM Language Environment (LE) runtimes

The following recommendations are for the LE runtime library access modifications, which might improve the performance of batch jobs running under the Batch Command Server:

- **SCEERUN** and **SCEERUN2** runtime libraries into your **LNLST**
 - **SCEELPA** data set in your LPA list (LPALSTxx)
 - Heavily used modules in the Link Pack Area (LPA)
- If these IBM® recommendations have not already been implemented in your system's environment, contact your systems' programming personnel to inquire about them.

[Performance Considerations - adjusting LE runtime options](#) discusses the runtime options module shipped with the IBM Transformation Extender for z/OS® and set specifically to avoid known performance-degrading options.

See *Language Environment Customization* for additional information.

- [Performance considerations - adjusting LE runtime options](#)

Performance considerations - adjusting LE runtime options

One way to try to improve the performance of batch jobs running under the Batch Command Server is to override Language Environment® (LE) runtime options in your JCL that runs the executable DTXCMDSV program. See the topic about overriding Language Environment (LE) runtime options in the IBM® Transformation Extender *Command Server* documentation.

IBM Transformation Extender for z/OS® is shipped with a copy of the **CEEUOPT** runtime options module linked into the IBM Transformation Extender executable module. This copy of **CEEUOPT** is included to ensure that known performance-degrading options cannot be included from the existing runtime environment.

The **STORAGE** initialization options cause the most notable performance degradation to IBM Transformation Extender. **HEAPCHK** can also adversely affect the performance of IBM Transformation Extender. **HEAP** initial size and increment and **STACK** initial size and increment might provide better IBM Transformation Extender performance if tuned for a specific customer environment or set of maps.

See the IBM z/OS Language Environment documentation for details about the **CEEUOPT** options and how to remove and replace the **CEEUOPT CSECT**. The **CEEUOPT CSECT** need only be included in the **DTXCMDSV** module.

The copy of **CEEUOPT** used in IBM Transformation Extender is coded as follows:

```
CEEUOPT  CSECT
CEEUOPT  AMODE ANY
CEEUOPT  RMODE ANY
    CEEXOPT HEAP=(1M,256K,ANY,FREE,8K,4K),
            STACK=(128K,128K,ANY,KEEP),          X
            ALL31=(ON),                         X
            STORAGE=(NONE,NONE,NONE,8K),          X
            HEAPPOOLS=(ON),                     X
            TERMTHDACT=(UADUMP)
    END
```

The **CEEUOPT** is contained in the **DTXCMDSV** module in the runtime library.

To start tuning the **CEEUOPT** settings, you will need an IBM Transformation Extender map that does not perform well at your installation, and a representative sample of the data that the map processes. Start by turning on the **RPTSTG** option **RPTSTG=(ON)**, and then running Command Server with your map or maps, and data.

The **RPTSTG** option will produce a report showing the maximum amount of storage used for the **Language Environment** **STACK** and **HEAP**. Use these as initial values when you reassemble and link-edit your new **CEEUOPT**. The goal is to minimize the amount of **STACK** and **HEAP** allocations as these have a significant effect on the performance of IBM Transformation Extender.

Note: Turn off the **RPTSTG** feature before your final performance-checks, as **RPTSTG** also impacts the performance of the **Language Environment** storage allocation modules.

Input Data Sets (Source)

When running IBM® Transformation Extender maps using input (source) data sets, the following recommendation might improve the performance of batch jobs running under the Batch Command Server.

Verify that all input (source) data sets were originally created with an optimum block size. Optimum block sizes on IBM DASD devices are one half-track of data.

This verification should occur on a case-by-case (job-by-job) basis if you suspect there might be performance problems relating to running Batch Command Server jobs.

If through this verification process, you determine that the input (source) data sets do not have optimal block sizes, you can perform the following:

- Identify the creators of the data sets
- Confirm that re-blocking the input (source) data sets will not have any adverse affect on any other potential consumers of them
- Re-block the input (source) data sets

Note: There might be instances where re-blocking the input (source) data sets might not be a viable option for various reasons including but not limited to external vendor specifications or other factors driving the application requirements.

Note: See the following IBM manuals for specific details:

- *DFSMS: Using Data Sets*
- *DFSMS: Implementing System-Managed Storage*

Output data sets (Target)

When running IBM® Transformation Extender maps to create output (target) data sets, the following recommendation for output data set JCL data definition (DD) modifications might improve the performance of batch jobs running under the Batch Command Server.

- Enable the system to determine the block size on all physical sequential (DSORG=PS) output data sets (non-temporary) created using the Batch Command Server.
 - If your system is not running SMS, modify the REVERSEO (output data set) data definition (DD) that is in the DTXBMJCL JCL example included with the Batch Command Server installation as follows:

```
/* Define the output data set
REVERSEO DD DSN=&MAPOUT,
           DCB=(DSORG=PS,RECFM=VB,LRECL=80,BLKSIZE=0),
           UNIT=&UNIT,
           SPACE=(TRK,(1,1),RLSE),
           DISP=(NEW,CATLG,DELETE)
```

- The DSORG=PS, RECFM=VB and BLKSIZE=0 DCB specifications on the REVERSEO DD will ensure that the system determines the block size for optimum performance.

See *DFSMS: Using Data Sets* and *DFSMS: Implementing System-Managed Storage* for additional information.

Temporary data sets (work files)

The Batch Command Server uses temporary data sets (work files), as described in *z/OS Batch* of the *Command Server* documentation. Temporary data sets are used throughout the JCL examples included in the Batch Command Server installation.

Temporary data set names must begin with &&, which indicates a temporary data set. They can use VIO or NON-VIO and can be statically or non-statically (dynamically) allocated.

When running IBM® Transformation Extender maps, the following recommendations for using temporary data sets might improve the performance of batch jobs running under the Batch Command Server:

- All required temporary data sets *should* be statically allocated using VIO, unless you are reusing work files.
- Static temporary data set allocations *must* be defined using RECFM=FBS (Fixed Block Standard).
- Static temporary data set allocations *should* specify LRECL=32760.
- Static temporary data set allocations *should not* specify a block size.

Using the recommendations stated above will provide the most optimal I/O performance for the Batch Command Servers' work files.

For an example JCL, see the **SYSTMP01** (temporary data set) data definition (DD) fragment from the DTXBMJCL JCL that is included in the Batch Command Server installation.

See the *Command Server* documentation for more information about statically allocated temporary data work files.

See *DFSMS: Using Data Sets* and the *DFSMS: Implementing System-Managed Storage* documentation for additional information.

Execution command settings

Execution command settings refer to those commands that are used in the Batch Command Server. They are documented in *z/OS Batch*.

Some performance improvements might be achieved with the execution commands used in the Batch Command Server.

- [WorkSpace Pagesize \(Paging\) \(-Psize:count\) or \(/Psize:count\)](#)
- [WorkSpace \(Work Files in Memory\) \(-WM\) or \(/WM\)](#)
- [WorkSpace \(Work Files in Memory - Hiperspace\) \(-WH\) or \(/WH\)](#)

WorkSpace Pagesize (Paging) (-Psize:count) or (/Psize:count)

Sets the page size and count. See the *Execution Commands* documentation for more details.

The execution region should always have enough space to hold all requested pages. The minimum region size (kilobytes) can be calculated by multiplying page size by page count (size * count). An even larger region size is preferable.

WorkSpace (Work Files in Memory) (-WM) or (/WM)

Sets the **WorkSpace** work files to reside in memory. See the *Execution Commands* documentation for more details.

WorkSpace (Work Files in Memory - Hiperspace) (-WH) or (/WH)

Sets the **WorkSpace** work files to reside in standard Hiperspaces. See *Execution Commands* documentation for more information.

Carefully consider the use of these execution commands to ensure that they do not monopolize your available operating system physical memory for both the **Work Files in Memory** and **Work Files in Memory - Hiperspace** execution commands.

Indiscriminate usage of these execution commands *might* result in excessive operating system paging. Use these execution command options on a case-by-case basis after consulting with your systems administration staff. An **IEFUSI** installation exit can be installed in your system's environment. This exit can protect memory usage when using the **Work Files in Memory** execution command. However, it will *not* protect Hiperspace memory usage when using the **Work Files in Memory - Hiperspace** execution command.

Striped data sets

Striping allows you to divide data into blocks and place them in various partitions on several hard disks. Striping data sets makes it possible to achieve performance improvements.

When running IBM® Transformation Extender maps, striping data sets might improve the performance of batch jobs running under the Batch Command Server.

- Examine your environment and determine if you can stripe sequential and VSAM data sets.
 - Data striping sequential and VSAM data sets can reduce the processing time required for batch jobs resulting in lowered EXCPS.
 - Do not stripe temporary data sets (SYSTMP01-99) processed in IBM Transformation Extender maps.

For additional information, see *DFSMS: Using Data Sets* and *DFSMS: Implementing System-Managed Storage*.

XPLINK performance build

IBM® Transformation Extender provides two Batch Command Server load libraries: non-XPLINK (default) and XPLINK (optional).

IBM XPLINK (Extra Performance Linkage) uses call linkage conventions that are intended to optimize performance of new and existing Batch Command Server jobs.

See the IBM z/OS documentation for details about XPLINK.

CICS execution environment

When executing the IBM® Transformation Extender under CICS® on the z/OS® operating environment, there are several areas where you might be able to improve performance results. These areas are:

- IBM Language Environment® (LE) Runtimes
- Temporary Data Sets (Work Files)
- Enqueuing on Data Files (-Q)
- Execution Command Settings
- Striped Data Sets
- CICS Shared Data Tables
 - See "[CICS Troubleshooting](#)", *CICS System Definition Guide* and *Language Environment Customization* for additional information.
- [IBM Language Environment \(LE\) runtimes](#)
- [Temporary data sets \(work files\)](#)
- [Enqueuing on data files \(-Q\)](#)
- [Execution command settings](#)
- [Striped data sets](#)
- [CICS shared data tables](#)

IBM Language Environment (LE) runtimes

IBM CICS® requires LE runtime libraries to be installed and available to operate CICS. Language Environment® can employ automatic storage tuning for CICS. Automatic storage tuning can improve the performance of LE applications running under CICS.

Automatic storage tuning is only available at certain levels of CICS Transaction Server.

See *CICS System Definition Guide* for additional information.

Temporary data sets (work files)

The IBM® Transformation Extender under CICS® uses temporary data sets (work files) differently in CICS than in Batch.

When running IBM Transformation Extender maps, the following recommendation for using temporary data sets, might improve the performance of CICS applications running the IBM Transformation Extender under CICS:

- The CICS Execution Option uses a **VSAM RRDS** data set defined at product installation and configuration time for its workspace (temporary files) data set.
- Verify that the **CSDSTRNO** parameter correctly reflects the total number of **DATAFILS** configured *plus* the **MAP KSDS** in your system's environment. Incorrect settings can lead to string waits causing performance degradation.

See *z/OS CICS* for detailed information about configuration requirements and options.

Enqueuing on data files (-Q)

The CICS® Execution Option can use enqueueing on data files (-Q) as described in *z/OS CICS* of the *Command Server* documentation.

By default, I/O operations against inputs and outputs are *not* serialized. Therefore, it is recommended that you:

- Examine any potential sharing of inputs or outputs, or both, for maps that run concurrently, which could possibly necessitate usage of this option.

Execution command settings

Execution command settings refer to those commands that are used in the IBM® Transformation Extender under CICS. They are documented in *z/OS CICS*.

Some performance improvements might be achieved with the execution commands used in the IBM Transformation Extender under CICS®.

- [WorkSpace Pagesize \(Paging\) \(-Psize:count\) or \(/Psize:count\)](#)
- [WorkSpace \(Work Files in Memory\) \(-WM\) or \(/WM\)](#)

WorkSpace Pagesize (Paging) (-Psize:count) or (/Psize:count)

Sets the page size and count. See the *Execution Commands* documentation for more details.

WorkSpace (Work Files in Memory) (-WM) or (/WM)

Sets the **WorkSpace** work files to reside in memory. See the *Execution Commands* documentation for more details.

Carefully consider the use of these execution commands to ensure that they do not monopolize your available operating system physical memory for the **Work Files in Memory** execution command. Indiscriminate use of these execution commands might result in excessive operating system paging. Use these execution command options on a case-by-case basis after consulting with your systems administration staff.

Striped data sets

Striping allows you to divide data into blocks and place them in various partitions on several hard disks. Striping data sets makes it is possible to achieve performance improvements.

When running IBM® Transformation Extender maps, striping data sets might improve the performance of batch jobs running under the Batch Command Server.

- Examine your environment and determine if you can stripe sequential and VSAM data sets.
 - Data striping sequential and VSAM data sets can reduce the processing time required for batch jobs resulting in lowered EXCPS.
 - Do not stripe temporary data sets (SYSTMP01-99) processed in IBM Transformation Extender maps.

For additional information, see *DFSMS: Using Data Sets* and *DFSMS: Implementing System-Managed Storage*.

CICS shared data tables

CICS® applications or transactions that run the CICS Command Server can define KSDS outputs or KSDS inputs (source) data sets within CICS Shared Data Tables. Shared data tables are intended to optimize performance. See the IBM® CICS documentation for details.

Troubleshooting

This documentation lists some of the types of questions on performance optimization and helps identify some areas in the system's environment that can be modified to help achieve performance objectives. It is divided into the following environments:

- Batch Troubleshooting
- CICS® Troubleshooting
- [Batch troubleshooting](#)
- [CICS troubleshooting](#)

Batch troubleshooting

The Batch Command Server can be subject to a wide variety of overall performance throughput. The performance factors considered here extend through:

- Usage and interpretation of the designed map or maps being executed by the Batch Command Server.
 - Internal functions used within the maps themselves.
- External factors that traditionally influence batch performance as a whole such as:
 - Input and output data sets and their corresponding block sizes.
 - Batch scheduling issues potentially impacting performance where it relates to potential resource contention and collisions.
 - Your system's environment's Workload Manager (WLM) policies and goals.

Some key areas targeted for improvement are:

- Excessive EXPS (I/Os)
 - Excessive CPU Time Used
 - [Excessive EXCPS \(I/Os\)](#)
 - [Excessive CPU time used](#)
 - [External factors](#)
-

Excessive EXCPS (I/Os)

If your job executing a map or systems of maps seems to generate an excessive amount of EXCPS (Execute Channel Programs) (I/Os), there are a number of items you can immediately examine and correct to improve by reducing the total EXCPS.

The following table lists some recommendations to make better use of resources required for a particular map executed, along with the references to additional documentation:

Recommended Action

Documentation Reference For Batch Execution Environment

Identify and verify that the output data sets that your map (or maps) generates are being created using a system-determined block size.

[Output Data Sets \(Target\)](#)

Identify and verify that your input data sets are using optimum block sizes.

[Input Data Sets \(Source\)](#)

Statically allocate, use VIO for temporary data sets, set LRECL=32760 and set RECFM=FBS on their definitions.

[Temporary Data Sets \(Work Files\)](#)

Calculate new WorkSpace PageSize size:count settings based upon your maps work. Increasing the amount of available paging memory can reduce EXCPs.

[Execution Command Settings](#)

Use striped data sets if applicable and available.

[Striped Data Sets](#)

Examine the usage of the -WM (Work Files in Memory) option.

[Execution Command Settings](#)

Examine the usage of the -WH (Work Files in Memory - Hiperspace) option.

[Execution Command Settings](#)

Proceed with any possible map tuning, if applicable.

[Map Performance Tuning Tips](#)

Install and run XPLINK load library version.

[XPLINK Performance Build](#)

Excessive CPU time used

If your job executing a map or systems of maps seems to be using an excessive amount of CPU (Central Processing Unit) time, there are a number of items you can immediately examine and correct to improve and reduce the total CPU time.

The following table lists some recommended actions you can take to make better use of valuable central processing resources required for a particular map execution, along with the reference to additional documentation:

Recommended Action

Documentation Reference For Batch Execution Environment

Calculate new WorkSpace PageSize size:count settings based upon your map(s) work.

[Execution Command Settings](#)

Examine the usage of the -WH (Work Files in Memory - Hiperspace) option.

[Execution Command Settings](#)

Proceed with any possible map tuning, if applicable.

[Map Performance Tuning Tips](#)

Reduce EXCP count. Reducing the EXCP count can lower CPU time spent managing I/O.

[Excessive EXCPS \(I/Os\)](#)

External factors

In addition to the recommended actions in ["Batch Troubleshooting"](#), there are external factors that can influence the overall performance of the Batch Command Server.

The following table lists some of these factors along with suggested references.

External Factors

Reference

Batch scheduling collisions and resource contention

- SMF data and the associated RMF reports.
- Consult your systems' programming, operations or support personnel.

Workload Manager Policies and Goals

- Consult your systems' programming or support personnel.

CICS troubleshooting

The IBM® Transformation Extender running under CICS® can be subject to a wide variety of overall performance throughput. The performance factors considered here extend through:

- Usage and interpretation of the designed maps being executed by the CICS Execution Option
 - Internal functions used within the maps themselves
- CICS application design and purpose as it relates to map usage and volume of data upon which is being operated
- External factors that traditionally influence CICS performance as a whole such as CICS:
 - Transaction mix
 - Journaling
 - Dispatching priority

Some key areas targeted for improvement are:

- Excessive CICS I/Os, Transaction CPU Time
- External Factors
- [Excessive CICS I/Os, transaction CPU time](#)
- [External factors](#)

Excessive CICS I/Os, transaction CPU time

If your CICS® application or transaction, which is executing a map or systems of maps, seems to generate an excessive amount of EXCPS (I/Os) and your transaction itself is using an excessive amount of CPU time, there are a number of items you can immediately examine and correct if needed, to improve the total required EXCPS, and CPU time.

The following table lists recommendations to make better use of CPU resources required for a particular map execution, along with documentation that contains additional information:

Recommended Action

Documentation References

Identify and verify LSR (Local Shared Resources) pools, strings and usage of CICS shared data tables, if applicable.

See the IBM® CICS documentation.

Use striped data sets if applicable and available.

[Striped Data Sets](#)

Calculate new `WorkSpace PageSize size:count` settings based upon your map(s) work.

[Execution Command Settings](#)

Examine the usage of the `-WM` (Work Files in Memory) option.

[Execution Command Settings](#)

Proceed with any possible map tuning, if applicable.

[Map Performance Tuning Tips](#)

External factors

In addition to the recommended actions in ["CICS® Troubleshooting"](#), there are external factors that can influence the overall performance of the IBM® Transformation Extender running under CICS on the z/OS® operating environment.

The following table lists some of these factors along with suggested references.

External Factors

Reference

Workload Manager Policies and Goals

Consult your systems programming or support personnel.

Other CICS performance information

See the IBM CICS documentation.

Glossary

Term	Definition	Term	Definition
Batch	Running in the background with no user assistance	LRECL	Logical Record Length
CICS®	Customer Information Control System; online transaction processing program; running in the foreground communicating with users	LSR	Local Shared Resources

Term	Definition	Term	Definition
CPU	Central Processing Unit; contains the logic functionality and processes the instructions that drive a computer.	Mainframe	Large processors or servers
DCB	Data Control Block parameter of DD statement in JCL	MIPS	Million Instructions Per Second
DD	Data Definition statement in JCL	MSU	Measured Service Units
EXCP	Execute Channel Program	MVS™	Multiple Virtual Storage; mainframe operating system
Hiperspace™	A virtual storage area (up to 2gigabytes in size) outside the user's virtual address space residing in real or expanded storage and backed up by auxiliary storage	OS/390®	Mainframe operating system (was MVS) (old name - now referred to as z/OS®)
I/O	Input and Output	Systems Z	Line of IBM® computer systems running operating systems such as z/OS
LE	IBM Language Environment®	VIO	Virtual Input/Output

LPA	Link Pack Area	z/OS	Mainframe operating system
RECFM	Record Format used in DCB parameter of DD statement in JCL		

Utility Commands overview

You can use the utility commands to do various functions.

The functions you can perform using utility commands include:

- Analyzing schema
- Importing and exporting schema
- Converting schema
- Converting schema properties from bytes to characters
- Compiling maps
- Importing to and exporting map source files
- Generating a map report HTML file containing information about a map source file
- Deploying systems
- Importing to and exporting systems
- Calculating suggested memory page size and count for maps
- Analyzing map execution behavior
- Converting XML type definitions
- Creating one map that can transform any input data into XML output, and a second map that can transform the XML that the first map produced into output data in a format described by the schema that you specified
Use the second map only when the schema that you specified was imported from a **COBOL** copybook.
- Updating a resource or virtual server in MRN files

Some of the commands offer basic functions that are performed by the Design Studio, but allow them to be executed from the command line or within a command script without running the Design Studio applications. Other commands offer other related functions and are executed in the same way.

There are utility commands for the schema designer, map designer, and Integration Flow Designer (IFD) applications as well as for other related tasks.

Schema designer:

[tanalyze utility command](#)

Analyzes schemas.

[timport utility command](#)

Imports to schemas

[texport utility command](#)

Exports schemas.

[tbccconv utility command](#)

Converts schema properties from bytes to characters.

Map Designer:

[mcompile utility command](#)

Compiles maps

[mimport utility command](#)

Imports to maps

[mexport utility command](#)

Exports maps

[mreport utility command](#)

Generates a map report HTML file from a map source file

Integration Flow Designer:

[sdeploy utility command](#)

Deploys systems

[msdimport utility command](#)

Imports to system files

[msdexport Utility Command](#)

Exports system files

Map Tuning:

[dtxpage Utility Command](#)

Calculates suggested settings for memory page size and count for maps

[dtxprof Utility Command](#)

Profiles and analyzes map execution behavior

Utility commands for XML:

[dtxany2xml Utility Command](#)

Automatically produces a map that can transform any input data into XML output

[Utility Commands for Resource Registry](#)

ResourceRegistryHelper.bat

ResourceRegistryHelper.sh

Updates a resource or virtual server in resource name (.mrn) files.

Utility commands for troubleshooting

After executing a utility command, a value is returned into the *ERRORLEVEL* environment variable indicating the success or failure of the execution. The *ERRORLEVEL* variable is a Windows environment variable that contains the return code of the last DOS command you executed.

To retrieve the value of the *ERRORLEVEL* variable, run the following DOS command.

```
ECHO % ERRORLEVEL %
```

Utility commands return the following valid values in the *ERRORLEVEL* variable:

Return Code	Description
0	This value indicates that the utility command was successful.
1	This value indicates that the utility command was <i>not</i> successful.

The *ERRORLEVEL* variable can also be used in batch files to retrieve the value of the return code.

Utility Commands for schema designer

Schema Designer utility commands are used to analyze schemas, import to and export schemas, convert schemas and convert schema properties from bytes to characters.

The utility commands for this application are:

- ["tanalyze Utility Command"](#) - analyzes schemas
- ["import Utility Command"](#) - imports metadata definitions to schemas
- ["texport Utility Command"](#) - exports schemas
- ["dtxmlconv Utility Command"](#) - converts schemas that were generated in earlier versions of IBM Transformation Extender.
- ["tbconv Utility Command"](#) - converts schema properties from bytes to characters
- [tanalyze Utility Command](#)
The tanalyze utility command is used to analyze one or more schemas from the command line, outside the schema designer GUI.
- [timport Utility Command](#)
The timport utility command is used to import metadata definitions to a schema from the command line, outside the Type Designer GUI.
- [texport Utility Command](#)
The texport utility command is used to export a schema from the command line, outside the schema designer GUI.
- [dtxmlconv Utility Command](#)
The dtxmlconv utility command is used to convert schemas that were generated in earlier versions (before 8.0) of IBM Transformation Extender from the command line, outside the schema designer GUI. It is called the XML Schema Compatibility Utility in the GUI.
- [tbconv Utility Command](#)
The tbconv utility command is used to automatically convert certain objects in a schema sized in bytes to characters from the command line.

tanalyze utility command

The tanalyze utility command is used to analyze one or more schemas from the command line, outside the schema designer GUI.

The tanalyze utility command returns 0 if the analysis is successful, and 1 if it is not successful. It is a batch operation and can also be used for automation.

See ["Troubleshooting"](#) for details about capturing and evaluating the return code resulting from the execution of this utility command.

- [Syntax summary for tanalyze](#)

- [Utility command options for tanalyze](#)
 - [Command line help for tanalyze](#)
 - [Using the tanalyze command](#)
-

Syntax summary for tanalyze

The `tanalyze` utility command is used to analyze schemas.

The `.mtt` file is a required field and is the name of the schema file that needs to be analyzed. If the full path of the schema file name is not specified, the `tanalyze` utility command will search for the schema file specified in the current directory.

None of the options in the `tanalyze` utility command are case sensitive. The following is the syntax of the `tanalyze` utility command:

```
tanalyze <.mtt file> { -L | -S | -L -S }
  [-R [<.dbe file name/location>]] [-SAVE]
  [(-LOG [
    | <log file name/location>
    [-FAIL] [-VERBOSE] [-APPEND])
  | -NOLOG]
```

Utility command options for tanalyze

The following command options are available with the `tanalyze` utility command:

• -L tanalyze Option	• -SAVE tanalyze Option
• -S tanalyze Option	• -VERBOSE tanalyze Option
• -R tanalyze Option	• -APPEND tanalyze Option
• -LOG tanalyze Option	• -NOLOG tanalyze Option
• -FAIL tanalyze Option	

If you type `tanalyze` with no options, the command line help that describes the command will display on your screen.

- [-L tanalyze option](#)
- [-S tanalyze option](#)
- [-R tanalyze option](#)
- [-LOG tanalyze option](#)
- [-FAIL tanalyze option](#)
- [-SAVE tanalyze option](#)
- [-VERBOSE tanalyze option](#)
- [-APPEND tanalyze option](#)
- [-NOLOG tanalyze option](#)

-L tanalyze option

The logic (`-L`) option of the `tanalyze` utility command is used to analyze a schema for logic. If this option is specified, the schema logic will be analyzed.

-S tanalyze option

The structure (`-S`) option of the `tanalyze` utility command is used to analyze a schema by structure. If this option is specified, the schema structure will be analyzed. If both (`-L` and `-S`) options of the `tanalyze` utility commands are specified, the schema is analyzed for both logic and structure.

-R tanalyze option

The results file (`-R`) option of the `tanalyze` utility command has a parameter to specify the path and the file name for the analyze results file produced by the schema analyzer. The specified parameter could be the name of the directory where the analyze results file will be written, the full file path specification in which a wildcard can be used to represent the analyze result file, or the full path in which the complete filename can be specified.

The default naming convention for the analyze results file is: **schema_name.dbe**.

If a wildcard is specified in the full path, for example, `tanalyze myschema.mtt -R C:\MyDev\AnalyzeResults\2002-02-28_*.err`, the analyze results file will be produced in the **C:\MyDev\AnalyzeResults** directory with the **2002-02-28_myschema.err** naming convention.

If the complete file name is specified, for example, `tanalyze myschema.mtt -R C:\MyDev\AnalyzeResults\MyAnalyzeResults.txt`, the **MyAnalyzeResults.txt** file will be produced in the **C:\MyDev\AnalyzeResults** directory.

If the (-R) option is not specified, the analyze results will be written to the console, and if (-R) is specified without a parameter, the analyze results will be written to the same directory as the schema file using the default **schema_name.dbe** naming convention.

-LOG tanalyze option

The log (-LOG) option of the `tanalyze` utility command is used to enable logging. The log file produced shows the results of the schema analysis. This option has an optional parameter to specify the file name and location for the log file. The default file name for the `tanalyze` log will be **tanalyze_schema_name.log**. The default location for the `tanalyze` log will be the directory where the schema file is located.

The file name or the location parameter, if specified with the (-LOG) option of the `tanalyze` utility command, could be the name of the directory where the `tanalyze` log file will be written, the full file path specification in which a wildcard can be used to represent the schema file, or the full path in which the complete filename can be specified. If the . is specified with the (-LOG) option, the `tanalyze` log will be written to the default location (or the directory where the schema file is located) using the default naming convention. If a wildcard is specified in the full path, for example, `tanalyze myschema.mtt -LOG C:\MyDev\AnalyzeResults\2002-02-28_*.results`, the `tanalyze` log file will be produced in the **C:\MyDev\AnalyzeResults** directory with the **2002-02-28_myschema.results** naming convention. If the complete file name is specified, for example, `tanalyze myschema.mtt -LOG C:\MyDev\AnalyzeResults\myschema_results.txt`, the **myschema_results.txt** file will be produced in the **C:\MyDev\AnalyzeResults** directory.

If the `tanalyze` utility command is unable to create the `tanalyze` log file, the schema analyzing process will terminate, and the `Fatal error : Could not start the process, unable to create the log file` fatal error message will display on the console. If nothing is specified in the command line for -LOG (neither -LOG or -NOLOG) or if no parameter is provided for -LOG, the command line assumes the (-LOG) option is included in the command line, and writes the log messages to the console.

-FAIL tanalyze option

The fail (-FAIL) option of the `tanalyze` utility command is used to indicate that only the schemas that had analyze errors or warnings during the analysis should be included in the `tanalyze` log file. If the log failures only (-FAIL) option is selected, the `tanalyze` log will contain only the schemas that had errors or warnings. If the log failures only (-FAIL) option is not selected in the command line, all the analyze results will be written to the `tanalyze` log file.

-SAVE tanalyze option

The save (-SAVE) option of the `tanalyze` utility command is used to save the schema after analysis. If this option is specified, after the schema is analyzed, the schema will be saved. Use this command option to save any changes since the last time the schema structure analysis was done.

-VERBOSE tanalyze option

The verbose (-VERBOSE) option of the `tanalyze` utility command is used to indicate whether or not the verbose `tanalyze` log should be produced. The verbose `tanalyze` log will contain an entry for the schema being analyzed or attempted, the schema name, the analyzing start date/time, the analyzing end date/time, the analyzing result, and the analyze results file name. If the Verbose (-VERBOSE) option is not selected, a concise version of the `tanalyze` log will be produced, which includes an entry for the schema name and the result of the schema analysis.

-APPEND tanalyze option

The append (-APPEND) option of the `tanalyze` utility command is used to indicate that the current `tanalyze` log messages should be appended to the existing `tanalyze` log file if it already exists. If the `tanalyze` log -APPEND option is selected, the `tanalyze` log messages will be appended to the existing file if it exists; otherwise, a new file will be created. If the -APPEND option is not selected, the `tanalyze` log file will be created if no log file exists, or it will be overwritten if the log file does exist.

-NOLOG tanalyze option

The disable log (-NOLOG) option of the `tanalyze` utility command is used to turn off logging. If the disable logging option is selected, the log file will be not produced. The optional (-FAIL, -APPEND, and -VERBOSE) options of the (-LOG) option cannot be used with the disable log (-NOLOG) option. If these options are selected with the (-NOLOG) option, the command line is invalid, and the `Not a valid command line : (-LOG) optional commands (-APPEND), (-FAIL), (-VERBOSE) cannot be used with disable log command (-NOLOG)` error message will display on the console.

Command line help for tanalyze

There is help that describes the `tanalyze` utility command usage in the command line.

To view the command line help for the `tanalyze` utility command:

Enter `tanalyze` at the command line prompt in the *install_dir*.
The syntax and descriptions of all the options appear on the console.

Using the tanalyze command

Use the `tanalyze` utility command to analyze one or more schemas from the command line, outside the schema designer GUI.

The following example shows how you can use the command:

```
install_dir> tanalyze myschema.mtt
  -L -S
  -R C:\MyDev\AnalyzeResults\myschema.dbe
  -LOG -APPEND
```

When you run the example, the following result occurs:

- If the `myschema.mtt` schema file is analyzed successfully, the `Analysis successful.` message displays on the console.
- The `myschema.dbe` analyze results file is produced in the `C:\MyDev\AnalyzeResults` directory.
- If the `myschema.log` log file does not exist, it is produced in the same directory as the schema file. If the `myschema.log` log file already exists, the log messages are appended to the existing file.

timport utility command

The `timport` utility command is used to import metadata definitions to a schema from the command line, outside the Type Designer GUI.

The `timport` utility command returns 0 if the schema import is successful and 1 if it is not successful. It is a batch operation and can also be used for automation.

See "[Troubleshooting](#)" for details about capturing and evaluating the return code resulting from the execution of this utility command.

- [Syntax summary for timport](#)
- [Utility command options for timport](#)
- [Command line help for timport](#)
- [Using the timport command](#)

Syntax summary for timport

`timport` is the name of the utility command used to import metadata definitions to schemas.

All the options in the `timport` utility command are case sensitive. The following is the syntax of the `timport` utility command:

```
timport [-IMP <IMPORTER_OPTIONS>]
  [-NO]
  [-O <.mtt file name/location >]
  [(-LOG [. | <log file name/location>]
    [-FAIL] [-VERBOSE] [-APPEND]
    [-HELP] [-KEEPMTS <.mts filename>])
   | -NOLOG]
```

Utility command options for timport

The following command options are available with the `timport` utility command:

• -APPEND timport option	• -HINTS timport option	• -NO timport option
• -BYTEORDER timport option	• -IMP timport option	• -NOLOG timport option
• -CHARSET timport option	• -KEEPMTS timport option	• -O timport option
• -CICS timport option	• -LANG timport option	• -OPT timport option
• -FAIL timport option	• -LOG timport option	• -VALIDATION timport option
• -HELP timport option	• -ND timport option	• -VERBOSE timport option

If you type `timport` with no options, the command-line help that describes the command displays on your screen.

- [-APPEND timport option](#)
- [-BYTEORDER timport option](#)
- [-CHARSET timport option](#)
- [-CICS timport option](#)
- [-FAIL timport option](#)
- [-HELP timport option](#)
- [-HINTS timport option](#)
- [-IMP timport option](#)
- [-KEEPMTS timport option](#)
- [-LANG timport option](#)

- [-LOG timport option](#)
 - [-ND timport option](#)
 - [-NO timport option](#)
 - [-NOLOG timport option](#)
 - [-O timport option](#)
 - [-OPT timport option](#)
 - [-VALIDATION timport option](#)
 - [-VERBOSE timport option](#)
 - [IMPORTER OPTIONS](#)
-

-APPEND timport option

The append (-APPEND) option of the `timport` utility command is used to indicate that the current `timport` log messages should be appended to the existing `timport` log file if it already exists. If the `timport` log -APPEND option is selected, the `timport` log messages will be appended to the existing file, if it already exists. If it does not exist, a new file will be created. If the -APPEND option is not selected, the `timport` log file will be created if no log file exists, or it will be overwritten if the log file does exist.

-BYTEORDER timport option

The byte order (-BYTEORDER) option of the `timport` utility command is available to use with the COPYBOOK importer option to import metadata definitions to a schema with the COBOL Copybook importer. It is specified together with a byte order set argument. The byte order set is the convention a machine processor uses to position its lowest byte within a word to begin either from the leftmost or the rightmost position and describes the execution-time data. Valid values for the byte order set argument are NATIVE, BIGENDIAN and LITTLEENDIAN. If no byte order set argument is specified, the default value is NATIVE.

-CHARSET timport option

The character set (-CHARSET) option of the `timport` utility command is available to use with the COPYBOOK importer option to import metadata definitions to a schema with the COBOL Copybook importer. It is specified together with a character set argument. The character set is the standard collection of letters, numbers and symbols that describes the execution-time data. The values for the character set argument are any one of the valid character set codes. If no character set argument is specified, the default value is NATIVE. For the list of valid character set codes, see the character set codes topic in the Functions and Expressions documentation.

-CICS timport option

The CICS (-CICS) option of the `timport` utility command is available to use with the COPYBOOK importer option to import metadata definitions to a schema with the COBOL Copybook importer. It specifies to the importer that it should generate a schema for a CICS adapter.

-FAIL timport option

The fail (-FAIL) option of the `timport` utility command is used to indicate that only the schemas that had errors during the importing should be included in the `timport` log file. If the log failures only when the (-FAIL) option is selected, the `timport` log will contain only the schemas that had failed importing. If the log failures only -FAIL option is not selected in the command line, all the imported results will be written to the `timport` log file.

-HELP timport option

The help (-HELP) option of the `timport` utility command is used to display information about the specified importer. It is used with the importer options presented in the "[IMPORTER OPTIONS](#)".

The syntax is:

```
timport -IMP <importer option> -HELP
```

Example

An example of the syntax to use to display information about the COPYBOOK importer option is as follows:

```
timport -IMP COPYBOOK -HELP
```

-HINTS timport option

The XSDL HINTS (-HINTS) `timport` option is available to use with the XML Schema importer.

The default value for the `HINTS` `timport` option for any schemas that are generated, is `NONE`. The other available options that you can specify are `ALLELEMENTS`, `GLOBALELEMENTS`, and `ROOTELEMENT`.

-IMP timport option

The import (`-IMP`) option of the `timport` utility command is used to specify the importer type to use to import the metadata definitions to the schema. The available importer types are presented in the ["IMPORTER OPTIONS"](#).

-KEEPMTS timport option

The keep `mts` file import (`-KEEPMTS`) option of the `timport` utility command is specified together with the system file location and name. This system file is the intermediate `mts` file that is generated when the `timport` utility command runs. The `-KEEPMTS` option ensures that the specified system file generated by the utility command, remains after the command is run, instead of being deleted.

The keep `mts` file import (`-KEEPMTS`) option of the `timport` utility command is not available to be used with the `MTS` importer option.

This option is also only used for the deprecated COBOL Copybook Importer. If you specify the option for the non-deprecated (`-ND`) COBOL Copybook Importer, the import process ignores it. Since the process ignores the `KEEPMTS` importer option, it does not produce an error message.

-LANG timport option

The language (`-LANG`) option of the `timport` utility command is available to use with the `XMLSHEMA` and `XMLDTD` importer options to import the metadata definitions to a schema with the XML Schema or XML DTD importers. It is specified together with a language option argument. The language option argument is the language type that describes the execution-time data. Valid values for the language option argument are `JAPANESE` and `WESTERN`. If no language option argument is specified, the default value is `WESTERN`.

-LOG timport option

The log (`-LOG`) option of the `timport` utility command is used to enable logging. The log file will be produced showing the result of the imported schema. The `-LOG` option has an optional parameter to specify the location or file name, or both, for the `timport` log file. The default file name for the `timport` log will be `mts_file_name.log`. The default location for the `timport` log will be the directory where the `mts` file is located.

The file name or the location parameter, if specified with the (`-LOG`) option of the `timport` utility command, could be the name of the directory where the `timport` log file will be written, the full file path specification in which a wildcard can be used to represent the `mts` file, or the full path in which the complete filename can be specified. If `.` is specified with the `-LOG` option, the `timport` log will be written to the default location (directory where the schema file is located) using the default naming convention. If a wildcard is specified in the full path, for example, `timport mymts.mts -LOG C:\MyDev\ImportResults\2002-02-28 *.results`, the `timport` log file will be produced in the `C:\MyDev\ImportResults` directory with the `2002-02-28_mymts.results` naming convention. If the complete file name is specified, for example, `timport mymts.mts -LOG C:\MyDev\ImportResults\mymts_results.txt`, the `mymts_results.txt` will be produced in the `C:\MyDev\ImportResults` directory.

If the `timport` utility command is unable to create the `timport` log file, importing of the metadata definitions to the schema will terminate, and the Fatal error – Could not start importing the schema, unable to create the log file fatal error message will display on the console. If nothing is specified in the command line for the log, by default, the command line assumes the `-LOG` option will be included in the command line, and writes the log messages to the console.

-ND timport option

The `-ND` `timport` option triggers the run of the non-deprecated COBOL Copybook Importer.

To run the non-deprecated COBOL Copybook Importer, specify the `-ND` `timport` option with the `COPYBOOK` importer option. The importer uses the default `XML` file, `importdefs.xml`, that contains the default importer option settings. You can use the `-OPT` `timport` option with the `-ND` option to explicitly specify the default importer options `XML` file. You can also specify an alternative `XML` file that contains different default importer option settings.

The `-ND` `timport` option is not used for the deprecated COBOL Copybook Importer. To run the deprecated COBOL Copybook Importer, specify the `COPYBOOK` importer option without the `-ND` option.

-NO timport option

The no overwrite (`-NO`) option of the `timport` utility command is used to indicate that an existing imported `mts` file (`.mts`) is not to be overwritten. If the no overwrite (`-NO`) option is specified in the command line of the `timport` utility command, and the file with the name of the schema file resulting from the importing process exists, it will not be overwritten, the schema exporting will fail, and the The imported mts file cannot be overwritten, file already exists message will be written to the `timport` log file, if enabled. If the (`-NO`) option is not specified, the file with the name of the schema resulting from the importing process will be overwritten.

-NOLOG timport option

The disable log (-NOLOG) option of the `timport` utility command is used to turn off the logging function of the `timport` utility command. If the disable logging option is selected, the log file will not be produced. The optional (-LOG) options (-APPEND, and -VERBOSE) cannot be used with the disable log (-NOLOG) option. If these options are selected with the (-NOLOG) option, the command line will be invalid, and the `Not a valid command line - (LOG) optional commands (-APPEND), (-VERBOSE)` cannot be used with disable log command (-NOLOG). error message will display on the console.

-O timport option

The output (-O) option of the `timport` utility command is used to specify, through a parameter, the location or file name, or both, for the output `.mtt` schema file produced by importing the `.mts` file. The specified parameter could be the name of the directory where the `.mtt` file is written, the full file path specification in which a wildcard can be used to represent the `.mtt` file, or the full path in which the complete filename can be specified. The default naming convention for the `.mtt` file is `mts_file_name.mtt`. If a wildcard is specified in the full path, for example, `timport mymts.mts -O C:\MyDev\ImportOutputs\2002-02-28_*.mtt`, the resulting `.mtt` file is produced in the `C:\MyDev\ImportOutputs` directory with the `2002-02-28_mymts.mtt` naming convention. If the complete file name is specified, for example, `timport mymts.mts -O C:\MyDev\ImportOutputs\MyMtt.mtt`, the `MyMtt.mtt` file is produced in the `C:\MyDev\ImportOutputs` directory. If the (-O) is selected and if the file name is not specified, the command line is invalid, and the `Not a valid command line - the file name parameter is required if command option (-O) is selected` error message displays on the console.

-OPT timport option

The options file (-OPT) `timport` option is available to use with the COPYBOOK `timport` importer option that is specified with the -ND option.

It is only used for the non-deprecated COBOL Copybook Importer.

Use -OPT to specify some of the options that are available under Window,>Preferences,>Importer,>COBOL. If you specify the -OPT `timport` option, you must also specify an XML (.xml) file that contains importer option settings. You can specify the default XML file, `importdefs.xml`, that contains the default importer option settings. You can also specify an alternative XML file that contains different default importer option settings that you need the COBOL Copybook Importer process to use instead.

If you do not include the -OPT `timport` option in your command that includes the -ND option, the COBOL Copybook Importer process uses the default XML file.

To use the COBOL Copybook Importer command with different options, examine the default XML file to see how to set up the options in an alternative XML file.

This option is not used for the deprecated COBOL Copybook Importer. If you specify the -OPT option for the deprecated COBOL Copybook, the import process does not detect it. Since the process does not detect the -OPT importer option in this case, it does not produce an error message.

-VALIDATION timport option

The validation (-VALIDATION) option of the `timport` utility command is available to use with the XMLSCHEMA and XMLDTD importer options to import the metadata definitions to a schema with the XML Schema or XML DTD importers. It is specified together with a validation type option argument. The validation type option argument is the validation type that describes the execution-time data. Valid values for the validation option argument are XERCES and CLASSIC. If no validation option argument is specified, the default value is XERCES.

-VERBOSE timport option

The verbose (-VERBOSE) option of the `timport` utility command indicates if the verbose `timport` log should be produced. The verbose `timport` log will contain an entry for the `.mts` file being imported, the import start date/time, the import end date/time, and the result of the `timport` utility command. If the -VERBOSE option is not selected, a concise version of the `timport` log will be produced, which includes an entry for the `.mts` file name and the result of the import.

IMPORTER OPTIONS

The following available IMPORTER OPTIONS of the `timport` utility command can be supplied:

[MTS timport importer option](#) (Default)
[COPYBOOK timport importer option](#) | [XMLSCHEMA timport importer option](#) | [XMLDTD timport importer option](#)

The following section includes the descriptions and the command syntaxes for each of these importer options.

Each importer-specific command line must be contained within a set of brackets ([]). To see syntax examples, see the specific importer option documentation.

To see how to view the command-line help information for more syntax and usage details, see the "[-HELP timport option](#)".

If you do not specify the output (-O) option, the import process saves the schema in the port directory. But, if you are using the MTS `timport` option, and you specified a full path in the `FileName` tag in the schema script (.mts) file, the following results occur. The import process saves the schema in the specified path instead of the port directory.

If you do specify the output (-O) option, the import process saves the schema in the specified location.

MTS timport importer option

MTS is one of the options that can be specified for IMPORTER OPTIONS on the `timport` utility command. It is used to import an mts file and is specified as follows:

```
[MTS <.mts file>]  
- or -  
<.mts file>
```

Because MTS is the default, the MTS option is optional. Only the mts file must be specified. If the MTS option is specified, the mts file must be provided. If it is not provided, the command line is invalid, and the Not a valid command line - the file name parameter is required if command option (MTS) is selected error message displays on the console.

The .mts file is a required field and is the file name of the mts file that you want to import. If the full path of the mts file name is not specified, the timport utility command searches for the mts file in the current directory.

COPYBOOK timport importer option

COPYBOOK is one of the options that can be specified for IMPORTER OPTIONS on the timport utility command. It is used to designate the COBOL Copybook importer as the schema importer type and is specified as follows:

```
COPYBOOK [<.cpy file> [-BYTEORDER timport option <byte order>  
-CHARSET timport option <charset> -CICS timport option  
[-ND timport option [-OPT <importer_opts_xml_file.xml>]]]
```

Specify the full path of the copybook file in the command line.

XMLDTD timport importer option

XMLDTD is one of the options that can be specified for IMPORTER OPTIONS on the timport utility command. It is used to designate the XML DTD importer as the schema importer type and is specified as follows:

```
XMLDTD [<.dtd file> [-LANG timport option <language>  
-VALIDATION timport option <validation_type>]]
```

Specify the full path of the dtd file in the command line.

XMLSCHEMA timport importer option

XMLSCHEMA is one of the options that can be specified for IMPORTER OPTIONS on the timport utility command. It is used to designate the XML Schema importer as the schema importer type and is specified as follows:

```
XMLSCHEMA [<.xsd file> [-LANG timport option <language>  
-HINTS timport option <xsd1_hints>  
-VALIDATION timport option <validation_type>]]
```

Specify the full path of the xsd file in the command line.

Command line help for timport

There is help that describes the timport utility command usage in the command line.

To view the command line help for the timport utility command:

Enter timport at the command line prompt in the *install_dir*.
The syntax and descriptions of all the options appear on the console.

Using the timport command

Use the timport utility command to:

- import metadata definitions to a schema file from the command line, outside the schema designer GUI.
- import Copybook metadata definitions to a schema from the command line, outside the schema designer GUI.
- [Import a schema file example](#)
- [Import a copybook schema example](#)
- [Import a copybook schema with ND option example](#)

Import a schema file example

The following example shows how you can use the timport utility command-line option to import metadata definitions in the mymts.mts file to the mymts.mtt schema file.

```
install_dir> timport mymts.mts  
-O C:\MyDev\ImportResults\mymts.mtt  
-LOG -APPEND
```

When you run the example, the following result occurs:

- If the mymts.mts file is imported successfully, the `timport - completed successfully.` message displays on the console.
- A mymts.mtt schema is created in the C:\MyDev\ImportResults directory.
- If the mymts.log log file does not exist, it is produced in the same directory as the .mts file. If the mymts.log log file exists, the log messages are appended to the existing file.

Import a copybook schema example

The following example shows how you can use the `timport` utility command-line option to import the COBOL Copybook wrapped.cpy metadata file to a schema for a CICS adapter. The COBOL Copybook importer is specified to use the `NATIVE` byte order set, `NATIVE` character set, create the wrapped.log file, and to retain the generated intermediate wrapped.mts system file.

```
timport -IMP COPYBOOK
[c:\install_dir\examples\general\copybook\wrapped.cpy
-BYTEORDER NATIVE -CHARSET NATIVE -CICS]
-O c:\install_dir\examples\general\copybook\wrapped.mtt
-LOG c:\install_dir\examples\general\copybook\wrapped.log
-KEEPMTS
c:\install_dir\examples\general\copybook\wrapped.mts
```

Import a copybook schema with ND option example

The following example shows how you can use the `timport` utility command-line option to import the COBOL Copybook examplecpybook.cpy metadata file to a schema for a CICS adapter. The non-deprecated COBOL Copybook importer is specified to use the `NATIVE` byte order set, and `NATIVE` character set. It is specified to use the COBOL Copybook importer options that are set in the importeropts.xml XML file. The importer is also specified to create the test.log log file.

```
timport -IMP COPYBOOK
[c:\install_dir\examples\general\copybook\examplecpybook.cpy
-BYTEORDER NATIVE -CHARSET NATIVE -CICS
-ND -OPT c:\install_dir\examples\general\copybook\importeropts.xml]
-O c:\install_dir\examples\general\copybook\examplecpybook.mtt
-LOG c:\install_dir\examples\general\copybook\test.log -NO -VERBOSE
```

texport utility command

The `texport` utility command is used to export a schema from the command line, outside the schema designer GUI.

The `texport` utility command returns 0 if the schema export is successful and 1 if it is not successful. It is a batch operation and can also be used for automation.

See ["Troubleshooting"](#) for details about capturing and evaluating the return code resulting from the execution of this utility command.

- [Syntax summary for texport](#)
- [Utility command options for texport](#)
- [Command line help for texport](#)
- [Using the texport command](#)

Syntax summary for texport

`texport` is the name of the utility command used to export schemas. The `.mtt` file is a required field and is the file name of the schema file that needs to be exported. If the full path of the schema file name is not specified, the `texport` utility command will search for the schema file specified in the current directory.

None of the options in the `texport` utility command are case sensitive. The following is the syntax of the `texport` utility command:

```
texport <.mtt file>
[-T <type name>]
[-NO]
[-O <.mts file name/location>]
[(- -LOG [.      | <log file name/location>]
          [-FAIL] [-VERBOSE] [-APPEND])
 | -NOLOG]
```

Utility command options for texport

The following command options are available with the `texport` utility command:

• -T texport Option	• -FAIL texport Option
• -O texport Option	• -APPEND texport Option
• -NO texport Option	• -VERBOSE texport Option
• -LOG texport Option	• -NOLOG texport Option

If you type `texport` with no options, the command line help that describes the command will display on your screen.

- [**-T texport option**](#)
- [**-O texport option**](#)
- [**-NO texport option**](#)
- [**-LOG texport option**](#)
- [**-FAIL texport option**](#)
- [**-APPEND texport option**](#)
- [**-VERBOSE texport option**](#)
- [**-NOLOG texport option**](#)

-T texport option

The type name (-T) option of the `texport` utility command is used to specify through a parameter, the specific type that needs to be exported. The type name is case sensitive and it should be the full path of the type. Specify the full path in descending order starting from the root type in the schema to the type that you want to export. You must separate each type in the hierarchy by a semi-colon. An example of the format is: `roottype:ancestortype:parenttype:actualtype`. If you did not specify the (-T) option, the whole schema from the root is exported.

If you specified the type name (-T) option but did not specify type name in the command line, it is an invalid command line, and the `Not a valid command line : Type name parameter is required if type name command option (-T) is selected` error message displays on the console. If the type name that you specified in the command line is not found in the schema, the `texport` execution terminates and the `Not a valid command line : Type name specified is not valid` error message displays on the console.

-O texport option

The output (-O) option of the `texport` utility command is used to specify, through a parameter, the location or file name, or both, for the exported mts file produced by exporting the schema. The specified parameter could be the name of the directory where the exported mts file is written, the full file path specification in which a wildcard can be used to represent the exported mts file, or the full path in which the complete filename can be specified. The default naming convention for the exported mts file is `schema_name.mts`. If a wildcard is specified in the full path, for example, `texport myschema.mtt -O C:\MyDev\ExportResults\2002-02-28_*.mts`, the analyze results file is produced in the `C:\MyDev\ExportResults` directory with the `2002-02-28_myschema.mts` naming convention. If the complete file name is specified, for example, `texport myschema.mtt -O C:\MyDev\ExportResults\MyExportedMts.mts`, the `MyExportedMts.mts` mts file is produced in the `C:\MyDev\ExportResults` directory. If the export output (-O) option is selected and if the file name is not specified, the command line is invalid, and the `Not a valid command line - the file name parameter is required if export command option (-O) is selected` error message displays on the console.

-NO texport option

The no overwrite (-NO) option of the `texport` utility command is used to indicate that an existing exported mts file (`.mts`) is not to be overwritten. If the no overwrite (-NO) option is specified in the command line of the `texport` utility command, and the file with the name of the schema file resulting from the exporting process exists, it will not be overwritten, the schema exporting will fail, and the `The exported mts file cannot be overwritten, file already exists` message will be written to the `texport` log file, if enabled. If the (-NO) option is not specified, the file with the name of the schema resulting from the exporting process, will be overwritten.

-LOG texport option

The log (-LOG) option of the `texport` utility command is used to enable logging. The log file will be produced showing the result of the exported schema. (-LOG) has an optional parameter to specify the location or file name, or both, for the `texport` log file. The default file name for the `texport` log will be `schema_file_name.log`. The default location for the `texport` log will be the directory where the schema file is located.

The file name or the location parameter, if specified with the (-LOG) option of the `texport` utility command, could be the name of the directory where the `texport` log file will be written, the full file path specification in which a wildcard can be used to represent the schema file, or the full path in which the complete filename can be specified. If the . is specified with the (-LOG) option, the `texport` log will be written to the default location (directory where the schema file is located) using the default naming convention. If a wildcard is specified in the full path, for example, `texport myschema.mtt -LOG C:\MyDev\ExportResults\2002-02-28_*.results`, the `texport` log file will be produced in the `C:\MyDev\ExportResults` directory with the `2002-02-28_myschema.results` naming convention. If the complete file name is specified, for example, `texport myschema.mtt -LOG C:\MyDev\ExportResults\myschema_results.txt`, the `myschema_results.txt` will be produced in the `C:\MyDev\ExportResults` directory.

If the `texport` utility command is unable to create the `texport` log file, the exporting schema will terminate, and the `Fatal error - Could not start exporting the schema, unable to create the log file` fatal error message will display on the console. If nothing is specified in the command line for the log, by default, the command line assumes the (-LOG) option is included in the command line, and writes the log messages to the console.

-FAIL texport option

The fail (-FAIL) option of the `texport` utility command is used to indicate that only the schemas that had errors during the exporting should be included in the `texport` log file. If log failures only (-FAIL) option is selected, the `texport` log will contain only the schemas that had failed exporting. If the log failures only (-FAIL) option is not selected in the command line, all the exported results will be written to the `texport` log file.

-APPEND texport option

The append (-APPEND) option of the `texport` utility command is used to indicate that the current `texport` log messages should be appended to the existing `texport` log file if it already exists. If the `texport` log append (-APPEND) option is selected, the `texport` log messages will be appended to the existing file if it already exists; otherwise, a new file will be created. If the (-APPEND) option is not selected, the `texport` log file will be created if no log file exists, or it will be overwritten if the log file does exist.

-VERBOSE texport option

The verbose (-VERBOSE) option of the `texport` utility command is used to indicate if the verbose `texport` log should be produced. The verbose `texport` log will contain an entry for the schema being exported, the schema name, the exporting start date/time, the exporting end date/time, the exported xml file name, and the result of the `texport` utility command. If the verbose (-VERBOSE) option is not selected, a concise version of the `texport` log will be produced, which includes an entry for the schema, schema name, and exporting result.

-NOLOG texport option

The disable log (-NOLOG) option of the `texport` utility command is used to turn off the `texport` logging capability. If the disable logging option is selected, log file will not be produced. The (-LOG) optional (-APPEND, and -VERBOSE) options cannot be used with the disable log (-NOLOG) option. If these options are selected with the (-NOLOG) option, the command line is invalid, and the Not a valid command line - (LOG) optional commands (-APPEND), (-VERBOSE) cannot be used with disable log command (-NOLOG). error message will display on the console.

Command line help for texport

There is help that describes the `texport` utility command usage in the command line.

To view the command line help for the `texport` utility command:

Enter `texport` at the command line prompt in the `install_dir`.
The syntax and descriptions of all the options appear on the console.

Using the texport command

Use the `texport` command to export a schema from the command line, outside the schema designer GUI.

- [Example 1](#)
- [Example 2](#)

Example 1

Use the `texport` utility command to export a schema from the command line, outside the Type Designer GUI.

The following example shows how you can use the command:

```
install_dir> texport myschema.mtt  
-O C:\MyDev\ExportResults\myschema.mts  
-LOG -APPEND
```

When you run the example, the following result occurs:

- If the `myschema.mtt` schema file is exported successfully, the `texport - completed successfully.` message displays on the console.
- The exported `myschema.mts` xml file is produced in the `C:\MyDev\ExportResults` directory. Because no type name is specified, the whole type schema from the root is exported.
- If the `myschema.log` log file does not exist, it is produced in the same directory as the schema. If the `myschema.log` log file already exists, the log messages are appended to the existing file.

Example 2

Use the `texport` utility command to export a schema from the command line, outside the Type Designer GUI.

The following example shows how you can use the command:

```
install_dir> texport myschema.mtt  
-T MyRoot:MyAncestor:MyParent:MyType
```

```
-O C:\MyDev\ExportResults\2002-02-28_myschema.mts  
-NOLOG
```

When you run the example, the following result occurs:

- If the MyType type of the **myschema.mtt** schema file is exported successfully, the `texport - completed successfully.` message displays on the console.
- The exported **2002-02-28_myschema.mts** xml file is produced in the **C:\MyDev\ExportResults** directory. The **2002-02-28_myschema.mts** xml file contains only the exported information of the MyType type.
- If the MyType type does not exist, or the full path leading to it is not valid, the `Type name specified is not valid` message displays on the console.

No log file is produced because the (`-NOLOG`) option has been selected.

dtxmlconv Utility command

The `dtxmlconv` utility command is used to convert schemas that were generated in earlier versions (before 8.0) of IBM Transformation Extender from the command line, outside the schema designer GUI. It is called the XML Schema Compatibility Utility in the GUI.

When run in batch mode, the `dtxmlconv` utility command returns `0` if the schema conversion is successful and `1` if it is not successful. It is a batch operation, which can also be used for batch automation.

The `.mtt` file is a required field and is the file name of the schema file that needs to be converted to the current format. If the full path of the schemafile name is not specified, the `dtxmlconv` utility command searches for the schema file specified in the current directory.

See "[Troubleshooting](#)" for details about capturing and evaluating the return code resulting from the execution of this utility command.

- [Syntax summary for dtxmlconv](#)
- [Utility command options for dtxmlconv](#)
- [Command line help for dtxmlconv](#)
- [Using the dtxmlconv command](#)

Syntax summary for dtxmlconv

`dtxmlconv <.mtt_file_name/location>`

```
[ -V 6.7|6.7.1|6.7.2|7.5] [-L]  
[ -S DTD_or_SCHEMA_file_name/location ]  
[ -B backup_file_name/location [-O]]  
[ ( -LOG [.|< log_file_name/location >]  
[-FAIL] [-VERBOSE] [-APPEND])  
| -NOLOG]
```

Utility command options for dtxmlconv

The following command options are available with the `dtxmlconv` utility command:

• -V dtxmlconv Option	• -LOG dtxmlconv Option
• -L dtxmlconv Option	• -FAIL dtxmlconv Option
• -S dtxmlconv Option	• -APPEND dtxmlconv Option
• -B dtxmlconv Option	• -VERBOSE dtxmlconv Option
• -O dtxmlconv Option	• -NOLOG dtxmlconv Option

If you type `dtxmlconv` with no options, the command line help that describes the command will display on your screen.

- [-V dtxmlconv option](#)
- [-L dtxmlconv option](#)
- [-S dtxmlconv option](#)
- [-B dtxmlconv option](#)
- [-O dtxmlconv option](#)
- [-LOG dtxmlconv option](#)
- [-FAIL dtxmlconv option](#)
- [-APPEND dtxmlconv option](#)
- [-VERBOSE dtxmlconv option](#)
- [-NOLOG dtxmlconv option](#)

-V dtxmlconv option

The version (-v) option of the `dtxmlconv` utility command has parameters to specify the version of the importer used to generate the schema. The valid values are:

- 6.7
- 6.7.1
- 6.7.2
- 7.5 (default)

-L dtxmlconv option

The language (-L) option argument of the `dtxmlconv` utility command is the language type that describes the execution-time data. The valid values are:

- JAPANESE
- WESTERN

If no language option argument is specified, the default value is WESTERN.

-S dtxmlconv option

The source document file name or URL (-s) option of the `dtxmlconv` utility command will have a parameter to specify the source document used to generate the original schema. This will either be a **.dtd** (DTD) or **.xsd** (schema) file and will represent the new XML grammar that will be used to generate the schema.

If there is no value specified, the utility will automatically use the value that is specified in the schema. If a value is specified, the utility will use that specified value instead of the one from the schema.

-B dtxmlconv option

The backup file (-B) option of the `dtxmlconv` utility command will have a parameter to specify the name of the backup file to be created. If no option is specified, a default backup file with the same name and the **.omt** extension is created.

-O dtxmlconv option

The overwrite (-O) option of the `dtxmlconv` utility command is used to indicate that if a file with the same name as the file specified with the backup file (-B) option exists, then that file is overwritten. If this option is not specified and a file with the same name as the file specified with the backup file (-B) option does exist, The specified backup file already exists and the overwrite option is not set. error message displays on the console.

-LOG dtxmlconv option

The log (-LOG) option of the `dtxmlconv` utility command is used to enable logging. The log option has an optional parameter to specify the user-defined location or file name, or both, for the `dtxmlconv` log file.

If the user-defined location or file name, or both, is not specified, the results of the converted schema will appear on the screen.

If the user-defined location or file name, or both, is specified, a log file will be created containing the results of the converted schema.

The information will be produced when the `dtxmlconv` utility command is run.

-FAIL dtxmlconv option

The fail (-FAIL) option of the `dtxmlconv` utility command is used to indicate that only the type schemas that had errors during the converting should be included in the `dtxmlconv` log file. If log failures only (-FAIL) option is selected, the `dtxmlconv` log will contain only the schemas that had failed converting. If the log failures only (-FAIL) option is not selected in the command line, all the converted results will be written to the `dtxmlconv` log file.

-APPEND dtxmlconv option

The append (-APPEND) option of the `dtxmlconv` utility command is used to indicate that the current `dtxmlconv` log messages should be appended to the existing `dtxmlconv` log file if it already exists. If the `dtxmlconv` log append (-APPEND) option is selected, the `dtxmlconv` log messages will be appended to the existing file if it already exists; otherwise, a new file will be created. If the (-APPEND) option is not selected, the `dtxmlconv` log file will be created if no log file exists, or it will be overwritten if the log file does exist.

-VERBOSE dtxmlconv option

The verbose (-VERBOSE) option of the dtxmlconv utility command is used to indicate if the verbose dtxmlconv log should be produced. The verbose dtxmlconv log will contain an entry for the schema being converted, the schema name, the conversion start date/time, the conversion end date/time, the converted xml file name, and the result of the dtxmlconv utility command.

-NOLOG dtxmlconv option

The disable log (-NOLOG) option of the dtxmlconv utility command is used to turn off the dtxmlconv logging capability. If the disable logging option is selected, log file will not be produced. The (-LOG) optional (-APPEND, and -VERBOSE) options cannot be used with the disable log (-NOLOG) option. If these options are selected with the (-NOLOG) option, the command line is invalid, and the Invalid argument in command line. error message will display on the console.

If you specify both the (-NOLOG) and (-LOG) options, the command line is invalid, and the Disable log option (-NOLOG) cannot be specified when log messages command line option (-LOG) is specified error message will display on the console.

Command line help for dtxmlconv

There is help that describes the dtxmlconv utility command usage in the command line.

To view the command line help for the dtxmlconv utility command:

Enter dtxmlconv at the command line prompt in the *install_dir*.
The syntax and descriptions of all the options appear on the console.

Using the dtxmlconv command

Use the dtxmlconv utility command to convert schemas that were generated in earlier versions (before 8.0) of IBM Transformation Extender from the command line, outside the schema designer GUI.

- [dtxmlconv example](#)

dtxmlconv example

The following example shows how you can use the command:

```
install_dir> dtxmlconv myschema.mtt  
-S C:\MyDev\ConversionResults\mydtd.dtd  
-LOG -APPEND
```

When you run the example, the following result occurs:

- If the **myschema.mtt** schema file is converted successfully, the `Conversion succeeded.` message displays on the console.
- The **mydtd.dtd** DTD file, specified as the input parameter and represents the new XML grammar, is used to generate the schema.
- If the **myschema.log** log file does not exist, it is produced in the same directory as the schema. If the **myschema.log** log file already exists, the log messages are appended to the existing file.

tbccconv utility command

The tbccconv utility command is used to automatically convert certain objects in a schema sized in bytes to characters from the command line.

The behavior of the command depends on the object types in the schema being converted (Text, Syntax, Number, and Date & Time) and the specific command options you use. The object types are represented by the Item Subclass property values in the schema.

There are two ways to use the tbccconv utility command that specifically affect how the conversion is done.

- without the pad sizing (-P) option ([tbccconv default behavior \(without -P option\)](#))
- with the pad sizing ([-P tbccconv option](#))

When run in batch mode, the tbccconv utility command returns 0 if the bytes-to-characters schema conversion is successful and 1 if it is not successful. It is a batch operation, which can also be used for batch automation.

The **.mtt** file is a required field and is the file name of the schema file that needs to be converted. If the full path of the schema file name is not specified, the tbccconv utility command will search for the schema file specified in the current directory.

See ["Troubleshooting"](#) for details about capturing and evaluating the return code resulting from the execution of this utility command.

- [Syntax summary for tbccconv](#)
The tbccconv utility command is used to convert certain objects that are sized in bytes to be sized in characters.
- [Utility command options for tbccconv](#)
The following command options are available with the tbccconv utility command:
 - [Command line help for tbccconv](#)

- [Using the tbccconv command](#)

Use the tbccconv utility command to convert certain objects in a schema sized in bytes to characters from the command line, outside the schema designer GUI.

Syntax summary for tbccconv

The tbccconv utility command is used to convert certain objects that are sized in bytes to be sized in characters.

None of the options in the tbccconv utility command are case sensitive. The following is the syntax of the tbccconv utility command:

```
tbccconv <.mtt file>
  [-P]
  [-R [<.dbe file name/location >]]
  [(- -LOG [
  | <log file name/location >]
  [-FAIL] [-VERBOSE] [-APPEND])
  | -NOLOG]
```

The bytes-to-character schema conversion utility expects to find a schema (.mtt) file present after the tbccconv utility command when other options are also specified. Therefore, if you do not specify an .mtt file but you do specify options, the bytes-to-character conversion utility will try to interpret the first option it encounters as an .mtt file. It will fail and display a message on the console that it could not find an .mtt file.

Utility command options for tbccconv

The following command options are available with the tbccconv utility command:

• -APPEND tbccconv Option	• -P tbccconv Option
• -FAIL tbccconv Option	• -R tbccconv Option
• -LOG tbccconv Option	• -VERBOSE tbccconv Option
• -NOLOG tbccconv Option	

If you type tbccconv with no options, the command line help that describes the command will display on your screen.

- [-APPEND tbccconv option](#)

The append (-APPEND) option of the tbccconv utility command is used to indicate that the current tbccconv log messages should be appended to the tbccconv log file if it already exists.

- [-FAIL tbccconv option](#)

The fail (-FAIL) option of the tbccconv utility command is used to indicate that only the schema that had errors during the byte-to-characters conversion should be included in the tbccconv log file.

- [-LOG tbccconv option](#)

The log (-LOG) option of the tbccconv utility command is used to enable logging.

- [-NOLOG tbccconv option](#)

The disable log (-NOLOG) option of the tbccconv utility command is used to turn off the tbccconv logging capability.

- [-P tbccconv option](#)

The pad sizing (-P) option of the tbccconv utility command is used to indicate for those items that have the PAD characteristic turned on, the PAD sizing value for the SizedAs property will be changed from Bytes to Characters. It also determines how the PAD value is sized when the data is being validated and written as output.

- [-R tbccconv option](#)

The results file (-R) option of the tbccconv utility command has a parameter to specify the path and the file name for the conversion results file produced by the schema bytes-to-characters conversion utility.

- [-VERBOSE tbccconv option](#)

The verbose (-VERBOSE) option of the tbccconv utility command is used to indicate if a verbose tbccconv log should be produced.

-APPEND tbccconv option

The append (-APPEND) option of the tbccconv utility command is used to indicate that the current tbccconv log messages should be appended to the tbccconv log file if it already exists.

If the tbccconv log append (-APPEND) option is selected, the tbccconv log messages will be appended to the file if it already exists. If it does not exist, a new log file will be created. If the (-APPEND) option is not selected, the tbccconv log file will be created if no log file exists, or it will be overwritten if the log file does exist.

-FAIL tbccconv option

The fail (-FAIL) option of the tbccconv utility command is used to indicate that only the schema that had errors during the byte-to-characters conversion should be included in the tbccconv log file.

If the log failures only (-FAIL) option is selected, the tbccconv log will contain only the schema that had failed during the conversion. If the log failures only (-FAIL) option is not selected in the command line, all the converted results will be written to the tbccconv log file.

-LOG tbccconv option

The log (-LOG) option of the `tbccconv` utility command is used to enable logging.

The log option has an optional parameter to specify the user-defined location or file name, or both, for the `tbccconv` log file.

If the user-defined location or file name, or both, is not specified, the results of the converted data will appear on the screen.

If the user-defined location or file name, or both, is specified, a log file will be created containing the results of the converted data.

The information will be produced when the `tbccconv` utility command is run.

-NOLOG tbccconv option

The disable log (-NOLOG) option of the `tbccconv` utility command is used to turn off the `tbccconv` logging capability.

If the disable logging option is selected, the log file will not be produced. The (-LOG) optional (-APPEND and -VERBOSE) options cannot be used with the disable log (-NOLOG) option. If these options are selected with the (-NOLOG) option, the command line is invalid, and the `Invalid argument in command line.` error message will display on the console.

-P tbccconv option

The pad sizing (-P) option of the `tbccconv` utility command is used to indicate for those items that have the PAD characteristic turned on, the PAD sizing value for the `SizedAs` property will be changed from Bytes to Characters. It also determines how the PAD value is sized when the data is being validated and written as output.

Items that have the Pad characteristic are Text, Date & Time and Number. Syntax items have no Pad property.

There are no additional parameters for the pad sizing (-P) option.

For those objects that meet this criteria (the Pad property is set to Yes, and Byte is specified for Text, Date & Time and Number items for the `SizedAs` property in the schema), when the `tbccconv` utility command is run with the -P option, the value for the `SizedAs` property set as Byte will be changed to Character.

-R tbccconv option

The results file (-R) option of the `tbccconv` utility command has a parameter to specify the path and the file name for the conversion results file produced by the schema bytes-to-characters conversion utility.

The specified parameter could be the name of the directory where the conversion results file will be written, the full file path specification in which a wildcard can be used to represent the conversion result file, or the full path in which the complete filename can be specified.

The default naming convention for the conversion results file is: `schema_name.dbe`.

If a wildcard is specified in the full path, for example, `tbccconv myschema.mtt -R C:\MyDev\ConversionResults\2002-02-28_*.err`, the conversion results file will be produced in the **C:\MyDev\ConversionResults** directory with the **2002-02-28_myschema.err** naming convention.

If the complete file name is specified, for example, `tbccconv myschema.mtt -R C:\MyDev\ConversionResults\MyConversionResults.txt`, the **MyConversionResults.txt** file will be produced in the **C:\MyDev\ConversionResults** directory.

If the (-R) option is not specified, the conversion results will be written to the console, and if (-R) is specified without a parameter, the conversion results will be written to the same directory as the schema file using the default `schema_name.dbe` naming convention.

-VERBOSE tbccconv option

The verbose (-VERBOSE) option of the `tbccconv` utility command is used to indicate if a verbose `tbccconv` log should be produced.

The verbose `tbccconv` log will contain an entry for the schema being converted, the names of the schema, the conversion start date/time, the conversion end date/time, the converted file names, and the result of the `tbccconv` utility command. If the verbose (-VERBOSE) option is not selected, a concise version of the `tbccconv` log will be produced, which includes an entry for the schema, schema name, and conversion result.

Command line help for tbccconv

There is help that describes the `tbccconv` utility command usage in the command line.

To view the command line help for the `tbccconv` utility command:

Enter `tbccconv` at the command line prompt in the *install_dir*.

The syntax and descriptions of all the options appear on the console.

Using the tbccconv command

Use the `tbccconv` utility command to convert certain objects in a schema sized in bytes to characters from the command line, outside the schema designer GUI.

When you use the `tbccconv` utility command, it automatically saves the original schema .mtt file.

- [**tbccconv default behavior \(without -P option\)**](#)

The default usage of the `tbccconv` utility command is without the pad sizing (-P) option specified.

- [**tbccconv behavior \(with -P option\)**](#)

The `tbccconv` utility command can be used with the pad sizing (-P) option specified.

tbccconv default behavior (without -P option)

The default usage of the `tbccconv` utility command is without the pad sizing (-P) option specified.

When the `tbccconv` utility command is used without the -P option, only Text and Syntax items with values for Bytes specified for the Min and optionally Max properties will be converted to Min and Max Characters properties, and the Min and Max Bytes sizes will be reset, meaning that Min Bytes size will be automatically set to 0, and the Max Bytes size will be set with no byte constraint. It does not affect Date & Time and Number items, which are sized according to the existing formats used.

By leaving no value for the Min property under Bytes, the Min property will be automatically set to 0. By leaving no value for the Max property under Bytes, there will not be a byte constraint.

- [**tbccconv default behavior examples**](#)

The following table lists the behavior of the `tbccconv` utility command depending on the values of the Min and Max Bytes properties.

- [**tbccconv default syntax example**](#)

This is an example of the `tbccconv` utility command default syntax, which is without the pad sizing (-P) option.

tbccconv default behavior examples

The following table lists the behavior of the `tbccconv` utility command depending on the values of the Min and Max Bytes properties.

When...	Behavior
• Min Bytes property for a type is set to 0 and Max Bytes property is not set to a value.	<ul style="list-style-type: none">Min and Max Bytes properties will not be converted to the Min and Max Characters properties because <code>tbccconv</code> will interpret this type as having no Min and Max Bytes properties set.Min Bytes and Characters sizes will be automatically set to 0.For example, if the Min Bytes property for a type is set to 0 and the Max Bytes property is not set, they will not be converted to the Min and Max Characters property and the Min Bytes and Characters sizes will be automatically set to 0.See example 1: "No constraints"
• Min Bytes property for a type is set to a value but Max Bytes property is not set to a value.	<ul style="list-style-type: none">Min Bytes property will be converted to the Min Characters property.Min Bytes size will be automatically set to 0.Max Bytes property will be not be converted to the Max Characters property.For example, if the Min Bytes property for a type is set to 10 and the Max Bytes property is not set, the Min Bytes property will be converted to the Min Characters property as 10, the Min Bytes size will be automatically set to 0 and the Max Bytes property will not be converted to the Max Characters property.See example 2: "Min Bytes constraints"
• Min Bytes property for a type is not set to a value but Max Bytes property is set to a value.	<ul style="list-style-type: none">Min Bytes property will be not be converted to the Min Characters property.Min Bytes and Characters sizes will be automatically set to 0.Max Bytes property will be converted to the Max Characters property.Max Bytes size will be reset.For example, if the Min Bytes property for a type is not set and the Max Bytes property is set to 10, the Min Bytes property will not be converted to the Min Characters property, the Min Bytes and Characters sizes will be automatically set to 0, the Max Bytes property will be converted to the Max Characters property as 10 and the Max Bytes property will be reset.See example 3: "Max Bytes constraints"
• Both Min and Max Bytes properties for a type are set to values.	<ul style="list-style-type: none">Min and Max Bytes properties will be converted to the Min and Max Characters properties.Min Bytes size will be automatically set to 0.Max Bytes size will be reset.For example, if the Min and Max Bytes properties for a type are set to 10 and 20, they will be converted to the Min and Max Characters properties as 10 and 20, the Min Bytes size will be automatically set to 0 and the Max Bytes size will be reset.See example 4: "Min and Max Bytes constraints"

Conversion activity will be reported in the log file.

- [**tbccconv example 1 \(no constraints\)**](#)

This is an example of how to use the `tbccconv` utility command to convert certain objects in schemas sized in bytes to characters from the command line where there are no Bytes constraints.

- [**tbccconv example 2 \(Min Bytes constraints\)**](#)

This is an example of how to use the `tbccconv` utility command to convert certain objects in schemas sized in bytes to characters from the command line where there are Min Bytes constraints.

- [**tbccconv example 3 \(Max Bytes constraints\)**](#)

This is an example of how to use the `tbccconv` utility command to convert certain objects in schemas sized in bytes to characters from the command line where there are Max Bytes constraints.

- **tbccconv example 4 (Min and Max Bytes constraints)**

This is an example of how to use the `tbccconv` utility command to convert certain objects in schemas sized in bytes to characters from the command line where there are Min and Max Bytes constraints.

tbccconv example 1 (no constraints)

This is an example of how to use the `tbccconv` utility command to convert certain objects in schemas sized in bytes to characters from the command line where there are no Bytes constraints.

To demonstrate this example, assume the schema you want to convert has a `Text` Item Subclass property with the following size properties and values:

```
Size (content) |
Min           |
Bytes         |0
Characters    |
Max           |
Bytes         |
Characters    |
```

The converted schema will have the following size properties and values:

```
Size (content) |
Min           |
Bytes         |0
Characters    |0
Max           |
Bytes         |
Characters    |
```

tbccconv example 2 (Min Bytes constraints)

This is an example of how to use the `tbccconv` utility command to convert certain objects in schemas sized in bytes to characters from the command line where there are Min Bytes constraints.

To demonstrate this example, assume the schema you want to convert has a `Text` Item Subclass property with the following size properties and values:

```
Size (content) |
Min           |
Bytes         |10
Characters    |
Max           |
Bytes         |
Characters    |
```

The converted schema will have the following size properties and values:

```
Size (content) |
Min           |
Bytes         |0
Characters    |10
Max           |
Bytes         |
Characters    |
```

tbccconv example 3 (Max Bytes constraints)

This is an example of how to use the `tbccconv` utility command to convert certain objects in schemas sized in bytes to characters from the command line where there are Max Bytes constraints.

To demonstrate this example, assume the schema you want to convert has a `Text` Item Subclass property with the following size properties and values:

```
Size (content) |
Min           |
Bytes         |0
Characters    |
Max           |
Bytes         |10
Characters    |
```

The converted schema will have the following size properties and values:

```
Size (content) |
Min           |
Bytes         |0
Characters    |0
Max           |
Bytes         |
Characters    |
```

```
Bytes      |
Characters | 10
```

tbccconv example 4 (Min and Max Bytes constraints)

This is an example of how to use the `tbccconv` utility command to convert certain objects in schemas sized in bytes to characters from the command line where there are Min and Max Bytes constraints.

To demonstrate this example, assume the schema you want to convert has a `Text` Item Subclass property with the following size properties and values:

```
Size (content) |
  Min          |
    Bytes     | 10
    Characters |
  Max          |
    Bytes     | 20
    Characters |
```

The converted schema will have the following size properties and values:

```
Size (content) |
  Min          |
    Bytes     | 0
    Characters | 10
  Max          |
    Bytes     | 20
    Characters | 20
```

tbccconv default syntax example

This is an example of the `tbccconv` utility command default syntax, which is without the pad sizing (`-P`) option.

The following command syntax example shows how you can use the `tbccconv` utility command with its default settings and logging options:

```
install_dir> tbccconv myschema.mtt
              -LOG -APPEND
```

When you run the example, the following result occurs:

- If the `myschema.mtt` file is converted successfully, the `Conversion succeeded.` message displays on the console.
- If the `myschema.log` log file does not exist, it is produced in the same directory as the `tschema` file. If the `myschema.log` log file already exists, the log messages are appended to the existing file.

tbccconv behavior (with -P option)

The `tbccconv` utility command can be used with the pad sizing (`-P`) option specified.

- [tbccconv example with -P option](#)
This is an example of how to use the `tbccconv` utility command with the pad sizing (`-P`) option to convert certain objects in schemas sized in bytes to characters from the command line.
- [tbccconv example syntax with -P option](#)
This is an example of the `tbccconv` utility command syntax with the pad sizing (`-P`) option.

tbccconv example with -P option

This is an example of how to use the `tbccconv` utility command with the pad sizing (`-P`) option to convert certain objects in schemas sized in bytes to characters from the command line.

To demonstrate this example, assume the schema you want to convert has a `Text` Item Subclass property with the following pad and size properties and values:

```
Pad      | Yes
Value   | <sp>
Padded to | Fixed Size
Length   | 0
SizedAs  | Bytes
Justify   | Left
Apply pad | Fixed Group
```

The converted schema will have the following property values set for the `Text` Item Subclass property:

```
Pad      | Yes
Value   | <sp>
```

Padded to	Fixed Size
Length	0
SizedAs	Characters
Justify	Left
Apply pad	Fixed Group

tbccconv example syntax with -P option

This is an example of the `tbccconv` utility command syntax with the pad sizing (`-P`) option.

The following command syntax example shows how you can use the `tbccconv` utility command with the `-P` option in addition to logging options.

```
install_dir> tbccconv myschema.mtt
          -P
          -LOG -APPEND
```

When you run the example, the following result occurs:

- If the `myschema.mtt` schema file is converted successfully, the `Conversion succeeded.` message displays on the console.
- If the `myschema.log` log file does not exist, it is produced in the same directory as the schema file. If the `myschema.log` log file already exists, the log messages are appended to the existing file.

Utility commands for map designer

Map designer utility commands are used to compile maps, import to maps, export maps, and generate map report HTML files from map source files.

- [mcompile utility command](#)
The `mcompile` utility command is used to compile one or more maps from the command line, outside of the Map Designer GUI.
- [mimport utility command](#)
The `mimport` utility command is used to import an xml file to a map source file from the command line, outside the Map Designer GUI.
- [mexport utility command](#)
The `mexport` utility command is used to export a map source file from the command line, outside the Map Designer.
- [mreport utility command](#)
The `mreport` utility command is used to generate a map report HTML file containing information about a map source file, from the command line, outside the Map Designer.

mcompile utility command

The `mcompile` utility command is used to compile one or more maps from the command line, outside of the Map Designer GUI.

The `mcompile` utility command returns 0 if the compilation is successful, and 1 if not. It is a batch operation that can also be used for automation. `mcompile` is supported on Windows and Linux platforms.

See "[Troubleshooting](#)" for details about capturing and evaluating the return code resulting from running this utility command.

- [mcompile utility command syntax summary](#)

- [mcompile utility command options](#)
The options that can be used with the `mcompile` utility command.
- [mcompile command line help](#)
You can view command line help for the `mcompile` utility command.
- [mcompile command usage](#)
Use the `mcompile` utility command to compile one or more maps from the command line, outside the Map Designer GUI.

mcompile utility command syntax summary

The syntax summary for the `mcompile` utility command.

The `mcompile` utility command is used to compile maps.

The `.mms` file is a required field and is the name of the map source file that needs to be compiled. The map source file can have any number of executable maps in it. The executable maps shall be defined as a map for which all sources and targets have the minimum amount of information specified for the actual source or target of data for that card's data. If the full path of the map source file name is not specified, the `mcompile` utility command will search for the map source file in the current directory. If the `.mms` file is not specified, the `Not a valid command line - map source file name should be given for the command` error message will display on the console.

The executable map name is the only option in the `mcompile` utility command that is case sensitive. The following is the syntax of the `mcompile` utility command:

```
mcompile <.mms file> -L [-DP | -TX]
```

```

- or -
mcompile <.mms file> -A
[-K] [-E] [-NO]
[-DP] [-TX]
[-P <platform>[;<platform>[;...]]]
[-O <.mmc file name/location>]
[-R <.mme file name/location>]
[( -LOG [
| <log file name/location>]
[-FAIL] [-VERBOSE] [-APPEND])
| -NOLOG]
- or -
mcompile <.mms file>
<executable map>
[-E]
[-NO]
[-P <platform>[;<platform>[;...]]]
[-O <.mmc file name/location>]
[-R <.mme file name/location>]
[( -LOG [
| <log file name/location>]
[-FAIL] [-VERBOSE] [-APPEND])
| -NOLOG]

```

mcompile utility command on Linux platform

The syntax summary for the mcompile utility command on Linux platform.

Syntax

The following is the syntax for the `mcompile` utility command on Linux platform:

```
mcompile <mms filename> [<executable map name> -O <compiled map file name>|-A|-L] [-P [WINDOWS; LINUX; AIX; ZOS; ZLINUX; PLINUX]]
```

<mms filename>: map source file, contains design of the maps, does not support wild characters.

<executable map name>: executable map name from the mms file, does not support wild characters.

-A: compile all maps in the specified mms file, the name of the compiled file name will be generated automatically <full path to mms name>.<executable map name>.mmc.

-O <compiled map file name>: the specified executable map will be compiled as specified.

-L List: All executable maps from the specified map source file.

The following are the examples of the `mcompile` utility command on Linux platform:

1. Compile processCVSDelimited:

```
>mcompile /myfolder/delimited.mms processCVSDelimited -O /my mmc folder/delimited.mms.processCVSDelimited.aol -P LINUX;WINDOWS
```
2. Compile processTABDelimited and processCVSDelimited, will generate two compiled map files, /myfolder/delimited.mms.processCVSDelimited.mmc and /myfolder/delimited.mms.processTABDelimited.mmc:

```
>mcompile /myfolder/delimited.mms -A -P LINUX;WINDOWS
```
3. List executable maps present in the mms file:

```
>mcompile /myfolder/delimited.mms -L
```

mcompile utility command options

The options that can be used with the `mcompile` utility command.

The following command options are available with the `mcompile` utility command:

• -L mcompile Option	• -TX mcompile Option
• -A mcompile Option	• -R mcompile Option
• -K mcompile Option	• -LOG mcompile Option
• -E mcompile Option	• -FAIL mcompile Option
• -P mcompile Option	• -APPEND mcompile Option
• -O mcompile Option	• -VERBOSE mcompile Option
• -NO mcompile Option	• -NOLOG mcompile Option
• -DP mcompile Option	

If you type `mcompile` with no options, the command line help that describes the command will display on your screen.

- **-L mcompile option**
The -L option that can be used with the mcompile utility command.
- **-A mcompile option**
The -A option that can be used with the mcompile utility command.
- **-K mcompile option**
The -K option that can be used with the mcompile utility command.
- **-E mcompile option**
The -E option that can be used with the mcompile utility command.
- **-P mcompile option**
The -P keyword of the **mcompile** utility command specifies one or more platforms for which to compile the executable map.
- **-O mcompile option**
The -O option that can be used with the mcompile utility command.
- **-NO mcompile option**
The -NO option that can be used with the mcompile utility command.
- **-DP mcompile option**
The -DP option that can be used with the mcompile utility command.
- **-TX mcompile option**
The -TX option that can be used with the mcompile utility command.
- **-R mcompile option**
The -R option can be used with the mcompile utility command.
- **-LOG mcompile option**
The -LOG option that can be used with the mcompile utility command.
- **-FAIL mcompile option**
The -FAIL option that can be used with the mcompile utility command.
- **-APPEND mcompile option**
The -APPEND option that can be used with the mcompile utility command.
- **-VERBOSE mcompile option**
The -VERBOSE option that can be used with the mcompile utility command.
- **-NOLOG mcompile option**
The -NOLOG option that can be used with the mcompile utility command.

-L mcompile option

The -L option that can be used with the mcompile utility command.

The list (-L) option of the **mcompile** utility command is used to list all executable maps that are present in the specified map source file. When this option is selected, the list of all executable maps will display in alphabetical order, each on a separate line. No other option can be selected with the (-L) option in the **mcompile** utility command, except the (-DP) and (-TX) options. If any other option of the **mcompile** utility command is selected with the (-L) option, other than the (-DP) and (-TX) options, the command line is invalid, and the **Not a valid command line - No other option is allowed with '-L' except -DP or -TX.** error message will display on the console.

Using the -L mcompile option with -TX or -DP options

The following table shows how the **mcompile** utility command behaves when you specify the (-L) option along with the different executable map type options.

When you specify the (-L) option along with...	Result
the (-TX) option of the mcompile utility command	mcompile will list IBM Transformation Extender executable maps that are present in the map source file
the (-DP) option of the mcompile utility command	mcompile will list IBM DataPower executable maps that are present in the map source file
both the (-TX) and (-DP) options of the mcompile utility command	The command line is invalid, and the Not a valid command line - No other option is allowed with '-L' except -DP or -TX. error message will display on the console.

-A mcompile option

The -A option that can be used with the mcompile utility command.

The all (-A) option of the **mcompile** utility command is used to compile all executable maps that are present in a map source file. The executable map name should not be specified in the command line if (-A) option is selected. If the executable map name is also specified with the (-A) option, the command line is invalid, and the **Not a valid command line - Executable map name should not be specified when '-A' all maps are selected** error message will display on the console.

Using the -A mcompile option with -TX and -DP options

The following table shows how the **mcompile** utility command behaves when you specify the (-A) option along with the different executable map type options.

When you specify the (-A) option along with...	mcompile will compile...
the (-TX) option of the mcompile utility command	IBM Transformation Extender executable maps that are present in the map source file
the (-DP) option of the mcompile utility command	IBM DataPower executable maps that are present in the map source file

When you specify the (-A) option along with...	mcompile will compile...
both the (-TX) and (-DP) options of the mcompile utility command	both IBM Transformation Extender and IBM DataPower executable maps that are present in the map source file, which is the same result as specifying (-A) without the two executable map type options

-K mcompile option

The -K option that can be used with the mcompile utility command.

The continue (-K) option of the **mcompile** utility command is used to continue the compiling of the executable maps that are present in the map source file when any errors are returned by the map compiler or upon the first **mcompile** error. This option can be used only with the all maps (-A) option. If the continue (-K) option is specified without (-A), the command line is invalid, and the **Not a valid command line - Continue compiling** option cannot be specified without '-A' all maps command option. error message will display on the console. If the continue compilation (-K) option is not selected, the compilation of the map on which the first error has occurred will be completed, and the **mcompile** will terminate. It will not continue with the rest of the executable maps that are present in the map source file. If the continue compilation (-K) option is selected, the map compilation will be performed for all the executable maps that are present in the map source file, regardless of whether the map compiler returns warnings or errors for any of the individual maps.

-E mcompile option

The -E option that can be used with the mcompile utility command.

The errors (-E) option of the **mcompile** utility command is used to control the type of messages (warnings or errors, or both) written to the build results file for each executable map that has been compiled. If the (-E) option is selected, the messages written to the build results file will be limited to map compiler errors only. The warning messages will be ignored and will not be written to the build results file. If the (-E) option is not selected, all the error and warning messages will be written to the build results.

-P mcompile option

The -P keyword of the **mcompile** utility command specifies one or more platforms for which to compile the executable map.

The command supports the following platforms as keywords:

- AIX
- HPITANIUM
- LINUX
- PLINUX
- SOLARIS
- WINDOWS
- ZLINUX
- ZOS

The -P keyword is optional. If you omit it, the **mcompile** command line uses **WINDOWS** as the default platform. If you specify more than one platform, the **mcompile** command compiles a multi-platform map. Delimit each platform with a semi-colon (;). For example:

```
mcompile test.mms -A -P WINDOWS;LINUX;SOLARIS;ZOS
```

The **mcompile** command is invalid and does not compile a map when:

- You specify the -P keyword but omit the platform.
- You specify one or more invalid platforms.

-O mcompile option

The -O option that can be used with the mcompile utility command.

The output (-O) option of the **mcompile** utility command is used to specify, through a parameter, the location or file name, or both, for the resulting compiled map file. There are 2 different cases where the output (-O) option can be used in the **mcompile** command.

In the first case, the output (-O) option is used with the compile all maps (-A) option. The specified parameter could be either the name of the directory where the resulting compiled map files are written or the full file path specification in which a wildcard can be used to represent the compiled map file naming convention. The default naming convention for the compiled map file is **executable_map_name.mmc**. If a wildcard is specified in the full path as **mcompile mymaps.mms -A -O C:\MyDev\Compiledmaps\2002-02-28_*.win**, the compiled maps are produced in the **C:\MyDev\Compiledmaps** directory with the **2002-02-28_<executable_map_name>.win** naming convention.

In the second case, the output (-O) option is used without the compile all maps (-A) option. The specified parameter could be the name of the directory where the resulting compiled map files are written, the full file path specification in which a wildcard can be used to represent the compiled map file, or the full path in which the complete filename can be specified. The default naming convention for the compiled map file is **executable_map_name.mmc**. If a wildcard is specified in the full path as **mcompile mymaps.mms MyExecMap -O C:\MyDev\Compiledmaps*.*.win**, the compiled maps are produced in the **C:\MyDev\Compiledmaps** directory with the **<executable_map_name>.win** naming convention. If the complete file name is specified, for example, **mcompile mymaps.mms MyExecMap -O C:\MyDev\Compiledmaps\MyExecForWin.win**, the **MyExecForWin.win** file is produced in the **C:\MyDev\Compiledmaps** directory.

If the (-o) option is not specified, the compile map is written to the same directory as of the map source file using the default naming convention executable_map_name.mmc. If the (-o) option is specified and the parameter is not provided, the command line is invalid, and the Not a valid command line - The file name for the resulting compiled map file should be provided when -O option is selected. error message displays on the console. If the file name or the path provided for the (-o) option is not valid or returns error while attempting to open or write to the file, the Compilation error - The file/path provided for the option (-O) is not valid, unable to write to the specified directory/file message is written to the mcompile log file if it is enabled.

-NO mcompile option

The -NO option that can be used with the mcompile utility command.

The no overwrite (-NO) option of the mcompile utility command is used to indicate that an existing compiled map file (.mmc) is not to be overwritten. If the no overwrite (-NO) option is specified in the command line of the mcompile utility command, and a file with the same name as the resulting compiled map file exists, it will not be overwritten, the map compilation will fail, and the Compilation error - The compiled map file cannot be overwritten, file already exists message will be written to the mcompile log file, if enabled. If the (-NO) option is not specified, the file with the same name as the compiled map file resulting from the compilation process will be overwritten.

-DP mcompile option

The -DP option that can be used with the mcompile utility command.

The IBM DataPower (-DP) option of the mcompile utility command is used to compile all IBM DataPower maps that are present in the specified map source file. This command option excludes any IBM Transformation Extender maps from being compiled.

For information about IBM DataPower maps, see the IBM Transformation Extender Map Designer documentation.

For information about IBM DataPower, see the IBM DataPower documentation.

Use the -L -DP combination to display a list of the IBM DataPower maps that are present in the map source file.

If you use both -DP and -TX options together with the (-A) option, the mcompile utility command will compile all maps present in the map source file. This behavior is the same as if you use the all (-A) option without specifying both -DP and -TX options together.

Any options used with -DP that are not valid for IBM DataPower maps are ignored. For example, because the platform (-P) option is not valid for IBM DataPower maps, it will not be used in the map compile process.

For more information about the other related mcompile options referenced here, see the following topics:

- [-L mcompile Option](#)
 - [-A mcompile Option](#)
 - [-TX mcompile Option](#)
-

-TX mcompile option

The -TX option that can be used with the mcompile utility command.

The IBM Transformation Extender (-TX) option of the mcompile utility command is used to compile all IBM Transformation Extender executable maps that are present in the specified map source file. This command option excludes any IBM DataPower maps from being compiled.

For information about IBM Transformation Extender maps, see the IBM Transformation Extender Map Designer documentation.

Use the -L -TX combination to display a list of the IBM Transformation Extender maps that are present in the map source file.

If you use both -DP and -TX options together, the default behavior of the mcompile utility command will be to use the all (-A) option and compile all maps present in the map source file.

For more information about the other related mcompile options referenced here, see the following topics:

- [-L mcompile Option](#)
 - [-A mcompile Option](#)
 - [-DP mcompile Option](#)
-

-R mcompile option

The -R option can be used with the mcompile utility command.

The results (-R) option of the mcompile utility command will have a parameter to specify the location or file name, or both, for the build results file produced by the map compiler for each executable map. There are 2 different cases where (-R) can be used in the mcompile utility command.

In the first case, the (-R) option is used with the compile all maps (-A) option. The specified parameter could be either the name of the directory where the build results files will be written or the full file path specification in which a wildcard can be used to represent the executable map naming convention. The default naming convention for the build results file is **executable_map_name.mme**. If a wildcard is specified in the full path as mcompile mymaps.mms -A -R

C:\MyDev\CompiledResults*.err, the build results files will be produced in the C:\MyDev\CompiledResults directory with the executable_map_name.err naming convention.

In the second case, the (-R) option is used without the compile all maps (-A) option. The specified parameter could be the name of the directory where the build results files will be written, the full file path specification in which a wildcard can be used to represent the build result file, or the full path in which the complete filename can be specified. The default naming convention for the build results file is executable_map_name.mme. If a wildcard is specified in the full path as mcompile mymaps.mms MyExecMap -R C:\MyDev\CompiledResults\2002-02-28_*.err, the build results file will be produced in the C:\MyDev\CompiledResults directory with 2002-02-28_MyExecMap.err naming convention. If the complete file name is specified as mcompile mymaps.mms MyExecMap -R C:\MyDev\CompiledResults\MyExecForWin.txt, the MyExecForWin.txt will be produced in the C:\MyDev\CompiledResults directory.

If the (-R) option is not specified, the build results will be written to the console. If the (-R) option is specified, but no parameter is provided, the build results will be written to the same directory as of the map source file using the default executable_map_name.mme naming convention. If the file name or the path provided for the (-R) option is not valid or returns error while attempting to open or write to the file, the Compilation error - The file/path provided for the option (-R) is not valid, unable to write to the specified directory/file message will be written to the mcompile log file, if it is enabled.

-LOG mcompile option

The -LOG option that can be used with the mcompile utility command.

The log (-LOG) option of the mcompile utility command is used to enable logging. The log file will be produced showing the results of each executable map's compilation. (-LOG) has an optional parameter to specify the location or file name, or both, for the mcompile log file. The mcompile log contains all the map compilations resulting from the current mcompile utility command on the command line. The default file name for the mcompile log will be map_source_file_name.mcl. The default location for the mcompile log will be the directory where the source map file is located.

The file name or the location parameter, if specified with the (-LOG) option of the mcompile utility command, could be the name of the directory where the mcompile log file will be written, the full file path specification in which a wildcard can be used to represent the map source file, or the full path in which the complete filename can be specified. The default naming convention for the mcompile log file is map_source_file_name.mcl. If the . is specified with the (-LOG) option, the mcompile log will be written to the default location (directory where the map source file is located) using the default naming convention. If a wildcard is specified in the full path as mcompile mymaps.mms -A -LOG C:\MyDev\CompileResults\2002-02-28_*.build.results, the mcompile log file will be produced in the C:\MyDev\CompileResults directory with the 2002-02-28_mymaps.build.results naming convention. If the complete file name is specified as mymaps.mms -A -LOG C:\MyDev\CompileResults\mymaps_buildresults.txt.txt, the mymaps_buildresults.txt will be produced in the C:\MyDev\CompileResults directory.

If the mcompile utility command is unable to create the mcompile log file, the map compilation will terminate and the Fatal error - Could not start map compilation, unable to create the log file fatal error message will display on the console. If nothing is specified in the command line for the log, by default, the command line assumes the (-LOG) option is included in the command line, and writes the log messages to the console.

-FAIL mcompile option

The -FAIL option that can be used with the mcompile utility command.

The fail (-FAIL) option of the mcompile utility command is used to indicate that only the maps that had compilation errors or warnings during compilation should be included in the mcompile log file. If the log failures only (-FAIL) option is selected, the mcompile log will contain only the maps that had errors or warnings. If the log failures only (-FAIL) option is not selected in the command line, all the compilation results will be written to the mcompile log file.

-APPEND mcompile option

The -APPEND option that can be used with the mcompile utility command.

The append (-APPEND) option of the mcompile utility command is used to indicate that the current mcompile log messages should be appended to the existing mcompile log file if it already exists. If the mcompile log append (-APPEND) option is selected, the mcompile log messages will be appended to the existing file if it already exists; otherwise, a new log file will be created. If the (-APPEND) option is not selected, the mcompile log file will be created if no log file exists, or it will be overwritten if the log file does exist.

-VERBOSE mcompile option

The -VERBOSE option that can be used with the mcompile utility command.

The verbose (-VERBOSE) option of the mcompile utility command is used to indicate that a verbose mcompile log should be produced. The verbose mcompile log will contain an entry for each map compilation attempted, the map name, the compile start date/time, the compile end date/time, the compilation result, and the name of the build results file. If the verbose (-VERBOSE) option is not selected, a concise version of the mcompile log will be produced, which includes an entry for each map compilation attempted, map name, and compilation result.

-NOLOG mcompile option

The -NOLOG option that can be used with the mcompile utility command.

The disable log (-NOLOG) option of the mcompile utility command is used to turn off logging. If the disable logging option is selected, the log file will not be produced. The (-APPEND, -FAIL, and -VERBOSE) options of the (-LOG) option cannot be used with the disable log (-NOLOG) option. If these options are selected with the (-NOLOG) option,

the command line is invalid, and the Not a valid command line - (LOG) optional commands (-APPEND), (-FAIL), (-VERBOSE) cannot be used with disable log command (-NOLOG). error message will display on the console.

mcompile command line help

You can view command line help for the mcompile utility command.

There is help that describes the `mcompile` utility command usage in the command line.

To view the command line help for the mcompile utility command:

Enter `mcompile` at the command line prompt in the *install_dir*.

The syntax and descriptions of all the options appear on the console.

mcompile command usage

Use the `mcompile` utility command to compile one or more maps from the command line, outside the Map Designer GUI.

The following examples show how you can use the command.

- [Scenario: run mcompile to display all executable maps](#)

In this scenario, you run the mcompile utility command to display all executable maps.

- [Scenario: run mcompile to compile all executable maps](#)

In this scenario, you run the mcompile utility command to compile all executable maps.

- [Scenario: run mcompile to compile an executable map](#)

In this scenario, you run the mcompile utility command to compile an executable map.

Scenario: run mcompile to display all executable maps

In this scenario, you run the mcompile utility command to display all executable maps.

Use the `mcompile` utility command to display all the executable maps on the console from the command line, outside the Map Designer GUI.

The following example shows how you can use the command with the `(-L)` option to display all the executable maps:

```
install_dir> mcompile mymaps.mms  
-L
```

Result:

```
Executable maps in mymaps.mms: FristMyExecMap MyExecMap NewExecMap  
Total executable maps: 3
```

The list of all executable maps for the specified map source file displays in alphabetical order on the console. The total number of executable maps display as well.

- [Scenario: run mcompile with -DP and -TX options](#)

In this scenario, you run the mcompile utility command with the `-DP` and `-TX` options.

Scenario: run mcompile with -DP and -TX options

In this scenario, you run the mcompile utility command with the `-DP` and `-TX` options.

In these examples, `myDPandTXmaps.mms` map source file contains five executable maps. Three are IBM DataPower executable maps (`MyDPEExec1Map`, `MyDPEExec3Map` and `MyDPEExec4Map`) and two are IBM Transformation Extender executable maps (`MyTXExec2Map` and `MyTXExec5Map`). The examples use combinations of the `(-DP)` and `(-TX)` mcompile command options along with the list `(-L)` option. The list of all executable maps for the specified map type and map source file will display in alphabetical order on the console. The total number of executable maps will display as well.

Display all IBM DataPower executable maps

An extension of the example is to use the `mcompile` utility command to display all the IBM DataPower executable maps on the console from the command line, outside the Map Designer GUI.

The following example shows how you can use the command with the `(-L)` option along with the `(-DP)` option:

```
install_dir> mcompile myDPandTXmaps.mms  
-L -DP
```

Result:

```
Executable maps in myDPandTXmaps.mms: MyDPEExec1Map MyDPEExec3Map MyDPEExec4Map  
Total executable maps: 3
```

Display all IBM Transformation Extender executable maps

An extension of the example is to use the `mcompile` utility command to display all the IBM Transformation Extender executable maps on the console from the command line, outside the Map Designer GUI.

The following example shows how you can use the command with the `(-L)` option along with the `(-TX)` option:

```
install_dir> mcompile myDPandTxmaps.mms  
-L -TX
```

Result:

```
Executable maps in myDPandTxmaps.mms: MyTXExec2Map MyTXExec5Map  
Total executable maps: 2
```

Display all IBM DataPower and IBM Transformation Extender executable maps

An extension of the example is to use the `mcompile` utility command to display all the IBM DataPower and IBM Transformation Extender executable maps on the console from the command line, outside the Map Designer GUI.

The following example shows how you can use the command with the `(-L)` option without specifying the `(-TX)` and `(-DP)` options:

```
install_dir> mcompile myDPandTxmaps.mms  
-L
```

Result:

```
Executable maps in myDPandTxmaps.mms: MyDPExec1Map MyTXExec2Map  
MyDPExec3Map MyDPExec4Map MyTXExec5Map  
Total executable maps: 5
```

Scenario: run `mcompile` to compile all executable maps

In this scenario, you run the `mcompile` utility command to compile all executable maps.

Use the `mcompile` utility command to compile all the executable maps from the command line, outside the Map Designer GUI.

The following example shows how you can use the command with the `(-A)` option to compile all the executable maps:

```
install_dir> mcompile mymaps.mms  
-A -E -P WINDOWS  
-O C:\MyDev\Compiledmaps\*.*.mmc  
-R C:\MyDev\CompiledResults\mymaps_*.*.mme  
-LOG C:\MyDev\CompiledResults\  
*.buildresults.txt  
-FAIL -APPEND
```

When you run the example, the following result occurs:

- If all the maps are compiled successfully, the `mcompile - completed successfully.` message displays on the console.
- The `FristMyExecMap.mmc`, `MyExecMap.mmc`, `NewExecMap.mmc` compiled map files are produced for WINDOWS in the `C:\MyDev\Compiledmaps` directory.
- The `mymaps_FristMyExecMap.mme`, `mymaps_MyExecMap.mme`, `mymaps_NewExecMap.mme` build results files are produced in the `C:\MyDev\CompiledResults` directory.

If the `mymaps_buildresults.txt` log file does not exist, it is produced in the `C:\MyDev\CompiledResults` directory. If the `mymaps_buildresults.txt` log file already exists, only the failed maps' log messages are appended to the existing file.

- [Scenario: run `mcompile` with `-DP` and `-TX` options](#)

In this scenario, you run the `mcompile` utility command with `-DP` and `-TX` options to compile all executable maps.

Scenario: run `mcompile` with `-DP` and `-TX` options

In this scenario, you run the `mcompile` utility command with `-DP` and `-TX` options to compile all executable maps.

In these examples, `myDPandTxmaps.mms` map source file contains five executable maps. Three are DP executable maps (`MyDPExec1Map`, `MyDPExec3Map` and `MyDPExec4Map`) and two are TX executable maps (`MyTXExec2Map` and `MyTXExec5Map`). The examples use combinations of the `(-DP)` and `(-TX)` `mcompile` command options along with the all `(-A)` option. All of the executable maps for the specified map type and map source file will be compiled.

Compile all IBM DataPower executable maps

An extension of the example is to use the `mcompile` utility command to compile all the IBM DataPower executable maps from the command line, outside the Map Designer GUI. The following command is an example of using the `(-A)` option on the `mcompile` utility command along with the `(-DP)` option:

```
install_dir> mcompile myDPandTxmaps.mms  
-A -DP
```

Result:

If all the executable IBM DataPower maps (MyDPExec1Map, MyDPExec3Map and MyDPExec4Map) in the myDPandTXmaps.mms map source file are compiled successfully, the `mcompile - completed successfully.` message will display on the console.

Compile all IBM Transformation Extender executable maps

An extension of the example is to use the `mcompile` utility command to compile all the IBM Transformation Extender executable maps from the command line, outside the Map Designer GUI. The following command is an example of using the `(-A)` option on the `mcompile` utility command along with the `(-TX)` option:

```
install_dir> mcompile myDPandTXmaps.mms  
-A -TX
```

Result:

If all the executable IBM Transformation Extender maps (MyTXExec2Map and MyTXExec5Map) in the myDPandTXmaps.mms map source file are compiled successfully, the `mcompile - completed successfully.` message will display on the console.

Compile all IBM DataPower and IBM Transformation Extender executable maps

An extension of the example is to use the `mcompile` utility command to display all the IBM DataPower and IBM Transformation Extender executable maps from the command line, outside the Map Designer GUI. The following command is an example of using the `(-A)` option on the `mcompile` utility command without specifying the `(-TX)` and `(-DP)` options:

```
install_dir> mcompile myDPandTXmaps.mms  
-A
```

Result:

If all the executable IBM DataPower and IBM Transformation Extender maps (MyDPExec1Map, MyTXExec2Map, MyDPExec3Map, MyDPExec4Map and MyTXExec5Map) in the myDPandTXmaps.mms map source file are compiled successfully, the `mcompile - completed successfully.` message will display on the console.

Scenario: run mcompile to compile an executable map

In this scenario, you run the `mcompile` utility command to compile an executable map.

Use the `mcompile` utility command to compile a specific executable map from the command line, outside the Map Designer GUI.

The following example shows how you can use the command to compile a specific executable map:

```
install_dir> mcompile MyExecMap  
-E -P WINDOWS  
-O C:\MyDev\Compiledmaps\MyCompiledMap.mmc  
-R C:\MyDev\CompiledResults\  
MyExecMapLogFile.err  
-NOLOG
```

When you run the example, the following result occurs:

- If the **MyExecMap** map compiled successfully, the `mcompile - completed successfully.` message displays on the console.
- The **MyCompiledMap.mmc** compiled map file is produced for **WINDOWS** in the **C:\MyDev\Compiledmaps** directory.
- The **MyExecMapLogFile.err** build results file is produced in the **C:\MyDev\CompiledResults** directory.

No log file is produced because (`-NOLOG`) option has been selected.

mimport utility command

The `mimport` utility command is used to import an xml file to a map source file from the command line, outside the Map Designer GUI.

The `mimport` utility command returns 0 if the map import is successful and 1 if it is not successful. It is a batch operation and can also be used for automation.

See "[Troubleshooting](#)" for details about capturing and evaluating the return code resulting from the execution of this utility command.

- **[mimport syntax summary](#)**
This is the syntax that is used with the `mimport` utility command.
- **[mimport utility command options](#)**
These are the command options that can be used with the `mimport` utility command.
- **[mimport command line help](#)**
You can access command line help for the `mimport` utility command.
- **[mimport command usage](#)**
You can use the `mimport` command to import an XML file to the map source file from the command line.

mimport syntax summary

This is the syntax that is used with the mimport utility command.

mimport is the name of the utility command used to import xml files to maps.

The .xml file is a required field and the file name of the xml source file. If the full path of the xml source file name is not specified, the mimport utility command will search for the xml source file in the current directory.

The following is the syntax of the mimport utility command:

```
mimport <.xml file>
[-NO]
[-O <.mms file name/location>]
[(-LOG [. | <log file name/location>]
[-FAIL] [-APPEND] [-VERBOSE])
| -NOLOG]
```

None of the options in the mimport utility command are case sensitive. Typing mimport with no options will display the command summary on the console.

mimport utility command options

These are the command options that can be used with the mimport utility command.

The following command options are available with the mimport utility command:

• -O mimport Option	• -APPEND mimport Option
• -NO mimport Option	• -VERBOSE mimport Option
• -LOG mimport Option	• -NOLOG mimport Option
• -FAIL mimport Option	

[-O mimport option](#)

The -O option can be used with the mimport utility command.

[-NO mimport option](#)

The -NO option can be used with the mimport utility command.

[-LOG mimport option](#)

The -LOG option can be used with the mimport utility command.

[-FAIL mimport option](#)

The -FAIL option can be used with the mimport utility command.

[-APPEND mimport option](#)

The -APPEND option can be used with the mimport utility command.

[-VERBOSE mimport option](#)

The -VERBOSE option can be used with the mimport utility command.

[-NOLOG mimport option](#)

The -NOLOG option can be used with the mimport utility command.

-O mimport option

The -O option can be used with the mimport utility command.

The output (-o) option of the mimport utility command is used to specify, through a parameter, the location or file name, or both, for the imported map source file produced by importing the xml file. The specified parameter could be the name of the directory where the imported map source file is written, the full file path specification in which a wildcard can be used to represent the imported map source file, or the full path in which the complete filename can be specified. The default naming convention for the imported map source file is **xml_file_name.mms**. If a wildcard is specified in the full path, for example, mimport myxmlfile.xml -O C:\MyDev\ImportResults\2002-02-28_*.mms, the resulting map source file is produced in the **C:\MyDev\ImportResults** directory with the **2002-02-28_myxmlfile.mms** naming convention. If the complete file name is specified, as in mimport myxmlfile.xml -O C:\MyDev\ImportResults\Myxmlmaps.mms, the **Myxmlmaps.mms** map source file is produced in the **C:\MyDev\ImportResults** directory. If the import output (-o) option is selected and if the file name is not specified, the command line is invalid, and the Not a valid command line - the file name parameter is required if import command option (-O) is selected error message displays on the console.

-NO mimport option

The -NO option can be used with the mimport utility command.

The no overwrite (-NO) option of the mimport utility command is used to indicate that an existing imported mms file (**.mms**) is not to be overwritten. If the no overwrite (-NO) option is specified in the command line of mimport , and if the file with the name of the map resulting from the imported process file exists, it will not be overwritten, the map importing will fail, and the Map Import error - The imported map source file cannot be overwritten, file already exists message will be written to the mimport log file if enabled. If the (-NO) option is not specified, the file with the name of the map resulting from the importing process will be overwritten.

-LOG mimport option

The **-LOG** option can be used with the `mimport` utility command.

The log **-LOG** option of the `mimport` utility command is used to enable logging. The log file will be produced showing the result of the imported map source file. (**-LOG**) has an optional parameter to specify the location or file name, or both, for the `mimport` log file. The default file name for the `mimport` log will be **xml_source_file_name.log**. The default location for the `mimport` log will be the directory where the xml file is located.

The file name or the location parameter, if specified with the (**-LOG**) option of the `mimport` utility command, could be the name of the directory where the `mimport` log file will be written, the full file path specification in which a wildcard can be used to represent the xml source file, or the full path in which the complete filename can be specified. If the `.` is specified with the (**-LOG**) option, the `mimport` log will be written to the default location (directory where the xml file is located) using the default naming convention. If a wildcard is specified in the full path, for example, `mimport myxmlfile.xml -LOG C:\MyDev\ImportResults\2002-02-28_*.results`, the `mimport` log file will be produced in the **C:\MyDev\ImportResults** directory with the **2002-02-28_myxmlfile.results** naming convention. If the complete file name is specified, for example, `mimport myxmlfile.xml -LOG C:\MyDev\ImportResults\myxmlimport_results.txt`, the **myxmlimport_results.txt** will be produced in the **C:\MyDev\ImportResults** directory.

If the `mimport` utility command is unable to create the `mimport` log file, the importing of the map source file will terminate and the **Fatal error - Could not start importing the map source file, unable to create the log file** fatal error message will display on the console. If nothing is specified in the command line for the log, by default, the command line assumes the (**-LOG**) option is included in the command line, and writes the log messages to the console.

-FAIL mimport option

The **-FAIL** option can be used with the `mimport` utility command.

The fail (**-FAIL**) option of the `mimport` utility command is used to indicate that only the maps that had errors during the importing should be included in the `mimport` log file. If the log failures only (**-FAIL**) option is selected, the `mimport` log will contain only the maps that had failed importing. If the log failures only (**-FAIL**) option is not selected in the command line, all the imported results will be written to the `mimport` log file.

-APPEND mimport option

The **-APPEND** option can be used with the `mimport` utility command.

The append (**-APPEND**) option of the `mimport` utility command is used to indicate that the current `mimport` log messages should be appended to the existing `mimport` log file if it already exists. If the `mimport` log append (**-APPEND**) option is selected, the `mimport` log messages will be appended to the existing file if it already exists; otherwise, a new file will be created. If the (**-APPEND**) option is not selected, the `mimport` log file will be created if no log file exists, or it will be overwritten if the log file does exist.

-VERBOSE mimport option

The **-VERBOSE** option can be used with the `mimport` utility command.

The verbose (**-VERBOSE**) option of the `mimport` utility command is used to indicate if the verbose `mimport` log should be produced. The verbose `mimport` log will contain an entry for the xml file being imported, the importing start date/time, the importing end date/time, the imported map source file name, and the result of the `mimport` utility command. If the verbose (**-VERBOSE**) option is not selected, a concise version of the `mimport` log will be produced, which includes an entry for the map source file name, and importing result.

-NOLOG mimport option

The **-NOLOG** option can be used with the `mimport` utility command.

The disable log (**-NOLOG**) option of the `mimport` utility command is used to turn off the `mimport` logging capability. If the disable logging option is selected, log file will not be produced. The (**-APPEND**, and **-VERBOSE**) optional commands of the (**-LOG**) option cannot be used with the disable log (**-NOLOG**) option. If these options are selected with the (**-NOLOG**) option, the command line is invalid, and the **Not a valid command line - (LOG) optional commands (-APPEND), (-VERBOSE) cannot be used with disable log command (-NOLOG)** . message will display on the console.

mimport command line help

You can access command line help for the `mimport` utility command.

There is help that describes the `mimport` utility command usage in the command line.

To view the command line help for the `mimport` utility command:

Enter `mimport` at the command line prompt in the `install_dir`.
The syntax and descriptions of all the options appear on the console.

mimport command usage

You can use the `mimport` command to import an XML file to the map source file from the command line.

Use the `mimport` utility command to import the xml file to the map source file from the command line, outside the Map Designer GUI.

The following example shows how you can use the command:

```
install_dir> mimport myxmlfile.xml  
-O C:\MyDev\ImportResults\myimportedmaps.mms  
-LOG -APPEND
```

When you run the example, the following result occurs:

- If the `myxmlfile.xml` xml file is imported successfully, the `mimport - completed successfully.` message displays on the console.
- The imported `myimportedmaps.mms` map source file is produced in the `C:\MyDev\ImportResults` directory.
- If the `myxmlfile.log` log file does not exist, it is produced in the same directory as the xml file. If the `myxmlfile.log` log file already exists, the log messages are appended to the existing file.

mexport utility command

The `mexport` utility command is used to export a map source file from the command line, outside the Map Designer.

The `mexport` utility command returns 0 if the map export is successful and 1 if it is not successful. It is a batch operation and can also be used for automation.

See "[Troubleshooting](#)" for details about capturing and evaluating the return code resulting from running this utility command.

- [mexport syntax summary](#)
This is the syntax that is used with the `mexport` utility command.
- [mexport utility command options](#)
These are the command options that can be used with the `mexport` utility command.
- [mexport command line help](#)
You can access command line help for the `mexport` utility command.
- [mexport command usage](#)
You can use the `mexport` command to export the map source file from the command line.

mexport syntax summary

This is the syntax that is used with the `mexport` utility command.

`mexport` is the name of the utility command used to export map source files.

The `.mms` file is a required field and is the file name of the map source file that needs to be exported. The map source file can have any number of maps in it. All maps will be exported to the same xml file if provided. If the full path of the map source file name is not specified, the `mexport` utility command will search for the map source file in the current directory.

The following is the syntax of the `mexport` utility command:

```
mexport <.mms file> [-NO]  
[-O <.xml file name/location>]  
[(-LOG [.| <log file name/location>]  
[-FAIL] [-APPEND] [-VERBOSE])  
|-NOLOG]
```

None of the options in the `mexport` utility command are case sensitive. Typing `mexport` with no options will display the command summary on the console.

mexport utility command options

These are the command options that can be used with the `mexport` utility command.

The following command options are available with the `mexport` utility command:

• -O mexport Option	• -APPEND mexport Option
• -NO mexport Option	• -VERBOSE mexport Option
• -LOG mexport Option	• -NOLOG mexport Option
• -FAIL mexport Option	

If you type `mexport` with no options, the command line help that describes the command will display on your screen.

- [-O mexport option](#)
The -O option can be used with the `mexport` utility command.
- [-NO mexport option](#)
The -NO option can be used with the `mexport` utility command.
- [-LOG mexport option](#)
The -LOG option can be used with the `mexport` utility command.

- **-FAIL mexport option**
The -FAIL option can be used with the mexport utility command.
 - **-APPEND mexport option**
The -APPEND option can be used with the mexport utility command.
 - **-VERBOSE mexport option**
The -VERBOSE option can be used with the mexport utility command.
 - **-NOLOG mexport option**
The -NOLOG option can be used with the mexport utility command.
-

-O mexport option

The -O option can be used with the mexport utility command.

The output (-o) option of the `mexport` utility command is used to specify, through a parameter, the location or file name, or both, for the exported xml file produced by exporting the map source file. The specified parameter could be the name of the directory where the exported xml file is written, the full file path specification in which a wildcard can be used to represent the exported xml file, or the full path in which the complete filename can be specified. The default naming convention for the exported xml file is `map_source_file_name.xml`. If a wildcard is specified in the full path, for example, `mexport mymaps.mms -O C:\MyDev\ExportResults\2002-02-28_*.xml`, the resulting xml file is produced in the **C:\MyDev\ExportResults** directory with the **2002-02-28_mymaps.xml** naming convention. If the complete file name is specified, for example, `mexport mymaps.mms -O C:\MyDev\ExportResults\MyMapsExportedfile.xml`, an xml file **MyMapsExportedfile.xml** is produced in the **C:\MyDev\ExportResults** directory. If the export output (-o) option is selected, and if the file name is not specified, the command line is invalid, and the **Not a valid command line - the file name parameter is required if export command option (-O) is selected** error message displays on the console.

-NO mexport option

The -NO option can be used with the mexport utility command.

The no output (-NO) option of the `mexport` utility command is used to indicate that an existing exported xml file (`.xml`) is not to be overwritten. If the no overwrite (-NO) option is specified in the command line of `mexport`, if the file with the name of the map source file resulting from the exporting process exists, it will not be overwritten, the map exporting process will fail, and the **Map Export error - The exported xml file cannot be overwritten, file already exists** message will be written to the `mexport` log file, if enabled. If the (-NO) option is not specified, the log file with the name of the map resulting from the exporting process will be overwritten.

-LOG mexport option

The -LOG option can be used with the mexport utility command.

The log (-LOG) option of the `mexport` utility command is used to enable the `mexport` logging capability. The log file will be produced showing the result of the exported map source file. (-LOG) has an optional parameter to specify the location or file name, or both, for the `mexport` log file. The default file name for the `mexport` log will be `map_source_file_name.log`. The default location for the `mexport` log will be the directory where the map source file is located.

The file name, or the location parameter, if specified with the (-LOG) option of the `mexport` utility command, could be the name of the directory where the `mexport` log file will be written, the full file path specification in which a wildcard can be used to represent the map source file, or the full path in which the complete filename can be specified. If the . is specified with the (-LOG) option, the `mexport` log will be written to the default location (directory where the map source file is located) using the default naming convention. If a wildcard is specified in the full path, for example, `mexport mymaps.mms -LOG C:\MyDev\ExportResults\2002-02-28_*.results` the `mexport` log file will be produced in the **C:\MyDev\ExportResults** directory with the **2002-02-28_mymaps.results** naming convention. If the complete file name is specified, for example, `mexport mymaps.mms -LOG C:\MyDev\ExportResults\mymaps_results.txt`, the **mymaps_results.txt** file will be produced in the **C:\MyDev\ExportResults** directory.

If the `mexport` utility command is unable to create the `mexport` log file, the exporting of the map source file will terminate and the **Fatal error - Could not start exporting the map source file, unable to create the log file** fatal error message will display on the console. If nothing is specified in the command line for the log, by default, the command line assumes the (-LOG) option is included in the command line, and writes the log messages to the console.

-FAIL mexport option

The -FAIL option can be used with the mexport utility command.

The fail (-FAIL) option of the `mexport` utility command is used to indicate that only the maps that had errors during the exporting should be included in the `mexport` log file. If the log failures only (-FAIL) option is selected, the `mexport` log will contain only the maps that had failed exporting. If the log failures only (-FAIL) option is not selected in the command line, all the exported results will be written to the `mexport` log file.

-APPEND mexport option

The -APPEND option can be used with the mexport utility command.

The append (-APPEND) option of the `mexport` utility command is used to indicate that the current `mexport` log messages should be appended to the existing `mexport` log file if it already exists. If the `mexport` log append (-APPEND) option is selected, the `mexport` log messages will be appended to the existing file if it already exists; otherwise, a new file will be created. If the (-APPEND) option is not selected, the `mexport` log file will be created if no log file exists, or it will be overwritten if the log file does exist.

-VERBOSE mexport option

The -VERBOSE option can be used with the mexport utility command.

The verbose (-VERBOSE) option of the `mexport` utility command is used to indicate if the verbose `mexport` log should be produced. The verbose `mexport` log will contain an entry for the map source file being exported, the map source name, the exporting start date/time, the exporting end date/time, the exported xml file name, and the result of the `mexport` utility command. If the verbose (-VERBOSE) option is not selected, a concise version of the `mexport` log will be produced, which includes entry for the map source file name and exporting result.

-NOLOG mexport option

The -NOLOG option can be used with the mexport utility command.

The disable log (-NOLOG) option of the `mexport` utility command is used to turn off the `mexport` logging capability. If the disable logging option is selected, the log file will not be produced. The optional (-APPEND, and -VERBOSE) options of the (-LOG) option cannot be used with the disable log (-NOLOG) option. If these options are selected with the (-NOLOG) option, the command line is invalid, and the Not a valid command line - (LOG) optional commands (-APPEND), (-VERBOSE) cannot be used with disable log command (-NOLOG). error message will display on the console.

mexport command line help

You can access command line help for the mexport utility command.

There is help that describes the `mexport` utility command usage in the command line.

To view the command line help for the mexport utility command:

Enter `mexport` at the command line prompt in the `install_dir`.

The syntax and descriptions of all the options appear on the console.

mexport command usage

You can use the `mexport` command to export the map source file from the command line.

Use the `mexport` utility command to export the map source file from the command line, outside the Map Designer GUI.

The following example shows how you can use the command:

```
install_dir> mexport mymaps.mms  
-O C:\MyDev\ExportResults\mymaps.xml  
-LOG -APPEND
```

When you run the example, the following result occurs:

- If the `mymaps.mms` map source file is exported successfully, the `mexport - completed successfully.` message displays on the console.
- The exported `mymaps.xml` xml file is produced in the `C:\MyDev\ExportResults` directory.
- If the `mymaps.log` log file does not exist, it is produced in the same directory as the map source file. If it already exists, the log messages are appended to the existing file.

mreport utility command

The `mreport` utility command is used to generate a map report HTML file containing information about a map source file, from the command line, outside the Map Designer.

The `mreport` utility command returns 0 if the map report generation is successful and 1 if it is not successful. It is a batch operation and can also be used for automation.

See "[Troubleshooting](#)" for details about capturing and evaluating the return code resulting from the execution of this utility command.

- [mreport syntax summary](#)
This is the syntax that is used with the mreport utility command.
- [mreport utility command options](#)
These are the command options that can be used with the mreport utility command.
- [mreport command line help](#)
You can access command line help for the mreport utility command.
- [mreport command usage](#)
You can use the mimport command to generate a map report HTML file containing information about a map source file.

mreport syntax summary

This is the syntax that is used with the mreport utility command.

`mreport` is the name of the utility command used to generate a map report HTML file containing information about a map source file.

The `.mms` file is a required field and the file name of the map source file. If the full path of the map source file name is not specified, the `mreport` utility command will search for the map source file in the current directory.

The following is the syntax of the `mreport` utility command:

```
mreport <.mms file>
[-NO]
[-O <.html file name/location>]
[(-LOG [. | <log file name/location>]
[-FAIL] [-VERBOSE] [-APPEND])
|-NOLOG]
```

None of the options in the `mreport` utility command are case sensitive. Typing `mreport` with no options will display the command summary on the console.

mreport utility command options

These are the command options that can be used with the `mreport` utility command.

The following command options are available with the `mreport` utility command:

• -NO mreport Option	• -VERBOSE mreport Option
• --O mreport Option	• -APPEND mreport Option
• -LOG mreport Option	• -NOLOG mreport Option
• -FAIL mreport Option	

• [**-O mreport option**](#)

The `-O` option can be used with the `mreport` utility command.

• [**-NO mreport option**](#)

The `-NO` option can be used with the `mreport` utility command.

• [**-LOG mreport option**](#)

The `-LOG` option can be used with the `mreport` utility command.

• [**-FAIL mreport option**](#)

The `-FAIL` option can be used with the `mreport` utility command.

• [**-VERBOSE mreport option**](#)

The `-VERBOSE` option can be used with the `mreport` utility command.

• [**-APPEND mreport option**](#)

The `-APPEND` option can be used with the `mreport` utility command.

• [**-NOLOG mreport option**](#)

The `-NOLOG` option can be used with the `mreport` utility command.

-O mreport option

The `-O` option can be used with the `mreport` utility command.

The output (`-O`) option of the `mreport` utility command is used to specify the location or file name, or both, for the generated HTML file. The specified parameter could be the name of the directory where the HTML file is written, the full file path specification in which a wildcard can be used to represent the HTML file, or the full path in which the complete filename can be specified. The default naming convention for the HTML file is `html_file_name.html`. If a wildcard is specified in the full path, for example, `mreport mymmsfile.mms -O C:\MyDev\MapReportResults\2002-02-28_*.html`, the resulting HTML file is produced in the **C:\MyDev\MapReportResults** directory with the **2002-02-28_mymmsfile.html** naming convention. If the complete file name is specified, as in `mreport mymmsfile.mms -O C:\MyDev\MapReportResults\Myhtmlfile.html`, the **Myhtmlfile.html** HTML file is produced in the **C:\MyDev\MapReportResults** directory. If the `mreport` output (`-O`) option is selected and if the file name is not specified, the command line is invalid, and the `Not a valid command line - the file name parameter is required if mreport command option (-O) is selected` error message displays on the console.

-NO mreport option

The `-NO` option can be used with the `mreport` utility command.

The no overwrite (`-NO`) option of the `mreport` utility command is used to indicate that an existing generated HTML file (`.html`) is not to be overwritten. If the no overwrite (`-NO`) option is specified in the command line of `mreport`, and if the file with the name of the HTML file resulting from the map report generation process exists, it will not be overwritten, the map report generation will fail, and the `Map Report error : The generated html file cannot be overwritten, file already exists : path\file.html` message will be written to the `mreport` log file if enabled. If the (`-NO`) option is not specified, the file with the name of the HTML file resulting from the map report generation process will be overwritten.

-LOG mreport option

The **-LOG** option can be used with the mreport utility command.

The log (**-LOG**) option of the `mreport` utility command is used to enable logging. The log file will be produced showing the result of the generated map report HTML file. (-**LOG**) has an optional parameter to specify the location or file name, or both, for the `mreport` log file. The default file name for the `mreport` log will be **map_source_file_name.log**. The default location for the `mreport` log will be the directory where the map source file is located.

The file name or the location parameter, if specified with the (**-LOG**) option of the `mreport` utility command, could be the name of the directory where the `mreport` log file will be written, the full file path specification in which a wildcard can be used to represent the HTML file, or the full path in which the complete filename can be specified. If the `.` is specified with the (**-LOG**) option, the `mreport` log will be written to the default location, which is the directory where the map source file is located, using the default naming convention. If a wildcard is specified in the full path, for example, `mreport mymmsfile.mms -LOG C:\MyDev\MapReportResults\2002-02-28_*.results`, the `mreport` log file will be produced in the **C:\MyDev\MapReportResults** directory with the **2002-02-28_mymmsfile.results** naming convention. If the complete file name is specified, for example, `mreport mymmsfile.mms -LOG C:\MyDev\MapReportResults\myhtmlmapreport_results.txt`, the **myhtmlmapreport_results.txt** file will be produced in the **C:\MyDev\MapReportResults** directory.

If the `mreport` utility command is unable to create the `mreport` log file, the map report generation of the map source file will terminate and the `Fatal error : Could not start the process, unable to create the log file` fatal error message will display on the console. There might be additional information in the error message depending on the cause of the fatal error. If nothing is specified in the command line for the log, by default, the command line assumes the (**-LOG**) option is included in the command line, and writes the log messages to the console.

-FAIL mreport option

The **-FAIL** option can be used with the mreport utility command.

The fail (**-FAIL**) option of the `mreport` utility command is used to indicate that only the maps that had errors during the report generation should be included in the `mreport` log file. If the log failures only (**-FAIL**) option is selected, the `mreport` log will contain only the maps that had failed the HTML file generation. If the log failures only (**-FAIL**) option is not selected in the command line, all the map report generation results will be written to the `mreport` log file.

-VERBOSE mreport option

The **-VERBOSE** option can be used with the mreport utility command.

The verbose (**-VERBOSE**) option of the `mreport` utility command is used to indicate if the verbose `mreport` log should be produced. The verbose `mreport` log will contain an entry for the HTML file being generated, the map report generation start date/time, the generation end date/time, the generated HTML file name, and the result of the `mreport` utility command. If the verbose (**-VERBOSE**) option is not selected, a concise version of the `mreport` log will be produced, which includes an entry for the HTML file name, and map report generation result.

-APPEND mreport option

The **-APPEND** option can be used with the mreport utility command.

The append (**-APPEND**) option of the `mreport` utility command is used to indicate that the current `mreport` log messages should be appended to the existing `mreport` log file if it already exists. If the `mreport` log append (**-APPEND**) option is selected, the `mreport` log messages will be appended to the existing file if it already exists; otherwise, a new file will be created. If the (**-APPEND**) option is not selected, the `mreport` log file will be created if no log file exists, or it will be overwritten if the log file does exist.

-NOLOG mreport option

The **-NOLOG** option can be used with the mreport utility command.

The disable log (**-NOLOG**) option of the `mreport` utility command is used to turn off the `mreport` logging capability. If the disable logging option is selected, the log file will not be produced. The (**-APPEND**, **FAIL**, and **-VERBOSE**) optional commands of the (**-LOG**) option cannot be used with the disable log (**-NOLOG**) option. If these options are selected with the (**-NOLOG**) option, the command line is invalid, and the `Not a valid command line : (-LOG) optional commands (-APPEND), (-FAIL), (-VERBOSE)` cannot be used with disable log command (**-NOLOG**). message will display on the console.

mreport command line help

You can access command line help for the mreport utility command.

There is help that describes the `mreport` utility command usage in the command line.

To view the command line help for the mreport utility command:

Enter `mreport` at the command line prompt in the `install_dir`.

The syntax and descriptions of all the options appear on the console.

mreport command usage

You can use the `mimport` command to generate a map report HTML file containing information about a map source file.

Use the `mreport` utility command to generate a map report HTML file containing information about a map source file, outside the Map Designer.

The following example shows how you can use the command:

```
install_dir> mreport mymmsfile.mms  
-O C:\MyDev\MapReportResults\myhtmlfile.html  
-LOG -APPEND
```

When you run the example, the following result occurs:

- If the `myhtmlfile.html` HTML file is generated successfully, the `Map report generated successfully.` message displays on the console.
- The generated `myhtmlfile.html` HTML file is produced in the `C:\MyDev\MapReportResults` directory.
- If the `myhtmlfile.log` log file does not exist, it is produced in the same directory as the map source file. If the `myhtmlfile.log` log file already exists, the log messages are appended to the existing file.

Utility commands for Integration Flow Designer

The Integration Flow Designer utility commands are used to deploy systems and import to and export systems.

- [sdeploy utility command](#)

The `sdeploy` utility command is used to analyze systems, build maps in the system, generate and deploy the system to the specified server from the command line, outside of the Integration Flow Designer.

- [ssftpdeploy utility command](#)

The `ssftpdeploy` command uses the SSH File Transfer Protocol (SFTP) to deploy an IBM Transformation Extender Launcher system to a remote host. The remote host must have an SSH server configured to accept remote SFTP requests. The computer that runs the `ssftpdeploy` command must be configured for SSH communication with the remote host. To establish SSH communication when SSH host key verification is in effect, the SSH public keys of the remote host must be specified in the `%userprofile%\.ssh\known_hosts` file on the host that deploys the system.

- [msdimport utility command](#)

The `msdimport` utility command is used to import an XML file to a system definition (`.msd`) source file in a system from the command line, outside of the Integration Flow Designer.

- [msdexport utility command](#)

The `msdexport` utility command is used to export a system source definition (`.msd`) file from the command line, outside of the Integration Flow Designer.

sdeploy utility command

The `sdeploy` utility command is used to analyze systems, build maps in the system, generate and deploy the system to the specified server from the command line, outside of the Integration Flow Designer.

The `sdeploy` utility command returns 0 if the system deployment is successful, and 1 if not. It is a batch operation that can also be used for automation.

See "[Troubleshooting](#)" for details about capturing and evaluating the return code resulting from running this utility command.

- [sdeploy syntax summary](#)

The `sdeploy` utility command is used to analyze systems, build maps in the system, and generate and deploy systems.

- [sdeploy utility command options](#)

These are the command options that can be used with the `sdeploy` utility command.

- [sdeploy command line help](#)

You can access command line help for the `sdeploy` utility command.

- [sdeploy command usage](#)

You can use the `sdeploy` command to analyze systems, build maps in the system, generate and deploy the system to the specified server from the command line, outside of the Integration Flow Designer.

sdeploy syntax summary

The `sdeploy` utility command is used to analyze systems, build maps in the system, and generate and deploy systems.

The `.msd` file is a required field and is the name of the system definition file, located on disk, that needs to be analyzed, compiled, generated, or deployed to the specified server. The system definition file can have any number of systems in it.

If you make modifications, such as changing the number or order of input or output cards in your maps, you must open the `.msd` file in the Integration Flow Designer and save the changes in the file there to synchronize the changes before you can deploy the system using the `sdeploy` utility command.

If the full path of the `.msd` file name is not specified, the `sdeploy` command will search for the `.msd` file in the current directory. Because the `sdeploy` command expects the map source definition (`.msd`) file to be specified after it, if the `.msd` file is not specified, the following error message will display on the console:

```
"Invalid or empty map source file. Cannot open file path\command_parameters"
```

The following is the syntax of the `sdeploy` utility command:

```
sdeploy <.msd file>  
-L  
- or -
```

```

sdeploy <.msd file>
  -A [-K] [-NO]
    <ANALYZE OPTIONS | BUILDMAPS OPTIONS
    | GENERATE OPTIONS>
  [(-LOG [. | <log file name/location>]
    [-FAIL] [-VERBOSE] [-APPEND])
  | -NOLOG]
  - or -
sdeploy <.msd file> <system> [-NO]
  <ANALYZE OPTIONS | BUILDMAPS OPTIONS
  | GENERATE OPTIONS | DEPLOY OPTIONS>
  [(-LOG [. | <log file name/location>]
    [-FAIL] [-VERBOSE] [-APPEND])
  | -NOLOG]

```

- sdeploy analyze syntax option**

The ANALYZE option can be used with the sdeploy utility command.

- sdeploy buildmaps syntax options**

The BUILDMAPS options can be used with the sdeploy utility command.

- sdeploy generate syntax option**

The GENERATE option can be used with the sdeploy utility command.

- sdeploy deploy syntax options**

The DEPLOY option can be used with the sdeploy utility command.

sdeploy analyze syntax option

The ANALYZE option can be used with the sdeploy utility command.

```
-ANALYZE [-EMODE {ES | CS}] [-R <MSEAnlz.txt file name/location>]
```

sdeploy buildmaps syntax options

The BUILDMAPS options can be used with the sdeploy utility command.

```
-BUILDMAPS [-P <platform>]
  [-O <file location>]
  | -A [-R <MSEBldz.txt file name/location>]
```

sdeploy generate syntax option

The GENERATE option can be used with the sdeploy utility command.

```
-GENERATE [-EMODE {ES | CS}] [-O <file name/location>]
```

sdeploy deploy syntax options

The DEPLOY option can be used with the sdeploy utility command.

```
-DEPLOY <script name>
  [-EMODE {ES | CS}]
  [-MRC <mrc file>]
  [<-SERVER <server name> | LOCAL>
    <-USER <userid>
    -PW <password>
    -IP <IP address>>]
  [-R <MSEDploy.txt file name/location>]
```

In the sdeploy utility command, the system name, script name, server name, if provided, userid and password options, are case sensitive.

Typing sdeploy with no options will display the command summary on the console.

sdeploy utility command options

These are the command options that can be used with the sdeploy utility command.

The following command options are available with the sdeploy utility command.

If you type sdeploy with no options, the command line help that describes the command will display on your screen.

- **-L sdeploy option**
The -L option can be used with the sdeploy utility command.
- **-A sdeploy option**
The -A option can be used with the sdeploy utility command.
- **-K sdeploy option**
The -K option can be used with the sdeploy utility command.
- **-EMODE sdeploy option**
The -EMODE option can be used with the sdeploy utility command.
- **-ANALYZE sdeploy option**
The -ANALYZE option can be used with the sdeploy utility command.
- **-BUILDMAPS sdeploy option**
The -BUILDMAPS option can be used with the sdeploy utility command.
- **-GENERATE sdeploy option**
The -GENERATE option can be used with the sdeploy utility command.
- **-DEPLOY sdeploy option**
The -DEPLOY option can be used with the sdeploy utility command.
- **-MRC sdeploy option**
The -MRC option can be used with the sdeploy utility command. The **-MRC** option specifies the path and file name of a resource configuration (.mrc) file. At system deployment time, the **sdeploy** command uses this resource configuration file to resolve aliases in the MapServerLocation, server user ID (-USER), and server password (-PW) settings.
- **-SERVER sdeploy option**
The -SERVER option can be used with the sdeploy utility command.
- **-USER -PW -IP -sdeploy options**
The -USER, -PW, and -IP options can be used with the sdeploy utility command.
- **-P sdeploy option**
The -P option can be used with the sdeploy utility command.
- **-O sdeploy option**
The -O option can be used with the sdeploy utility command.
- **-NO sdeploy option**
The -NO option can be used with the sdeploy utility command.
- **-R sdeploy option**
The -R option can be used with the sdeploy utility command.
- **-LOG sdeploy option**
The -LOG option can be used with the sdeploy utility command.
- **-FAIL sdeploy option**
The -FAIL option can be used with the sdeploy utility command.
- **-APPEND sdeploy option**
The -APPEND option can be used with the sdeploy utility command.
- **-VERBOSE sdeploy option**
The -VERBOSE option can be used with the sdeploy utility command.
- **-NOLOG sdeploy option**
The -NOLOG option can be used with the sdeploy utility command.

-L sdeploy option

The -L option can be used with the sdeploy utility command.

The list (-L) option of the **sdeploy** utility command is used to list all systems that are present in the specified msd file. When this option is selected, the list of all systems will display in alphabetical order, each on a separate line. No other option can be selected with the (-L) option in the **sdeploy** utility command. If any other option of the **sdeploy** utility command is selected with the (-L) option, the command line is invalid, and the **Not a valid command line - No other option is allowed to with '-L'** option error message will display on the console.

-A sdeploy option

The -A option can be used with the sdeploy utility command.

The all (-A) option of the **sdeploy** utility command is used to analyze all systems, compile all maps that are present in all systems and to generate msl files for all systems present in the msd file. The system name should not be specified in the command line if (-A) option is selected. If the system name is also specified with the (-A) option, the command line is invalid, and the **Not a valid command line - System name should not be specified when '-A' process all systems are selected** error message will display on the console.

-o command line option cannot be used with the -A command line option.

-K sdeploy option

The -K option can be used with the sdeploy utility command.

The continue (-K) option of the **sdeploy** utility command is used to indicate whether to continue the specified process for all systems even though an error is found for a system. This option can be used only with the all maps (-A) option. If the continue (-K) option is specified without the (-A) option, the command line is invalid, and the **Not a valid command line : Continue compilation option (-K) can only be used along with compile all option (-A)** error message will display on the console. If the continue compilation (-K) option is not selected, the processing of the systems will not be completed and the **sdeploy** will terminate. It will not

continue with the rest of the systems that are present in the msd file. If the continue compilation (-K) option is selected, the processing will be performed for all the systems that are present in the msd file, regardless of any errors found during the processing for any of the individual systems.

-EMODE sdeploy option

The -EMODE option can be used with the sdeploy utility command.

The execution mode (-EMODE) option of the sdeploy utility command is used to specify the mode in which the operations need to be performed. The available options for (-EMODE) are ES (Launcher mode) and CS (Command Server mode). If the (-EMODE) option is not specified, the ES (Launcher) mode will be the default. If the (-EMODE) option is specified and the (ES | CS) options are not specified, or if both are specified, the command line is invalid, and the Not a valid command line - ES(Launcher) or CS(Command Server) modes has to be specified when (-EMODE) option is selected. error message will display on the console. If the (-EMODE) option is specified with the (-BUILDMAPS) option, the command line is invalid, and the Not a valid command line - (-EMODE) option cannot be specified along with (-BUILDMAPS) command option. error message will display on the console.

-ANALYZE sdeploy option

The -ANALYZE option can be used with the sdeploy utility command.

The analyze (-ANALYZE) option of the sdeploy utility command is used to analyze the systems present in the msd file. If the (-ANALYZE) option is specified with the (-A) option, it processes all systems' options. It is specifying that all the systems must be analyzed, and the results files are generated, one for each system that was analyzed. If the (-ANALYZE) option is specified with a system name only, that system is analyzed.

For ANALYZE OPTIONS, the following information can be supplied:

```
-ANALYZE [-EMODE {ES | CS}]  
[-R <MSLEANlz.txt file name/location>]
```

-BUILDMAPS sdeploy option

The -BUILDMAPS option can be used with the sdeploy utility command.

The build maps (-BUILDMAPS) option of the sdeploy utility command is used to build all the maps that are in the systems present in the msd file. If the (-BUILDMAPS) option is specified with the (-A) option, process all the systems' options. It is specifying that all the maps in all systems need to be compiled with the platform specified in the command line, the output .mmc files will be produced in the specified directory, and the results files will be generated one for each system that has been called. If the (-BUILDMAPS) option is specified with a system name only, all the maps in that system will be compiled.

-O command line option cannot be used with the -A command line option.

BUILDMAPS OPTIONS information

For BUILDMAPS OPTIONS, the following information can be supplied:

```
-BUILDMAPS [-P <platform>]  
           [-O <file location>]  
           | -A [-R  
                 <MSEBlds.txt file name/location>]
```

-GENERATE sdeploy option

The -GENERATE option can be used with the sdeploy utility command.

The -GENERATE option of the sdeploy utility command generates the systems that are present in the system definition (.msd) file.

When you specify the -A option with the -GENERATE option, the command processes all of the systems in the system definition file. When you specify a system name with the -GENERATE option, the command produces the output file for the specified system only. Depending on the specified -EMODE option, the command produces the output Launcher (.msl) file or Command Server file in the specified output (-O) directory.

Launcher (.msl) files are binary files. Command Server files are text files and can have any extension, but avoid using the dedicated .msl file extension with Command Server mode.

GENERATE options

```
-GENERATE      [-EMODE {ES | CS}]      [-O file_path/file_name]
```

-DEPLOY sdeploy option

The -DEPLOY option can be used with the sdeploy utility command.

The deploy (-DEPLOY) option of the sdeploy utility command is used to deploy the deploy scripts to the specified server in the msd file. The (-DEPLOY) option cannot be specified with the (-A) option. It is specifying that all systems' options be processed as the script name is specific to each system, and can only be specified with a system name. The script defined in the msd file for a system can be deployed to the specified server with the (ES | CS) mode specified in the command line. The server can be specified with the (-SERVER) option. The **MSED**ploy_system_name.txt results file will be generated for the system that has been called.

DEPLOY OPTIONS information

For DEPLOY OPTIONS, the following information can be supplied:

```
-DEPLOY <script name>
  [-EMODE {ES | CS}]
  [-MRC <mrc_file>]
  [<-SERVER <server name> | LOCAL]
    <-USER <userid>
    -PW <password>
    -IP <IP address>>]
  [-R <MSEDploy.txt file name/location>]
```

-MRC sdeploy option

The -MRC option can be used with the sdeploy utility command. The -MRC option specifies the path and file name of a resource configuration (.mrc) file. At system deployment time, the sdeploy command uses this resource configuration file to resolve aliases in the MapServerLocation, server user ID (-USER), and server password (-PW) settings.

-SERVER sdeploy option

The -SERVER option can be used with the sdeploy utility command.

The server (-SERVER) option of the sdeploy utility command is used to specify the server name to which the deploy script needs to be deployed. The (-SERVER) option can be specified only with the (-DEPLOY) option. If specified with the (-ANALYZE, -BUILDMAPS, or -GENERATE) or the (-USER, -PW, or -IP) options, the command line is invalid, and the Not a valid command line - -SERVER option cannot be specified with -ANALYZE, -BUILDMAPS, -GENERATE, -USER, -PW, -IP. error message will display on the console. The server name can be LOCAL or any defined server name in the msd file. A new server can be defined by specifying the IP address of the server with the (-IP) option, the username with the (-USER) option, and the password with the (-PW) option.

-USER -PW -IP -sdeploy options

The -USER, -PW, and -IP options can be used with the sdeploy utility command.

The server (-USER, -PW, and -IP) options of the sdeploy utility command are used to specify a new server for deploying the deploy script. All three options are mandatory for specifying a new server. If any one of the three options are not specified, the command line is invalid, and the Not a valid command line - all three (-USER), (-PW), (-IP) need to be specified to for a new server. error message displays on the console. If you are able to create a server, the deploy script is deployed to this new server, or the Unable to create a server with the user options and IP given error message is written to the log file, if enabled, and the operation is terminated.

For IP address, you can specify one that is in IPv4 (for example, 1.2.3.4) or IPv6 (for example, a:b:c:d:0:1:2:3) format.

-P sdeploy option

The -P option can be used with the sdeploy utility command.

The parameter (-P) option of the sdeploy utility command is used to indicate a parameter to specify the platform for which the maps are to be compiled, the platform for which the systems must be generated, and to which the systems must be deployed. The sdeploy utility command line uses WINDOWS as the default platform if the (-P) option is not specified. The other platforms that are allowed are AIX, HPITANIUM, LINUX, PLINUX, SOLARIS, ZLINUX, and ZOS. If the (-P) option is specified and no platform parameter is provided, the command line is invalid, and the Not a valid command line : Platform parameter should be provided if option -P is selected. The valid platforms are AIX, SOLARIS, WINDOWS, ZOS, LINUX, HPITANIUM, ZLINUX, PLINUX. error message displays on the console.

-O sdeploy option

The -O option can be used with the sdeploy utility command.

The output (-o) option of the sdeploy utility command is used to specify, through a parameter, the location or file name, or both, for the resulting compiled map files when (-BUILDMAPS) option is chosen, or resulting generated msl file when (-GENERATE) option is chosen. This is a description of how the output (-o) option can be used in the sdeploy utility command.

The specified parameter for the output (-o) option could be the name of the directory where the resulting compiled map files or the resulting generated msl file is written, the full file path specification in which a wildcard can be used to represent the compiled map file or the generated msl file, or the full path in which the complete filename can be specified only for the msl file. The default naming convention for the compiled map file is **executable_map_name.mmc**, and for the generated msl file is **system_name.msl**. If a wildcard is specified in the sdeploy mysystems.msd MySystem -BUILDMAPS -O C:\MyDev\Compiledmaps*.win full path, the compiled

maps are produced in the **C:\MyDev\Compiledmaps** directory with the **<executable_map_name>.win** naming convention. If a wildcard is specified in the **sdeploy mysystems.msd MySystem -GENERATE -O C:\MyDev\Systemfiles*.*.win** full path, the generated msl is produced in the **C:\MyDev\Systemfiles** directory with the **<system_name>.win** naming convention. If the complete file name is specified, for example, **sdeploy mysystems.msd MySystem -GENERATE -O C:\MyDev\Systemfiles\MyExecForWin.win**, the **MyExecForWin.win** file is produced in the **C:\MyDev\Systemfiles** directory.

If the **(-O)** option is not specified, the compile map is written to the same directory as the map source file using the default **executable_map_name.mmc** naming convention and the msl file is written to the source directory of the msd file with the **system_name.msl** default naming convention. If the **(-O)** option is specified and the parameter is not provided, the command line is invalid, and the **Not a valid command line : The file name for the resulting output file should be provided when (-O) option is selected** error message displays on the console. If the file name or the path provided for the **(-O)** option is not valid or returns error while attempting to open or write to the file, the **Compilation error - The file/path provided for the option (-O) is not valid, unable to write to the specified directory/file** error message is written to the **sdeploy log file**, if it is enabled. If the **(-O)** option is specified without the **(-BUILDMAPS or -GENERATE) command options**, the command line is invalid, and the **Not a valid command line : (-GENERATE) or (-BUILDMAPS) or (-DEPLOY) or (-L) or (-ANALYZE) is missing**. error message displays on the console.

Note: **-O** command line option cannot be used with the **-A** command line option.

-NO sdeploy option

The **-NO** option can be used with the **sdeploy** utility command.

The no overwrite **(-NO)** option of the **sdeploy** utility command is used to indicate that an existing (**.mmc** or **.msl**) output file is not to be overwritten. If the no overwrite **(-NO)** option is specified in the command line of **sdeploy**, and a file with the same name as the resulting output file exists, it will not be overwritten, the **sdeploy** operation will fail, and the **Compilation error - The output file cannot be overwritten, file already exists** message will be written to the **sdeploy log file**, if enabled. If the **(-NO)** option is not specified, the file with the same name as the resulting output file will be overwritten.

-R sdeploy option

The **-R** option can be used with the **sdeploy** utility command.

The results **(-R)** option of the **sdeploy** utility command will have a parameter to specify the location or file name, or both, for the results file produced by the **sdeploy** operation for each system. There are 2 different cases where **(-R)** can be used in the **sdeploy** utility command.

In the first case, the **(-R)** option is used with the process all systems **(-A)** option. The specified parameter could either be the name of the directory where the results files will be written, or the full file path specification in which a wildcard can be used to represent the system or executable map naming convention. The default naming convention for the results file is **MSEBlds_system_name.txt** for the **(-BUILDMAPS)** option and **MSEAnlz_system_name.txt** for the **(-ANALYZE)** option. If a wildcard is specified in the **sdeploy mysystems.msd -ANALYZE -A -R C:\MyDev\AnalyzeResults*.*.err** full path, the results files will be produced in the **C:\MyDev\AnalyzeResults** directory with the **MSEAnlz_system_name.err** naming convention. If a wildcard is specified in the full path as **sdeploy mysystems.msd -BUILDRSULTS -A -R C:\MyDev\BuildResults*.*.err**, the results files will be produced in the **C:\MyDev\BuildResults** directory with the **MSEBlds_system_name.err** naming convention.

In the second case, the **(-R)** option is used without the process all systems **(-A)** option. The specified parameter could be the name of the directory where the results files will be written, the full file path specification in which a wildcard can be used to represent the result file, or the full path in which the complete filename can be specified. The default naming convention for the results file is **MSEBlds_system_name.txt** for the **(-BUILDMAPS)** option, **MSEAnlz_system_name.txt** for the **(-ANALYZE)**, and **MSEDploy_system_name.txt** for the **(-DEPLOY)** option. If a wildcard is specified in the full path as **sdeploy mysystems.msd mysystem -ANALYZE -R C:\MyDev\AnalyzeResults*.*.err**, the results files will be produced in the **C:\MyDev\AnalyzeResults** directory with the **MSEAnlz_system_name.err** naming convention. If a wildcard is specified in the full path as **sdeploy mysystems.msd mysystem -BUILDRSULTS -R C:\MyDev\BuildResults*.*.err**, the results files will be produced in the **C:\MyDev\BuildResults** directory with the **MSEBlds_system_name.err** naming convention. If a wildcard is specified in the full path as **sdeploy mysystems.msd mysystem -DEPLOY -R C:\MyDev\DeployResults*.*.err**, the results files will be produced in the **C:\MyDev\DeployResults** directory with the **MSEDploy_system_name.err** naming convention.

If the **(-R)** option is not specified, the results will be written to the console. If the **(-R)** option is specified, but no parameter is provided, the command line is invalid, and the **Not a valid command line - The file name for the resulting result file should be provided when -R option is selected** error message will display on the console. If the file name or the path provided for the **(-R)** option is not valid or returns error while attempting to open or write to the file, the **Compilation error - The file/path provided for the option (-R) is not valid, unable to write to the specified directory/file** message will be written to the **sdeploy log file**, if it is enabled. If the **(-R)** option is specified without the **(-ANALYZE, -BUILDMAPS, or -DEPLOY) options**, the command line is invalid, and the **Not a valid command line - (-R) option can be specified only with (-ANALYZE) or (-BUILDMAPS) or (-DEPLOY) command options**. error message will display on the console.

-LOG sdeploy option

The **-LOG** option can be used with the **sdeploy** utility command.

The log **(-LOG)** option of the **sdeploy** utility command is used to enable the **sdeploy** logging capability. The log file will be produced with the results of each operation performed. The **(-LOG)** option has an optional parameter to specify the location or file name, or both, for the **sdeploy** log file. The scope of the **sdeploy** log depends on which **(-ANALYZE, -BUILDMAPS, -GENERATE, or -DEPLOY)** option has been chosen with the **sdeploy** utility command. The default file name for the **sdeploy** log will be **msd_file_name.scl**. The default location for the **sdeploy** log will be the directory where the **msd** file is located.

The file name or the location parameter, if specified with the **(-LOG)** option of the **sdeploy** utility command, could be the name of the directory where the **sdeploy** log file will be written, the full file path specification in which a wildcard can be used to represent the **msd** file, or the full path in which the complete filename can be specified. The default naming convention for the **sdeploy** log file is **msd_file_name.scl**. If the **.** is specified with the **(-LOG)** option, the **sdeploy** log will be written to the default location (directory where the **msd** file is located) using the default naming convention. If a wildcard is specified in the full path as **sdeploy mysystems.msd -A -LOG C:\MyDev\Systemfiles\2002-02-28_*.results**, the **sdeploy** log file will be produced in the **C:\MyDev\Systemfiles** directory with the **2002-02-28_myystems.results** naming convention. If the complete file name is specified as **sdeploy mysystems.msd -A -LOG C:\MyDev\Systemfiles\mysystems_results.txt**, the **mysystems_results.txt** will be produced in the **C:\MyDev\Systemfiles** directory.

If the `sdeploy` utility command is unable to create the `sdeploy` log file, the any operation of `sdeploy` will terminate and the Fatal error - Could not start processing, unable to create the log file fatal error message will display on the console. If nothing is specified in the command line for the log, by default, the command line assumes the (`-LOG`) option is included in the command line, and writes the log messages to the console.

-FAIL sdeploy option

The `-FAIL` option can be used with the `sdeploy` utility command.

The fail (`-FAIL`) option of the `sdeploy` utility command is used to indicate that only the process that had errors during operation should be included in the `sdeploy` log file. If the log failures only (`-FAIL`) option is selected, the `sdeploy` log will contain only the logs of failed operations. If the log failures only (`-FAIL`) option is not selected in the command line, all the results will be written to the `sdeploy` log file.

-APPEND sdeploy option

The `-APPEND` option can be used with the `sdeploy` utility command.

The append (`-APPEND`) option of the `sdeploy` utility command is used to indicate that the current `sdeploy` log messages should be appended to the existing `sdeploy` log file if it already exists. If the `sdeploy` log append (`-APPEND`) option is selected, the `sdeploy` log messages will be appended to the existing file if it already exists; otherwise, a new file will be created. If the (`-APPEND`) option is not selected, the `sdeploy` log file will be created if no log file exists, or it will be overwritten if the log file does exist.

-VERBOSE sdeploy option

The `-VERBOSE` option can be used with the `sdeploy` utility command.

The verbose (`-VERBOSE`) option of the `sdeploy` utility command is used to indicate that a verbose `sdeploy` log should be produced. The verbose `sdeploy` log will contain an entry for each (`-ANALYZE`, `-BUILDMAPS`, `-GENERATE`, and `-DEPLOY`) operation attempted, the `.msd` file name, operation start date/time, operation end date/time, operation result, and the name of the results file, if it exists. If the verbose (`-VERBOSE`) option is not selected, a concise version of the `sdeploy` log will be produced, which includes an entry for each `msd` file, attempted system name, and operation result.

-NOLOG sdeploy option

The `-NOLOG` option can be used with the `sdeploy` utility command.

The disable log (`-NOLOG`) option of the `sdeploy` utility command is used to turn off the `sdeploy` logging capability. If the disable logging option is selected, the log file will not be produced. The (`-APPEND`, `-FAIL`, and `-VERBOSE`) options of the (`-LOG`) option cannot be used with the disable log (`-NOLOG`) option. If these options are selected with (`-NOLOG`), the command line is invalid, and the Not a valid command line - (`LOG`) optional commands (`-APPEND`), (`-FAIL`), (`-VERBOSE`) cannot be used with disable log command (`-NOLOG`). error message will display on the console.

sdeploy command line help

You can access command line help for the `sdeploy` utility command.

There is help that describes the `sdeploy` utility command usage in the command line.

To view the command line help for the `sdeploy` utility command:

Enter `sdeploy` at the command line prompt in the `install_dir`.

The syntax and descriptions of all the options appear on the console.

sdeploy command usage

You can use the `sdeploy` command to analyze systems, build maps in the system, generate and deploy the system to the specified server from the command line, outside of the Integration Flow Designer.

The following examples show how you can use the `sdeploy` utility command from the command line to:

- display all systems on the console
 - analyze all systems
 - build maps in all systems
 - generate all systems
 - deploy scripts to a specified server
- [Using sdeploy to display all systems on the console](#)
 - [Using sdeploy to analyze all systems](#)
 - [Using sdeploy to build maps from the command line - example 1](#)
 - [Using sdeploy to generate systems from the command line - example 2](#)

- [Using sdeploy to deploy scripts from the command line - example 3](#)
- [Using sdeploy to deploy scripts from the command line - example 4](#)

Using sdeploy to display all systems on the console

Use the `sdeploy` utility command to display all systems on the console from the command line, outside the Integration Flow Designer GUI.

The following example shows how you can use the `(-L)` option on the `sdeploy` utility command to display all the systems on the console:

```
install_dir> sdeploy mysystems.msd -L
```

When you run the example, the list of all systems displays in alphabetical order and the total number of systems display on the console:

```
Systems in mysystems.msd:  
  FristSystem  
  MySystem  
  NewSystem  
Total systems: 3
```

Using sdeploy to analyze all systems

Use the `sdeploy` utility command to analyze all systems from the command line, outside the Integration Flow Designer GUI.

The following example shows how you can use the `(-A)` option on the `sdeploy` utility command to analyze all the systems:

```
install_dir> sdeploy mysystems.msd  
-ANALYZE -A -EMODE ES  
-R C:\MyDev\AnalyzeResults\*.txt  
-LOG C:\MyDev\AnalyzeResults\*.results.txt  
-FAIL -APPEND
```

When you run the example, the following result occurs:

- If all the systems are analyzed successfully, the `sdeploy - completed successfully.` message displays on the console.
- The `MSEAnlz_FristSystem.txt`, `MSEAnlz_MySystem.txt`, `MSEAnlz_NewSystem.txt` analyzed results files are produced for launcher mode in the `C:\MyDev\AnalyzeResults` directory.
- If the `mysystems_results.txt` analyzed results file does not exist, the `sdeploy`'s log file is produced in the `C:\MyDev\AnalyzeResults` directory. If the `mysystems_results.txt` analyzed results file already exists, only the failed system's log messages are appended to the existing file.

Using sdeploy to build maps from the command line - example 1

Use the `sdeploy` utility command to build maps in all systems from the command line, outside the Integration Flow Designer GUI.

The following example shows how you can use the `(-A)` option on the `sdeploy` utility command to build all the maps in all systems:

```
install_dir> sdeploy mysystems.msd  
-BUILDMAPS -A -P WINDOWS  
-R C:\MyDev\BuildResults\*.txt  
-LOG C:\MyDev\BuildResults\*.results.txt  
-FAIL -APPEND
```

When you run the example, the following result occurs:

- If all the maps in the systems are compiled successfully, the `sdeploy - completed successfully.` message displays on the console.
- The `MSEBld_FristSystem.txt`, `MSEBld_MySystem.txt`, `MSEBld_NewSystem.txt` build results files and the compiled `executable_map_name.mmc` map are produced in the current directory.

If the `mysystems_results.txt` file does not exist, the `sdeploy`'s log file is produced in the `C:\MyDev\BuildResults` directory. If the `mysystems_results.txt` already exists, only the failed systems log messages are appended to the existing file.

Using sdeploy to generate systems from the command line - example 2

Use the `sdeploy` utility command to generate all systems from the command line, outside the Integration Flow Designer GUI.

The following example shows how you can use the `(-A)` option on the `sdeploy` utility command to generate all the systems:

```
install_dir> sdeploy mysystems.msd  
-GENERATE -A -EMODE ES -P WINDOWS  
-LOG C:\MyDev\GenerateResults\*.results.txt  
-FAIL -APPEND
```

When you run the example, the following result occurs:

- If all the systems are generated successfully, the `sdeploy - completed successfully.` message displays on the console.
- The `FristSystem.msl`, `MySystem.msl`, `NewSystem.msl` generated output files are produced in the current directory.
- If the `mysystems_results.txt` file does not exist, the `sdeploy`'s log file are produced in the `C:\MyDev\GenerateResults` directory. If the `mysystems_results.txt` file already exists, only the failed systems log messages are appended to the existing file.

Using `sdeploy` to deploy scripts from the command line - example 3

Use the `sdeploy` utility command to deploy scripts from the command line, outside the Integration Flow Designer GUI.

The following example shows how you can use the `sdeploy` utility command to deploy scripts to the specified server:

```
install_dir> sdeploy mysystems.msd NewSystem
-DEPLOY MyScript -EMODE ES -SERVER MyServer
-R C:\MyDev\DeployResults\*.txt
-LOG C:\MyDev\DeployResults\*.results.txt
-FAIL -APPEND
```

When you run the example, the following result occurs:

- If the deploy script is deployed successfully, the `sdeploy - completed successfully.` message displays on the console.
- The `MyScript` map is deployed to the `MyServer` and the results files are produced in the `C:\MyDev\DeployResults` directory.
- If the `mysystems_results.txt` file does not exist, the `sdeploy`'s log file is produced in the `C:\MyDev\DeployResults` directory. If `mysystems_results.txt` file already exists, only the failed systems log messages are appended to the existing file.

Using `sdeploy` to deploy scripts from the command line - example 4

Use the `sdeploy` utility command to deploy scripts from the command line, outside the Integration Flow Designer GUI.

The following example shows how you can use the `sdeploy` utility command to deploy scripts to the new server created with the specified IP address, the userid, and the password:

```
install_dir> sdeploy mysystems.msd NewSystem
-DEPLOY MyScript -EMODE ES
-USER userid -PW password -IP 192.82.65.46
-R C:\MyDev\DeployResults\*.txt
-LOG C:\MyDev\DeployResults\*.results.txt
-FAIL -APPEND
```

When you run the example, the following result occurs:

- If the deploy script is deployed successfully, the `sdeploy - completed successfully.` message displays on the console.
- The `MyScript` map is deployed to the new server created with the specified IP address, the userid, and the password, and the results files are produced in the `C:\MyDev\DeployResults` directory.
- If the `mysystems_results.txt` file does not exist, it is created in the `C:\MyDev\DeployResults` directory. If the file exists, append only the failed systems log messages.

You can specify an IP address that is in IPv4 (for example, `1.2.3.4`) or IPv6 (for example, `a:b:c:d:0:1:2:3`) format.

ssftpdeploy utility command

The `ssftpdeploy` command uses the SSH File Transfer Protocol (SFTP) to deploy an IBM Transformation Extender Launcher system to a remote host. The remote host must have an SSH server configured to accept remote SFTP requests. The computer that runs the `ssftpdeploy` command must be configured for SSH communication with the remote host. To establish SSH communication when SSH host key verification is in effect, the SSH public keys of the remote host must be specified in the `%userprofile%\.ssh\known_hosts` file on the host that deploys the system.

```
ssftpdeploy [deployment_options] sys_def.msd system deployment_script
```

Required parameters

`sys_def.msd`

The name and path of the system definition file, relative to the current directory. This parameter is required and positional.

`system`

The name of the system. This parameter is required and positional.

`deployment_script`

The name of the deployment script in the system definition (.msd) file. This parameter is required and positional.

Deployment options

The `deployment_options` of the `ssftpdeploy` command are:

```
[-EMODE {ES | CS}]
[-MRC resource_cfg.mrc]
[-SERVER server_name] [-USER user_name] [-PW password] [-IP IP_address]
```

```
[-R [results_file_location] [results_file_name]]
[-LOG [log_file_location] [log_file_name]]
[-VERIFYHOSTKEY]
[-H]
```

-EMODE mode

The processing mode for running the systems:

ES

Launcher mode. This is the default.

CS

Command server mode.

-MRC resource_cfg.mrc

The name and path of the resource registry configuration file, relative to the current directory. The resource registry configuration file resolves the aliases used in the systems.

-SERVER server_name

The server to which to deploy the system. The server specified on the -SERVER keyword must be defined in the system definition (.msd) file. The -SERVER keyword is optional. If specified, the -SERVER keyword overrides a server specified in the deployment definition script.

-USER user_name

The user name required to log in to the SFTP server to which the system is deployed. The -USER keyword is optional. The -USER keyword overrides the user name of a server specified by the -SERVER keyword or a server specified by the deployment definition script. You can use the -USER keyword together with the -PW and -IP keywords to specify a server that is not defined in the system definition (.msd) file. A server specified by the -USER, -PW and -IP keywords overrides a server specified on the -SERVER keyword or in the deployment definition script.

-PW password

The password required to log in to the SFTP server to which the system is deployed. The -PW keyword is optional. The -PW keyword overrides the password of a server specified by the -SERVER keyword or a server specified by the deployment definition script. You can use the -PW keyword together with the -USER and -IP keywords to specify a server that is not defined in the system definition (.msd) file. A server specified by the -USER, -PW and -IP keywords overrides a server specified on the -SERVER keyword or in the deployment definition script.

-IP IP_address

The IP address required to log in to the SFTP server to which the system is deployed. The -IP keyword is optional. The -IP keyword overrides the IP address of a server specified by the -SERVER keyword or a server specified by the deployment definition script. You can use the -IP keyword together with the -USER and -PW keywords to specify a server that is not defined in the system definition (.msd) file. A server specified by the -USER, -PW and -IP keywords overrides a server specified on the -SERVER keyword or in the deployment definition script.

-R [results_file_location] [results_file_name]

Logs the result of each **ssftpdeploy** operation for each system to a results file. In addition to the status of the deployment, the results log includes map processing details such as number of successful builds. This keyword is optional. If you omit it, the results are written to the default MSEsftpdeploy.txt file in the current directory. If you omit the results file name and location, the -R keyword creates a results file with path where the system definition (.msd) file is located. You can specify the name or location of the results file in the following ways:

Variable	Results file location and name
directory_name	directory_name\MSEsftpdeploy.txt
full_path*.err	full_path\MSEsftpdeploy.err
full_path\results_filename	full_path\results_filename

-LOG [log_file_location] [log_file_name]

Enables logging of all **ssftpdeploy** processes to a log file. This keyword is optional. If you omit it, the log messages are written to the default MSEsftpdeploy.log file in the current directory. You can specify the name or location of the log file in the following ways:

Variable	Log file location and name
directory_name	directory_name\MSEsftpdeploy.log
full_path*.err	full_path\MSEsftpdeploy.err
full_path\log_filename	full_path\log_filename

-VERIFYHOSTKEY

Restricts SSH communication to remote hosts that are defined in the %userprofile%\ssh\known_hosts file on the local server. This keyword is optional. If you omit it, the local server accepts any public key from a remote SSH hosts to establish SSH communication.

-H

Displays the **ssftpdeploy** command help to the console.

Examples

The examples use the following common artifacts:

Server:	tx-bld-cloud1
System definition (.msd) file:	decypher_big.msd
System name:	System1
System deployment definition script:	tx-bld-cloud-def1
Resource registry configuration file:	decypher.mrc

Use the SSH protocol to deploy System1 to the tx-bld-cloud1 server:

```
ssftpdeploy -SERVER tx-bld-cloud1 decypher_big.msd System1 tx-bld-cloud-def1
```

Use the SSH protocol to deploy System1 to the tx-bld-cloud1 server. Override the IP address and password of the server, and use the specified resource registry configuration file to resolve aliases in System1:

```
ssftpdeploy -SERVER tx-bld-cloud1 -MRC decypher.mrc -IP 10.134.55.79 -PW hclpnp123 decypher_big.msd System1 tx-bld-cloud-def1
```

Use the SSH protocol to deploy System1 to the tx-bld-cloud1 server. Override the IP address and password of the server. Use the specified resource registry configuration file to resolve aliases in System1. Verify that the SSH key of the remote host is defined in the %userprofile%\ssh\known_hosts file on the local server:

```
ssftpdeploy -SERVER tx-bld-cloud1 -MRC decypher.mrc -IP 10.134.55.79 -PW hclpnp123 -VERIFYHOSTKEY decypher_big.msd System1 tx-bld-cloud-def1
```

msdimport utility command

The `msdimport` utility command is used to import an xml file to a system definition (`.msd`) source file in a system from the command line, outside of the Integration Flow Designer.

The `msdimport` utility command returns 0 if the import is successful, and 1 if not. It is a batch operation that can also be used for automation.

See "[Troubleshooting](#)" for details about capturing and evaluating the return code resulting from running this command.

- [**msdimport syntax summary**](#)

This is the syntax that is used with the `msdimport` utility command.

- [**msdimport utility command options**](#)

These are the command options that can be used with the `msdimport` utility command.

- [**msdimport command line help**](#)

You can access command line help for the `msdimport` utility command.

- [**msdimport command usage**](#)

You can use the `msdimport` command to import an XML file to the map source file from the command line.

msdimport syntax summary

This is the syntax that is used with the `msdimport` utility command.

`msdimport` is the name of the utility command used to import xml files to system source files.

The `.xml` file is a required field and the file name of the xml source file. If the full path of the xml source file name is not specified, the `msdimport` utility command will search for the xml source file in the current directory.

The following is the syntax of the `msdimport` utility command:

```
msdimport <.xml file>
[-NO]
[-O <.msd file name/location>]
  [-ASVR [<server names>]] [-ASYS [<system names>]]
  [-OSYS] [-OSVR] [-REFSYS] [-REFSVR]
  [-LOG [. | <log file name/location>]
  [-FAIL] [-VERBOSE] [-APPEND]
  |-NOLOG]
```

None of the options in the `msdimport` utility command are case sensitive.

Typing `msdimport` with no options will display the command summary on the console.

msdimport utility command options

These are the command options that can be used with the `msdimport` utility command.

The following command options are available with the `msdimport` utility command:

• -APPEND msdimport Option	• -O msdimport Option
• -ASVR msdimport Option	• -OSVR msdimport Option
• -ASYS msdimport Option	• -OSYS msdimport Option
• -FAIL msdimport Option	• -REFSVR msdimport Option
• -LOG msdimport Option	• -REFSYS msdimport Option
• -NO msdimport Option	• -VERBOSE msdimport Option
• -NOLOG msdimport Option	

- [**-APPEND msdimport option**](#)

The -APPEND option can be used with the `msdimport` utility command.

- [**-ASVR msdimport option**](#)

The -ASVR option can be used with the `msdimport` utility command.

- [**-ASYS msdimport option**](#)

The -O option can be used with the msdimport utility command.
- **[-OSVR msdimport option](#)**
The -OSVR option can be used with the msdimport utility command.
- **[-OSYS msdimport option](#)**
The -OSYS option can be used with the msdimport utility command.
- **[-REFSVR msdimport option](#)**
The -REFSVR option can be used with the msdimport utility command.
- **[-REFSYS msdimport option](#)**
The -REFSYS option can be used with the msdimport utility command.
- **[-VERBOSE msdimport option](#)**
The -VERBOSE option can be used with the msdimport utility command.

-APPEND msdimport option

The -APPEND option can be used with the msdimport utility command.

The append (-APPEND) option of the `msdimport` utility command is used to indicate that the current `msdimport` log messages should be appended to the existing `msdimport` log file if it already exists. If the `msdimport` log append (-APPEND) option is selected, the `msdimport` log messages will be appended to the existing file if it already exists; otherwise, a new file will be created. If the (-APPEND) option is not selected, the `msdimport` log file will be created if no log file exists, or it will be overwritten if the log file does exist.

-ASVR msdimport option

The -ASVR option can be used with the msdimport utility command.

The server (-ASVR) option of the `msdimport` utility command is used to import only servers from the xml file. If the option is used alone, the `msdimport` utility command will import all the servers from the xml file. If the option is followed by a string of server names separated by commas, for example, -ASVR server1,server2,server3, the `msdimport` utility command will import those specific servers from the xml file.

-ASYS msdimport option

The -ASYS option can be used with the msdimport utility command.

The system (-ASYS) option of the `msdimport` utility command is used to import only systems from the xml file. If the option is used alone, the `msdimport` utility command will import all the systems from the xml file. If the option is followed by a string of system names separated by commas, for example, -ASVR system1,system2,system3, the `msdimport` utility command will import those specific systems from the xml file.

Any combination of the -ASYS and -ASVR options used with the `msdimport` utility command will be executed as separate individual options.

-FAIL msdimport option

The -FAIL option can be used with the msdimport utility command.

The fail (-FAIL) option of the `msdimport` utility command is used to indicate that only the systems that had errors during the importing should be included in the `msdimport` log file. If the log failures only (-FAIL) option is selected, the `msdimport` log will contain only the systems that failed importing. If the log failures only (-FAIL) option is not selected in the command line, all the imported results will be written to the `msdimport` log file.

-LOG msdimport option

The -LOG option can be used with the msdimport utility command.

The log (-LOG) option of the `msdimport` utility command is used to enable logging. The log file will be produced showing the result of the imported system source file. (-LOG) has an optional parameter to specify the location or file name, or both, for the `msdimport` log file. The default file name for the `msdimport` log will be **system_source_file_name_import.log**. The default location for the `msdimport` log will be the directory where the system definition (**.msd**) source file is located.

The file name or the location parameter, if specified with the (-LOG) option of the `msdimport` utility command, could be the name of the directory where the `msdimport` log file will be written, the full file path specification in which a wildcard can be used to represent the xml source file, or the full path in which the complete filename can be specified. If the . is specified with the (-LOG) option, the `msdimport` log will be written to the default location (directory where the xml file is located) using the default naming convention. If a wildcard is specified in the full path, for example, `msdimport myxmlfile.xml -LOG C:\MyDev\ImportResults\2003-10-03_*.results`, the `msdimport` log file will be produced in the **C:\MyDev\ImportResults** directory with the **2003-10-03_myxmlfile.results** naming convention. If the complete file name is specified, for example, `msdimport myxmlfile.xml -LOG C:\MyDev\ImportResults\myxmlimport_results.txt`, the **myxmlimport_results.txt** will be produced in the **C:\MyDev\ImportResults** directory.

If the `msdimport` utility command is unable to create the `msdimport` log file, the importing of the system source file will terminate and the Fatal error - Could not start importing the system source file, unable to create the log file fatal error message will display on the console. If nothing is specified in the

command line for the log, by default, the command line assumes the (-LOG) option is included in the command line, and writes the log messages to the console.

-NO msdimport option

The -NO option can be used with the msdimport utility command.

The no overwrite (-NO) option of the msdimport utility command is used to indicate that an existing imported system definition (.msd) source file is not to be overwritten. If the no overwrite (-NO) option is specified in the command line of msdimport, and a file with the same name as the resulting .msd file exists, it will not be overwritten, the msdimport operation will fail, and the IFD import error - The imported system source file cannot be overwritten, file already exists message will be written to the msdimport log file, if enabled. If the (-NO) option is not specified, the file with the same name as the resulting .msd file, will be overwritten.

-NOLOG msdimport option

The -NOLOG option can be used with the msdimport utility command.

The disable log (-NOLOG) option of the msdimport utility command is used to turn off the msdimport logging capability. If the disable logging option is selected, the log file will not be produced. The (-APPEND, and -VERBOSE) optional commands of the (-LOG) option cannot be used with the disable log (-NOLOG) option. If these options are selected with the (-NOLOG) option, the command line is invalid, and the Not a valid command line - (LOG) optional commands (-APPEND), (-VERBOSE) cannot be used with disable log command (-NOLOG). message will display on the console.

-O msdimport option

The -O option can be used with the msdimport utility command.

The output (-O) option of the msdimport utility command is used to specify, through a parameter, the location or file name, or both, of the system definition (.msd) file produced by importing the xml file. The specified parameter could be the name of the directory to where the imported .msd file is written, or the full file path specification in which a wildcard can be used to represent the imported system source file, or the full path in which the complete file name can be specified. The default naming convention for the imported .msd file is `xml_file_name.msd'. If a wildcard is specified in the full path, for example, MSDImport myxmlfile.xml -O C:\MyDev\ImportResults\2003-10-03_* .msd, the resulting .msd file is produced in the C:\MyDev\ImportResults directory with the 2003-10-03_myxmlfile.msd naming convention. If the complete file name is specified, for example, msdimport myxmlfile.xml -O C:\MyDev\ImportResults\Myxmlsystems.msd, a Myxmlsystems.msd system definition (.msd) file is produced in the C:\MyDev\ImportResults directory.

-OSVR msdimport option

The -OSVR option can be used with the msdimport utility command.

The output (-OSVR) option of the msdimport utility command is used to override servers if the servers are already present in the system definition (.msd) file.

-OSYS msdimport option

The -OSYS option can be used with the msdimport utility command.

The output (-OSYS) option of the msdimport utility command is used to override systems if the systems are already present in the system definition (.msd) file.

-REFSVR msdimport option

The -REFSVR option can be used with the msdimport utility command.

The reference server (-REFSVR) option of the msdimport utility command is used to allow reference servers to be imported.

-REFSYS msdimport option

The -REFSYS option can be used with the msdimport utility command.

The reference system (-REFSYS) option of the msdimport utility command is used to allow reference systems to be imported, also. If the -REFSYS command is specified, the msdimport utility command will also import the dependent systems.

-VERBOSE msdimport option

The -VERBOSE option can be used with the msdimport utility command.

The verbose (-VERBOSE) option of the msdimport utility command is used to indicate if the verbose msdimport log should be produced. The verbose msdimport log will contain an entry for the xml file being imported, the importing start date/time, the importing end date/time, the imported system source file name, and the result of the msdimport utility command. If the verbose (-VERBOSE) option is not selected, a concise version of the msdimport log will be produced, which includes an entry for the system source file name, and importing result.

msdimport command line help

You can access command line help for the msdimport utility command.

There is help that describes the msdimport utility command usage in the command line.

To view the command line help for the msdimport utility command:

Enter msdimport at the command line prompt in the *install_dir*.

The syntax and descriptions of all the options appear on the console.

msdimport command usage

You can use the msdimport command to import an XML file to the map source file from the command line.

Use the msdimport utility command to import the xml file to a system definition (.msd) file from the command line, outside the Integration Flow Designer.

The following example shows how you can use the command:

```
install_dir> msdimport myxmlfile.xml  
-O C:\MyDev\ImportResults\myimportedsystem.msd  
-LOG -APPEND
```

When you run the example, the following result occurs:

- If the **myxmlfile.xml** xml file is imported successfully, the msdimport – completed successfully. message displays on the console.
- The imported **myimportedsystem.msd** system definition file is produced in the **C:\MyDev\ImportResults** directory.

If the **myxmlfile.log** log file does not exist, it is produced in the same directory as the system file. If the **myxmlfile.log** log file already exists, the log messages are appended to the existing file.

msdexport utility command

The msdexport utility command is used to export a system source definition (.msd) file from the command line, outside of the Integration Flow Designer.

The msdexport utility command returns 0 if the export is successful, and 1 if not. It is a batch operation that can also be used for automation.

See "[Troubleshooting](#)" for details about capturing and evaluating the return code resulting from running this command.

- [**msdexport syntax summary**](#)
This is the syntax that is used with the msdexport utility command.
- [**msdexport utility command options**](#)
These are the command options that can be used with the msdexport utility command.
- [**msdexport command line help**](#)
You can access command line help for the msdexport utility command.
- [**Using the msdexport command**](#)
You can use the msdexport command to export the system source file from the command line.

msdexport syntax summary

This is the syntax that is used with the msdexport utility command.

msdexport is the name of the utility command used to export system source files.

The .msd file is a required field and is the file name of the system source file that needs to be exported. If the full path of the system source file name is not specified, the msdexport utility command will search for the system source file in the current directory.

None of the options in the msdexport utility command are case sensitive. The following is the syntax of the msdexport utility command:

```
msdexport <.msd file>  
[-NO]  
[-O <.xml file name/location>]  
[-ASVR [<server names>]] [-ASYS [<system names>]]  
[-EPWD] [-REFSYS] [-REFSVR]  
[(-LOG [. | <log file name/location>]  
[-FAIL] [-VERBOSE] [-APPEND])  
|-NOLOG]
```

Typing `msdexport` with no options will display the command summary on the console.

msdexport utility command options

These are the command options that can be used with the `msdexport` utility command.

The following command options are available with the `msdexport` utility command:

• -APPEND msdexport Option	• -NO msdexport Option
• -ASVR msdexport Option	• -NOLOG msdexport Option
• -ASYS msdexport Option	• -O msdexport Option
• -EPWD msdexport Option	• -REFSVR msdexport Option
• -FAIL msdexport Option	• -REFSYS msdexport Option
• -LOG msdexport Option	• -VERBOSE msdexport Option

-APPEND msdexport option

The `-APPEND` option can be used with the `msdexport` utility command.

-ASVR msdexport option

The `-ASVR` option can be used with the `msdexport` utility command.

-ASYS msdexport option

The `-ASYS` option can be used with the `msdexport` utility command.

-EPWD msdexport option

The `-EPWD` option can be used with the `msdexport` utility command.

-FAIL msdexport option

The `-FAIL` option can be used with the `msdexport` utility command.

-LOG msdexport option

The `-LOG` option can be used with the `msdexport` utility command.

-NO msdexport option

The `-NO` option can be used with the `msdexport` utility command.

-NOLOG msdexport option

The `-NOLOG` option can be used with the `msdexport` utility command.

-O msdexport option

The `-O` option can be used with the `msdexport` utility command.

-REFSVR msdexport option

The `-REFSVR` option can be used with the `msdexport` utility command.

-REFSYS msdexport option

The `-REFSYS` option can be used with the `msdexport` utility command.

-VERBOSE msdexport option

The `-VERBOSE` option can be used with the `msdexport` utility command.

-APPEND msdexport option

The `-APPEND` option can be used with the `msdexport` utility command.

The `append` (`-APPEND`) option of the `msdexport` utility command is used to indicate that the current `msdexport` log messages should be appended to the existing `msdexport` log file if it already exists. If the `msdexport` log `append` (`-APPEND`) option is selected, the `msdexport` log messages will be appended to the existing file if it already exists; otherwise, a new file will be created. If the (`-APPEND`) option is not selected, the `msdexport` log file will be created if no log file exists, or it will be overwritten if the log file does exist.

-ASVR msdexport option

The `-ASVR` option can be used with the `msdexport` utility command.

The server (`-ASVR`) option of the `msdexport` utility command is used to export only servers from the system definition (`.msd`) file. If the option is used alone, the `msdexport` utility command will export all the servers from the `.msd` file. If the option is followed by a string of server names separated by commas, for example, `-ASVR server1, server2, server3`, the `msdexport` utility command will export those specific servers from the `.msd` file.

-ASYS msdexport option

The `-ASYS` option can be used with the `msdexport` utility command.

The system (`-ASYS`) option of the `msdexport` utility command is used to export only systems from system definition (`.msd`) file. If the option is used alone, the `msdexport` utility command will export all the systems from the `.msd` file. If the option is followed by a string of system names separated by commas, for example, `-ASVR system1, system 2, system 3`, the `msdexport` utility command will export those specific systems from the `.msd` file.

Any combination of the **-ASYS** and **-ASVR** options used with the `msdexport` utility command will be executed as separate individual options.

-EPWD msdexport option

The **-EPWD** option can be used with the `msdexport` utility command.

The encrypt password (**-EPWD**) option of the `msdexport` utility command is used to encrypt the password while writing to a file.

-FAIL msdexport option

The **-FAIL** option can be used with the `msdexport` utility command.

The fail (**-FAIL**) option of the `msdexport` utility command is used to indicate that only the systems that had errors during the exporting should be included in the `msdexport` log file. If the log failures only (**-FAIL**) option is selected, the `msdexport` log will contain only the systems that failed exporting. If the log failures only (**-FAIL**) option is not selected in the command line, all the exported results will be written to the `msdexport` log file.

-LOG msdexport option

The **-LOG** option can be used with the `msdexport` utility command.

The log (**-LOG**) option of the `msdexport` utility command is used to enable logging. The log file will be produced showing the result of the exported system source file. (**-LOG**) has an optional parameter to specify the location or file name, or both, for the `msdexport` log file. The default file name for the `msdexport` log will be **system_source_file_name_export.log**. The default location for the `msdexport` log will be the directory where the system definition (**.msd**) file is located.

The file name or the location parameter, if specified with the (**-LOG**) option of the `msdexport` utility command, could be the name of the directory where the `msdexport` log file will be written, the full file path specification in which a wildcard can be used to represent the xml source file, or the full path in which the complete filename can be specified. If the **.** is specified with the (**-LOG**) option, the `msdexport` log will be written to the default location (directory where the (**.msd**) file is located) using the default naming convention. If a wildcard is specified in the full path, for example, `msdexport mysystems.msd -LOG C:\MyDev\ExportResults\2003-10-03_*.results`, the `msdexport` log file will be produced in the **C:\MyDev\ExportResults** directory with the **2003-10-03_mysystems.results** naming convention. If the complete file name is specified, for example, `msdexport mysystems.mms -LOG C:\MyDev\ExportResults\mysystemsexport_results.txt`, the **mysystemsexport_results.txt** will be produced in the **C:\MyDev\ExportResults** directory.

If the `msdexport` utility command is unable to create the `msdexport` log file, the exporting of the system source file will terminate and the **Fatal error - Could not start exporting the system source file, unable to create the log file** fatal error message will display on the console. If nothing is specified in the command line for the log, by default, the command line assumes the (**-LOG**) option is included in the command line, and writes the log messages to the console.

-NO msdexport option

The **-NO** option can be used with the `msdexport` utility command.

The no overwrite (**-NO**) option of the `msdexport` utility command is used to indicate that an existing exported xml (**.xml**) file is not to be overwritten. If the no overwrite (**-NO**) option is specified in the command line of `msdexport`, and a file with the same name as the resulting **.msd** file exists, it will not be overwritten, the `msdexport` operation will fail, and the **IFD export error - The exported xml file cannot be overwritten, file already exists** message will be written to the `msdexport` log file, if enabled. If the (**-NO**) option is not specified, the file with the same name as the resulting **.msd** file, will be overwritten.

-NOLOG msdexport option

The **-NOLOG** option can be used with the `msdexport` utility command.

The disable log (**-NOLOG**) option of the `msdexport` utility command is used to turn off the `msdexport` logging capability. If the disable logging option is selected, the log file will not be produced. The optional (**-APPEND**, and **-VERBOSE**) options of the (**-LOG**) option cannot be used with the disable log (**-NOLOG**) option. If these options are selected with the (**-NOLOG**) option, the command line is invalid, and the **Not a valid command line - (LOG) optional commands (-APPEND), (-VERBOSE)** cannot be used with disable log command (**-NOLOG**). error message will display on the console.

-O msdexport option

The **-O** option can be used with the `msdexport` utility command.

The output (**-O**) option of the `msdexport` utility command is used to specify, through a parameter, the location or file name, or both, for the exported xml file produced by exporting the system source file. The specified parameter could be the name of the directory where the exported xml file is written, the full file path specification in which a wildcard can be used to represent the exported xml file, or the full path in which the complete filename can be specified. The default naming convention for the exported xml file is **system_source_file_name.xml**. If a wildcard is specified in the full path, for example, `msdexport mysystem.msd -O C:\MyDev\ExportResults\2003-10-03_*.xml`, the resulting xml file is produced in the **C:\MyDev\ExportResults** directory with the **2003-10-03_mysystem.xml** naming convention. If the complete file name is specified, for example, `msdexport mysystem.mms -O C:\MyDev\ExportResults\MysystemExportedfile.xml`, an xml file **MysystemExportedfile.xml** is produced in the **C:\MyDev\ExportResults** directory. If the export output (**-O**) option is selected, and if the file name is not specified, the command line is invalid, and the

Not a valid command line – the file name parameter is required if export command option (-O) is selected error message displays on the console.

-REFSVR msdexport option

The -REFSVR option can be used with the msdexport utility command.

The reference server (-REFSVR) option of the `msdexport` utility command is used to allow reference servers to be exported.

-REFSYS msdexport option

The -REFSYS option can be used with the msdexport utility command.

The reference system (-REFSYS) option of the `msdexport` utility command is used to allow reference systems to be exported, also. If the -REFSYS command is specified, the `msdexport` utility command will also export the dependent systems.

-VERBOSE msdexport option

The -VERBOSE option can be used with the msdexport utility command.

The verbose (-VERBOSE) option of the `msdexport` utility command is used to indicate if the verbose `msdexport` log should be produced. The verbose `msdexport` log will contain an entry for the system source file being exported, the exporting start date/time, the exporting end date/time, the exported system source file name, and the result of the `msdexport` utility command. If the verbose (-VERBOSE) option is not selected, a concise version of the `msdexport` log will be produced, which includes an entry for the system source file name, and exporting result.

msdexport command line help

You can access command line help for the msdexport utility command.

There is help that describes the `msdexport` utility command usage in the command line.

To view the command line help for the msdexport utility command:

Enter `msdexport` at the command line prompt in the `install_dir`.

The syntax and descriptions of all the options appear on the console.

Using the msdexport command

You can use the msdexport command to export the system source file from the command line.

Use the `msdexport` utility command to export the system source file from the command line, outside the Integration Flow Designer.

The following example shows how you can use the command:

```
install_dir> msdexport mysystem.mms  
-O C:\MyDev\ExportResults\mysystem.xml  
-LOG -APPEND
```

When you run the example, the following result occurs:

- If the `mysystems.mms` system source file is exported successfully, the `msdexport` – completed successfully. message displays on the console.
- The exported `mysystems.xml` xml file is produced in the `C:\MyDev\ExportResults` directory.
- If the `mysystems.log` log file does not exist, it is produced in the same directory as the system source file. If it already exists, the log messages are appended to the existing file.

Utility commands for map tuning

The map tuning utility commands are used to calculate map memory page size and count and running your maps to create output consisting of statistical data regarding the execution of your maps.

Map tuning utility commands are tools to calculate map memory page size and count and running your maps to create output consisting of statistical data regarding the execution of your maps. This data can assist you in tuning your maps to attain improved performance.

The following list briefly describes the functions of each of the map tuning utility commands:

- "["dtxpath Utility Command"](#)" - calculates suggested settings for memory page size and count for maps
- "["dtxpath Utility Command"](#)" - profiles maps and analyzes map execution behavior

- [dtxpage utility command](#)

The dtxpage utility command is used to invoke the **Page Setting Assistant for Maps** application to calculate suggested settings for memory page size and count for work files used in maps. To use this utility command, the Command Server must be installed.

- [dtxprof utility command](#)

The dtxprof utility command is used to profile maps and analyze map execution behavior from the command line, outside of the Map Designer GUI. To use this utility command, the Command Server must be installed.

dtxpage utility command

The dtxpage utility command is used to invoke the **Page Setting Assistant for Maps** application to calculate suggested settings for memory page size and count for work files used in maps. To use this utility command, the Command Server must be installed.

The dtxpage utility command returns 0 if the calculations are successful, and 1 if not successful. It is a batch operation that can also be used for automation.

The .mmc file is a required parameter and is the file name of the map for which the page size and count is being calculated. If the full path of the map file name is not specified, the dtxpage utility command will search for the map in the current directory.

The **Page Setting Assistant for Maps** application will run iterations of the specified map to calculate suggested memory page size and count settings. Because of the multiple iterations of map runs, the overall run time will be longer than a typical run. Because of the additional run time, follow these guidelines:

- use a smaller representation of the input data when you are using a map that normally takes a long time to run
- use this utility command only when there is a limited number of other processes running so that CPU utilization is not adversely affected

See "[Troubleshooting](#)" for details about capturing and evaluating the return code resulting from the execution of this utility command.

You can use the dtxpage utility command to calculate suggested settings for memory page size and count for work files used in maps that you are running with the z/OS Batch Command Server. See "[z/OS Batch Command Server dtxpage Usage](#)".

- [dtxpage syntax summary](#)

This is the syntax that is used with the dtxpage utility command.

- [dtxpage command line help](#)

You can access command line help for the dtxpage utility command.

- [dtxpage command usage](#)

You can use the dtxpage command to invoke the **Page Setting Assistant for Maps** application to calculate suggested settings for memory page size and count for work files used in maps.

dtxpage syntax summary

This is the syntax that is used with the dtxpage utility command.

dtxpage is the name of the utility command used to calculate suggested memory page size and count settings for work files.

The following is the syntax of the dtxpage utility command:

`dtxpage <.mmc file name/location>`

There are no other options besides the compiled map (.mmc) file name and location.

Typing dtxpage with no options will display the command summary on the console.

dtxpage command line help

You can access command line help for the dtxpage utility command.

There is help that describes the dtxpage utility command usage in the command line.

To view the command line help for the dtxpage utility command

1. Enter dtxpage at the command line prompt in the *install_dir*.
The syntax and descriptions of all the options appear on the console.

dtxpage command usage

You can use the dtxpage command to invoke the **Page Setting Assistant for Maps** application to calculate suggested settings for memory page size and count for work files used in maps.

The following example shows how you can use the dtxpage utility command:

`install_dir> dtxpage mymap.mmc`

When you run the example, the following result occurs:

- If the suggested settings for memory page size and count are calculated for the map file successfully, first a list of the sizes and counts for each map run by the `dtxpage` utility command displays on the console. The list also includes the time stamp for each map run.
- Following the list of the sizes and counts for each map, are the suggested settings for memory page size and count that the `dtxpage` utility command calculated.
- [dtxpage command usage with the z/OS Batch Command Server](#)
You can use the `dtxpage` command with the z/OS Batch Command Server.

dtxpage command usage with the z/OS Batch Command Server

You can use the `dtxpage` command with the z/OS Batch Command Server.

The `dtxpage` utility command is available to use with the z/OS Batch Command Server. It calculates suggested settings for memory page size and count for the work files used in a specified map.

To use the `dtxpage` utility command:

1. Make a copy of the JCL file that executes the map on which the `dtxpage` utility command performs its calculations.
2. Change the program name from **MERCATOR** or **DTXCMDSV** to **DTXPAGE** in one of the copies of the JCL file.
The **Page Analysis Usage** report is written to an output specified on the **SYSPRINT** Data Definition (**DD**) statement.

dtxprof utility command

The `dtxprof` utility command is used to profile maps and analyze map execution behavior from the command line, outside of the Map Designer GUI. To use this utility command, the Command Server must be installed.

The `dtxprof` utility command returns 0 if the Map Profiler is successful and 1 if it is not successful. It is a batch operation that can also be used for automation.

The Map Profiler is a user-configurable utility that captures and reports map execution statistics. The profiler focuses on component and mapping rules and the functions and types within those rules. The resulting information enables you to see where performance is lagging and in turn make improvements in your maps.

For example, in the profile report you see that the processing time for a `LOOKUP` function is significantly more than other functions. You can modify the rule to use a better choice, such as the `SEARCHUP` function (because in this specific case the data in the `LOOKUP` is ascending), and as a result the processing time is greatly reduced. See *Data Search Usage* in the IBM Transformation Extender *Performance Recommendations* documentation for more information about recommended usages of the different search functions to achieve your performance objectives.

See "[Troubleshooting](#)" for details about capturing and evaluating the return code resulting from the execution of this utility command.

You can use the `dtxprof` utility command to calculate suggested settings for memory page size and count for work files used in maps that you are running with the z/OS Batch Command Server. See "[z/OS Batch Command Server dtxprof Usage](#)".

- [Syntax summary for dtxprof](#)
- [Utility command options for dtxprof](#)
- [Command line help for dtxprof](#)
- [Using the dtxprof command](#)

Syntax summary for dtxprof

`dtxprof` is the name of the utility command used to analyze map execution behavior.

The output file name and compiled map name (.mmc) are required fields.

The following is the syntax of the `dtxprof` utility command:

```
dtxprof
[-f [x]]
[-t [x]]
[-fs]
[-ts]
[-d]
-o output_file
-dtx "map_name [map_options]"
```

None of the options in the `dtxprof` utility command are case sensitive. Typing `dtxprof` with no options will display the command summary on the console.

Utility command options for dtxprof

The following command options are available with the `dtxprof` utility command:

• -f dtxprof Option	• -ts dtxprof Option
• -fx dtxprof Option	• -d dtxprof Option
• -t dtxprof Option	• -o dtxprof Option

• -tx dtxprof Option	• -dtx dtxprof Option
• -fs dtxprof Option	

If you type `dtxprof` with no options, the command line help that describes the command will display on your screen.

- [-f dtxprof option](#)
- [-fx dtxprof option](#)
- [-t dtxprof option](#)
- [-tx dtxprof option](#)
- [-fs dtxprof option](#)
- [-ts dtxprof option](#)
- [-d dtxprof option](#)
- [-o dtxprof option](#)
- [-dtx dtxprof option](#)

-f dtxprof option

The function times (-f) option of the `dtxprof` utility command is used to specify that all the function processing times are to be reported in the output.

-fx dtxprof option

The function times exceeding x milliseconds (-fx) option of the `dtxprof` utility command is used to specify that all the function processing times that exceed a specified value (x) are to be reported in the output. The value must be between 0 and 250 (1/10 milliseconds).

-t dtxprof option

The type times (-t) option of the `dtxprof` utility command is used to specify that all the type processing times are to be reported in the output.

-tx dtxprof option

The type times exceeding x milliseconds (-tx) option of the `dtxprof` utility command is used to specify that all the type processing times that exceed a specified value (x) are to be reported in the output. The value must be between 0 and 250 (1/10 milliseconds).

-fs dtxprof option

The function times summary output (-fs) option of the `dtxprof` utility command is used to specify that all the function processing times are to be reported in summary form in the output.

-ts dtxprof option

The type times summary output (-ts) option of the `dtxprof` utility command is used to specify that all the type processing times are to be reported in summary form in the output.

-d dtxprof option

The comma-delimited output (-d) option of the `dtxprof` utility command is used to specify that the output format will be comma-delimited.

The default value is fixed-width so if the -d option is omitted, the output will be created in fixed-width format.

-o dtxprof option

The output file name (-o) option of the `dtxprof` utility command is used to specify the output file name (*filename*).

-dtx dtxprof option

The (-dtx) option of the `dtxprof` utility command is used to specify the compiled map name (*map_name*) with optional map options (*map_options*). Quotation marks around the map name are required.

Command line help for `dtxprof`

There is help that describes the `dtxprof` utility command usage in the command line.

To view the command line help for the `dtxprof` utility command:

Enter `dtxprof` at the command line prompt in the *install_dir*.
The syntax and descriptions of all the options appear on the console.

Using the `dtxprof` command

Use the `dtxprof` utility command to profile maps and analyze map execution behavior.

The Map Profiler can capture the following statistics:

- Amount of time spent processing component and mapping rules and subordinate functions.
- Number of times rules and functions are executed (from validation through output).
- Number of times type objects are accessed.
- Depth (nesting level) of the object being profiled.
- [Type names](#)
- [Function Times](#)
- [RUN maps](#)
- [Output examples](#)
- [For best results](#)
- [z/OS Batch Command Server `dtxprof` usage](#)

Type names

Similar to the map trace file, the type names referred to in the profile output represent the full type name in the original schema, not the name of the type object that is visible in the Map Designer.

Function Times

The processing time of any subfunctions rolls up into the processing time of the top-level function. For example, if an `EITHER` function contains an `IF` function, the recorded time for the `EITHER` function would include the processing time of the `IF` function.

RUN maps

When a parent map contains a `RUN` map, the `RUN` map is not profiled. To profile a `RUN` map, it must be done outside of the `RUN` rule. You can do this by running it as a top-level executable map.

Output examples

Full report

The following command produces a full report containing both function and type information:

```
dtxprof -f -t -o sinkpro  
-dtx "C:\IBM\WebSphere Transformation Extender 9.0.0\  
examples\general\map\sinkmap\sinkmap.mmc"
```

Individual Function Breakdown

TIMETOTEXT	10	34
TEXTTONUMBER	10	35

For best results

- If you have a large amount of data, the profiler output could be very large or unmanageable. For this reason, it is best to profile only a subset of the original data.
- You can reduce profiler output by specifying a time limit so that nothing is reported until it exceeds the time limit that you specify.
- When running the profiler, always limit or terminate other processes running on your machine to avoid adverse results.

z/OS Batch Command Server dtxprof usage

The `dtxprof` utility command is available to use with the z/OS Batch Command Server. It profiles maps and analyzes map execution behavior.

To use the `dtxprof` utility command:

1. Make a copy of the JCL file that executes the map on which the `dtxprof` utility command profiles.
2. Change the program name from **MERCATOR** or **DTXCMDSV** to **DTXPROF** in one of the copies of the JCL file.
3. Specify the command line switches you want to use with the `dtxprof` utility command in the **PARM** field on the **EXEC** statement of the JCL.
If the **PARM** field length exceeds the 100-character limit, place the **DTXCMDSV** map command line in a file and specify `-dtx "-@ddname"` in the **PARM** field along with the `dtxprof` command line you want to use.
4. Add **PROF1** and **PROF2** Data Definition (**DD**) cards.

dtxprof JCL example

The following example JCL code shows how you can use the `dtxprof` utility command with the z/OS Batch Command Server.

```
//STEP1 EXEC PGM=DTXPROF,REGION=0M,
// PARM='-f -t -fs -ts -o DD:PROFOUT -dtx "-@CMD" '
...
...
//CMD      DD *
      REVERSE /VX0D,X0A REVERSEI /VX0D,X0A REVERSEO
/*
//PROF1    DD DSN=&&PROF01,DCB=(RECFM=FBS,LRECL=23476,BLKSIZE=23476),
//           UNIT=3390,SPACE=(CYL,(0100,050),RLSE),
//           DISP=(NEW,DELETE,DELETE)
//PROF2    DD DSN=&&PROF02,DCB=(RECFM=FBS,LRECL=23476,BLKSIZE=23476),
//           UNIT=3390,SPACE=(CYL,(0100,050),RLSE),
//           DISP=(NEW,DELETE,DELETE)
//PROFOUT DD SYSOUT=*
...
...
```

`-@ddname` identifies the Data Definition (**DD**) name that points to the file containing the **DTXCMDSV** map command line.

Utility command for dtxany2xml

The `dtxany2xml` utility is used to produce a map that can transform any input data into XML output.

The `dtxany2xml` utility performs the following tasks during execution:

- Exports the input schema as an XML Schema
- Creates an XML schema from the generated XML Schema
- Creates a map source file containing two maps:
 - The first map has the name that you specified in the command line.
 - The second map has the same name as the first map but with `_r` appended to the end of it.

Use the second map only when the schema that you specified in the first parameter of the `dtxany2xml` utility command was imported from a **COBOL** copybook.

The `dtxany2xml` utility command returns 0 if the transformation into XML output is successful and 1 if it is not successful. It is a batch operation and can also be used for automation.

See "["Troubleshooting"](#)" for details about capturing and evaluating the return code resulting from the execution of this utility command.

- [dtxany2xml syntax summary](#)
The `dtxany2xml` utility command produces a map that can transform any input data into XML output.
- [dtxany2xml command line help](#)
There is help that describes the `dtxany2xml` utility command usage in the command line.

- [dtxany2xml command usage](#)

Use the **dtxany2xml** command to produce a map that can transform any input data into XML output.

dtxany2xml syntax summary

The **dtxany2xml** utility command produces a map that can transform any input data into XML output.

It creates one map that can transform any input data into XML output, and a second map that can transform the XML that the first map produced into output data in a format described by the schema that you specified.

Use the second map only when the schema that you specified in the first parameter of the **dtxany2xml** utility command was imported from a COBOL copybook.

Use the following syntax for the **dtxany2xml** utility command:

```
dtxany2xml <.mtt file name/location>
    <exported root type path>
    <input file name/location>
    <output file name/location>
    <output map name>
    [<-schema <schema_file_name/location>]
    [<log file name/location>]
```

The **dtxany2xml** utility generates the default schema name *orig_schema_name_exported_type_name.xsd*. If a schema with that name already exists, the utility overwrites it.

You can use the **-schema** keyword to specify a unique name and path for the schema. The **-schema** keyword is optional and positional.

dtxany2xml command line help

There is help that describes the **dtxany2xml** utility command usage in the command line.

To view the command line help for the **dtxany2xml** utility command:

1. Enter **dtxany2xml** at the command line prompt of the installation directory. The syntax and command descriptions are displayed.

dtxany2xml command usage

Use the **dtxany2xml** command to produce a map that can transform any input data into XML output.

This procedure assumes that you know the schema and type name that models the XML output you want to produce. It also assumes that if you are using the second map, you know the format of the schema that was imported from a **COBOL** copybook.

1. Open a command prompt and change to the product installation directory.
2. Use the following command format. The names and paths of the schema file and the log file are optional. All other command elements are required.
`dtxany2xml <schema (.mtt) name and path> <root type path to export> <input file name and path> <new output file name (.xml) and path> <new map name> [<-schema <schema_file_name/location>][<log file name and path >]`

When the utility runs successfully, you can find the expected files in the directory that you selected. No "success" message is displayed. A log file is generated only when the process does not complete successfully.

- [Scenario: dtxany2xml usage](#)

The following example shows how you can use the **dtxany2xml** utility command:

Scenario: dtxany2xml usage

The following example shows how you can use the **dtxany2xml** utility command:

This exercise uses sample files that are shipped with the product.

To create a map that can transform any input data into XML output:

1. From a command prompt, change your directory location:
`cd c:/Program Files/IBM/WebSphere Transformation Extender 8.1/ examples/general/states`
2. Enter the following command:
`dtxany2xml states.mtt Data:Input:UnitedStates sts.txt xml_output.xml XML_map XML_log.log`

This command produces the following results:

- A new XML Schema – named using the schema name plus the selected type name (*states_UnitedStates.xsd*).
- A new map source file (*XML_map.mms*) that contains two maps:
 - first map (*XML_map*)
 - The input card references the original schema (*states.mtt*) and input file (*sts.txt*).
 - The output card references the newly created XML schema (*states_UnitedStates.mtt*).
 - The type is **Doc XSD**.
 - The output file is *xml_output.xml*.

- second map (XML_map_r)
 - The input card references the newly created XML schema (states_UnitedStates.mtt) and file (xml_output.xml).
 - The output card references the original schema (states.mtt).
 - The type is **Data Input UnitedStates**.
 - The output file is sts.txt.
- Use the second map only when the schema that you specified in the first parameter of the **dtxany2xml** utility command was imported from a **COBOL** copybook.

- The log file (XML_log.log) is created only when an error occurs.
3. Using Map Designer, open *install_dir\examples\general\states\ XML_map.mms*.
 4. Build and run XML_map.

The input (sts.txt) is converted to XML output (xml_output.xml). The input (xml_output.xml), which was created by the first map, is converted back to text output (sts.txt).

Utility command for map trace-file conversion

The **dtxmaptrace** utility converts a map trace file from binary format to text format.

Syntax summary

```
dtxmaptrace [[-summaryonly | -nosummary] -o output_file] [-toascii] binary_trace.mtr
```

You can display a summary of the converted trace messages on the computer screen, or save the full set of converted trace messages to a file, with or without the summary.

Table 1. Trace output options for the **dtxmaptrace** utility

Trace message format	Trace message destination	Summary keyword	Output file
Summary only	screen	null	null
Summary only	file	-summaryonly	-o output_file
All trace messages	screen	Not supported (with or without summary)	Not applicable
All trace messages without summary	file	-nosummary	-o output_file
All trace messages with summary	file	null	-o output_file

-summaryonly

Produces a concise summary of the trace messages in outline format. This keyword is optional. If you omit it, the output file includes all trace messages, preceded by the message summary.

-nosummary

Includes all trace messages in the output file. This keyword is optional. If you omit it, the output file includes all trace messages, preceded by the message summary.

-o *output_file*

The name of the converted trace file. The output file name must be different from the binary trace file name. This keyword is optional. If you omit it, the **dtxmaptrace** utility prints summary-only trace information to the computer screen.

-toascii

Use the **-toascii** option on a non-z/OS® system to convert a binary trace file that was created on a z/OS system. When the z/OS trace file is converted to text, the **-toascii** option changes the character encoding from EBCDIC to ASCII, so that the file is readable on the non-z/OS system.

binary_trace.mtr

The name of the input binary trace file to be converted. This keyword is required and positional. It must be the last option on the **dtxmaptrace** command.

Utility command for Resource Registry

The Resource Registry utility command updates resources and virtual servers in resource name (.mrn) files by using the command line.

The utility command for this application is:

- ResourceRegistryHelper.bat on Windows and
- ResourceRegistryHelper.sh on UNIX

Use the Resource Registry utility command to make the following updates to .mrn files:

- Add resources and virtual servers to .mrn files.
- Modify resources and virtual servers in .mrn files.
- Remove resources and virtual servers from .mrn files.

- [Resource Registry syntax summary](#)

This is the syntax that is used with the Resource Registry utility command.

- [Resource registry command usage](#)

These examples use the Resource Registry utility commands to add, remove, or change resources in a resource name (.mrn) file. The examples use ResourceRegistryHelper.bat for the Windows platform. For UNIX, use ResourceRegistryHelper.sh.

Resource Registry syntax summary

This is the syntax that is used with the Resource Registry utility command.

Use the ResourceRegistryHelper.bat utility command on Windows systems or the ResourceRegistryHelper.sh on UNIX systems to update resources and virtual servers in resource name (.mrn) files. The command returns 0 if the update is successful, and 1 if it is not successful. It is a batch operation that you can use for automation.

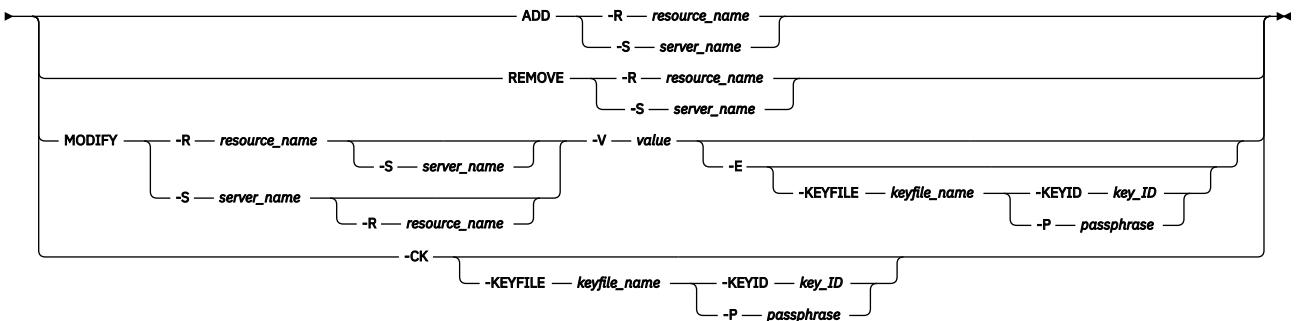

To display help for the command, enter `ResourceRegistryHelper.bat` at the command line prompt in the IBM Transformation Extender installation directory.

The options in the Resource Registry utility command are not case-sensitive.

```
resourceRegistryhelper.bat [path/file_name.mrn]
-A { ADD {-R resource_name | -S virtual_server_name}
| REMOVE {-R resource_name | -S virtual_server_name}
| MODIFY {-R resource_name | -S virtual_server_name | -R resource_name -S virtual_server_name}
-V value
[-E [-KEYFILE keyfile_path [-KEYID keyID | -P passphrase]]]
| -CK [-E [-KEYFILE keyfile_path [-KEYID keyID | -P passphrase]]]}
```

The command is shown in railroad track format below:

`>> resourceRegistryhelper.bat — path/file_name.mrn — -A —>`

Keyword

Description

- A The action (-A) option of the Resource Registry utility command indicates the action (MODIFY, ADD or REMOVE) to perform on a specified resource or virtual server in the resource name file (.mrn) file.
- ADD Adds a specified resource or virtual server to the resource name (.mrn) file.
- REMOVE Removes a specified resource or virtual server from the .mrn file.
- MODIFY Changes the value of a specified resource, virtual server, or both resource and virtual server in the .mrn file. The -V parameter is required with the MODIFY command.
 - If you specify only the resource name (-R), the command changes the value of that resource across all servers.
 - If you specify only the server name (-S), the command changes all of that server's resources to the new value.
 - If you specify both the resource name and the server name, the command changes the resource value only for the specified server.
- CK Changes the master key that encrypts the values in the specified .mrn file to a different master key. You can specify an existing master key by using the -KEYID option, or generate a new master key with a custom passphrase or a random passphrase.
- R *resource_name* Specifies the name of the resource that you want to add, remove, or change.
- S *virtual_server_name* Specifies the name of the virtual server that you want to add, remove, or change.
- V *value* Specifies the new value of the resource or virtual server that you are changing.
- E Encrypts the specified resource or virtual server value in the .mrn file. The -E option is valid only on the MODIFY command. When you omit the -E option, the resource or virtual server name is not encrypted. This is the default.
- KEYFILE *keyfile_path* Specifies the name and path of the master key (.mkf) file, relative to the .mrn file. The .mkf file stores Resource Registry encryption keys. -KEYFILE is optional. If you omit it, the command uses the default itx.mkf file in the .mrn file directory as the source of existing master keys or to store a new master key. To generate a new random master key, specify the -KEYFILE option without the -KEYID or the -P options.
- KEYID *key_ID* The numeric identifier of an existing key that the MODIFY command is to use to encrypt a resource value. The key identifier is optional. If you do not specify the -KEYID option or the -P option, the command generates a new encryption key with a random passphrase. You cannot regenerate a key that was created with a random passphrase.
- P *passphrase* A 32-byte passphrase that is to identify a new encryption key. Any character restrictions?The passphrase is optional. If you omit both the -KEYID option and the -P option, the command generates a new encryption key with a random passphrase. You cannot regenerate a key that was created with a random passphrase.

Resource registry command usage

These examples use the Resource Registry utility commands to add, remove, or change resources in a resource name (.mrn) file. The examples use `ResourceRegistryHelper.bat` for the Windows platform. For UNIX, use `ResourceRegistryHelper.sh`.

Modify examples

These examples modify a resource or virtual server in the modifyingresource.mrn file.

- Change the value of the **test** resource to *c:/server/location*:

```
install_dir\resourceregistryhelper.bat modifyingresource.mrn
-A modify
-R test
-V c:/server/location
```

- Encrypt the value of the **test** resource. Use encryption key 3257 located in the itx.mkf master key file in the .mrn directory:

```
install_dir\resourceregistryhelper.bat modifyingresource.mrn
-A modify
-R test
-E -KEYFILE itx.mkf -KEYID 3257
```

- Change the resource value of the **aix** virtual server to */server/location*. Remove the current encryption and re-encrypt the value with a new encryption key. The key is generated with a random passphrase and stored in the TempAIXServers.mkf master key file :

```
install_dir\resourceregistryhelper.bat modifyingresource.mrn
-A modify
-S aix
-V /server/location
-CK -KEYFILE TempAIXServers.mkf
```

Add examples

These examples add a resource or virtual server to the addingintoresource.mrn resource name file.

- Add the **test** resource to the .mrn file:

```
install_dir\resourceregistryhelper.bat addingintoresource.mrn
-A add
-R test
```

- Add the **aix** virtual server to the .mrn file:

```
install_dir\resourceregistryhelper.bat addingintoresource.mrn
-A add
-S aix
```

Remove examples

These examples remove a resource or virtual server from the removinginresource.mrn resource name file.

- Remove the **test** resource from the .mrn file:

```
install_dir\resourceregistryhelper.bat removinginresource.mrn
-A remove
-R test
```

- Remove the **aix** virtual server from the .mrn file:

```
install_dir\resourceregistryhelper.bat removinginresource.mrn
-A remove
-S aix
```

TX programming interface introduction

The TX programming interface includes language-specific methods and objects that provide common functionality across multiple environments.

TX programming interface overview

The TX programming interface is an object-oriented approach that enables applications to invoke IBM Transformation Extender maps, thus removing reliance on command lines.

For more information about the TX PI client interfaces, see the Javadocs by opening the package-summary.html file located in
install_dir\docs\dtxpi\java\com\ibm\websphere\dtx\dtxpi.

- [**TX programming interface methods**](#)

The TX programming interface map, card, and adapter object properties define the properties that can be set for each object. Use these methods to GET or SET the object properties.

- [**TX programming interface object overview**](#)

The TX programming interface is based on map, card, adapter, connection, and stream objects.

- [**TX programming interface function overview**](#)

Use the TX programming interface to load, run and control maps.

TX programming interface methods

The TX programming interface map, card, and adapter object properties define the properties that can be set for each object. Use these methods to GET or SET the object properties.

- [**GetAllPropertiesXML**](#)
Retrieves all object properties in XML document.
 - [**GetBinaryProperty**](#)
This method gets a pointer to the specified binary property of the object. The data is not copied by this method.
 - [**GetCountProperty**](#)
This method returns the number of defined property values.
 - [**GetIntegerProperty**](#)
This method gets the specified integral property of the object.
 - [**GetTextProperty**](#)
This method gets a pointer to the specified text property of the object. The data is not copied by this method.
 - [**GetPropertiesXML**](#)
Retrieves requested property values as an XML document. Properties are specified in the form of an XML document.
 - [**SetBinaryProperty**](#)
This method sets the specified binary property on the object.
 - [**SetIntegerProperty**](#)
This method sets the specified integral property on the object.
 - [**SetTextProperty**](#)
This method sets the specified text property on the object.
 - [**SetPropertiesXML**](#)
Sets properties specified in XML document. Properties are specified in the form of an XML document.
-

GetAllPropertiesXML

Retrieves all object properties in XML document.

Properties are specified in the form of an XML document.

The XML schema for this XML document is txpi_properties.xsd, located in the installation directory. Both the request document, which specifies which properties to return, and the returned document comply to this XML schema.

GetBinaryProperty

This method gets a pointer to the specified binary property of the object. The data is not copied by this method.

GetCountProperty

This method returns the number of defined property values.

This is the maximum index value for indexed properties. For most properties, this method will return a count of 1.

GetIntegerProperty

This method gets the specified integral property of the object.

GetTextProperty

This method gets a pointer to the specified text property of the object. The data is not copied by this method.

GetPropertiesXML

Retrieves requested property values as an XML document. Properties are specified in the form of an XML document.

The XML schema for this XML document is txpi_properties.xsd located in the installation directory. Both the request document, which specifies which properties to return, and the returned document comply to this XML schema.

SetBinaryProperty

This method sets the specified binary property on the object.

SetIntegerProperty

This method sets the specified integral property on the object.

SetTextProperty

This method sets the specified text property on the object.

SetPropertiesXML

Sets properties specified in XML document. Properties are specified in the form of an XML document.

The XML schema for this XML document is txpi_properties.xsd located in the installation directory.

TX programming interface object overview

The TX programming interface is based on map, card, adapter, connection, and stream objects.

Objects are used for source and target overrides for map execution.

- If no card overrides are required, only the map object is referenced. All other objects are created internally.
- If card overrides are required, the card and adapter objects are referenced.

Overrides are accomplished using the defined property interface.

Adapter objects interface with the adapter API. The TX programming interface is based on IBM Transformation Extender objects.

Object	Datatype	Object description
Map	HMPIMAP	An object that represents an instance of a map in the program memory. Methods allow the map properties to be modified and for the map to be executed and its execution controlled.
Card	HMPICARD	An object that represents an input or output card of a map in program memory. Defined methods allow the card properties to be modified.
Adapter	HMPIADAPT	An object that represents a resource adapter. Defined methods allow the adapter properties to be modified.
Connection	HMPICONNECT	An object that represents a connection to a resource. When a map executes, a Connection object is associated with one or more Adapter objects.
Stream	HMPISTREAM	An object that provides a means to pass data to, or get data from, a map. Stream objects eliminate the need for large, contiguous, memory buffers for passing data directly to a map object.

- [TX programming interface object hierarchy](#)

The TX programming interface objects have a relationship to each other defined by a specific hierarchy.

- [TX programming interface properties](#)

The TX programming interface methods provide a means to query or modify properties of objects.

- [TX programming interface map object](#)

The TX programming interface creates a map object instance from the byte array representing a compiled map file. The hierarchies of map, card and adapter objects are created by this method.

- [Card object overview](#)

The card object is an abstraction of a card in a map.

- [Adapter object overview](#)

An adapter object is created for each card when a map instance object is created.

TX programming interface object hierarchy

The TX programming interface objects have a relationship to each other defined by a specific hierarchy.

Under the map object is the card object and under the card object is the adapter object. Each card object always has an adapter object associated with it. A map object has a number of card objects. The number is dependent on the number of input and output cards in a map.

TX programming interface properties

The TX programming interface methods provide a means to query or modify properties of objects.

Each of these method calls has an index parameter, used in cases where there might be more than one instance of a property method (for example, multiple input card objects for a map).

For properties that are not indexed, the index should be specified as zero (0).

TX programming interface map object

The TX programming interface creates a map object instance from the byte array representing a compiled map file. The hierarchies of map, card and adapter objects are created by this method.

The map object is created when a map is loaded from a compiled map (.mmc) file or from memory. The TX programming interface caches maps. Therefore, if multiple map objects are created for the same map, the map file is read only once.

A map object is reentrant; that is, after a map object has been created, the map can be run an infinite number of times without any need for the map to be reloaded.

Multiple threads cannot reference the same map object concurrently; If multiple threads need to execute the same map concurrently, a separate map object should be obtained for each thread.

The identifier is used to identify the specific map. This might be the name of the map or any other identifier that the application will use. Subsequent calls to this method with the same identifier will not introduce additional processing of the compiled map. Therefore, after the initial call to this method, the memory consumed by compiledMap can be freed.

There are several properties and methods supported by the map object.

- [**Map object properties**](#)
Properties can be set and their values can be obtained by executing the methods defined by the map object.
- [**Map object methods**](#)
The map object methods are defined by the map object.

Map object properties

Properties can be set and their values can be obtained by executing the methods defined by the map object.

The map object supports several property types.

- [**General map properties**](#)
The general properties for map objects provide high-level information about the map object.
- [**Map trace properties**](#)
The trace properties for map objects allow you to set the trace settings for map execution.
- [**Map workspace properties**](#)
The workspace properties for map objects allow you to define the workspace settings for map execution.
- [**Map sliding century properties**](#)
Use the sliding century properties for map objects to define the sliding century settings for map execution.
- [**Map custom validation properties**](#)
Use the custom validation properties for map objects to define custom validation settings for map execution.
- [**Map audit properties**](#)
The audit properties for map objects allow you to set the audit settings for map execution.
- [**Map retry properties**](#)
The map retry properties for map objects allow you to define the map retry settings for map execution.

General map properties

The general properties for map objects provide high-level information about the map object.

- [**MPIP_MAP_DESTROY_OBJECT_POOL**](#)
If the value is set to TRUE, the objects related to the map instance will be destroyed after the map is executed.
- [**MPIP_MAP_INSTANCE**](#)
This is a unique instance number for the map object.
- [**MPIP_MAP_MAP_NAME**](#)
This is the fully qualified name of the map for the map object.
- [**MPIP_OBJECT_ERROR_CODE**](#)
The error code from the last operation on the map object.
- [**MPIP_OBJECT_ERROR_MSG**](#)
The error message from the last operation on the map object.

MPIP_MAP_DESTROY_OBJECT_POOL

If the value is set to TRUE, the objects related to the map instance will be destroyed after the map is executed.

The default value is FALSE.

Type	Values
Integer	MPI_TRUE MPI_FALSE

MPIP_MAP_INSTANCE

This is a unique instance number for the map object.

Type	Values
Integer	None

MPIP_MAP_MAP_NAME

This is the fully qualified name of the map for the map object.

Type	Values
Text	None

MPIP_OBJECT_ERROR_CODE

The error code from the last operation on the map object.

Type	Values
Integer	None

MPIP_OBJECT_ERROR_MSG

The error message from the last operation on the map object.

Type	Values
Text	None

Map trace properties

The trace properties for map objects allow you to set the trace settings for map execution.

- [**MPIP_MAP_TRACE_DIRECTORY**](#)
The directory for the trace file is either map or custom.
- [**MPIP_MAP_TRACE_DIRECTORY_CUSTOM_VALUE**](#)
This is the directory for the trace file if MPIP_MAP_TRACE_DIRECTORY is set to MPI_DIRECTORY_CUSTOM.
- [**MPIP_MAP_TRACE_FILENAME**](#)
The trace file name can be the default name (*mapname.mtr*), a custom name, or a unique, system-generated name (*prefix_mapname_processIDtime_number_hostname.mtr*), where *prefix* is Mer for executable maps or Run for run maps.
- [**MPIP_MAP_TRACE_FILENAME_CUSTOM_VALUE**](#)
This is the filename for the trace file if MPIP_MAP_TRACE_FILENAME is set to MPI_FILENAME_CUSTOM.
- [**MPIP_MAP_TRACE_FORMAT**](#)
This property creates the map trace file in text format (the default) or binary format.
- [**MPIP_MAP_TRACE_INPUT_CARD_END**](#)
This is the number of the last card to trace if MPIP_MAP_TRACE_INPUT_CONTENT is MPI_TRACE_RANGE.
- [**MPIP_MAP_TRACE_INPUT_CARD_NUMBER**](#)
This is the number of the card to trace if MPIP_MAP_TRACE_INPUT_CONTENT is MPI_TRACE_CARD.
- [**MPIP_MAP_TRACE_INPUT_CARD_START**](#)
This is the number of the first card to trace if MPIP_MAP_TRACE_INPUT_CONTENT is MPI_TRACE_RANGE.
- [**MPIP_MAP_TRACE_INPUT_CONTENT**](#)
This determines the scope of the input tracing.
- [**MPIP_MAP_TRACE_LOCATION**](#)
Create the trace information in a file or memory.
- [**MPIP_MAP_TRACE_RULES_CARD_NUMBER**](#)
This specifies the card number if MPIP_MAP_TRACE_RULES_CONTENT is set to MPI_TRACE_CARD.
- [**MPIP_MAP_TRACE_RULES_CONTENT**](#)
This turns the trace rules content on or off.
- [**MPIP_MAP_TRACE_SUMMARY_CONTENT**](#)
Controls whether the trace file contains a summary of the validation status of each input and the build status of each output.
- [**MPIP_MAP_TRACE_SWITCH**](#)
This is the master switch for map trace.

MPIP_MAP_TRACE_DIRECTORY

The directory for the trace file is either map or custom.

Type	Values
Integer	MPI_DIRECTORY_MAP MPI_DIRECTORY_CUSTOM

MPIP_MAP_TRACE_DIRECTORY_CUSTOM_VALUE

This is the directory for the trace file if MPIP_MAP_TRACE_DIRECTORY is set to MPI_DIRECTORY_CUSTOM.

Type	Values
Text	None

MPIP_MAP_TRACE_FILENAME

The trace file name can be the default name (*mapname.mtr*), a custom name, or a unique, system-generated name (*prefix_mapname_processIDtime_number_hostname.mtr*), where *prefix* is Mer for executable maps or Run for run maps.

Type	Values
Integer	<ul style="list-style-type: none">• MPI_FILENAME_DEFAULT• MPI_FILENAME_CUSTOM• MPI_FILENAME_UNIQUE

MPIP_MAP_TRACE_FILENAME_CUSTOM_VALUE

This is the filename for the trace file if MPIP_MAP_TRACE_FILENAME is set to MPI_FILENAME_CUSTOM.

Type	Values
Text	None

MPIP_MAP_TRACE_FORMAT

This property creates the map trace file in text format (the default) or binary format.

Type	Values
Integer	<ul style="list-style-type: none">• MPIP_MAP_TRACE_FORMAT_TEXT• MPIP_MAP_TRACE_FORMAT_BINARY

MPIP_MAP_TRACE_INPUT_CARD_END

This is the number of the last card to trace if MPIP_MAP_TRACE_INPUT_CONTENT is MPI_TRACE_RANGE.

Type	Values
Integer	2, ...

MPIP_MAP_TRACE_INPUT_CARD_NUMBER

This is the number of the card to trace if MPIP_MAP_TRACE_INPUT_CONTENT is MPI_TRACE_CARD.

Type	Values
Integer	1, ...

MPIP_MAP_TRACE_INPUT_CARD_START

This is the number of the first card to trace if MPIP_MAP_TRACE_INPUT_CONTENT is MPI_TRACE_RANGE.

Type	Values
Integer	1, ...

MPIP_MAP_TRACE_INPUT_CONTENT

This determines the scope of the input tracing.

Type	Values
Integer	MPI_TRACE_OFF
	MPI_TRACE_ALL
	MPI_TRACE_CARD
	MPI_TRACE_RANGE

MPIP_MAP_TRACE_LOCATION

Create the trace information in a file or memory.

Type	Values
Integer	MPI_LOCATION_FILE
	MPI_LOCATION_MEMORY

MPIP_MAP_TRACE_RULES_CARD_NUMBER

This specifies the card number if MPIP_MAP_TRACE_RULES_CONTENT is set to MPI_TRACE_CARD.

Type	Values
Integer	1, ...

MPIP_MAP_TRACE_RULES_CONTENT

This turns the trace rules content on or off.

Type	Values
Integer	MPI_TRACE_OFF
	MPI_TRACE_ALL
	MPI_TRACE_CARD
	MPI_TRACE_RANGE

MPIP_MAP_TRACE_SUMMARY_CONTENT

Controls whether the trace file contains a summary of the validation status of each input and the build status of each output.

Type	Values
Integer	<ul style="list-style-type: none">MPI_SWITCH_ONMPI_SWITCH_OFF

MPIP_MAP_TRACE_SWITCH

This is the master switch for map trace.

Turn trace on or off. When off, all other trace properties are ignored.

Type	Values
Integer	<ul style="list-style-type: none">MPI_SWITCH_ONMPI_SWITCH_OFF

Map workspace properties

The workspace properties for map objects allow you to define the workspace settings for map execution.

- MPIP_MAP_WORKSPACE_DIRECTORY**

The directory for the workspace file is either map or custom.

- MPIP_MAP_WORKSPACE_DIRECTORY_CUSTOM**

This is the directory for the workspace file if MPIP_MAP_WORKSPACE_DIRECTORY is set to MPI_DIRECTORY_CUSTOM.

- **MPIP_MAP_WORKSPACE_FILE_ACTION**
If MPIP_MAP_WORKSPACE_FILE_PREFIX is set to MPI_FILE_PREFIX_MAP, this determines whether workfiles can be reused.
 - **MPIP_MAP_WORKSPACE_FILE_PREFIX**
If MPIP_MAP_WORKSPACE_LOCATION is set to MPI_LOCATION_FILE, this property determines the prefix of the file.
 - **MPIP_MAP_WORKSPACE_LOCATION**
Create the workspace in files or memory.
 - **MPIP_MAP_WORKSPACE_PAGING_COUNT**
This is the number of workspace pages to create.
 - **MPIP_MAP_WORKSPACE_PAGING_SIZE**
This is the size of each workspace page.
-

MPIP_MAP_WORKSPACE_DIRECTORY

The directory for the workspace file is either map or custom.

Type	Values
Integer	MPI_DIRECTORY_MAP
	MPI_DIRECTORY_CUSTOM

MPIP_MAP_WORKSPACE_DIRECTORY_CUSTOM

This is the directory for the workspace file if MPIP_MAP_WORKSPACE_DIRECTORY is set to MPI_DIRECTORY_CUSTOM.

Type	Values
Text	None

MPIP_MAP_WORKSPACE_FILE_ACTION

If MPIP_MAP_WORKSPACE_FILE_PREFIX is set to MPI_FILE_PREFIX_MAP, this determines whether workfiles can be reused.

Type	Values
Integer	MPI_WORK_AREA_REUSE
	MPI_WORK_AREA_DONTREUSE

MPIP_MAP_WORKSPACE_FILE_PREFIX

If MPIP_MAP_WORKSPACE_LOCATION is set to MPI_LOCATION_FILE, this property determines the prefix of the file.

Type	Values
Integer	MPI_FILE_PREFIX_MAP
	MPI_FILE_PREFIX_UNIQUE

MPIP_MAP_WORKSPACE_LOCATION

Create the workspace in files or memory.

Type	Values
Integer	MPI_LOCATION_FILE
	MPI_LOCATION_MEMORY

MPIP_MAP_WORKSPACE_PAGING_COUNT

This is the number of workspace pages to create.

Type	Values
Integer	None

MPIP_MAP_WORKSPACE_PAGING_SIZE

This is the size of each workspace page.

Type	Values
Integer	None

Map sliding century properties

Use the sliding century properties for map objects to define the sliding century settings for map execution.

- [MPIP_MAP_SLIDING_CENTURY](#)
This is the master switch for sliding century properties.
- [MPIP_MAP_SLIDING_CENTURY_CCLOOKUP](#)
This is the base year that defines the beginning of the sliding century.

MPIP_MAP_SLIDING_CENTURY

This is the master switch for sliding century properties.

Turn sliding century on or off. When off, all other sliding century properties are ignored.

Type	Values
Integer	MPI_SWITCH_ON
Integer	MPI_SWITCH_OFF

MPIP_MAP_SLIDING_CENTURY_CCLOOKUP

This is the base year that defines the beginning of the sliding century.

Type	Values
Integer	None

Map custom validation properties

Use the custom validation properties for map objects to define custom validation settings for map execution.

- [MPIP_MAP_CUSTOM_VALIDATION](#)
This is the master switch for custom validation.
- [MPIP_MAP_CV_COMPONENT_RULE](#)
Ignore or raise a validation error if component rules are violated.
- [MPIP_MAP_CV_PRESENTATION_ERROR](#)
Ignore or raise a validation error if item presentations are violated.
- [MPIP_MAP_CV_RESTRICTION_ERROR](#)
Ignore or raise a validation error if restrictions are violated.
- [MPIP_MAP_CV_SIZE_ERROR](#)
Ignore or raise a validation error if item sizes are violated.
- [MPIP_MAP_CV_VALIDATION_ERROR](#)
Stop or continue mapping if a validation error occurs.

MPIP_MAP_CUSTOM_VALIDATION

This is the master switch for custom validation.

Turn custom validation on or off. When off, all other custom validation properties are ignored.

Type	Values
Integer	MPI_SWITCH_ON
Integer	MPI_SWITCH_OFF

MPIP_MAP_CV_COMPONENT_RULE

Ignore or raise a validation error if component rules are violated.

Type	Values
Integer	MPI_ACTION_IGNORE
Integer	MPI_ACTION_VALIDATE

MPIP_MAP_CV_PRESENTATION_ERROR

Ignore or raise a validation error if item presentations are violated.

Type	Values
Integer	MPI_ACTION_IGNORE MPI_ACTION_VALIDATE MPI_ACTION_IGNORE_NO_WARNINGS

MPIP_MAP_CV_RESTRICTION_ERROR

Ignore or raise a validation error if restrictions are violated.

Type	Values
Integer	MPI_ACTION_IGNORE MPI_ACTION_VALIDATE MPI_ACTION_IGNORE_NO_WARNINGS

MPIP_MAP_CV_SIZE_ERROR

Ignore or raise a validation error if item sizes are violated.

Type	Values
Integer	MPI_ACTION_IGNORE MPI_ACTION_VALIDATE MPI_ACTION_IGNORE_NO_WARNINGS

MPIP_MAP_CV_VALIDATION_ERROR

Stop or continue mapping if a validation error occurs.

Type	Values
Integer	MPI_ACTION_IGNORE MPI_ACTION_VALIDATE MPI_ACTION_IGNORE_NO_WARNINGS

Map audit properties

The audit properties for map objects allow you to set the audit settings for map execution.

- [MPIP_MAP_AUDIT_BURST_DATA](#)
Turn data audit on or off.
- [MPIP_MAP_AUDIT_BURST_DATA_SIZE_VALIDATION](#)
Specifies whether to use two separate audit log status codes or a single code to indicate a size error or warning for data items that fail the minimum/maximum criteria when the Validation > SizeError map setting is set to Ignore.
- [MPIP_MAP_AUDIT_BURST_EXECUTION](#)
Turn execution audit on or off.
- [MPIP_MAP_AUDIT_DIRECTORY](#)
The directory for the audit file is either map or custom.
- [MPIP_MAP_AUDIT_DIRECTORY_CUSTOM_VALUE](#)
This is the directory for the audit file if MPIP_MAP_AUDIT_DIRECTORY is set to MPI_DIRECTORY_CUSTOM.
- [MPIP_MAP_AUDIT_FILENAME](#)
The filename for the audit file is either the default or a custom name.
- [MPIP_MAP_AUDIT_FILENAME_ACTION](#)
The audit file can either be appended to or created anew.
- [MPIP_MAP_AUDIT_FILENAME_CUSTOM_VALUE](#)
This is the filename for the audit file if MPIP_MAP_AUDIT_FILENAME is set to MPI_FILENAME_CUSTOM.
- [MPIP_MAP_AUDIT_LOCATION](#)
Create the audit information in a file or in memory.
- [MPIP_MAP_AUDIT_MEMORY_SIZED](#)
If MPIP_MAP_AUDIT_LOCATION is set to MPI_LOCATION_MEMORY, this determines whether the memory should be sized.
- [MPIP_MAP_AUDIT_SETTINGS_DATA](#)
Turn data settings audit on or off.
- [MPIP_MAP_AUDIT_SETTINGS_MAP](#)
Turn map settings audit on or off.

- [**MPIP_MAP_AUDIT_SUMMARY_EXECUTION**](#)
Turn execution summary audit on or off for the map object.
 - [**MPIP_MAP_AUDIT_SWITCH**](#)
This is the master switch for map audit.
-

MPIP_MAP_AUDIT_BURST_DATA

Turn data audit on or off.

Type	Values
Integer	MPI_AUDIT_ALWAYS MPI_AUDIT_NEVER MPI_AUDIT_ONERROR MPI_AUDIT_ONWARNING_ERROR

MPIP_MAP_AUDIT_BURST_DATA_SIZE_VALIDATION

Specifies whether to use two separate audit log status codes or a single code to indicate a size error or warning for data items that fail the minimum/maximum criteria when the Validation > SizeError map setting is set to Ignore.

MPI_DATAAUDIT_WRONGSIZE specifies one code while MPI_DATAAUDIT_MINMAXERR specifies two separate codes.

Type	Values
Integer	MPI_DATAAUDIT_WRONGSIZE MPI_DATAAUDIT_MINMAXERR

MPIP_MAP_AUDIT_BURST_EXECUTION

Turn execution audit on or off.

Type	Values
Integer	MPI_AUDIT_ALWAYS MPI_AUDIT_NEVER MPI_AUDIT_ONERROR MPI_AUDIT_ONWARNING_ERROR

MPIP_MAP_AUDIT_DIRECTORY

The directory for the audit file is either map or custom.

Type	Values
Integer	MPI_DIRECTORY_MAP MPI_DIRECTORY_CUSTOM

MPIP_MAP_AUDIT_DIRECTORY_CUSTOM_VALUE

This is the directory for the audit file if MPIP_MAP_AUDIT_DIRECTORY is set to MPI_DIRECTORY_CUSTOM.

Type	Values
Integer	None

MPIP_MAP_AUDIT_FILENAME

The filename for the audit file is either the default or a custom name.

Type	Values
Integer	MPI_FILENAME_DEFAULT MPI_FILENAME_CUSTOM

MPIP_MAP_AUDIT_FILENAME_ACTION

The audit file can either be appended to or created anew.

Type	Values
Integer	MPI_FILE_CREATE MPI_FILE_APPEND

MPIP_MAP_AUDIT_FILENAME_CUSTOM_VALUE

This is the filename for the audit file if MPIP_MAP_AUDIT_FILENAME is set to MPI_FILENAME_CUSTOM.

Type	Values
Text	None

MPIP_MAP_AUDIT_LOCATION

Create the audit information in a file or in memory.

Type	Values
Integer	MPI_LOCATION_FILE MPI_LOCATION_MEMORY

MPIP_MAP_AUDIT_MEMORY_SIZED

If MPIP_MAP_AUDIT_LOCATION is set to MPI_LOCATION_MEMORY, this determines whether the memory should be sized.

Type	Values
Integer	MPI_TRUE MPI_FALSE

MPIP_MAP_AUDIT_SETTINGS_DATA

Turn data settings audit on or off.

Type	Values
Integer	MPI_SWITCH_ALWAYS MPI_SWITCH_NEVER MPI_SWITCH_ONERROR MPI_SWITCH_ONWARNING_ERROR

MPIP_MAP_AUDIT_SETTINGS_MAP

Turn map settings audit on or off.

Type	Values
Integer	MPI_SWITCH_ALWAYS MPI_SWITCH_NEVER MPI_SWITCH_ONERROR MPI_SWITCH_ONWARNING_ERROR

MPIP_MAP_AUDIT_SUMMARY_EXECUTION

Turn execution summary audit on or off for the map object.

Type	Values
Integer	MPI_SWITCH_ON MPI_SWITCH_OFF MPI_SWITCH_ONERROR MPI_SWITCH_ONWARNING_ERROR

MPIP_MAP_AUDIT_SWITCH

This is the master switch for map audit.

Turn audit on or off. When off, all other audit properties are ignored.

Type	Values
Integer	MPI_SWITCH_ON
	MPI_SWITCH_OFF
	MPI_SWITCH_ONERROR
	MPI_SWITCH_OWARNING_ERROR

Map retry properties

The map retry properties for map objects allow you to define the map retry settings for map execution.

- [**MPIP_MAP_MAP_RETRY**](#)
This is the master switch for map retry.
- [**MPIP_MAP_MAP_RETRY_ATTEMPTS**](#)
This is the maximum number of attempts to attempt to retry map execution.
- [**MPIP_MAP_MAP_RETRY_INTERVAL**](#)
This is the interval in seconds after which map retries are attempted.

MPIP_MAP_MAP_RETRY

This is the master switch for map retry.

Turn map retry on or off. When off, all other map retry properties are ignored.

Type	Values
Integer	MPI_SWITCH_ON
	MPI_SWITCH_OFF

MPIP_MAP_MAP_RETRY_ATTEMPTS

This is the maximum number of attempts to attempt to retry map execution.

Type	Values
Integer	None

MPIP_MAP_MAP_RETRY_INTERVAL

This is the interval in seconds after which map retries are attempted.

Type	Values
Integer	None

Map object methods

The map object methods are defined by the map object.

The map object provides several methods.

- [**MapGetInputCardNumber**](#)
This method returns the number of input cards.
- [**MapGetInputCardObject**](#)
This method returns the handle to the specified input card.
- [**MapGetOutputCardNumber**](#)
This method returns the number of output cards.
- [**MapGetOutputCardObject**](#)
This method returns the handle to the specified output card.

MapGetInputCardNumber

This method returns the number of input cards.

MapGetInputCardObject

This method returns the handle to the specified input card.

MapGetOutputCardNumber

This method returns the number of output cards.

MapGetOutputCardObject

This method returns the handle to the specified output card.

Card object overview

The card object is an abstraction of a card in a map.

A card object is created for each card when a map object is created. This object is a container for the card properties and associates a map and an adapter object with the card object.

- [Card object properties](#)
Properties can be set and their values can be obtained by executing the methods defined by the card object.
- [Card object methods](#)
The card object methods are defined by the card object.

Card object properties

Properties can be set and their values can be obtained by executing the methods defined by the card object.

The card object supports the General and Backup property types.

- [General card properties](#)
The general properties for card objects provide high-level information about the card object.
- [Backup card properties](#)
Use the backup properties for card objects to define the backup settings of the card for map execution.

General card properties

The general properties for card objects provide high-level information about the card object.

The MPIP_CARD_MODE and MPIP_CARD_REUSE_WORK_AREA properties apply to input cards only.

- [MPIP_CARD_DIRECTION](#)
Indicates whether the card is an input or output card.
- [MPIP_CARD_DOCUMENT_VERIFICATION](#)
Determines under what circumstances to call the external document verification program when an instance of an object with an XML type property is found.
- [MPIP_CARD_METADATA_LOCATION](#)
This is the location of the metadata (XML schema or DTD).
- [MPIP_CARD_MODE](#)
MPIP_CARD_MODE is the mode of the card (input card only).
- [MPIP_CARD_NAME](#)
The name of the card.
- [MPIP_CARD_NUMBER](#)
The number of the card.
- [MPIP_CARD_OBJECT_COUNT](#)
The number of objects found in validation (if an input card) or found in build (if an output card).
- [MPIP_CARD_REUSE_WORK_AREA](#)
Determines whether the work area for the card is reused (input card only).
- [MPIP_OBJECT_ERROR_CODE](#)
The error code from the last operation on the map object.
- [MPIP_OBJECT_ERROR_MSG](#)
The error message from the last operation on the map object.

MPIP_CARD_DIRECTION

Indicates whether the card is an input or output card.

Type	Values
Integer	MPI_CARD_INPUT
	MPI_CARD_OUTPUT

MPIP_CARD_DOCUMENT_VERIFICATION

Determines under what circumstances to call the external document verification program when an instance of an object with an XML type property is found.

Type	Values
Integer	MPI_VERIFY_NEVER
	MPI_VERIFY_ALWAYS
	MPI_VERIFY_ONFAILURE
	MPI_VERIFY_ONSUCCESS
	MPI_VERIFY_WELLFORMED

MPIP_CARD_METADATA_LOCATION

This is the location of the metadata (XML schema or DTD).

Use this card object property to override the metadata location specified on the map card settings at run time.

Type	Values
Text	user-defined

MPIP_CARD_MODE

MPIP_CARD_MODE is the mode of the card (input card only).

Type	Values
Integer	MPI_MODE_INTEGRAL
	MPI_MODE_BURST

MPIP_CARD_NAME

The name of the card.

Type	Values
Text	None

MPIP_CARD_NUMBER

The number of the card.

Type	Values
Integer	1, ...

MPIP_CARD_OBJECT_COUNT

The number of objects found in validation (if an input card) or found in build (if an output card).

Type	Values
Integer	None

MPIP_CARD_REUSE_WORK_AREA

Determines whether the work area for the card is reused (input card only).

Type	Values

Type	Values
Integer	MPI_TRUE MPI_FALSE

MPIP_OBJECT_ERROR_CODE

The error code from the last operation on the map object.

Type	Values
Integer	None

MPIP_OBJECT_ERROR_MSG

The error message from the last operation on the map object.

Type	Values
Text	None

Backup card properties

Use the backup properties for card objects to define the backup settings of the card for map execution.

- [**MPIP_CARD_BACKUP**](#)
This is the master switch for turning backup on or off.
- [**MPIP_CARD_BACKUP_ACTION**](#)
Determines whether to append to an existing file or to create a new file.
- [**MPIP_CARD_BACKUP_DIRECTORY**](#)
The directory in which the backup file is located.
- [**MPIP_CARD_BACKUP_DIRECTORY_CUSTOM_VALUE**](#)
The filename for the trace file if MPIP_CARD_BACKUP_DIRECTORY is set to MPI_DIRECTORY_CUSTOM.
- [**MPIP_CARD_BACKUP_FILENAME**](#)
The name of the backup file.
- [**MPIP_CARD_BACKUP_FILENAME_CUSTOM_VALUE**](#)
The filename for the trace file if MPIP_CARD_BACKUP_FILENAME is set to MPI_FILENAME_CUSTOM.
- [**MPIP_CARD_BACKUP_FILEPATH**](#)
The path of the backup file.
- [**MPIP_CARD_BACKUP_WHEN**](#)
Determines under what circumstances to create a backup file.

MPIP_CARD_BACKUP

This is the master switch for turning backup on or off.

Turn backup on or off. When off, all other backup properties are ignored.

Type	Values
Integer	MPI_SWITCH_ON MPI_SWITCH_OFF

MPIP_CARD_BACKUP_ACTION

Determines whether to append to an existing file or to create a new file.

Type	Values
Integer	MPI_ACTION_CREATE MPI_ACTION_APPEND

MPIP_CARD_BACKUP_DIRECTORY

The directory in which the backup file is located.

Type	Values
Integer	MPI_DIRECTORY_MAP MPI_DIRECTORY_CUSTOM

MPIP_CARD_BACKUP_DIRECTORY_CUSTOM_VALUE

The filename for the trace file if MPIP_CARD_BACKUP_DIRECTORY is set to MPI_DIRECTORY_CUSTOM.

Type	Values
Text	None

MPIP_CARD_BACKUP_FILENAME

The name of the backup file.

Type	Values
Integer	MPI_FILENAME_DEFAULT MPI_FILENAME_CUSTOM MPI_FILENAME_UNIQUE

MPIP_CARD_BACKUP_FILENAME_CUSTOM_VALUE

The filename for the trace file if MPIP_CARD_BACKUP_FILENAME is set to MPI_FILENAME_CUSTOM.

Type	Values
None	None

MPIP_CARD_BACKUP_FILEPATH

The path of the backup file.

Type	Values
Text	None

MPIP_CARD_BACKUP_WHEN

Determines under what circumstances to create a backup file.

Type	Values
Integer	MPI_WHEN_ALWAYS MPI_WHEN_ONERROR

Card object methods

The card object methods are defined by the card object.

The card object provides several methods.

- [**CardGetAdapterObject**](#)
This method returns the adapter object associated with the specified card object.
- [**CardGetAdapterType**](#)
This method returns the type of the adapter object that is currently associated with the specified card object.
- [**CardGetMapObject**](#)
This method returns the map object associated with the specified card object.
- [**CardOnNotify**](#)
This method can be called to provide a notification for adapters of key events.
- [**CardOverrideAdapter**](#)
This method can be called to associate a new adapter object with the card object. This is used whenever the type of the adapter needs to be changed programmatically from the type that is compiled into the map.

CardGetAdapterObject

This method returns the adapter object associated with the specified card object.

CardGetAdapterType

This method returns the type of the adapter object that is currently associated with the specified card object.

Adapter types are listed in the adapters.xml file. The type is the 'id' attribute of each adapter entry.

CardGetMapObject

This method returns the map object associated with the specified card object.

CardOnNotify

This method can be called to provide a notification for adapters of key events.

Value	Description
MPIN_ADAPTER_GETSTART	Prior to any get calls for the card
MPIN_ADAPTER_GETSTOP	After all get calls for the card
MPIN_ADAPTER_PUTSTART	Prior to any put calls for the card
MPIN_ADAPTER_PUTSTOP	After all put calls for the card
MPIN_ADAPTER_LISTENSTART	Prior to any listen calls for the card
MPIN_ADAPTER_LISTENSTOP	After all listen calls for the card
MPIN_ADAPTER_LISTENABORT	Called to abort a non-polling listener
MPIN_ADAPTER_MAPABORT	When a map is cancelled by user action
MPIN_OBJECT_PREPARE_DESTROY	Called prior to an object being destroyed

These entry points provide the opportunity for an adapter to initialize or clean up the GET, PUT or LISTEN methods.

For example, the adapter might need to query a queue to find out some properties about the queue. This would be done in the onNotify (*_START) call. If this was done with the GET, PUT, or LISTEN methods and they were called multiple times, unnecessary work would be performed repeatedly.

onNotify is called with *_START prior to any GET, PUT, or LISTEN method and is called with *_STOP after all GET, PUT, or LISTEN calls.

For example, if a map is executing multiple bursts and within each burst, GET is called multiple times to get multiple messages, there will be only one onNotify call with MPIN_GET_START, prior to the first get. Only after all bursts and all gets within a burst, will onNotify be called with MPIN_GET_STOP to allow the adapter to clean up.

If a user cancels a map execution, onNotify will be called with MPIN_ADAPTER_MAPABORT. The GET or PUT methods should be aborted by the adapter as soon as possible after the notification.

The MPIN_ADAPTER_LISTENABORT notification is delivered only to adapters that have defined listenerBlocks as TRUE. In this scenario, onNotify is called on a separate thread from the listen call. For all other notifications, the call is made on the connection thread. When an adapter receives this notification, it should abort the LISTEN method using whatever mechanism or API that is supported by the adapter.

CardOverrideAdapter

This method can be called to associate a new adapter object with the card object. This is used whenever the type of the adapter needs to be changed programmatically from the type that is compiled into the map.

The new type can be specified either by an alias string (for example, DATABASE or STREAM) or by using a numeric adapter type. If the alias is given as NULL, iAdapterType is assumed to be set to a valid adapter type.

The adapter types are listed in the adapters.xml file. The 'id' attribute of each adapter entry represents the adapter name. Additional types are listed in CardOverrideAdapter.

Adapter object overview

An adapter object is created for each card when a map instance object is created.

This adapter object is used for custom adapter implementations.

- [Adapter object properties](#)
Properties are defined for all adapter objects, though each adapter can also GET and SET its own adapter-specific properties (for example, QueueManagerName for MQSeries®).
- [Adapter object methods](#)
The adapter object methods are defined by the adapter object.

Adapter object properties

Properties are defined for all adapter objects, though each adapter can also GET and SET its own adapter-specific properties (for example, QueueManagerName for MQSeries®).

The adapter object supports several property types.

General, On Success, On Failure, Retry, Scope, and Warning properties apply to both source and target adapter objects.

Aggregation applies only to source adapter objects.

- [**General adapter properties**](#)

These properties provide high-level information about the adapter object.

- [**Adapter retry properties**](#)

Use the adapter retry properties for adapter objects to define the settings for the retry settings for map execution.

- [**Adapter on failure properties**](#)

Use the MPIP_ADAPTER_ON_FAILURE property for adapter objects to define the settings for the OnFailure transactional settings for map execution.

- [**Adapter on success properties**](#)

Use the MPIP_ADAPTER_ON_SUCCESS property for adapter objects to define the settings for the OnSuccess transactional settings for map execution.

- [**Adapter scope properties**](#)

Use the MPIP_ADAPTER_SCOPE property for adapter objects to define the settings for the scope of the transaction for map execution.

- [**Adapter warning properties**](#)

Use the MPIP_ADAPTER_WARNINGS property for adapter objects to define the settings for action on adapter warnings for map execution.

- [**Adapter aggregation properties**](#)

Use the aggregation properties for adapter objects to define the settings that determine the number of messages that are returned from an input adapter for map execution.

General adapter properties

These properties provide high-level information about the adapter object.

- [**MPIP_ADAPTER_ABBREV**](#)

The alias of the adapter.

- [**MPIP_ADAPTER_COMMANDLINE**](#)

The command line that determines the connection parameters and the behavior of the adapter associated with the adapter object.

- [**MPIP_ADAPTER_CONTEXT**](#)

The context in which the adapter is being called.

- [**MPIP_ADAPTER_MSG_COLLECTION**](#)

The message collection object that is used to pass event messages (MMessage objects) from a Listen call to the Launcher, and from the Launcher to a GET call.

- [**MPIP_ADAPTER_NUM_MESSAGES**](#)

This property MUST be set by an adapter before returning from a GET call. This informs the Resource Manager how many messages have been received and are being returned in the GET. This is used in association with the Quantity and Fetch Unit properties to determine whether the GET should be called again or not.

- [**MPIP_ADAPTER_PROVIDER_CODE**](#)

The return code from the resource to which the adapter communicates upon execution of the input or output adapter.

- [**MPIP_ADAPTER_PROVIDER_MSG**](#)

This is the return error message from the resource to which the adapter communicates upon execution of the input or output adapter.

- [**MPIP_ADAPTER_TYPE**](#)

The type of the adapter object.

- [**MPIP_ADAPTER_USER_DATA**](#)

This property is used to associate binary data with an adapter object and can be used for various purposes, such as to pass configuration data, specific environment settings, or possibly real time data.

- [**MPIP_ADAPTER_USESAMECONN**](#)

This property is set by an adapter in the Listen method to inform the Resource Manager that the same connection thread should be used in the subsequent corresponding GET call.

- [**MPIP_ADAPTER_WILDCARD**](#)

The value of a wildcard returned from an event.

- [**MPIP_OBJECT_ERROR_CODE**](#)

The error code from the last operation on the map object.

- [**MPIP_OBJECT_ERROR_MSG**](#)

The error message from the last operation on the map object.

MPIP_ADAPTER_ABBREV

The alias of the adapter.

Type	Values
Text	None

MPIP_ADAPTER_COMMANDLINE

The command line that determines the connection parameters and the behavior of the adapter associated with the adapter object.

Type	Values
Text	None

MPIP_ADAPTER_CONTEXT

The context in which the adapter is being called.

If not SOURCE, _SOURCE_EVENT, or _TARGET, there is no card object associated with the adapter object.

Type	Values
Integer	MPI_CONTEXT_SOURCE MPI_CONTEXT_SOURCE_EVENT MPI_CONTEXT_TARGET MPI_CONTEXT_GET MPI_CONTEXT_PUT MPI_CONTEXT_DBLOOKUP MPI_CONTEXT_DBQUERY

MPIP_ADAPTER_MSG_COLLECTION

The message collection object that is used to pass event messages (MMessage objects) from a Listen call to the Launcher, and from the Launcher to a GET call.

In a GET call, the adapter should consult the collection to see if it is being called in response to an event.

Type	Values
Object	None

MPIP_ADAPTER_NUM_MESSAGES

This property MUST be set by an adapter before returning from a GET call. This informs the Resource Manager how many messages have been received and are being returned in the GET. This is used in association with the Quantity and Fetch Unit properties to determine whether the GET should be called again or not.

If this property is set to 0, this informs the Resource Manager that there is no more data to fetch, and hence the GET function will not be called again.

Type	Values
Integer	None

MPIP_ADAPTER_PROVIDER_CODE

The return code from the resource to which the adapter communicates upon execution of the input or output adapter.

Whether this is set is determined by each individual adapter.

Type	Values
Integer	None

MPIP_ADAPTER_PROVIDER_MSG

This is the return error message from the resource to which the adapter communicates upon execution of the input or output adapter.

Whether this is set is determined by each individual adapter.

Type	Values
Text	None

MPIP_ADAPTER_TYPE

The type of the adapter object.

Type	Values
Integer	The id values from the adapters.xml file.

MPIP_ADAPTER_USER_DATA

This property is used to associate binary data with an adapter object and can be used for various purposes, such as to pass configuration data, specific environment settings, or possibly real time data.

Type	Values
Binary	None

For example, the adapter might receive a command line option that requires it to process a certain file. The contents of that file could be parsed during command line validation and placed in the adapter's MPIP_ADAPTER_USER_DATA setting. The data placed in the MPIP_ADAPTER_USER_DATA setting could then be subsequently referenced by the adapter after it is invoked to get or put data at map execution time. Another example is that the adapter might want to store certain runtime data there. While bursting or upon completion of the adapter's transaction scope, the data could be referenced for additional run time or logging purposes.

MPIP_ADAPTER_USESAMECONN

This property is set by an adapter in the Listen method to inform the Resource Manager that the same connection thread should be used in the subsequent corresponding GET call.

Type	Values
Integer	None

MPIP_ADAPTER_WILDCARD

The value of a wildcard returned from an event.

Type	Values
Text	None

MPIP_OBJECT_ERROR_CODE

The error code from the last operation on the map object.

Type	Values
Integer	None

MPIP_OBJECT_ERROR_MSG

The error message from the last operation on the map object.

Type	Values
Text	None

Adapter retry properties

Use the adapter retry properties for adapter objects to define the settings for the retry settings for map execution.

- [MPIP_ADAPTER_RETRY](#)
This is the master "switch" for all adapter retry properties.
- [MPIP_ADAPTER_RETRY_ATTEMPTS](#)
The maximum number of attempts to attempt to retry adapter execution.
- [MPIP_ADAPTER_RETRY_INTERVAL](#)
The interval, in seconds, after which adapter retries are attempted.

MPIP_ADAPTER_RETRY

This is the master "switch" for all adapter retry properties.

Turn adapter retry on or off. When off, all other adapter retry properties are ignored.

Type	Values
Integer	MPI_SWITCH_ON MPI_SWITCH_OFF

MPIP_ADAPTER_RETRY_ATTEMPTS

The maximum number of attempts to attempt to retry adapter execution.

Type	Values
Integer	None

MPIP_ADAPTER_RETRY_INTERVAL

The interval, in seconds, after which adapter retries are attempted.

Type	Values
Integer	None

Adapter on failure properties

Use the MPIP_ADAPTER_ON_FAILURE property for adapter objects to define the settings for the OnFailure transactional settings for map execution.

- [MPIP_ADAPTER_ON_FAILURE](#)

This is the action to take if the map is unsuccessful.

MPIP_ADAPTER_ON_FAILURE

This is the action to take if the map is unsuccessful.

Not all settings are applicable to all values of MPIP_ADAPTER_TYPE.

Type	Values
Integer	MPI_ACTION_COMMIT MPI_ACTION_ROLLBACK

Adapter on success properties

Use the MPIP_ADAPTER_ON_SUCCESS property for adapter objects to define the settings for the OnSuccess transactional settings for map execution.

- [MPIP_ADAPTER_ON_SUCCESS](#)

This is the action to take if the map is successful.

MPIP_ADAPTER_ON_SUCCESS

This is the action to take if the map is successful.

Not all settings are applicable to all values of MPIP_ADAPTER_TYPE.

Type	Values
Integer	For source adapter objects: MPI_ACTION_KEEP MPI_ACTION_KEEPONCONTENT MPI_ACTION_DELETE For target adapter objects: MPI_ACTION_CREATE MPI_ACTION_CREATEONCONTENT MPI_ACTION_DONT_CREATE MPI_ACTION_APPEND

Adapter scope properties

Use the MPIP_ADAPTER_SCOPE property for adapter objects to define the settings for the scope of the transaction for map execution.

- [MPIP_ADAPTER_SCOPE](#)

This is the scope of the adapter's transaction.

MPIP_ADAPTER_SCOPE

This is the scope of the adapter's transaction.

Type	Values
Integer	MPI_SCOPE_CARD
	MPI_SCOPE_BURST
	MPI_SCOPE_MAP

Adapter warning properties

Use the MPIP_ADAPTER_WARNINGS property for adapter objects to define the settings for action on adapter warnings for map execution.

- [MPIP_ADAPTER_WARNINGS](#)

If the adapter returns a warning, this determines whether the map should fail.

MPIP_ADAPTER_WARNINGS

If the adapter returns a warning, this determines whether the map should fail.

Type	Values
Integer	MPI_ACTION_IGNORE
	MPI_ACTION_FAIL

Adapter aggregation properties

Use the aggregation properties for adapter objects to define the settings that determine the number of messages that are returned from an input adapter for map execution.

These properties apply to source adapter objects only.

- [MPIP_ADAPTER_FETCH_UNIT](#)

The fetch unit for a single burst.

- [MPIP_ADAPTER_LISTEN_TIME](#)

The listen timeout (in seconds).

- [MPIP_ADAPTER_QUANTITY](#)

The quantity of messages to return for the map.

MPIP_ADAPTER_FETCH_UNIT

The fetch unit for a single burst.

Type	Values
Integer	MPI_NUMBER_SOME or a positive integer

MPIP_ADAPTER_LISTEN_TIME

The listen timeout (in seconds).

Type	Values
Integer	MPI_INFINITE or a positive integer

MPIP_ADAPTER_QUANTITY

The quantity of messages to return for the map.

Type	Values
Integer	MPI_NUMBER_SOME or a positive integer

Adapter object methods

The adapter object methods are defined by the adapter object.

The map object provides several methods.

The AdaptGetCardObject, AdaptGetInputStreamObject, and AdaptGetOutputStreamObject methods are applicable to all adapter objects.

- [**AdaptGetCardObject**](#)
Returns the card object associated with the adapter object.
 - [**AdaptGetInputStreamObject**](#)
Retrieves the input stream object.
 - [**AdaptGetOutputStreamObject**](#)
Retrieves the output stream object.
-

AdaptGetCardObject

Returns the card object associated with the adapter object.

AdaptGetInputStreamObject

Retrieves the input stream object.

AdaptGetOutputStreamObject

Retrieves the output stream object.

TX programming interface function overview

Use the TX programming interface to load, run and control maps.

This interface makes it possible for users to execute and control maps within their own programs. Benefits that this interface provides:

- Object-oriented interface
 - Ability to control when you want the TX programming interface to load the maps
 - Ability to track the progress of a map execution
 - Ability to override any properties of maps, cards, or adapter objects
 - Ability to control the execution of the map
- [**Scenario: running TX programming interface maps**](#)
Code examples of running maps are installed with the Development Kit in the *install_dir\examples\dk\dtxi* directory, where *install_dir* represents the directory in which the DK is installed.
- [**Monitor and manage map overview**](#)
These methods enable the execution of a map to be controlled from another thread, and for the progress of a map to be reported.
- [**Load and run map overview**](#)
Use the loading and running methods to load specific maps, refresh maps when the maps have changed, and run maps.
-

Scenario: running TX programming interface maps

Code examples of running maps are installed with the Development Kit in the *install_dir\examples\dk\dtxi* directory, where *install_dir* represents the directory in which the DK is installed.

Example files

These examples range from the simplest possible case to a more complicated scenario involving modification of map and adapter settings.

- example1.xxx: Running a single map
- example2.xxx: Running multiple instances of a map in parallel
- example3.xxx: Overriding a card in a map
- example4.xxx: Using a user-provided status method
- example5.xxx: Using streams to override inputs and outputs
- example6.xxx: Loading a map from a byte array
- example7.xxx: Getting and setting properties

These example files demonstrate many of the interfaces described in the documentation.

Note: The examples are available for each language for which the programming interface is available. Therefore, the filename extensions vary accordingly.

Monitor and manage map overview

These methods enable the execution of a map to be controlled from another thread, and for the progress of a map to be reported.

- **[Abort](#)**
This method aborts the map defined by the map object. The map must be in the running or paused state when this method is called.
 - **[Continue](#)**
This method continues the map defined by the map object.
 - **[Pause](#)**
This method pauses the map defined by the map object.
 - **[RegisterStatusMethod](#)**
This method allows for a user-provided status method to be registered for a particular map object.
-

Abort

This method aborts the map defined by the map object. The map must be in the running or paused state when this method is called.

This map does not destroy the map instance. Therefore, it is possible to run the map once more by calling Run. It is not possible to continue the execution of a map after Abort is called. Note that Abort must be called from a thread that is separate from the thread that is executing Run.

Continue

This method continues the map defined by the map object.

The map must be in a paused state when this method is called. If the map is not paused, the call will not change the state of the map instance. Note that Continue must be called from a thread that is separate from the thread that is executing Run.

Pause

This method pauses the map defined by the map object.

The map is paused indefinitely until Continue is executed. Note that Pause must be called from a thread that is separate from the thread that is executing Run.

RegisterStatusMethod

This method allows for a user-provided status method to be registered for a particular map object.

This status method will be invoked at critical points during the execution of the map.

If the status method returns MPI_STATE_ABORTED, execution of the map will stop immediately. After aborting a map, it is possible to start it again from the beginning using the Run method.

iNotifyWhen is a bitmask that governs when the status method will be called. It can be any combination of the values listed.

Value	Description
MPI_EVENT_START_MAP	Notify whenever a map is started.
MPI_EVENT_MAP_COMPLETE	Notify whenever a map completes.
MPI_EVENT_START_BURST	Notify whenever a burst is started.
MPI_EVENT_BURST_COMPLETE	Notify whenever a burst completes.
MPI_EVENT_START_INPUT	Notify whenever an input starts.
MPI_EVENT_INPUT_COMPLETE	Notify whenever an input completes.
MPI_EVENT_START_OUTPUT	Notify whenever an output starts.
MPI_EVENT_OUTPUT_COMPLETE	Notify whenever an output completes.
MPI_EVENT_CARD_EVENTS	Notify whenever any card is started or completes.
MPI_EVENT_BURST_EVENTS	Notify whenever a burst starts or completes.
MPI_EVENT_MAP_EVENTS	Notify whenever a map starts or completes.
MPI_EVENT_ALL_EVENTS	Notify all card, map, and burst events.

Load and run map overview

Use the loading and running methods to load specific maps, refresh maps when the maps have changed, and run maps.

- **[LoadFile](#)**
This method reads the compiled map file (.mmc) if it has not previously been read.
- **[LoadMemory](#)**
This method processes the map code (CompiledMap) if it has not been previously processed. LoadMemory then creates and populates the hierarchy of map, card, and adapter objects.
- **[Refresh](#)**
This method updates a map instance with a new map definition following an invocation of Reload.

- **[ReloadFile](#)**
This method instructs the engine to read the compile map file specified by MapName and to update its internal map cache.
 - **[ReloadMemory](#)**
This method instructs the TX programming interface to process the compiled map (CompiledMap) and to update its internal map cache.
 - **[Run](#)**
This method executes the map defined by the map object.
 - **[Unload](#)**
This method destroys the map object, and other card and adapter objects associated with it.
-

LoadFile

This method reads the compiled map file (.mmc) if it has not previously been read.

LoadFile then creates and populates the hierarchy of map, card, and adapter objects. If the map has already been read, and is stored in the map cache, a subsequent call to LoadFile creates another instance of the map.

LoadMemory

This method processes the map code (CompiledMap) if it has not been previously processed. LoadMemory then creates and populates the hierarchy of map, card, and adapter objects.

If the map has already been read, and is stored in the map cache, a subsequent call to LoadMemory creates another instance of the map. The Identifier is used to identify the specific map; this might be the name of the map or any other identifier that the application will use.

Subsequent calls to this method with the same identifier will not introduce additional processing of the compiled map. Therefore, after the initial call to LoadMemory, the memory consumed by CompiledMap can be freed.

Refresh

This method updates a map instance with a new map definition following an invocation of Reload.

If a compiled map changes during the execution of a process, the changed map will not be picked up by the TX programming interface unless an explicit call to Refresh is made.

It is recommended that you not add or remove cards while there are existing map objects referencing the map. This could lead to unpredictable behavior. If such changes are made, all map instances referencing the map must be terminated (by invoking Unload). If the only changes to maps are to the map rules, it is valid to call Reload and Refresh to pick up the changes to the map.

ReloadFile

This method instructs the engine to read the compile map file specified by MapName and to update its internal map cache.

If any map objects currently exist that refer to this map, they will continue to use the old map definition unless they execute the Refresh method. Any map, card, or adapter overrides are preserved.

If any map objects are created after this method has been invoked, they will always use the reloaded map, rather than any previous version of the map.

ReloadMemory

This method instructs the TX programming interface to process the compiled map (CompiledMap) and to update its internal map cache.

If any map objects currently exist that refer to this map, they will continue to use the old map definition unless they execute the Refresh method. Any map, card, or adapter overrides are preserved.

Run

This method executes the map defined by the map object.

It can be invoked any number of times in sequence. Note that to run multiple instances of the same map in parallel, you must load the map multiple times (by calling LoadFile or LoadMemory).

Unload

This method destroys the map object, and other card and adapter objects associated with it.

If there are no other map instances that have this map loaded, this call will flush the map from the map cache.

C API overview

The C API enables applications to invoke maps and to develop adapters to use with IBM Transformation Extender.

- [C API interface methods overview](#)

The map, card, and adapter object properties define the properties that can be set for each object. Use the C API interface methods to GET or SET the adapter object properties.

- [Loading, running, and controlling maps](#)

There are various methods you can use to load, run, and control maps when you use APIs with IBM Transformation Extender.

- [Custom adapters](#)

The custom adapters interface makes it possible for users to develop adapters with as much functionality as those provided with the product.

C API interface methods overview

The map, card, and adapter object properties define the properties that can be set for each object. Use the C API interface methods to GET or SET the adapter object properties.

- [mpiPropertyGetBinary](#)

The C API uses different interface methods, including [mpiPropertyGetBinary](#).

- [mpiPropertyGetCount](#)

The C API uses different interface methods, including [mpiPropertyGetCount](#).

- [mpiPropertyGetInteger](#)

The C API uses different interface methods, including [mpiPropertyGetInteger](#).

- [mpiPropertyGetPtr](#)

The C API uses different interface methods, including [mpiPropertyGetPtr](#).

- [mpiPropertyGetText](#)

The C API uses different interface methods, including [mpiPropertyGetText](#).

- [mpiPropertySetBinary](#)

The C API uses different interface methods, including [mpiPropertySetBinary](#).

- [mpiPropertySetInteger](#)

The C API uses different interface methods, including [mpiPropertySetInteger](#).

- [mpiPropertySetPtr](#)

The C API uses different interface methods, including [mpiPropertySetPtr](#).

- [mpiPropertySetText](#)

The C API uses different interface methods, including [mpiPropertySetText](#).

- [mpiPropertyGetAllPropertiesXML](#)

The C API uses different interface methods, including [mpiPropertyGetAllPropertiesXML](#).

- [mpiPropertyGetPropertiesXML](#)

The C API uses different interface methods, including [mpiPropertyGetPropertiesXML](#).

- [mpiPropertySetPropertiesXML](#)

The C API uses different interface methods, including [mpiPropertySetPropertiesXML](#).

mpiPropertyGetBinary

The C API uses different interface methods, including [mpiPropertyGetBinary](#).

```
MPIRC mpiPropertyGetBinary (HMPIOBJ hObject,MPIPROP iProperty,Void **ppData,size_t *pnSize)
```

Inputs

hObject

Handle of the IBM Transformation Extender object.

iProperty

Property ID

iIndex

Index of the property.

iValue

Integer value of the property.

Outputs

ppData

Pointer to the binary item.

pnSize

Size of the item.

Returns

Success status

mpiPropertyGetCount

The C API uses different interface methods, including **mpiPropertyGetCount**.

```
MPIRC mpiPropertyGetCount (HMPIOBJ hObject,MPIPROP iProperty,int *piCount)
```

Inputs

hObject
Handle of the IBM Transformation Extender object.
iProperty
Property ID

Outputs

piCount
Count of the property values.

Returns

Success status

mpiPropertyGetInteger

The C API uses different interface methods, including **mpiPropertyGetInteger**.

```
MPIRC mpiPropertyGetInteger (HMPIOBJ hObject,MPIPROP iProperty,int iIndex,int *pValue)
```

Inputs

hObject
Handle of the IBM Transformation Extender object.
iProperty
Property ID
iIndex
Index of the property.

Outputs

pValue
Integer value of the property.

Returns

Success status

mpiPropertyGetPtr

The C API uses different interface methods, including **mpiPropertyGetPtr**.

```
MPIRC mpiPropertyGetPtr (HMPIOBJ hObject,MPIPROP iProperty,int *iIndex,const void **ppValue)
```

Inputs

hObject
Handle of the IBM Transformation Extender object.
iProperty
Property ID
iIndex
Index of the property.
FALSE. Only the properties of the object are returned.

Outputs

ppValue
Pointer to the pointer value.

Returns

Success status

mpiPropertyGetText

The C API uses different interface methods, including **mpiPropertyGetText**.

```
MPIRC mpiPropertyGetText (HMPIOBJ hObject,MPIPROP iProperty,int iIndex,const char **ppText,size_t *pnLen)
```

Inputs

hObject
Handle of the IBM Transformation Extender object.
iProperty
Property ID
iIndex
Index of the property.

Outputs

ppText
Pointer to the pointer value.
pnLen
Length of the text item.

Returns

Success status.

Note: If pnLen is returned as 0, the string is null- terminated.

mpiPropertySetBinary

The C API uses different interface methods, including **mpiPropertySetBinary**.

```
MPIRC mpiPropertySetBinary (HMPIOBJ hObject,MPIPROP iProperty,int iIndex,const void *pData,size_t nSize)
```

Inputs

hObject
Handle of the IBM Transformation Extender object.
iProperty
Property ID
iIndex
Index of the property.
FALSE. Only the properties of the object are returned.

Outputs

pData
Pointer to the pointer value.
nSize
Size of the binary item.

Returns

Success status

Note: The data passed in pData is copied by this method.

mpiPropertySetInteger

The C API uses different interface methods, including **mpiPropertySetInteger**.

```
MPIRC mpiPropertySetInteger (HMPIOBJ hObject,MPIPROP iProperty,int iIndex,int iValue)
```

Inputs

hObject
Handle of the IBM Transformation Extender object.

iProperty
Property ID

iIndex
Index of the property.

iValue
Integer value of the property.

Outputs

None

Returns

Success status

mpiPropertySetPtr

The C API uses different interface methods, including **mpiPropertySetPtr**.

This method stores a pointer value as a property of the object. The data passed in pValue is not copied by this method. The application must ensure that this memory is not freed during the life of the object.

Additionally, the application must free up this memory when the object is destroyed. If the size of the data being pointed to must be stored, a separate integer property must be used.

```
MPIRC mpiPropertySetPtr (HMPIOBJ hObject,MPIPROP iProperty,int iIndex,const void *pValue)
```

Inputs

hObject
Handle of the IBM Transformation Extender object.

iProperty
Property ID

iIndex
Index of the property.

pValue
Pointer value.

Outputs

None

Returns

Success status.

mpiPropertySetText

The C API uses different interface methods, including **mpiPropertySetText**.

```
MPIRC mpiPropertySetText (HMPIOBJ hObject,MPIPROP iProperty,int iIndex,const char *pText,size_t nLen)
```

Inputs

hObject
Object handle.

iProperty
Property ID

iIndex
Property index

Outputs

pText
Pointer to the pointer value.
nLen
Length of the text item.

Returns

Success status

If the length is specified as 0, the string passed in pText is assumed to be null-terminated. The data passed in pText is copied by this method.

mpiPropertyGetAllPropertiesXML

The C API uses different interface methods, including **mpiPropertyGetAllPropertiesXML**.

```
MPIRC mpiPropertyGetAllPropertiesXML (HMPIOBJ hObject, char *pszOutXML, size_t *pnLen, int bRecurse)
```

Inputs

hObject
Object for which the properties are being requested.
pnLen
Size of the buffer passed in pszOutXML.
bRecurse
TRUE. Properties of related objects will also be returned. Specifically:

- If it is a card object, then the properties of the card and the related adapter object are returned.
- If it is a map object, then the properties of the map, all of its associated card objects, and the related adapter objects are returned.

FALSE. Only the properties of the object are returned.

Outputs

pszOutXML
Returned XML document conforming to dtxi_properties.xsd, which contains the values of the requested properties.
pnLen
Size of the XML document returned.

Returns

Success status

mpiPropertyGetPropertiesXML

The C API uses different interface methods, including **mpiPropertyGetPropertiesXML**.

```
MPIRC mpiPropertyGetPropertiesXML (HMPIOBJ hObject, int pIDs[], int iOffset, int iCount, char *pszOutXML, size_t *pnLen);
```

Inputs

hObject
Object for which the properties are being requested.
pIDs
Integer array which lists the property IDs that are to be returned. For indexed type properties all index values are returned.
iOffset
Start offset in the array of property IDs.
iCount
Number of elements of the property ID array to use.
pnLen
Size of the buffer passed in pszOutXML.

Outputs

pszOutXML
Returned XML document conforming to dtxi_properties.xsd, which contains the values of the requested properties.
pnLen
Size of the XML document returned.

Returns

Success status

mpiPropertySetPropertiesXML

The C API uses different interface methods, including **mpiPropertySetPropertiesXML**.

```
MPIIRC mpiPropertySetPropertiesXML (HMPIOBJ hObject, const char *pszInXML)
```

Inputs

hObject

Object for which the properties are set.

pszInXML

XML document conforming to dtxp1_properties.xsd which lists the properties that are to be set. It is possible to set properties on an object and on its related objects in a single call. Specifically,

- If called on a adapter object, only adapter properties can be set.
- If called on an card object, then the properties of the card and its related adapter object can be set
- If called on an map object, then the properties of the map and its related card and adapter objects can be set.

Outputs

None

Returns

Success status.

C API map object methods overview

The following methods are supported by the C API map object.

- [mpiMapGetInputCardNumber](#)
The C API uses different map object methods, including **mpiMapGetInputCardNumber**.
- [mpiMapGetOutputCardNumber](#)
The C API uses different map object methods, including **mpiMapGetOutputCardNumber**.
- [mpiMapGetInputCardObject](#)
The C API uses different map object methods, including **mpiMapGetInputCardObject**.
- [mpiMapGetOutputCardObject](#)
The C API uses different map object methods, including **mpiMapGetOutputCardObject**.
- [mpiMapGetUniqueMapInstance](#)
The C API uses different map object methods, including **mpiMapGetUniqueMapInstance**.

mpiMapGetInputCardNumber

The C API uses different map object methods, including **mpiMapGetInputCardNumber**.

```
MPIIRC mpiMapGetInputCardNumber (HMPIMAP hMap, int *piCount)
```

Inputs

hMap

Map object

Outputs

piCount

Address of an integer variable to receive the card count.

Returns

Success status

mpiMapGetOutputCardNumber

The C API uses different map object methods, including **mpiMapGetOutputCardNumber**.

```
MPIRC mpiMapGetInputCardObject (HMPIMAP hMap,int iCard,HMPICARD *hCard)
```

Inputs

hMap
Map object

Outputs

piCount
Address of an integer variable to receive the card count.

Returns

Success status

mpiMapGetInputCardObject

The C API uses different map object methods, including **mpiMapGetInputCardObject**.

```
MPIRC mpiMapGetInputCardObject (HMPIMAP hMap,int iCard,HMPICARD *hCard)
```

Inputs

hMap
Map object
iCard
Number of the input card (starting at 1).

Outputs

hCard
Card object

Returns

Success status

mpiMapGetOutputCardObject

The C API uses different map object methods, including **mpiMapGetOutputCardObject**.

```
MPIRC mpiMapGetOutputCardObject (HMPIMAP hMap,int iCard,HMPICARD *hCard)
```

Inputs

hMap
Map object
iCard
Number of the input card (starting at 1).

Outputs

hCard
Card object

Returns

Success status

mpiMapGetUniqueMapInstance

The C API uses different map object methods, including **mpiMapGetUniqueMapInstance**.

If the map instance is not set before you run the map, IBM Transformation Extender automatically assigns a unique integer as the map instance number. However, if an API user uses IBM Transformation Extender Object Pools, the unique map instance must be assigned through the API code. This method obtains the unique map instance value and sets the MPIP_MAP_INSTANCE property with this unique value.

To call this method in C++:

```
int mpiMapGetUniqueMapInstance()
```

To call this method in Java:

```
int MMap.getUniqueMapInstance()
```

Inputs

None.

Outputs

Unique Map Instance Number

Integer representing the unique instance number of the map. This method does not assign the integer number but rather returns it. The map instance number is assigned by setting the IBM Transformation Extender map integer property MPIP_MAP_INSTANCE to the value returned by this call.

Returns

Unique integer that represents the map instance.

C API card object methods overview

The following methods are supported by the C API card object.

- [mpiCardGetAdapterObject](#)
The C API uses different card object methods, including **mpiCardGetAdapterObject**.
- [mpiCardGetAdapterType](#)
The C API uses different card object methods, including **mpiCardGetAdapterType**.
- [mpiCardGetMapObject](#)
The C API uses different card object methods, including **mpiCardGetMapObject**.
- [mpiCardOverrideAdapter](#)
The C API uses different card object methods, including **mpiCardOverrideAdapter**.

mpiCardGetAdapterObject

The C API uses different card object methods, including **mpiCardGetAdapterObject**.

```
MPIIRC mpiCardGetAdapterObject (HMPICARD hCard, HMPIADAPT *hAdapter)
```

Inputs

hCard
Card object

Outputs

hAdapter
Adapter object

Returns

Success status

mpiCardGetAdapterType

The C API uses different card object methods, including **mpiCardGetAdapterType**.

```
MPIIRC mpiCardGetAdapterType (HMPICARD hCard, int *piAdapterType)
```

Inputs

hCard
Card object

Outputs

piAdapterType
Type of adapter.

Returns

Success status

Some types are not listed in this file. These are listed below, along with their reserved values:

Type	Value
Buffer	4
Stream	31

mpiCardGetMapObject

The C API uses different card object methods, including **mpiCardGetMapObject**.

```
MPIIRC mpiCardGetMapObject (HMPICARD hCard, HMPIMAP *hMap)
```

Inputs

hCard
Card object

Outputs

hmap
Map object

Returns

Success status

mpiCardOverrideAdapter

The C API uses different card object methods, including **mpiCardOverrideAdapter**.

```
MPIIRC mpiCardOverrideAdapter (HMPICARD hCard, int iAdapterType, char *pszAlias)
```

Inputs

hCard
Card object

Outputs

iAdapterType
Numeric type of the adapter.
pszAlias
Alias name for the adapter.

Returns

Success status

Adapter object methods

The following methods are supported by the adapter objects.

- [mpiAdaptGetCardObject](#)
The C API uses different adapter object methods, including **mpiAdaptGetCardObject**.
- [mpiAdaptGetInputStreamObject](#)
The C API uses different adapter object methods, including **mpiAdaptGetInputStreamObject**.
- [mpiAdaptGetOutputStreamObject](#)
The C API uses different adapter object methods, including **mpiAdaptGetOutputStreamObject**.

mpiAdaptGetCardObject

The C API uses different adapter object methods, including **mpiAdaptGetCardObject**.

```
MPIRC mpiAdaptGetCardObject (HMPIADAPT hAdapter,HMPICARD *hCard)
```

Inputs

hAdapter
Adapter object

Outputs

hCard
Card object

Returns

Success status

mpiAdaptGetInputStreamObject

The C API uses different adapter object methods, including **mpiAdaptGetInputStreamObject**.

```
MPIRC mpiAdaptGetInputStreamObject (HMPIADAPT hAdapter,HMPISTREAM *phStream)
```

Inputs

hAdapter
Adapter object

Outputs

phStream
Stream object

Returns

Success status

mpiAdaptGetOutputStreamObject

The C API uses different adapter object methods, including **mpiAdaptGetOutputStreamObject**.

```
MPIRC mpiAdaptGetOutputStreamObject (HMPIADAPT hAdapter,HMPISTREAM *phStream)
```

Inputs

hAdapter
Adapter object

Outputs

phStream
Stream object

Returns

Success status

Loading, running, and controlling maps

There are various methods you can use to load, run, and control maps when you use APIs with IBM Transformation Extender.

- [Loading and running maps](#)
Use the following methods to load specific maps, refresh maps when the maps have changed, and run maps.
- [Controlling and monitoring maps](#)
These methods allow map execution to be controlled from another thread and to report map progress.
- [Initialization and termination methods](#)
The following methods initialize the environment required for running maps and clean up the environment after the map run is complete.
- [Callbacks](#)
An API application uses callback to receive logging messages on a per-map basis or for global logging based on WebSphere Transformation Extender initialization.
- [C API examples](#)
The examples included with the C API are located in the following directory: *install_dir\examples\dk\dtspi\c*

Loading and running maps

Use the following methods to load specific maps, refresh maps when the maps have changed, and run maps.

- [mpiMapLoadFile](#)
The C API uses different methods to load, run, and control maps, including **mpiMapLoadFile**.
- [mpiMapLoadMemory](#)
The C API uses different methods to load, run, and control maps, including **mpiMapLoadMemory**.
- [mpiMapRefresh](#)
The C API uses different methods to load, run, and control maps, including **mpiMapLoadRefresh**.
- [mpiMapReloadFile](#)
The C API uses different methods to load, run, and control maps, including **mpiMapReloadFile**.
- [mpiMapReloadMemory](#)
The C API uses different methods to load, run, and control maps, including **mpiMapReloadMemory**.
- [mpiMapRun](#)
The C API uses different methods to load, run, and control maps, including **mpiMapRun**.
- [mpiMapUnload](#)
The C API uses different methods to load, run, and control maps, including **mpiMapUnload**.

mpiMapLoadFile

The C API uses different methods to load, run, and control maps, including **mpiMapLoadFile**.

```
MPIIRC mpiMapLoadFile (HMPIMAP *hMap,const char *lpszMapName)
```

Inputs

lpszMapName
Name of the compiled map file (.mmc).

Outputs

hMap
Map object

Returns

Success status

mpiMapLoadMemory

The C API uses different methods to load, run, and control maps, including **mpiMapLoadMemory**.

```
MPIIRC mpiMapLoadMemory (HMPIMAP *hMap,const char *lpszIdentifier,const char *lpszWorkingDirectory,const char *pcCompiledMap,int iSize)
```

Inputs

lpszIdentifier
Text string used to identify the compiled map. The string cannot exceed 32 characters.
lpszWorkingDirectory
Directory that should be used as the working directory for the map.
pcCompiledMap
Bytes that comprise a compiled map.
iSize
Number of bytes pointed to pcCompiledMap.

Outputs

hMap
Map object

Returns

Success status

```
HMPIMAP hMap1;
HMPIMAP hMap2;
char *pMapData =
MY_COMPILED_MAP_BYTES;
int iSize =
sizeof(MY_COMPILED_MAP_BYTES);
mpiMapLoadMemory (&hMap1, "MyMap", pMapData, iSize);
mpiMapLoadMemory (&hMap2, "MyMap", NULL, 0);
```

mpiMapRefresh

The C API uses different methods to load, run, and control maps, including **mpiMapLoadRefresh**.

```
MPIRC mpiMapRefresh (HMPIMAP hMap)
```

Inputs

hMap
Map object

Outputs

None

Returns

Success status

mpiMapReloadFile

The C API uses different methods to load, run, and control maps, including **mpiMapReloadFile**.

```
MPIRC mpiMapReloadFile (const char *lpszMapName)
```

Inputs

lpszMapName
Name of the compiled map file (.mmc).

Outputs

None

Returns

Success status

The following code demonstrates the usage of mpiMapReloadFile:

```
HMPIMAP hMap1;
HMPIMAP hMap2;
mpiMapLoadFile (&hMap1, "fred.mmc");
mpiMapLoadFile (&hMap2, "fred.mmc");
mpiMapRun (&hMap1);
mpiMapRun (&hMap2);
/* Now the program detects that the map file fred.mmc has changed */
mpiMapReloadFile ("fred.mmc");
/* hMap1 will pick up the updates and run with the 'new' map */
mpiMapRefresh (hMap1);
mpiMapRun (&hMap1);
/* HMAP2 did not refresh will run with the 'old' map */
mpiMapRun (&hMap2);
```

mpiMapReloadMemory

The C API uses different methods to load, run, and control maps, including **mpiMapReloadMemory**.

```
MPIIRC mpiMapReloadMemory (const char *lpszIdentifier, const char *WorkingDirectory, const char *pcCompiledMap, int iSize)
```

Inputs

lpszIdentifier
Text string used to identify the compiled map.
WorkingDirectory
Directory from which relative paths are determined.
pcCompiledMap
Bytes that comprise a compiled map.
iSize
Number of bytes pointed to pcCompiledMap.

Outputs

None

Returns

Success status

mpiMapRun

The C API uses different methods to load, run, and control maps, including **mpiMapRun**.

```
MPIIRC mpiMapRun (HMPIMAP hMap)
```

Inputs

hMap
Map object

Outputs

None

Returns

Success status

mpiMapUnload

The C API uses different methods to load, run, and control maps, including **mpiMapUnload**.

```
MPIIRC mpiMapUnload (HMPIMAP *hMap)
```

Inputs

hMap
Map object

Outputs

None

Returns

Success status

Controlling and monitoring maps

These methods allow map execution to be controlled from another thread and to report map progress.

- [**mpiMapAbort**](#)
The C API uses different methods to control and monitor maps, including **mpiMapAbort**.
- [**mpiMapContinue**](#)
The C API uses different methods to control and monitor maps, including **mpiMapContinue**.
- [**mpiMapPause**](#)
The C API uses different methods to control and monitor maps, including **mpiMapPause**.
- [**mpiMapRegisterStatusMethod**](#)
The C API uses different methods to control and monitor maps, including **mpiMapRegisterStatusMethod**.

mpiMapAbort

The C API uses different methods to control and monitor maps, including **mpiMapAbort**.

```
MPIRC mpiMapAbort (HMPIMAP hMap)
```

Inputs

hMap
Map object

Outputs

None

Returns

Success status

mpiMapContinue

The C API uses different methods to control and monitor maps, including **mpiMapContinue**.

```
MPIRC mpiMapContinue (HMPIMAP hMap)
```

Inputs

hMap
Map object

Outputs

None

Returns

Success status

mpiMapPause

The C API uses different methods to control and monitor maps, including **mpiMapPause**.

```
MPIRC mpiMapPause (HMPIMAP hMap)
```

Inputs

hMap
Map object

Outputs

None

Returns

Success status

mpiMapRegisterStatusMethod

The C API uses different methods to control and monitor maps, including **mpiMapRegisterStatusMethod**.

```
MPIRC mpiMapRegisterStatusMethod  
(HMPIMAP hMap MPICTRLMTD lpfnControl, int iNotifyWhen)
```

Inputs

hMap
 Map object
lpfnControl
 Address of the user-provided status method
iNotifyWhen
 Bitmask indicating the events of which the registrar wished to be notified

Outputs

None

Returns

Success status

Initialization and termination methods

The following methods initialize the environment required for running maps and clean up the environment after the map run is complete.

- [mpiInitAPI](#)
The C API uses different methods to initialize and terminate map execution, including **mpiInitAPI**.
- [mpiInitAPIex](#)
The C API uses different methods to initialize and terminate map execution, including **mpiInitAPIex**.
- [mpiTermAPI](#)
The C API uses different methods to initialize and terminate map execution, including **mpiTermAPI**.

mpiInitAPI

The C API uses different methods to initialize and terminate map execution, including **mpiInitAPI**.

This method initializes the IBM Transformation Extender environment. It should be called prior to any other call and only once per process. The lpszConfigFile can be passed in as NULL as long as name resolution is not required.

```
MPIRC mpiInitAPI (char *lpszConfigFile)
```

Inputs

lpszConfigFile
 Name of the configuration file used to determine the resource files used.

Outputs

None

Returns

Success status

Related reference

- [mpiInitAPIex](#)

mpiInitAPIex

The C API uses different methods to initialize and terminate map execution, including **mpiInitAPIex**.

This method initializes the WebSphere Transformation Extender environment. Call this method only once per process, before any other call. Both the Resource Registry configuration (.mrc) file and a log function callback can be passed to the **mpiInitAPIex** method.

```
MPIIRC mpiInitAPIex(const char *lpszResourceConfigFile, MPI_LOGFNCALLBACK logFnCB);
```

Related reference

- [mpiInitAPI](#)

mpiTermAPI

The C API uses different methods to initialize and terminate map execution, including [mpiTermAPI](#).

This method cleans up the IBM Transformation Extender environment. This method can be called after any other call, but only called one time for each process.

```
MPIIRC mpiTermAPI (void)
```

Inputs

None

Outputs

None

Returns

Success status

Callbacks

An API application uses callback to receive logging messages on a per-map basis or for global logging based on WebSphere Transformation Extender initialization.

- [MPI_TRACE_CALLBACK_PROC](#)
An API application can use **MPI_TRACE_CALLBACK_PROC** to receive logging messages such as I/O operations and Resource Manager operations on a per-map instance basis.
- [MPI_LOGFNCALLBACK](#)
An API application can use **MPI_LOGFNCALLBACK** as a global process API callback. **MPI_LOGFNCALLBACK** is registered during the Transformation Extender API initialization, and includes Connection Manager and Resource Registry logging. An API application can use both **MPI_TRACE_CALLBACK_PROC** and **MPI_LOGFNCALLBACK** in order to log WebSphere Transformation Extender I/O, Resource Manager, Connection Manager operations and Resource Registry messages to a central logging facility.

MPI_TRACE_CALLBACK_PROC

An API application can use **MPI_TRACE_CALLBACK_PROC** to receive logging messages such as I/O operations and Resource Manager operations on a per-map instance basis.

Related reference

- [MPI_LOGFNCALLBACK](#)
- [mpiInitAPI](#)
- [mpiInitAPIex](#)

MPI_LOGFNCALLBACK

An API application can use **MPI_LOGFNCALLBACK** as a global process API callback. **MPI_LOGFNCALLBACK** is registered during the Transformation Extender API initialization, and includes Connection Manager and Resource Registry logging. An API application can use both **MPI_TRACE_CALLBACK_PROC** and **MPI_LOGFNCALLBACK** in order to log WebSphere Transformation Extender I/O, Resource Manager, Connection Manager operations and Resource Registry messages to a central logging facility.

C API examples

The examples included with the C API are located in the following directory: *install_dir\examples\dk\dtspi\c*

- [Running a single map](#)

This example shows the simplest way to load and run a map. After the map is loaded, it can be run any number of times.

- [Running multiple instances of a map in parallel](#)

This example shows how to create multiple instances of map objects and how to run these map instances in parallel.

- [Overriding a card in a map](#)

This example shows how to set properties of card objects to override the settings of the compiled map.

- [Using a user-provided status method](#)

This example shows how to provide a status method to the C API and how to receive notification of the progress of a map execution.

- [Using streams to override inputs and outputs](#)

This example shows how to pass data to an input card of a map and how to get data from an output card of a map (the sending of a single buffer to the API).

- [Loading a map from a byte array](#)

This example shows how to load a map from a byte array.

- [Getting and setting properties](#)

This example shows how to GET and SET properties.

- [Developing a custom adapter](#)

To develop a custom adapter, please see the **filesamp.c** example, which demonstrates all of the interfaces that are described in this documentation. The example is well-commented and should be consulted to aid in the understanding of the adapter interface.

Running a single map

This example shows the simplest way to load and run a map. After the map is loaded, it can be run any number of times.

```
#include "dtspi.h"
#define CHECK_ERR(rc) if(MPIRC_FAILED(rc)) { printf("Last error is: %s\n",mpiErrorGetText(rc)); return -1; }

int main()
{
const char      *szMsg;
int             iRC;
MPIRC          rc;
HMPIMAP        hMap;

rc = mpiInitAPI(NULL);
CHECK_ERR(rc);

rc = mpiMapLoadFile (&hMap, "test1.mmc");
CHECK_ERR(rc);

rc = mpiMapRun (hMap);
CHECK_ERR(rc);

rc = mpiPropertyGetText (hMap, MPIP_OBJECT_ERROR_MSG, 0, &szMsg, NULL);
CHECK_ERR(rc);

rc = mpiPropertyGetInteger (hMap, MPIP_OBJECT_ERROR_CODE, 0, &iRC);
CHECK_ERR(rc);
printf("Map status: %s (%d)\n", szMsg, iRC);

rc = mpiMapUnload (hMap);
CHECK_ERR(rc);

rc = mpiTermAPI();
CHECK_ERR(rc);
return 0;
}
```

Running multiple instances of a map in parallel

This example shows how to create multiple instances of map objects and how to run these map instances in parallel.

```
#include "dtspi.h"

Overriding a card in a map

This example shows how to set properties of card objects to override the settings of the compiled map.

Note: This example is written to be used with the GZIP adapter ,which is not available on all platforms. If necessary, override the GZIP adapter type in this example with a substitute adapter to correctly run the example.

```
#include "dtxpi.h"

#define CHECK_ERR(rc) if(MPIRC_FAILED(rc))  
{ printf("Last error is: %s\n",mpiErrorGetText(rc));  
return -1;}

int main()  
{  
const char    *szMsg;

```

Using streams to override inputs and outputs

This example shows how to pass data to an input card of a map and how to get data from an output card of a map (the sending of a single buffer to the API).

If the data is received in a number of smaller pieces, it is acceptable, and indeed efficient, to write the data to the stream in small pieces.

```

#include "dtxpi.h"

#define CHECK_ERR(rc) if(MPIRC_FAILED(rc)) \
{ printf("Last error is: %s\n",mpiErrorGetText(rc)); return -1; }

int main()
{
const char      *szMsg;
char szInputBuffer[] = "This is my input data";
int             iRC;
int             bIsEnd;

Developing a custom adapter

To develop a custom adapter, please see the **filesamp.c** example, which demonstrates all of the interfaces that are described in this documentation. The example is well-commented and should be consulted to aid in the understanding of the adapter interface.

Custom adapters

The custom adapters interface makes it possible for users to develop adapters with as much functionality as those provided with the product.

- [Developing custom adapters](#)

The custom adapters interface makes it possible for users to develop adapters with as much functionality as those provided with the product.

- [Adapter registration and the library virtual table](#)

The first step required to develop an adapter is to add the adapter to the adapters.xml registration file.

- [Initializing the adapter](#)

InitializeLibrary provides an entry point by which any global structures, critical sections, or lists that are required by the adapter can be initialized.

- [Point to adapter methods](#)

After your adapter is loaded, you call the virtual table (vtable) structure to obtain pointers to the methods.

- [Adapter registration file](#)

The adapters.xml registration file contains a single tag for each adapter, including a number of attributes to provide information about the adapter.

- [Additional adapter methods](#)

There are a number of additional methods that are part of the Transformation Extender Programming Interface library that are of particular relevance to adapter developers.

- [Passing data to and from maps](#)

Data is passed between adapters and the engine through stream objects. From the adapter perspective, there is no need to create these stream objects; they are already created when either the Get or Put method is called.

- [Listener scenario overview](#)

These are listener scenario examples that demonstrate the flow of calls for input events.

- [Threads, connections, and transactions overview](#)

It is important to understand how threads, connections, and transactions interact.

Developing custom adapters

The custom adapters interface makes it possible for users to develop adapters with as much functionality as those provided with the product.

The C API provides:

- The ability to integrate adapters into IBM Transformation Extender products using the XML registration file.
- The ability to participate in connection pooling.
- The ability to provide an event listener.
- An object-oriented interface.

Adapter information originates in the adapters.xml registration file and the vtable adapter library.

Adapter registration and the library virtual table

The first step required to develop an adapter is to add the adapter to the adapters.xml registration file.

The following line is an example of how to add an adapter to the adapters.xml file:

```
<UserAdapter name="File Sample" alias="SFILE"
id="home_markdown_jenkins_workspace_Transform_in_SSVSD8_11.0.1_com.ibm.websphere.dtx.capi.doc_creating_and_initializing_object_201" type="file"
library="filesamp" vendor="abc"/>
```

This contains one key field: the name of the library (library="filesamp"). Note that name must not contain a .DLL, .SO, .SL, or any other library extension.

The adapter must export the library virtual table, which must be given the same name as the library, with _config appended. For example, filesamp_config.

The library virtual table contains a number of pointers to methods and configuration information for the adapter. Its structure is:

```
struct MPI_LIBRARY_VTABLE
{
    size_t nSize; /* size of this structure */
    MPIRC (*pfInitializeLibrary)(void);
    MPIRC (*pfDestroyLibrary)(void);
    MPIRC (*pfCreateAdapterInstance)(HMPPIADAPT *phAdapter, HMPICARD hCard);
    MPIRC (*pfDestroyAdapterInstance)(HMPPIADAPT hAdapter);
    MPIRC (*pfCreateConnectionInstance)(HMPICONNECT *phConnection);
    MPIRC (*pfDestroyConnectionInstance)(HMPICONNECT hConnection);
    MPIRC (*pfCombinedListen)(HMPPIADAPTCOLL hColl, HMPICONNECT hConn);

    char lpszCommandMask; /* Mask of command line arguments defining connection */
}
int nTransMode; /* single, multiple or non-transactional */
```

```

int nBurstType;      /* Unit of work - message or logical */
int bListener;       /* Does the adapter support listener interface */
int bListenerBlocks; /* Does the listener block */
int bListenerTrans;  /* Is the listener transactional? */
int bRetries;        /* Does the adapter support retries */

/* Source settings */
int bSourceManage;   /* Should RM manage the source? */
int bSourceWarnings; /* Does the adapter return warnings on sources? */
int nSourceScopes;   /* Which adapter Scope settings are supported for source?
*/
int nSourceOnSuccess; /* Which OnSuccess settings are supported for source?
*/
int nSourceOnFailure; /* Which OnFailure settings are supported for source?
*/
int nDefSourceScope;  /* Default Scope setting for source */
int nDefSourceOnSuccess; /* Default OnSuccess setting for source */
int nDefSourceOnFailure; /* Default OnFailure setting for source */

/* Target settings */
int bTargetManage;   /* Should RM manage the target? */
int bTargetWarnings; /* Does the adapter return warnings on targets? */
int nTargetScopes;   /* Which adapter scope settings are supported for target?
*/
int nTargetOnSuccess; /* Which OnSuccess settings are supported for target?
*/
int nTargetOnFailure; /* Which OnFailure settings are supported for target?
*/
int nDefTargetScope;  /* Default Scope setting for target */
int nDefTargetOnSuccess; /* Default OnSuccess setting for target */
int nDefTargetOnFailure; /* Default OnFailure setting for target */
};

typedef struct MPI_LIBRARY_VTABLE MPI_LIBRARY_VTABLE;

```

Initializing the adapter

InitializeLibrary provides an entry point by which any global structures, critical sections, or lists that are required by the adapter can be initialized.

After the adapter has been loaded, the InitializeLibrary method is called. This method provides an entry point whereby any global structures, critical sections, lists, and so on required by the adapter can be initialized.

The DestroyLibrary method should be provided to clean up these same data structures.

- [InitializeLibrary](#)

The InitializeLibrary method initializes any memory, data structures, or critical sections that are required by the adapter.

- [DestroyLibrary](#)

The DestoyLibrary method frees any memory, data structures, critical sections and other resources allocated by the adapter (typically those created by the InitializeLibrary method). It is called only once after any other adapter method invocations.

InitializeLibrary

The InitializeLibrary method initializes any memory, data structures, or critical sections that are required by the adapter.

This method is called only once before any other adapter method invocations other than those contained within the property interface at design time. It is not called at design time.

MPIRC InitializeLibrary (void)

Inputs

None

Outputs

None

Returns

Success status

DestroyLibrary

The DestoyLibrary method frees any memory, data structures, critical sections and other resources allocated by the adapter (typically those created by the InitializeLibrary method). It is called only once after any other adapter method invocations.

This method is not called at design time.

```
MPIRC_DestroyLibrary (void)
```

Inputs

None

Outputs

None

Returns

Success status

Point to adapter methods

After your adapter is loaded, you call the virtual table (vtable) structure to obtain pointers to the methods.

Tip: These method names are used in the context of this documentation. However, they are user-definable and can be changed.

Adapter registration file

The **adapters.xml** registration file contains a single tag for each adapter, including a number of attributes to provide information about the adapter.

```
<UserAdapter name="File Sample" alias="SFILE"
id="_home_markdown_jenkins_workspace_Transform_in_SSVSD8_11.0.1_com.ibm.websphere.dtx.capi.doc_adapter_registration_file_201"
type="file"
library="filesamp" vendor="abc"/>
```

Attribute	Description
name	Name of the adapter used in the adapter list in the Map Designer and Information Flow Designer (for example, Database or MQSeries® (server)).
alias	Abbreviated name of the adapter that is used in GET and PUT functions as well as command line overrides (for example, DB for database or MQS for MQSeries).
id	Identification type of the adapter. For adapters developed by IBM®, these numbers are between 0 and 200. For external, user-developed adapters, the id numbers should be >= 200.
type	Class type of the adapter. For example, database (db) or messaging (msg).
library	Name of the DLL or shared library. The DLL/SO/SL file extension should not be provided. In addition, for UNIX adapters, the name should not be prefixed with lib. This will be added when accessing the adapter.
vendor	Name of the adapter manufacturer. The vendor name is displayed along with the adapter name in the Map Designer.

Adapters.xml example

```
<Adapters>
  <M4Adapters>
    <M4Adapter name="File" alias="FILE"
id="_home_markdown_jenkins_workspace_Transform_in_SSVSD8_11.0.1_com.ibm.websphere.dtx.capi.doc_adapter_registration_file_0"
type="file"
library="m4file"/>
    <M4Adapter name="Buffer" alias="BUF"
id="_home_markdown_jenkins_workspace_Transform_in_SSVSD8_11.0.1_com.ibm.websphere.dtx.capi.doc_adapter_registration_file_4"
type="buff" />
    <M4Adapter name="Database" alias="DB"
id="_home_markdown_jenkins_workspace_Transform_in_SSVSD8_11.0.1_com.ibm.websphere.dtx.capi.doc_adapter_registration_file_5"
type="db"
library="dbutil"/>
    <M4Adapter name="Application" alias="APP"
id="_home_markdown_jenkins_workspace_Transform_in_SSVSD8_11.0.1_com.ibm.websphere.dtx.capi.doc_adapter_registration_file_6"
type="app" />
  </M4Adapters>
  <UserAdapters>
    <UserAdapter name="File Sample" alias="SFILE"
id="_home_markdown_jenkins_workspace_Transform_in_SSVSD8_11.0.1_com.ibm.websphere.dtx.capi.doc_adapter_registration_file_201"
type="file"
library="filesamp" vendor="abc"/>
  </UserAdapters>
</Adapters>
```

Virtual table adapter library

The virtual table (vtable) adapter library contains configuration information about the adapter, including the names of functions, transactional capabilities, and so on. This vtable is exported from the DLL/shared library of each adapter.

Virtual table library values

The virtual table (vtable) adapter library contains configuration information about the adapter, including the names of functions, transactional capabilities, and so on. This vtable is exported from the DLL/shared library of each adapter.

Field	Permitted Values and Description
nSize	=sizeof (MPI_LIBRARY_VTABLE) Ensures that the correct structure definition is being used.
nTransMode	MPI_TRANSACTIONS_SINGLE One transaction per connection. MPI_TRANSACTIONS_MULTIPLE Multiple transactions per connection. MPI_TRANSACTIONS_NONE The adapter does not support transactions.
nBurstType	TRUE The adapter supports the listener interface. FALSE The adapter does not support the Listener interface
bListenerBlocks	TRUE The LISTEN function of the adapter blocks indefinitely and requires an external abort to request termination. FALSE The LISTEN function of the adapter does not block.
bListenerTrans	TRUE The listener is transactional and requires a BeginTransaction call. FALSE The listener is not transactional.
bRetries	TRUE The adapter supports retries. FALSE The adapter does not support retries.
bSourceWarningS	TRUE The adapter can return warning codes from a source. FALSE The adapter does not return warning codes from a source.
nSourceScopes	MPI_SCOPE_MAP MPI_SCOPE_BURST MPI_SCOPE_CARD Values can be ORed together to provide a list of Scope settings that are permissible for a source.
nSourceOnSuccess	MPI_ACTION_COMMIT MPI_ACTION_ROLLBACK Values can be ORed together to provide a list of OnFailure settings that are permissible for a source.
nSourceOnFailure	MPI_ACTION_COMMIT MPI_ACTION_ROLLBACK Values can be ORed together to provide a list of OnFailure settings that are permissible for a source.
nDefSourceScope	Default value for Scope.
nDefSourceOnSuccess	Default value for OnSuccess.
nDefSourceOnFailure	TRUE The Resource Manager should manage targets to ensure there is no conflict. FALSE The Resource Manager should not manage targets.
bTargetWarnings	TRUE The adapter can return warning codes from a target. FALSE The adapter does not return warning codes from a target.
nTargetScopes	MPI_SCOPE_MAP MPI_SCOPE_BURST MPI_SCOPE_CARD Values can be ORed together to provide a list of Scope settings that are permissible for a target.
nTargetOnSuccess	MPI_ACTION_CREATE MPI_ACTION_CREATEONCONTENT MPI_ACTION_DONT_CREATE MPI_ACTION_APPEND (file only) MPI_ACTION_UPDATE (file only) Values can be ORed together to provide a list of OnSuccess settings that are permissible for a target.
nTargetOnFailure	MPI_ACTION_COMMIT MPI_ACTION_ROLLBACK Values can be ORed together to provide a list of OnFailure settings that are permissible for a target.
nDefTargetScope	Default value for Scope.
nDefTargetOnSuccess	Default value for OnSuccess.
nDefTargetOnFailure	Default value for OnFailure.

Virtual table example structure

The virtual table (vtable) adapter library contains configuration information about the adapter, including the names of functions, transactional capabilities, and so on. This vtable is exported from the DLL/shared library of each adapter. This is an example of the vtable structure.

```
EXPORT MPI_LIBRARY_VTABLE M4MQS_config =
{
sizeof(MPI_LIBRARY_VTABLE),
InitializeLibrary, /* InitializeLibrary */
DestroyLibrary, /* Destroy Library */
CreateAdapterInstance, /* CreateAdapterInstance */
DestroyAdapterInstance, /* DestroyAdapterInstance */
CreateConnectionInstance, /* CreateConnectionInstance */
DestroyConnectionInstance L, /* DestroyConnectionInstance */
NULL, /* CombinedListen */
"-QN % -MID %" /* Command line mask */
MPI_TRANSACTIONS_SINGLE, /* Transactional mode */
MPI_UNIOTOFWORK_MESSAGE, /* Unit of work */
TRUE, /* Listener interface supported */
FALSE, /* Listener does not block */
FALSE, /* Listener is not transactional */
TRUE, /* Retries */

/** Source Settings ***/
FALSE, /* Resource manage source */
TRUE, /* Warnings */
MPI_SCOPE_MAP | MPI_SCOPE_BURST | MPI_SCOPE_CARD, /* Source scopes */
MPI_ACTION_KEEPONCONTENT | MPI_ACTION_KEEP |
MPI_ACTION_DELETE, /* Source OnSuccess*/
MPI_ACTION_ROLLBACK | MPI_ACTION_COMMIT, /* Source OnFailure */
MPI_SCOPE_MAP, /* Default scope */

MPI_ACTION_ROLLBACK /* Default OnFailure */
};

```

Methods provided by an adapter

Various methods must be provided by an adapter.

The following types of methods must be provided by an adapter. Some of these methods are mandatory, while others are optional.

- Library initialization and termination methods
- Adapter instance creation and destruction
- Connection instance creation and destruction
- Source/target interface
- Property interface
- Connection interface
- Listener interface

To see if the adapter method is required or optional, see the following table.

Method	Required (Yes/No)
InitializeLibrary	N
DestroyLibrary	N
CreateAdapterInstance	Y
DestroyAdapterInstance	Y
CreateConnectionInstance	Y
DestroyConnectionInstance	Y
CombinedListen	N ³
Connect	Y
Disconnect	Y
Get	N ¹
Put	N ¹
OnNotify	N ¹
BeginTransaction	N ²
EndTransaction	N ²
Listen	N ³
ValidateProperties	Y
CompareConnection	Y
ValidateConnection	N
CompareWatches	N ^{3,4}

^{1,2,3,4}

¹ Some adapters do not support both Source and Target interfaces, and therefore might only provide a Get or Put method.

² This method is not required if the resource is non-transactional.

³ This method is required for only those adapters that support the Listen interface.

⁴ CompareWatches is required only if CombinedListen is provided by the adapter. If Listen is provided, CompareWatches is not needed.

Adapter methods used post-instance creation

After you create an instance of the adapter and connection objects, the map can use these objects to get data, put data, or to listen for events. The adapter virtual table, MPI_ADAPTER_VTABLE, points to a number of methods that are provided by the adapter.

The methods in the following table can be used after instances of the adapter and connection objects have been created.

Method	Description
BeginTransaction	Start a transaction
EndTransaction	End a transaction
Get	Get data for a source resource
Put	Send data to a target resource
Listen	Listen for an event
ValidateProperties	Check the validity of the adapter's properties
CompareConnection	Determine whether an existing connection can be reused
ValidateConnection	Ensure an existing connection is still alive
CompareWatches	Determine whether two watches are equivalent
OnNotify	This is called to notify the adapter of key events

There is an additional method, CombinedListen, that works with collections of adapters and is not, therefore, a method of the adapter object.

Adapter instance overview

When a map executes, there are a number of objects created (for example, map and card). Each card has an associated adapter instance. The adapter instance contains a number of properties that determine the behavior of the adapter. The number and type of these properties are defined through the mpiObjectNewPropColl method.

When an instance of your adapter is required, the CreateAdapterInstance method is called. This method must call the mpiAdapterCreate method to create the physical object and associate the adapter virtual table with the object. The adapter virtual table has the following structure:

```
struct MPI_ADAPTER_VTABLE
{
    size_t nSize; /* size of this structure */
    MPIIRC (*pfCompareWatches) (HMPIDADAPT hAdapter1, HMPIDADAPT hAdapter2,
                                MPICOMP *peComp);
    MPIIRC (*pfCompareResources) (HMPIDADAPT hAdapter1, HMPIDADAPT hAdapter2,
                                  MPICOMP *peComp);
    MPIIRC (*pfGet) (HMPIDADAPT hAdapter, HMPICONNECT hConnection);
    MPIIRC (*pfPut) (HMPIDADAPT hAdapter, HMPICONNECT hConnection);
    MPIIRC (*pfBeginTransaction) (HMPIDADAPT hAdapter, HMPICONNECT hConnection);
    MPIIRC (*pfEndTransaction) (HMPIDADAPT hAdapter, HMPICONNECT hConnection,
                               MPITRANS eAction);
    MPIIRC (*pfListen) (HMPIDADAPT hAdapter, HMPICONNECT hConnection);
    MPIIRC (*pfValidateProperties) (HMPIDADAPT hAdapter);
    MPIIRC (*pfValidateConnection) (HMPIDADAPT hAdapter, HMPICONNECT hConnection);
    MPIIRC (*pfCompareConnection) (HMPIDADAPT hAdapter, HMPICONNECT hConnection,
                                  MPICOMP *peComp);
    MPIIRC (*pfOnNotify) (HMPIOBJ hObject, int iId, int iParam, HMPIOBJ hParam);
};

typedef struct MPI_ADAPTER_VTABLE MPI_ADAPTER_VTABLE;
```

CreateAdapterInstance example

```
MPI_ADAPTER_VTABLE AdapterTable = { /* Initialize */ };
/* Define the adapter properties */
enum
{
    MYP_USERNAME = MPI_PROPBASE_USER,
    MYP_PASSWORD,
    MYP_SERVER
};

const static int AdapterProperties[] =
{
    MPI_PROP_TYPE_TEXT, /* MYP_USERNAME */
    MPI_PROP_TYPE_TEXT, /* MYP_PASSWORD */
    MPI_PROP_TYPE_TEXT /* MYP_SERVER */
};
#define NUM_ADAPTER_PROPERTIES (sizeof(AdapterProperties)/sizeof(int))

MPIIRC CreateAdapterInstance (HMPIDADAPT *phAdapter, HMPICARD hCard)
{
    MPIIRC rc;

    rc = mpiAdapterCreate(phAdapter, hCard, &AdapterTable);

    if (rc == MPI_SUCCESS)
    {
        /* Define the number and type of adapter properties */
        rc = mpiObjectNewPropColl(*phAdapter,
                                 MPI_PROPBASE_USER,
                                 NUM_ADAPTER_PROPERTIES,
                                 AdapterProperties);

        /* Do any initialization of instance of adapter object */
    }
    return rc;
}
```

DestroyAdapterInstance example

The DestroyAdapterInstance method should do the reverse, that is, it should delete the adapter object and free up any data structures that were created by the create method. The following code example deletes an object.

```
MPIIRC DestroyAdapterInstance (HMPIDADAPT hAdapter)
{
    /* Free up any memory or data structures use by the adapter instance */
    return (mpiObjectDestroy(hAdapter));
}
```

- [Adapter instance creation and destruction](#)

The following methods are called to create an instance of an adapter object, and to destroy this object.

Adapter instance creation and destruction

- [CreateAdapterInstance](#)
This CreateAdapterInstance method creates an adapter object and initializes it.
- [DestroyAdapterInstance](#)
The DestroyAdapterInstance method cleans up and destroys an adapter object.

CreateAdapterInstance

This CreateAdapterInstance method creates an adapter object and initializes it.

```
MPIRC CreateAdapterInstance  
(HMPIDADAPT *phAdapter)
```

Inputs

None

Outputs

phAdapter
Adapter handle

Returns

Success status

DestroyAdapterInstance

The DestroyAdapterInstance method cleans up and destroys an adapter object.

Inputs

```
MPIRC DestroyAdapterInstance  
(HMPIDADAPT hAdapter)
```

phAdapter
Adapter handle

Outputs

None

Returns

Success status

Connection instance overview

Instances of connection objects are created in the same way as adapter instances. When a new connection is required, a connection instance is created.

When an instance of a connection is required, the CreateConnectionInstance method is called. This method must call the mpiConnectionCreate method to create the physical object and associate the connection virtual table with the object.

The connection virtual table has the following structure:

```
struct MPI_CONNECTION_VTABLE  
{  
size_t nSize; /* size of this structure */  
MPIRC (*pfConnect) (HMPICONNECT hConnection, HMPIDADAPT hAdapter);  
MPIRC (*pfDisconnect) (HMPICONNECT hConnection);  
};  
typedef struct MPI_CONNECTION_VTABLE MPI_CONNECTION_VTABLE;
```

CreateConnectionInstance example

The following code is an example of creating a connection instance.

```
MPI_CONNECTION_VTABLE ConnectionTable = { /* Initialize */ };  
  
MPIRC CreateConnectionInstance(HMPICONNECT *phConnection)  
{  
MPIRC rc;  
rc = mpiConnectionCreate(phConnection, &ConnectionTable);
```

```

if (rc == MPI_SUCCESS)
{
/* Define the number and type of adapter properties */
rc = mpiObjectNewPropColl(*phConnection,
MPI_PROPBASE_USER,
NUM_CONNECTION_PROPERTIES,
ConnectionProperties);

/* Do any initialization of instance of connection object */
}
return rc;
}

```

DestroyConnectionInstance example

The DestroyConnectionInstance method should do the reverse, that is, it should delete the connection object and free up any data structures that were created by the create method.

The following code is an example of deleting an object.

```

MPIRC
DestroyConnectionInstance(HMPICONNECT hConnection)
{
/* Free up any memory or data structures used by the connection instance */

return (mpiObjectDestroy(hConnection));
}

```

Returns

Success status

Connection interface overview

The connection interface methods are called to connect to a resource and to control connection pooling.

- **[Connect interface method](#)**

The Connect method is called to connect to the resource specified by the adapter object. Context information returned from the connection, such as handles, cursors or other contextual information, is returned by setting properties of the connection object.

- **[Disconnect interface method](#)**

The Disconnect method disconnects from the resource referenced by the connection object. The connection context is obtained by getting the properties of the connection object that were set in the Connect call.

- **[CompareConnection interface method](#)**

The CompareConnection method is called by the Resource Manager to determine whether a connection can be reused.

- **[ValidateConnection interface method](#)**

The ValidateConnection method is called by the Resource Manager on an idle connection to determine whether a connection is still valid. It is invoked when the period specified in the Launcher configuration file expires. The method should ping the connection to determine whether it is still valid, using whatever mechanism the resource supports to do this.

Connect interface method

The Connect method is called to connect to the resource specified by the adapter object. Context information returned from the connection, such as handles, cursors or other contextual information, is returned by setting properties of the connection object.

In addition, this method should copy properties that are relevant for determining whether a connection can be shared (CompareConnection method). For example, if a connection can be shared when the datasource name matches, the datasource property should be obtained from the adapter object and set in the connection object.

```
MPIRC Connect  
(HMPICONNECT hConnection, HMPIADAPT hAdapter)
```

Inputs

hConnection
 Connection handle
hAdapter
 Adapter handle

Outputs

None

Returns

Success status

Disconnect interface method

The Disconnect method disconnects from the resource referenced by the connection object. The connection context is obtained by getting the properties of the connection object that were set in the Connect call.

Inputs

```
MPIRC Disconnect (HMPICONNECT hConnection)  
  
hConnection  
    Connection handle
```

Outputs

None

Returns

Success status

CompareConnection interface method

The CompareConnection method is called by the Resource Manager to determine whether a connection can be reused.

It is called in two cases:

- To determine whether multiple adapter references within the same map can share a connection.
- To determine whether a connection that is currently inactive can be used by a map.

This method can be logically equivalent to CompareWatches.

```
MPIRC CompareConnection (HMPIDADAPT hAdapter, HMPICONNECT hConnection,  
                           MPICOMP *peComp)
```

Inputs

hAdapter
Adapter handle for the potentially new connection.
hConnection
Connection handle for the existing connection.

Outputs

peComp

MPI_CMP_EQUAL
 Connection corresponds.
MPI_CMP_DIFFER
 Connection does not correspond.
MPI_CMP_LESS
 Connection is less than adapter.
MPI_CMP_GREATER
 Connection is greater than adapter.

Returns

Success status

The adapter consults the properties for the adapter object and the connection object and determines whether the properties correspond such that the connection might be reused for the adapter object. The MPIP_CONNECTION_INUSE property determines whether the connection object is currently being used in a map. If this property is FALSE, the connection is currently idle.

Besides adapter-specific properties, other properties might be important in determining whether a connection can be reused. For example, MPIP_ADAPTER_ON_FAILURE determines whether to rollback or commit at the end of the transaction. If this is set to MPI_ACTION_COMMIT for one adapter object, but MPI_ACTION_ROLLBACK for another, it is most unlikely that the connection should be shared if the connection is active.

If the sense of ordering in comparisons can be made, the number of comparisons can be reduced because every existing connection does not have to be compared when searching for a valid connection to use.

In the following code example, a resource is identified by QueueManager.

```
mpiPropertyGetText(hAdapter, MYPROP_Q_MGR, 0, &pAdaptQMgr, &iLen);  
mpiPropertyGetText(hConnection, MYPROP_Q_MGR, 0, &pConnQMgr, &iLen);  
rc = strcmp(pAdaptQMgr, pConnQMgr);  
if (rc == 0)  
    return MPI_CMP_EQUAL;  
else if (rc < 0)  
    return MPI_CMP_LESS;  
else  
    return MPI_CMP_GREATER;
```

ValidateConnection interface method

The ValidateConnection method is called by the Resource Manager on an idle connection to determine whether a connection is still valid. It is invoked when the period specified in the Launcher configuration file expires. The method should ping the connection to determine whether it is still valid, using whatever mechanism the resource supports to do this.

```
MPIRC ValidateConnection (HMPIDADAPT  
                           hAdapter, HCONNECTION hConnection)
```

Inputs

hAdapter
Adapter handle
hConnection

Connection handle

Outputs

None

Returns

MPIIRC_SUCCESS

Connection is good.

MPIIRC_BAD_CONNECTION

Connection is no longer good.

This method is optional. If not provided, the connection is assumed to be invalid when its expiration timeout occurs. This timeout is currently defined in the **config.yaml** configuration file.

Library initialization and termination methods

The InitializeLibrary and DestroyLibrary custom adapter methods are called to perform one-time initialization tasks and to clean up from these tasks.

Listener interface overview

The Listener interface uses the Listen, CombinedListen, and CompareWatches methods to listen for single or multiple events from the resource.

There are two distinct ways to implement a listener:

- A listener listens for a single event. If there are other listeners for the adapter, those also listen for single events. If there is any overlap in what is being listened for this, it is handled by the Resource Manager.
For example, there might be two listeners listening on the same queue, both of which might report the same event to the Resource Manager. For this scenario, the adapter should provide a Listen method. In this instance, there is no need to provide a CompareWatches method.
- A listener listens for multiple events. If it is not possible to have more than one listener listening on the same queue or for the same file and so on, or if it is inefficient to do so, a single listener should be provided that handles multiple events.
For this scenario, the adapter should provide a CombinedListen method. If CompareWatches returns MPI_CMP_EQUAL, the watches that were returned as being equal are passed to the CombinedListen method.

Only one of these methods should be provided, depending entirely on whether multiple separate threads can listen for the same resource.

- [Listen method](#)
The Listen method listens for events and returns when an event has occurred.
 - [CombinedListen method](#)
The CombinedListen method is generally the same as the Listen method. The difference is that the CombinedListen method listens for multiple watches.
 - [CompareWatches method](#)
The CompareWatches method compares two watches to see whether they are equivalent. This method is equivalent to CompareConnection method.
-

Listen method

The Listen method listens for events and returns when an event has occurred.

For example, a message has been received, a database update has occurred, and so on. In addition, should a connection become unusable, the Listen method should return a status indicating this.

```
MPIIRC Listen (HMPIDADAPT  
hAdapter,HCONNECTION hConnection)
```

Inputs

hConnection

Connection handle

Outputs

None

Returns

MPIIRC_BAD_CONNECTION

Connection failed other success status

In the vtable library, there is a bListenerBlocks configuration option that specifies whether the listener is interruptible. To be interruptible means that the function that the adapter calls to listen for an event must be able to be interrupted by a call from another thread.

Generally, unless the API provides a break call, the adapter is non-interruptible. If the adapter is non-interruptible, the Listen method should never execute for more than a few seconds. After being called, the adapter makes a call to its resource to discover new events. If, after a few seconds, no event has occurred, the Listen method should return.

Returning back to the Resource Manager allows the Resource Manager to determine whether to invoke Listen again, the most common scenario, or to shutdown the watch either because the Launcher has asked for the watch to be deleted, or the Launcher is in the process of shutting down. In the latter cases, the Resource Manager will invoke Disconnect to clean up the watch.

If the Listen method for the adapter is interrupted, it does not need to return to the Resource Manager every few seconds if no event occurs, although it must return whenever an event occurs.

Instead, whenever a listener must be terminated by the Resource Manager, the OnNotify method will be called with a notification code of MPIN_ADAPTER_LISTENABORT on another thread from the listener. Within this call, the adapter should execute the break function on the listener's connection context to cause it to terminate and return control back to the Resource Manager.

If one or more events occur, the Listen method should return immediately, adding the event data to the message collection. For example,

```
MyGetMessageID(&pMID);  
mpiPropertyGetObject(hAdapter,  
MPIP_ADAPTER_MSG_COLLECTION, 0, &hMsgColl);  
mpiMsgCollNewMsg(hMsgColl, pMID, strlen(pMID),  
NULL, 0, NULL, NULL);
```

- [Listen method attributes](#)

The Listen method listens for events and returns when an event has occurred. The Listen method uses the attributes Resource ID, Wildcard, and Userdata.

Listen method attributes

The Listen method listens for events and returns when an event has occurred. The Listen method uses the attributes Resource ID, Wildcard, and Userdata.

A message that is an event contains one to three of the following attributes that you set when a message is added to the collection.

Resource ID

An identifier that uniquely identifies the message, file or buffer (for example, message ID, memory address, and file handle). The Resource ID is used in the Get method to actually retrieve the physical data.

Wildcard

If a property of the adapter contains a wildcard, the actual value that represents the wildcard is specified as an attribute of the message. The mpiExtractWildcard method can be called to get the value of the wildcard.

Userdata

The userdata attribute is provided so that any other data can be associated with the message. Some adapters actually get the data for the event during the Listen call. For example, messaging systems that do not permit non-destructive browsing. For these, the message data should be associated with the userdata attribute.

If userdata is provided, the adapter must provide a method to free up the memory used by the userdata. This method is of type MPI_PF_FREEUSERDATA which is defined as:

```
typedef void (*MPI_PF_FREEUSERDATA)(void *);
```

CombinedListen method

The CombinedListen method is generally the same as the Listen method. The difference is that the CombinedListen method listens for multiple watches.

```
MPIRC_CombinedListen (HMPIADAPTCOLL  
hAdapterColl, HCONNECTION hConnection)
```

Inputs

hAdapterColl
Adapter collection handle
hConnection
Connection handle

Outputs

None

Returns

MPIRC_EVENT
Event occurred
MPIRC_NO_EVENT
No event occurred
MPIRC_BAD_CONNECTION
Connection failed other success status

This method receives an adapter collection object, which is a container for adapter objects. Notice that there is only one connection object because all watches are accessing the same resource. To determine the number of adapter objects in the collection, the following method should be invoked:

```
mpiAdaptCollGetCount (hAdapterColl, &iCount);
```

Upon detection of an event, CombinedListen must determine the watches for which the event applies. For example, the combined listener is looking for the following files:

- Watch #1: A*.txt
- Watch #2: ABC*.txt

If a file is discovered with the name AXYZ.txt, the event is applicable to the first watch only. However, if a file with name of ABCXYZ.txt is discovered, this would be applicable to both Watch 1 and 2.

Having determined the watches to which the event applies, a message should be added to the MPIP_ADAPTER_MSG_COLLECTION property for each corresponding adapter object (in the same way as described in the Listen method). Note that in the above example, the value of the wildcard would differ in the two message collections.

Between successive calls to CombinedListen, a watch might be added or removed. This means that it is necessary for the adapter to check the number of adapter objects in the collection on each invocation. If the number of adapter objects changes between invocations, the adapter might need to do additional processing. For example, to adjust filtering of messages accordingly.

CompareWatches method

The CompareWatches method compares two watches to see whether they are equivalent. This method is equivalent to CompareConnection method.

```
MPIRC CompareWatches (HMPIADAPT hAdapter1, HMPIADAPT hAdapter2, MPICOMP *peComp)
```

Inputs

hAdapter1
Adapter handle
hAdapter2
Adapter handle

Outputs

peComp

MPI_CMP_EQUAL
 Watches correspond
MPI_CMP_DIFFER
 Watches do not correspond
MPI_CMP_LESS
 Watch1 is less than Watch2
MPI_CMP_GREATER
 Watch1 is greater than Watch2

Returns

Success status

If the adapter does not combine listeners, that is provides Listen as opposed to the CombinedListen method, there is no need to provide a CompareWatches method.

If the method returns MPI_CMP_EQUAL, only one listener thread is created to handle multiple equivalent watches, and the CombinedListen method will be called to handle the multiple combined watches.

If wildcards are part of the command, it might not be possible to combine watches. For example, if there are two commands, to the same queue but one has MID="FRED" and the other MID="*", in some instances, the resource is the same, but not in others.

In this instance, the adapter might handle both events, returning MPI_CMP_EQUAL from this call, or two separate listeners might be spawned, returning MPI_CMP_DIFFER, MPI_CMP_LESS or MPI_CMP_GREATER from this method. The determination of the path to follow can be determined by performance reasons or limitation in the resource's API.

If the sense of ordering in comparisons can be made, the number of comparisons can be reduced because every existing watch does not have to be compared when searching for a valid connection to use.

The following example shows a resource identified by QueueManager:

```
mpiPropertyGetText(hAdapter1, MYPROP_Q_MGR, 0, &pAdapt1QMgr, &iLen);  
mpiPropertyGetText(hAdapter2, MYPROP_Q_MGR, 0, &pAdapt2QMgr, &iLen);  
rc = strcmp(pAdapt1QMgr, pAdapt2QMgr);  
if (rc == 0)  
    return MPI_CMP_EQUAL;  
else if (rc < 0)  
    return MPI_CMP_LESS;  
else  
    return MPI_CMP_GREATER;
```

Method invocation examples

The method invocation examples demonstrate the sequence of calls made to an adapter by Launcher.

- [Get and put method invocation examples](#)

These are examples of the sequence of calls that occur for Get or Put within a map.

- [Quantity, FetchUnit, and listen time method invocation examples](#)

These are examples of the sequence of calls that occur for Quantity, FetchUnit, or Listen Time method within a map.

Get and put method invocation examples

These are examples of the sequence of calls that occur for Get or Put within a map.

It demonstrates sharing connections, both active (the connection is already being used in the current map) and inactive (the connection is not being used by any current map).

Sequence of calls

1. The map calls **ValidateProperties**.
2. The map determines if an active connection exists.

For inactive connections

1. The map calls **CompareConnections**.
2. The map determines if there is a match.
3. If there is a match, the map calls:
 - **BeginTransaction**
 - **OnNotify(Start)**
4. If there is no match, the map calls:
 - **Connect**
 - **BeginTransaction**
 - **OnNotify(Start)**
5. The map then calls **Get** or **Put** for every message available to process.

For active connections

1. The map calls **CompareConnections**.
2. The map determines if there is a match.
3. If there is a match, the map calls:
 - **OnNotify(Start)**
4. If there is no match, the map calls:
 - **Connect**
 - **BeginTransaction**
 - **OnNotify(Start)**
5. The map then calls **Get** or **Put** for every message available to process.

No more messages to process

1. If there are no more messages to process, the map calls:
 - **OnNotify(Stop)**
 - **EndTransaction**
 - **Disconnect**

The Disconnect call is not made immediately after the EndTransaction, but only after the process has terminated or the connection expiration timeout occurs. The description shows the scenario in which the Scope setting is set to Map. Even if there are multiple bursts, there is only one call to BeginTransaction and one to EndTransaction. If the Scope setting was instead set to Burst, BeginTransaction would be called at the start of each burst, and EndTransaction at the end of the burst. This scenario for adapters is for allowing only one transaction for each connection. For an adapter to allow multiple transactions on a connection, the BeginTransaction call is made even if the CompareConnection call returns MPI_CMP_EQUAL.

Quantity, FetchUnit, and listen time method invocation examples

These are examples of the sequence of calls that occur for Quantity, FetchUnit, or Listen Time method within a map.

For an input card that is not a source event, the Resource Manager might call the Get method more than once if it determines there is more data to be returned. The Resource Manager interprets two special command line options that can be specified in the adapter's command line:

- -QTY: number of messages to be processed by the map
- -LSN: amount of time to listen for messages for each burst of the map

In addition to these command options, the FetchUnit card setting determines how many messages are returned from each burst. Therefore, if the FetchUnit is greater than one (1) or the -QTY (quantity) command is provided on the adapter command line, the Get method will be called more than once.

Carefully adhere to the following rules to ensure that the Get method is called correctly. Note that "X messages" means X messages per burst of the map. For example, if the map has multiple bursts, then each burst will fetch the FetchUnit and decrement this number from the quantity. Therefore, if FetchUnit = 3 and QTY = 7, X is 3 (burst #1), 3 (burst #2), and 1 (burst #3).

- When X messages, -LSN Y (where Y > 0) The Get method is called repeatedly until either: The adapter has been listening for Y seconds (cumulatively across all Get calls for the burst). X messages have been returned for the burst. Note that returning zero (0) messages from a Get call does not mark the end of the data. The Get will be called again as long as the elapsed time does not exceed Y and the total number of messages does not exceed X.
- When X messages, -LSN 0
 - The purpose of -LSN 0 is to fetch all data that is immediately available, such as all messages that are sitting on a queue, without ever waiting for data to arrive. Therefore, whenever an absence of data is detected, it marks the end of the input.
- The Get method is called repeatedly until either:
 - The adapter returns no messages from a call to Get if (MPIP_ADAPTER_NUM_MESSAGES) is 0. The adapter will not be called again for this burst (contrast with -LSN Y where Y > 0)
 - X messages have been returned for the burst
- X messages, -LSN not specified
 - If -LSN is not specified, this implies listen forever (an infinite time). Therefore, the Get will be called repeatedly until -QTY messages have been received.
- -QTY S, -LSN not specified
 - This is an invalid configuration because it means get all of the messages that are returned in an infinite amount of time, (that is, the map will never complete). The Resource Manager will detect this and return an error at the point of property validation.

On each call to Get, the adapter must set the MPIP_ADAPTER_NUM_MESSAGES property to the number of messages being returned.

If an adapter recognizes that there is no more data (for example, a database query has retrieved all of the rows in the result set), the adapter should return MPIRC_W_END_OF_DATA. The adapter will not be called back for more data.

Source and target interface overview

Source and target interface methods are called to get data from a resource, to put data to a resource, and to control a transaction while developing custom adapters.

- [Get method overview](#)
The Get method is called to obtain data from a resource for input to a map.
- [Put method overview](#)
The Put method is called to send data to a resource for output from a map.
- [OnNotify method overview](#)
The OnNotify method is called to notify an adapter about the progress of the map as related to the adapter.
- [BeginTransaction method overview](#)
The BeginTransaction method is called to explicitly start a transaction.
- [EndTransaction method overview](#)
The EndTransaction method is called at the end of the transaction to complete the transaction.

Get method overview

The Get method is called to obtain data from a resource for input to a map.

The Get method is called for an input card, GET function, or for a DBLOOKUP and DBQUERY if the source is a database. The call accesses the resource for which the hConnection handle is associated and returns data. This data is passed to the map server through a stream object.

```
MPIRC Get (HMPIADAPT hAdapter, HMPICONNECT  
hConnection)
```

Inputs

hAdapter	Adapter handle
hConnection	Connection handle

Outputs

None

Returns

Success status

If the Get method is invoked as a result of an input event (the card acts as a watch for the Launcher and a Listen method has returned an event), the Get method should process the event. To determine whether the call is in the context of an event, see the MPIP_ADAPTER_CONTEXT property. For example:

```
mpiPropertyGetInteger(hAdapter, MPIP_ADAPTER_CONTEXT,  
&iContext);
```

This will return MPI_CONTEXT_SOURCE_EVENT if the card is an input event.

If Get is not being called from an event, the method should get a single unit of work from the input (for example, a result set from a database query, a file, or a message from a queue), and return the unit of work through a stream object associated with the MPIP_ADAPTER_DATA_FROM_ADAPT property. For example:

```
mpiPropertyGetObject (hAdapter,  
MPIP_ADAPTER_DATA_FROM_ADAPT, 0, &hStream);  
mpiStreamNewPage(hStream, &hPage, iSize);
```

```
mpiStreamPageGetInfo(hPage, &pData, &iSize);
get data into pData
mpiStreamWritePage(hStream, hPage);
```

Quantity or FetchUnit values do not affect the adapter; this is handled by the Resource Manager. Each call to Get should return a single unit of work. If Get is called from the GET mapping function (the MPIP_ADAPTER_CONTEXT will be set to MPI_CONTEXT_GET), data might be passed to the Get call from the third parameter in the GET mapping function. This applies to adapters that require data to be sent out in the form of a request, such that the corresponding reply is returned from the Get call.

To determine whether any data has been passed, the adapter should get the MPIP_ADAPTER_DATA_TO_ADAPT property. If this returns an MPIRC_NULL_OBJECT error, it means that no data was passed to the Get. If data was passed, use the stream object to get the data.

If Get is called as the result of an input event (the MPIP_ADAPTER_CONTEXT property is MPI_CONTEXT_SOURCE_EVENT), information about the event or events is obtained from the MPIP_ADAPTER_MSG_COLLECTION property by repeatedly calling mpiMsgCollGetNext until there are no more messages in the collection. These messages have previously been added to a collection by the adapter's Listen method.

Put method overview

The Put method is called to send data to a resource for output from a map.

The method is called for an output card or PUT function. The call accesses the resource for which the hConnection handle is associated and sends data to the resource. This data is passed from the map server through a stream object.

```
MPIRC Put (HMPIADAPT hAdapter,
HMPICONNECT hConnection)
```

Inputs

hAdapter
Adapter handle
hConnection
Connection handle

Outputs

None

Returns

Success status

OnNotify method overview

The OnNotify method is called to notify an adapter about the progress of the map as related to the adapter.

```
MPIRC OnNotify (HMPIOBJ hAdapter, int
iEvent,int iParam,HMPIOBJ hConnection)
```

Inputs

hAdapter
Adapter handle
iEvent
Event ID
iParam
[ignore this parameter]
hConnection
Connection handle

Outputs

None

Returns

Success status

The OnNotify method is called at the following times and with the following IDs:

Notification	Description
MPIN_ADAPTER_GETSTART	Prior to any Get calls for the card
MPIN_ADAPTER_GETSTOP	After all Get calls for the card
MPIN_ADAPTER_PUTSTART	Prior to any Put calls for the card

Notification	Description
MPIN_ADAPTER_PUTSTOP	After all Put calls for the card
MPIN_ADAPTER_LISTENSTART	Prior to any Listen calls for the card
MPIN_ADAPTER_LISTENSTOP	After all Listen calls for the card
MPIN_ADAPTER_LISTENABORT	Called to abort a non-polling listener
MPIN_ADAPTER_MAPABORT	When a map is cancelled by user action

These entry points provide the opportunity for the adapter to initialize or clean up the Get, Put, or Listen method. For example, the adapter might need to query a queue to find out some properties about the queue. This would be done in the OnNotify (*_START) call. If it was done in the Get, Put, or Listen and these methods were called multiple times, unnecessary work would be performed repeatedly.

OnNotify is called with *_START prior to any Get, Put, or Listen, and is called with *_STOP after all Get, Put, or Listen calls. For example, if a map is executing multiple bursts and within each burst, Get is called multiple times to get multiple messages, there will be only one OnNotify call with MPIN_GET_START, prior to the first Get. Only after all bursts and all Gets within a burst, will OnNotify be called with MPIN_GET_STOP to allow the adapter to clean up.

If a user cancels a map execution, OnNotify will be called with MPIN_MAP_ABORT. The Get or Put methods should be aborted by the adapter as soon as possible after the notification.

The MPIN_ADAPTER_LISTENABORT notification is delivered only to adapters that have defined bListenerBlocks as TRUE in the vtable library. In this scenario, OnNotify is called on a separate thread from the Listen call. For all other notifications, the call is made on the connection thread.

When an adapter receives this notification, it should abort the Listen method using whatever mechanism or API that is supported by the adapter.

BeginTransaction method overview

The BeginTransaction method is called to explicitly start a transaction.

This method is optional because some resources are non-transactional, and for others, a transaction is implicitly started when the connection is established.

```
MPIRC BeginTransaction (HMPIDADPT
hAdapter, HMPICONNECT hConnection)
```

Inputs

hAdapter
Adapter handle
hConnection
Connection handle

Outputs

None

Returns

Success status

This method is always invoked following a Connect call and before any Get or Put calls. If the adapter operates in the mode in which the listener and map connection threads are combined, BeginTransaction is called prior to the Listen call.

EndTransaction method overview

The EndTransaction method is called at the end of the transaction to complete the transaction.

eAction will have the value MPI_ACTION_COMMIT or MPI_ACTION_ROLLBACK to indicate the course of action that the adapter should take. Note that the end of the transaction might be the end of the card, the burst or the map.

```
MPIRC EndTransaction (HMPIDADPT
hAdapter, HMPICONNECT hConnection, MPITRANS eAction)
```

Inputs

hAdapter
Adapter handle
hConnection
Connection handle
eAction
Indicates whether to commit or rollback the transaction.

Outputs

None

Returns

Success status

If there are multiple cards sharing a connection and the adapter allows for only one transaction per connection, the hAdapter passed to EndTransaction is the hAdapter of the card that corresponds to the one passed to the BeginTransaction call.

Property interface overview

The ValidateProperties custom adapter method is called to validate the adapter's properties.

- [ValidateProperties method overview](#)

The ValidateProperties method is called to ensure that all required properties are set and that there are no mutually exclusive property settings.

ValidateProperties method overview

The ValidateProperties method is called to ensure that all required properties are set and that there are no mutually exclusive property settings.

MPIRC ValidateProperties (HMPIADAPT hAdapter)

Inputs

hAdapter
Adapter handle

Outputs

None

Returns

Success status

The adapter properties are not set by most modes of execution. Therefore, it is necessary for the adapter to get the command line property, to parse it, and to set the properties within this method.

To get the command line property, issue the following property call:

```
mpiPropertyGetText(hAdapter, MPIP_ADAPTER_COMMANDLINE, 0, &lpszCmdLine, &nLen)
```

After the command line has been fetched, it should be parsed and a number of mpiPropertySet* calls should be made. In the process, the options should be validated to ensure that they are consistent and mutually compatible.

To store additional properties or other information for the adapter, set the MPIP_ADAPTER_USER_DATA property in the adapter object. In subsequent calls, the user data can be retrieved by calling mpiGetPropertyBinaryPointer. If the MPIP_ADAPTER_USER_DATA property is set, the adapter must free this memory in the DestroyAdapterInstance call.

C API return codes

There are three types of C API return codes: success, warning, or error.

- Success: The call succeeded. The only success code is MPIRC_SUCCESS.
- Warning: The call succeeded, but some condition arose that might be of concern. For example, MPIRC_W_NO_DATA.
- Error: The call failed.

The following return codes, which are defined in the dtspi.h header file along with many others, should be used by an adapter.

Return code	Description
MPIRC_SUCCESS	This operation was successful.
MPIRC_W_NO_DATA	The adapter has no data to return from a Get.
MPIRC_W_END_OF_DATA	All data has been retrieved from the input.
MPIRC_E_BAD_CONNECTION	The connection became unusable.

In addition to predefined codes, an adapter might provide its own return codes. Error and warning codes returned should be defined using the following macros:

- MAKEUSERWARNING(code) - sets the code as a warning code
- MAKEUSERERROR(code) - sets the code as an error code

Example

```
#define MY_E_CONNECT_FAILED  
MAKEUSERERROR(1)  
  
#define MY_E_BAD_PARMS  
MAKEUSERERROR(2)
```

```

#define MY_E_NO_MEMORY
MAKEUSERERROR(3)

#define MY_W_NO_MSG_AVAIL
MAKEUSERWARNING(1)

#define MY_W_TIMED_OUT
MAKEUSERWARNING(2)

```

Zero (0) should not be used as the parameter of MAKEUSERERROR or MAKEUSERWARNING.

These codes must then be returned as properties of the object.

Example

```
mpiPropertySetInteger(hAdapter,
MPIP_OBJECT_ERROR_CODE, 0, rc);
```

Return codes from the resource to which the adapter connects might also be returned, (for example, a SQL State or code from an R/3 API) by setting the MPIP_ADAPTER_PROVIDER_CODE property. The return code from the adapter methods determines program flow. If an error occurs in an adapter method, an error code must be returned in the return code. The MPIP_OBJECT_ERROR_CODE property does not determine flow, but is used to maintain error information related to various objects. This information can then be displayed in the trace and audit logs.

Additional adapter methods

There are a number of additional methods that are part of the Transformation Extender Programming Interface library that are of particular relevance to adapter developers.

- [Wildcard methods overview](#)

These methods are used to perform wildcard matching and determine the value for which a wildcard stands.

- [mpiMapReportStatus method overview](#)

The mpiMapReportStatus method allows an adapter to display a short message in the map status window, and to determine whether the map has been cancelled by a user action.

Wildcard methods overview

These methods are used to perform wildcard matching and determine the value for which a wildcard stands.

- [mpiCompareWildcard method overview](#)

The mpiCompareWildcard method compares a string (passed in pActual) with a wildcard pattern (pPattern) to determine whether it matches.

- [mpiExtractWildcard method overview](#)

The mpiExtractWildcard method compares a string (passed in pActual) with a wildcard pattern (pPattern) to see whether it matches. If it does, the string that substitutes for the wildcard value is returned in the buffer provided by the caller in pBuf.

mpiCompareWildcard method overview

The mpiCompareWildcard method compares a string (passed in pActual) with a wildcard pattern (pPattern) to determine whether it matches.

For example, if pPattern is A*123 and pActual is ABCD123, the return status will be MPI_CMP_EQUAL because pActual does match the pPattern string.

```
MPIRC mpiCompareWildcard (const char
*pPattern,int nPatternLen,const char
*pActual,int nActualLen)
```

Inputs

pPattern
Wildcard pattern
nPatternLen
Length of the pPattern string.
pActual
Actual data which might match the wildcard.
nActualLen
Length of the actual data.

Outputs

pBuf
A buffer to receive the wildcard value if one exists.
pLen
Size of the buffer on input and the length of the wildcard value on output.

Returns

MPI_CMP_EQUAL
Wildcard matches.
MPI_CMP_LESS
Wildcard does not match.

mpiExtractWildcard method overview

The mpiExtractWildcard method compares a string (passed in pActual) with a wildcard pattern (pPattern) to see whether it matches. If it does, the string that substitutes for the wildcard value is returned in the buffer provided by the caller in pBuf.

For example, if pPattern is A*123 and pActual is ABCD123, the value returned in pBuf will be BCD.

```
MPIRC mpiExtractWildcard (const char
    *pPattern,int nPatternLen,const char
    *pActual,int nActualLen,char *pBuf,int
    *pLen)
```

Inputs

pPattern
Wildcard pattern
nPatternLen
Length of the pPattern string
pActual
Actual data which might match the wildcard
nActualLen
Length of the actual data

Outputs

pBuf
A buffer to receive the wildcard value if one exists
pLen
Size of the buffer on input and the length of the wildcard value on output

Returns

MPI_CMP_EQUAL
Wildcard matches
MPI_CMP_LESS
Wildcard does not match

mpiMapReportStatus method overview

The mpiMapReportStatus method allows an adapter to display a short message in the map status window, and to determine whether the map has been cancelled by a user action.

mpiMapReportStatus is used to display a message in the map status window.

If an adapter attempts to determine the state of a map, that is, to see whether the map has been cancelled, it will receive an MPIN_MAP_ABORT notification through its OnNotify method. On receipt of this notification, the adapter should abort any current activity as soon as possible.

This little command copies things.

Passing data to and from maps

Data is passed between adapters and the engine through stream objects. From the adapter perspective, there is no need to create these stream objects; they are already created when either the Get or Put method is called.

Data is stored within the stream objects in pages which might be of variable size. The adapter is responsible for writing pages to the stream (in a Get), or reading pages from the stream (in a Put).

- [Receiving data from a map](#)
Use the Put method to receive data from a map through stream objects. There are two different ways of accomplishing this. The method chosen depends on the manner in which the data has to be sent to the resource.
- [Sending data to a map](#)
Use a Get method to return (send) data to the engine through stream objects. There are a number of different ways to accomplish this task. The method chosen depends on the manner in which the resource returns data to the adapter.

Receiving data from a map

Use the Put method to receive data from a map through stream objects. There are two different ways of accomplishing this. The method chosen depends on the manner in which the data has to be sent to the resource.

- The data must be passed to the resource as a single, contiguous buffer.

In this example, the buffer is obtained from the stream and passed to the resource:

```
mpiStreamGetSize (hStream, &nSizeOfData);

pData = malloc(nSizeOfData);

mpiStreamRead (hStream, pData, nSizeOfData,
&iBytesRead);
```

This copies the data from the stream page(s) to the buffer.

- The data can be passed to the resource as a number of small buffers.

In this example, each page is obtained from the stream and is then passed to the resource:

```
while(TRUE)
{
mpiStreamIsEnd (hStream, &bIsEnd);
if (bIsEnd)
break;
mpiStreamReadPage (hStream, &hPage);
mpiStreamPageGetInfo (hPage, &pData, &nSizeOfPage, &nSizeOfData);
MySendData (pData, nSizeOfData);
}
```

There might be scenarios where it is acceptable to send data to the resources in pieces, but the size of the pieces might not correspond to the size of a page. As an example, consider database rows. It is possible that a row of data spans across page boundaries. The adapter must expect and be able to handle this.

Sending data to a map

Use a Get method to return (send) data to the engine through stream objects. There are a number of different ways to accomplish this task. The method chosen depends on the manner in which the resource returns data to the adapter.

- A memory buffer is returned from the resource that can be passed to the engine.

In this scenario, only a single call to mpiStreamWrite is required:

```
mpiStreamWrite (hStream, pData, nSizeOfData);
```

This will create a page, copy the data to the page and append the page to the stream.

- The adapter allocates a single buffer that is then populated by the resource.

If the adapter is receiving data into a buffer that it has allocated, the buffer should be allocated through the stream interface as shown in the following example:

```
/* Create a page */
mpiStreamNewPage (hStream, &hPage, nSizeOfBuffer);

/* Get the address of the buffer */
mpiStreamPageGetInfo (hPage, &pData, &nSizeOfBuffer);

/* Get the data into the buffer */
MyGetData (pData, &ActualDataSize);

/* Add the page to the stream */
mpiStreamWritePageEx (hStream, hPage, nActualDataSize);
```

This will create a page and append the page to the stream. This is the preferable way to handle this kind of resource because it requires no memory copies or reallocations.

- The adapter gets data in pieces from the resource.

This is identical to the above scenario except that it is allocated repeatedly. Each call to mpiStreamWritePage appends a page to the stream.

Listener scenario overview

These are listener scenario examples that demonstrate the flow of calls for input events.

To determine the model that best fits the requirements of the resource, follow these examples to understand the flow of calls for input events as they summarize the available alternatives.

- Adapters Process Similar Events
- Resource Manager Processes Similar Events
- Listener and Map Connection Threads are Combined

The meaning of the following similar events is that the connection is identical in both cases, but the event itself might differ. For example, consider:

```
"QueueName = fred, MessageID = 100"
```

and

```
"QueueName = fred, MessageID = 200"
```

If the API for the resource allows the Message ID to be provided to a Get call, such that only the message with the specified Message ID is returned, it is probably easiest to create multiple threads, one getting messages with ID 100; the other messages with ID 200. This is the model used in the Resource Manager Processes Similar Events example.

However, if the API cannot do this selection or it is not possible to have multiple connections to the same resource, the adapter must handle the filtering of messages itself. In the latter scenario, a single Listen method will have to handle multiple events.

- [**Listener scenario: adapters process similar events**](#)

This is an example scenario in which the adapter combines watches and provides CombinedListen and CompareWatches methods.

- [**Listener scenario: Resource Manager processes similar events**](#)

This is an example of a Listener scenario in which the adapter does not, or can not, combine watches.

- [**Listener scenario: Listener and map connection threads are combined**](#)

This is an example scenario in which an adapter requires that all activities related to an input event are carried out within the same thread.

Listener scenario: adapters process similar events

This is an example scenario in which the adapter combines watches and provides CombinedListen and CompareWatches methods.

This example describes a scenario where the adapter combines watches and provides CombinedListen and CompareWatches methods. The adapter in this example is an input to two maps and is marked as an input event for both. The following events occur at initialization:

1. The Launcher starts and reads the system file (.msl) and calls the Resource Manager, passing the details of two watches for the adapter.
2. The Resource Manager calls the ValidateProperties method of the adapter with Watch 1 data.
3. The Resource Manager calls the ValidateProperties method of the adapter with Watch 2 data.
4. The Resource Manager calls the CompareWatches method with adapter objects from the above calls. Because the adapter will handle the events itself, it returns information indicating that the watches are the same (MPI_CMP_EQUAL).
5. The Resource Manager creates a thread (T1) and calls the Connect method with the adapter object (from Step 2). Resource Manager has an arbitrary choice. Because the adapter has indicated that the watches are equivalent, it should not matter which adapter object is used to determine the connection parameters.
6. (T1): The Resource Manager calls the OnNotify (MPIN_LISTEN_START) method and then the CombinedListen method with both of the adapter objects from Steps 2 and 3 in an HAdapterCollection.
7. The Resource Manager notifies the Launcher that the listener started successfully.
Now an event occurs.
8. (T1): The CombinedListen method identifies whether the adapter objects have been triggered and adds messages to the collection objects of the adapters.
9. (T1): The Resource Manager notifies the Launcher passing the appropriate adapter object.
10. (T1): The Resource Manager calls the CombinedListen method again.
11. The map runs and the Resource Manager is called for input.

Listener scenario: Resource Manager processes similar events

This is an example of a Listener scenario in which the adapter does not, or can not, combine watches.

This example describes a scenario where the adapter does not, or cannot, combine watches itself. This means that the adapter provides a Listen method, and does not provide CombinedListen or CompareWatches methods. The adapter in this example is an input to two maps and is marked as an input event for both. The following occurs at initialization:

1. The Launcher starts and reads the Launcher system file (.msl) and calls the Resource Manager, passing the details of two watches for the adapter.
2. The Resource Manager calls the ValidateProperties method of the adapter with Watch 1 data.
3. The Resource Manager calls the ValidateProperties method of the adapter with Watch 2 data.
4. The Resource Manager creates a thread (T1) and calls the Connect method of the adapter object from Step 2.
5. (T1): The Resource Manager calls the OnNotify (MPIN_LISTEN_START) and then the Listen method with Watch 1 details.
6. The Resource Manager creates a thread (T2) and calls the Connect method of the adapter object from Step 3.
7. (T2): Resource Manager calls the OnNotify (MPIN_LISTEN_START) and then the Listen method with Watch 2 details.
8. The Resource Manager notifies the Launcher that the listeners started successfully. Now an event occurs.
9. (T1): The Listen method returns with an event, returning a message. (T1): The Resource Manager notifies the Launcher passing the message collection object.
10. (T1): The Resource Manager calls the Listen method again.
11. The map runs and the Resource Manager is called for input. However, the connection goes bad on Watch 2.
12. (T2): The Listen method returns MPIRC_BAD_CONNECTION.
13. (T2): The Resource Manager notifies the Launcher, which logs the error and notifies interested network management applications using SNMP. The Resource Manager then calls the OnNotify (MPI_LISTEN_STOP) method and the Disconnect method to clean up the connection.
14. (T2): The Resource Manager calls the Connect method again with the adapter object.
15. (T2): The Resource Manager calls the OnNotify (MPI_LISTEN_START) method and then the Listen method.

Listener scenario: Listener and map connection threads are combined

This is an example scenario in which an adapter requires that all activities related to an input event are carried out within the same thread.

This example describes a scenario where an adapter is requiring that all activities related to an input event are carried out within that same thread (for example, SAP BW).

1. A watch is to be added. The Resource Manager sees from the vtable adapter library that bListenThread is TRUE. It gets the listener thread count from the **config.yaml** configuration file. (Call this n).
2. The Resource Manager calls the ValidateProperties method with watch data.
3. The Resource Manager starts n threads, each of which calls the Connect, BeginTransaction, OnNotify (MPIN_LISTEN_START), and Listen methods.
4. When a Listen method returns messages in the message collection object, the Resource Manager calls the Launcher passing the connection context.
5. The Launcher calls the Resource Manager to initiate the Get method, passing the connection context back to the Resource Manager.
6. The Resource Manager communicates with the thread corresponding to the connection context, calling its Get method.
7. Possibly, other Get or Put methods are called during the processing of this map.
8. The EndTransaction method is called at the appropriate time.

9. When the map completes, the Resource Manager first calls the BeginTransaction method and then the Listen method once more on the same thread.

Threads, connections, and transactions overview

It is important to understand how threads, connections, and transactions interact.

You must separate threads for adapter connections and map logic. This allows connections to remain open even after maps complete. The Resource Manager maintains a pool of connection threads and associates one or more with a map thread during the execution of a map.

There is always a one-to-one relationship between a connection and a thread; one connection is associated with one thread. Multiple calls associated with one connection all occur on a single thread, that is, if the Connect method is called from thread n, all subsequent Listen, Get, Put, BeginTransaction, EndTransaction, and Disconnect calls for that connection will also be called from thread n.

Adapters fit into one of two categories:

- Those that have a one-to-one relationship between a connection and a transaction.
- Those that allow for multiple, concurrent transactions on the same connection.

The determination as to the category into which an adapter falls is normally made by the implementation of the transaction mechanism in the resource to which the adapter interfaces.

The adapter defines the mode in which it is operating by setting the nTransMode value in the vtable library to one of the following values:

- MPI_TRANSACTIONS_NONE
- MPI_TRANSACTIONS_SINGLE
- MPI_TRANSACTIONS_MULTIPLE

This parameter takes affects when the BeginTransaction and EndTransaction methods are called as follows:

- For adapters allowing for a single transaction per connection, there is only one call to BeginTransaction and EndTransaction.
- For adapters allowing for multiple transactions per connection, there will be multiple calls.
- For adapters with a transaction mode of NONE, there will be no calls to BeginTransaction or EndTransaction.

The following example shows the sequence of calls for a map that has two output cards, both with Scope setting set to Map, which can operate within the same connection:

Single transaction per connection	Multiple transactions per connection
Connect	Connect
BeginTransaction (1)	BeginTransaction (1)
Put (1)	Put (1)
CompareConnection --> MPI_CMP_EQUAL	CompareConnection --> MPI_CMP_EQUAL
Put (2)	BeginTransaction (2)
EndTransaction (1)	Put (2)
Disconnect	EndTransaction (1) EndTransaction (2) Disconnect

There is a requirement of some resources that all activity for a single resource occurs on a single thread. The capability to execute Listen, Get and Put with the same connection thread is possible.

Obviously, if a connection thread is being used during the execution of a map, it cannot be listening for the arrival of new events. Therefore, multiple listener threads must be started to enable concurrent execution and responsive handling of events. This adds a new constraint for the Resource Manager—the number of maps that can run concurrently to process a specific watch depends on the number of listener threads that have been created.

The **config.yaml** configuration file has a parameter (MaxWatchThreads), which is the maximum number of threads that can be created for connections for a given resource. This is used to determine the number of threads that will be started to listen for a given event if the adapter property MPIP_ADAPTER_LISTEN_USESAMECONN is TRUE.

COM API overview

The COM API enables applications to invoke maps remotely.

This API provides interfaces for running and controlling maps. It provides additional functionality, masks the need for visible structures, and removes the need to construct command lines.

The COM API is based on Map, Card, Adapter, and Stream objects. Card, Adapter, and Stream objects are used for source and target overrides.

Adapter objects interface with the adapter API. Stream objects eliminate the need for large, contiguous, memory buffers for passing data directly to a map object.

- [COM API interfaces overview](#)
The COM API uses interfaces for map, card, adapter and stream objects.
- [COM API object hierarchy](#)
The COM API objects exist in a defined hierarchy.

COM API interfaces overview

The COM API uses interfaces for map, card, adapter and stream objects.

- [IMFactory interface overview](#)
The IMFactory interface initializes or uninitialized the TX Programming Interface and creates a map object.
- [IMMap interface overview](#)
The IMMap method creates a map object instance from the byte array representing a compiled map file. This method creates hierarchies of map, card and adapter objects.
- [IMCard interface overview](#)
The IMCard interface uses a card object from the TX Programming Interface that represents an input or output card of a map in program memory.
- [IMAdapter interface overview](#)
The IMAdapter interface uses an adapter object from the TX Programming Interface that represents a resource adapter.
- [IMStream interface overview](#)
The IMStream interface uses a Stream object from the TX Programming Interface that represents an input or output card of a map in program memory.
- [IMStreamPage interface overview](#)
The IMStreamPage interface uses a StreamPage object from the TX Programming Interface that represents an input or output card of a map in program memory.

IMFactory interface overview

The IMFactory interface initializes or uninitialized the TX Programming Interface and creates a map object.

- [IMFactory virtual table order](#)
The IMFactory virtual table (vtable) lists all the methods for this interface.

IMFactory virtual table order

The IMFactory virtual table (vtable) lists all the methods for this interface.

- [IMFactory::InitMercAPI method](#)
The **IMFactory::InitMercAPI** method initializes the IBM Transformation Extender environment.
- [IMFactory::ExitMercAPI method](#)
The **IMFactory::ExitMercAPI** method cleans up the IBM Transformation Extender environment.
- [IMFactory::MapLoadMemory method](#)
The **IMFactory::MapLoadMemory** method is used with the IMFactory interface to load map memory.
- [IMFactory::MapReloadMemory method](#)
The **IMFactory::MapReloadMemory** method is used with the IMFactory interface to reload map memory.
- [IMFactory::MapLoadFile method](#)
The **IMFactory::MapLoadFile** method is used with the IMFactory interface to load a map file.
- [IMFactory::MapReloadFile method](#)
The **IMFactory::MapReloadFile** method is used with the IMFactory interface to reload a map file.

IMFactory::InitMercAPI method

The **IMFactory::InitMercAPI** method initializes the IBM Transformation Extender environment.

It should be called prior to any other call and only one time for each process. The bstrConfigFile can be passed in as `NULL` as long as name resolution is not required.

Quick info

```
HRESULT InitMercAPI(BSTR bstrConfigFile)
```

Parameters

bstrConfigFile
[in] - name of the configuration file used to determine the resource files used

Return values

The following value is returned when this method is called:

`S_OK`
Success status

IMFactory::ExitMercAPI method

The **IMFactory::ExitMercAPI** method cleans up the IBM Transformation Extender environment.

It should be called after any other call and only one time for each process.

Quick info

```
HRESULT ExitMercAPI()
```

Return values

The following value is returned when this method is called:

S_OK

Success status

IMFactory::MapLoadMemory method

The **IMFactory::MapLoadMemory** method is used with the IMFactory interface to load map memory.

Quick info

```
HRESULT MapLoadMemory([in] BSTR bstrIdentifier, [in] BSTR bstrWorkingDirectory,  
[in] VARIANT byteArray, [in] long sSize)
```

Parameters

bstrIdentifier

[in] - text string used to identify the compiled map

bstrWorkingDirectory

[in] - directory that should be used as the working directory for the map

byteArray

[in] - bytes that comprise a compiled map

sSize

[in] - number of bytes pointed to pcCompiledMap

Return values

The following value is returned when this method is called:

S_OK

Success status

IMFactory::MapReloadMemory method

The **IMFactory::MapReloadMemory** method is used with the IMFactory interface to reload map memory.

Quick info

```
HRESULT MapReloadMemory([in] BSTR bstrIdentifier,  
[in] BSTR bstrWorkingDirectory, [in] VARIANT byteArray, [in] long sSize)
```

Parameters

bstrIdentifier

[in] - text string used to identify the compiled map

bstrWorkingDirectory

[in] - directory that should be used as the working directory for the map

byteArray

[in] - bytes that comprise a compiled map

sSize

[in] - number of bytes pointed to pcCompiledMap

Return values

The following value is returned when this method is called:

S_OK

Success status

IMFactory::MapLoadFile method

The **IMFactory::MapLoadFile** method is used with the IMFactory interface to load a map file.

Quick info

```
HRESULT MapLoadFile(BSTR lpszMapFileName, IIMMap** pMMMap);
```

Parameters

lpszMapFileName
[in] - name of the map file (MMC)
pMMMap
[out, retval] - handle to map interface

Return values

The following value is returned when this method is called:

S_OK
Success status

IMFactory::MapReloadFile method

The **IMFactory::MapReloadFile** method is used with the IMFactory interface to reload a map file.

Quick info

```
HRESULT MapReloadFile(BSTR lpszMapFileName, IIMMap** pMMMap);
```

Parameters

lpszMapFileName
[in] - name of the map file (MMC)
pMMMap
[out, retval] - handle to map interface

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap interface overview

The IMMap method creates a map object instance from the byte array representing a compiled map file. This method creates hierarchies of map, card and adapter objects.

Client applications call the methods of the IMMap to do the following map functions:

- load
- control
- run

The map object is created when a map is loaded from a compiled map (.mmc) file or from memory. The TX Programming Interface caches maps. Therefore, if multiple map objects are created for the same map, the map file is read only one time.

A map object is reentrant. After a map object has been created, the map can be run an infinite number of times without any need for the map to be reloaded.

Multiple threads cannot reference the same map object concurrently. If multiple threads need to execute the same map concurrently, a separate map object should be obtained for each thread.

The identifier is used to identify the specific map. This might be the name of the map or any other identifier that the application will use. Subsequent calls to this method with the same identifier will not introduce additional processing of the compiled map. Therefore, after the initial call to this method, the memory consumed by **compiledMap** might be freed.

- [IMMap virtual table order](#)
The IMMap virtual table (vtable) lists all the methods for this interface.
- [IMMap properties](#)
The IMMap method creates a map object instance from the byte array representing a compiled map file. This method creates hierarchies of map, card and adapter objects. The map object supports the following types of properties:

IMMap virtual table order

The IMMap virtual table (vtable) lists all the methods for this interface.

- **[IMMap::Run method](#)**
The **IMMap::Run** method is used with the IMMap interface to run a map.
- **[IMMap::Refresh method](#)**
The **IMMap::Refresh** method is used with the IMMap interface.
- **[IMMap::Abort method](#)**
The **IMMap::Abort** method is used with the IMMap interface.
- **[IMMap::Pause method](#)**
The **IMMap::Pause** method is used with the IMMap interface.
- **[IMMap::Continue method](#)**
The **IMMap::Continue** method is used with the IMMap interface.
- **[IMMap::GetInputCard method](#)**
The **IMMap::GetInputCard** method is used with the IMMap interface.
- **[IMMap::GetOutputCard method](#)**
The **IMMap::GetOutputCard** method is used with the IMMap interface.
- **[IMMap::MapSetupNotifications method](#)**
The **IMMap::MapSetupNotifications** method is used with the IMMap interface.
- **[IMMap::GetInputCardCount method](#)**
The **IMMap::GetInputCardCount** method is used with the IMMap interface.
- **[IMMap::GetOutputCardCount method](#)**
The **IMMap::GetOutputCardCount** method is used with the IMMap interface.
- **[IMMap::GetPropertyCount method](#)**
The **IMMap::GetPropertyCount** method is used with the IMMap interface.
- **[IMMap::MapUnload method](#)**
The **IMMap::MapUnload** method is used with the IMMap interface.
- **[IMMap::GetIntegerProperty method](#)**
The **IMMap::GetIntegerProperty** method is used with the IMMap interface.
- **[IMMap::SetIntegerProperty method](#)**
The **IMMap::SetIntegerProperty** method is used with the IMMap interface.
- **[IMMap::GetTextProperty method](#)**
The **IMMap::GetTextProperty** method is used with the IMMap interface.
- **[IMMap::SetTextProperty method](#)**
The **IMMap::SetTextProperty** method is used with the IMMap interface.
- **[IMMap::GetBinaryProperty method](#)**
The **IMMap::GetBinaryProperty** method is used with the IMMap interface.
- **[IMMap::SetBinaryProperty method](#)**
The **IMMap::SetBinaryProperty** method is used with the IMMap interface.
- **[IMMap::GetPropertiesXML method](#)**
The **IMMap::GetPropertiesXML** method is used with the IMMap interface.
- **[IMMap::SetPropertiesXML method](#)**
The **IMMap::SetPropertiesXML** method is used with the IMMap interface.
- **[IMMap::GetAllPropertiesXML method](#)**
The **IMMap::GetAllPropertiesXML** method is used with the IMMap interface.

IMMap::Run method

The **IMMap::Run** method is used with the IMMap interface to run a map.

Quick info

HRESULT Run ()

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::Refresh method

The **IMMap::Refresh** method is used with the IMMap interface.

Quick info

HRESULT Refresh ()

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::Abort method

The **IMMap::Abort** method is used with the IMMap interface.

Quick info

```
HRESULT Abort()
```

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::Pause method

The **IMMap::Pause** method is used with the IMMap interface.

Quick info

```
HRESULT Pause()
```

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::Continue method

The **IMMap::Continue** method is used with the IMMap interface.

Quick info

```
HRESULT Continue()
```

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::GetInputCard method

The **IMMap::GetInputCard** method is used with the IMMap interface.

Quick info

```
HRESULT GetInputCard([in] long sCardNum, [out, retval] IMCard **pIMCard)
```

Parameters

sCardNum
[in] - number of the input card (starting at 1)

pIMCard
[out, retval] - handle to the card interface

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::GetOutputCard method

The **IMMap::GetOutputCard** method is used with the IMMap interface.

Quick info

```
HRESULT GetOutputCard([in] long sCardNum, [out, retval] IMCARD **pIMCard)
```

Parameters

sCardNum
[in] - number of the output card (starting at 1)

pIMCard
[out, retval] - handle to the card interface

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::MapSetupNotifications method

The **IMMap::MapSetupNotifications** method is used with the IMMap interface.

Quick info

```
HRESULT MapSetupNotifications (long sNotifyWhen)
```

Parameters

sNotifyWhen
[in] - bitmask indicating the events of which the registrator wished to be notified

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::GetInputCardCount method

The **IMMap::GetInputCardCount** method is used with the IMMap interface.

Quick info

```
HRESULT GetInputCardCount ([out, retval] long* InputCardCount)
```

Parameters

InputCardCount
[out, retval] - address of the integer variable to receive the card count

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::GetOutputCardCount method

The **IMMap::GetOutputCardCount** method is used with the IMMap interface.

Quick info

```
HRESULT GetOutputCardCount(long* pOutputCardCount)
```

Parameters

pOutputCardCount
[out, retval] - address of the integer variable to receive the card count

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::GetPropertyCount method

The **IMMap::GetPropertyCount** method is used with the IMMap interface.

Quick info

```
HRESULT GetPropertyCount(long lProperty, long *pValue)
```

Parameters

lProperty
[in] - property ID
pValue
[out, retval] - count of the property values

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::MapUnload method

The **IMMap::MapUnload** method is used with the IMMap interface.

Quick info

```
HRESULT MapUnload()
```

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::GetIntegerProperty method

The **IMMap::GetIntegerProperty** method is used with the IMMap interface.

Quick info

```
HRESULT GetIntegerProperty([in] long sProperty,  
                           [in] long sIndex, [out, retval] long *pVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property

pVal
[out, retval] - integer value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::SetIntegerProperty method

The **IMMap::SetIntegerProperty** method is used with the IMMap interface.

Quick info

```
HRESULT SetIntegerProperty([in] long sProperty, [in] long sIndex, [in] long newVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property

newVal
[in] - integer value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::GetTextProperty method

The **IMMap::GetTextProperty** method is used with the IMMap interface.

Quick info

```
HRESULT GetTextProperty(LONG sProperty, LONG sIndex, BSTR* pVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property

pVal
[out, retval] - text property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::SetTextProperty method

The **IMMap::SetTextProperty** method is used with the IMMap interface.

Quick info

```
HRESULT SetTextProperty(long sProperty, long sIndex, BSTR newVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property

pVal
[out, retval] - text value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::GetBinaryProperty method

The **IMMap::GetBinaryProperty** method is used with the IMMap interface.

Quick info

```
HRESULT GetBinaryProperty([in] long sProperty,  
                         [in] long sIndex, [out] VARIANT *pVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property

pVal
[out] - binary value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::SetBinaryProperty method

The **IMMap::SetBinaryProperty** method is used with the IMMap interface.

Quick info

```
HRESULT SetIntegerProperty([in] long sProperty, [in] long sIndex, [in] long newVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property

newVal
[out, retval] - binary value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::GetPropertiesXML method

The **IMMap::GetPropertiesXML** method is used with the IMMap interface.

Quick info

```
HRESULT GetPropertiesXML(long* idArray, long cmax, BSTR* xmlProperties)
```

Parameters

idArray
[in] - an integer array which lists the property IDs that are to be returned. For indexed type properties all index values are returned
cmax
[in] - array length
xmlProperties
[out, retval] - populated XML property document. Each property that was requested is returned in the XML document.

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap::SetPropertiesXML method

The **IMMap::SetPropertiesXML** method is used with the IMMap interface.

Quick info

```
HRESULT SetPropertiesXML(BSTR xmlProperties)
```

Parameters

xmlProperties
[in] - populated XML property document

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap:: GetAllPropertiesXML method

The **IMMap:: GetAllPropertiesXML** method is used with the IMMap interface.

Quick info

```
HRESULT GetAllPropertiesXML(BOOL bRecurse, BSTR* xmlProperties)
```

Parameters

bRecurse
[in] - If false then only the properties of the object will be returned. If true then properties of related objects will also be returned. Specifically:

- If the object is an IMCard, then the properties of the IMCard and the related IMAdapter object will be returned.
- If the object is an IMMap, then the properties of the IMMap, all of its associated IMCard objects and the related IMAdapter objects will be returned.

xmlProperties
[out, retval] - populated XML property document. Each property that was requested is returned in the XML document.

Return values

The following value is returned when this method is called:

S_OK
Success status

IMMap properties

The IMMap method creates a map object instance from the byte array representing a compiled map file. This method creates hierarchies of map, card and adapter objects. The map object supports the following types of properties:

- [General](#)
- [Audit](#)
- [Trace](#)
- [Workspace](#)
- [Sliding century](#)
- [Custom validation](#)
- [Map retry](#)

IMCard interface overview

The IMCard interface uses a card object from the TX Programming Interface that represents an input or output card of a map in program memory.

- [IMCard virtual table order](#)
The IMCard virtual table (vtable) lists all the methods for the IMCard interface.
- [IMCard properties](#)
The IMCard object supports the following types of properties:

IMCard virtual table order

The IMCard virtual table (vtable) lists all the methods for the IMCard interface.

- [IMCard::GetAdapter](#)
The **IMCard::GetAdapter** method is used with the IMCard interface.
- [IMCard::GetAdapterType](#)
The **IMCard::GetAdapterType** method is used with the IMCard interface.
- [IMCard::OverrideAdapter](#)
The **IMCard::OverrideAdapter** method is used with the IMCard interface.
- [IMCard::GetMap](#)
The **IMCard::GetMap** method is used with the IMCard interface.
- [IMCard::GetIntegerProperty](#)
The **IMCard::GetIntegerProperty** method is used with the IMCard interface.
- [IMCard::SetIntegerProperty](#)
The **IMCard::SetIntegerProperty** method is used with the IMCard interface.
- [IMCard::GetTextProperty](#)
The **IMCard::GetTextProperty** method is used with the IMCard interface.
- [IMCard::SetTextProperty](#)
The **IMCard::SetTextProperty** method is used with the IMCard interface.
- [IMCard::GetBinaryProperty](#)
The **IMCard::GetBinaryProperty** method is used with the IMCard interface.
- [IMCard::SetBinaryProperty](#)
The **IMCard::SetBinaryProperty** method is used with the IMCard interface.
- [IMCard::GetPropertiesXML](#)
The **IMCard::GetPropertiesXML** method is used with the IMCard interface.
- [IMCard::SetPropertiesXML](#)
The **IMCard::SetPropertiesXML** method is used with the IMCard interface.
- [IMCard::GetAllPropertiesXML](#)
The **IMCard::GetAllPropertiesXML** method is used with the IMCard interface.

IMCard::GetAdapter

The **IMCard::GetAdapter** method is used with the IMCard interface.

Quick info

```
HRESULT GetAdapter(IMAdapter **pIMAdapter)
```

Parameters

pIMAdapter

[ret, out] - handle to the adapter interface

Return values

The following value is returned when this method is called:

S_OK
Success status

IMCard::GetAdapterType

The **IMCard::GetAdapterType** method is used with the IMCard interface.

Quick info

```
HRESULT GetAdapterType(long *pVal)
```

Parameters

pVal
[out, retval] - type of the adapter

Return values

The following value is returned when this method is called:

S_OK
Success status

IMCard::OverrideAdapter

The **IMCard::OverrideAdapter** method is used with the IMCard interface.

Quick info

```
HRESULT OverrideAdapter(BSTR bstrAlias, long sType)
```

Parameters

bstrAlias
[in] - alias name of the adapter
sType
[in] - numeric type of the adapter

Return values

The following value is returned when this method is called:

S_OK
Success status

IMCard::GetMap

The **IMCard::GetMap** method is used with the IMCard interface.

Quick info

```
HRESULT GetMap(IMMap **pMMap)
```

Parameters

pMMap
[out, retval] - handle to the map interface

Return values

The following value is returned when this method is called:

S_OK
Success status

IMCard::GetIntegerProperty

The **IMCard::GetIntegerProperty** method is used with the IMCard interface.

Quick info

```
HRESULT GetIntegerProperty([in] long sProperty,  
                           [in] long sIndex, [out, retval] long *pVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property

pVal
[out, retval] - integer value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMCard::SetIntegerProperty

The **IMCard::SetIntegerProperty** method is used with the IMCard interface.

Quick info

```
HRESULT SetIntegerProperty([in] long sProperty, [in] long sIndex, [in] long newVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property

newVal
[in] - integer value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMCard::GetTextProperty

The **IMCard::GetTextProperty** method is used with the IMCard interface.

Quick info

```
HRESULT GetTextProperty(LONG sProperty, LONG sIndex, BSTR* pVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property
pVal
[out, retval] - text property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMCard::SetTextProperty

The **IMCard::SetTextProperty** method is used with the IMCard interface.

Quick info

```
HRESULT SetTextProperty(long sProperty, long sIndex, BSTR newVal)
```

Parameters

sProperty
[in] - property ID
sIndex
[in] - index of the property
pVal
[out, retval] - text value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMCard::GetBinaryProperty

The **IMCard::GetBinaryProperty** method is used with the IMCard interface.

Quick info

```
HRESULT GetBinaryProperty([in] long sProperty,  
                         [in] long sIndex, [out] VARIANT *pVal)
```

Parameters

sProperty
[in] - property ID
sIndex
[in] - index of the property
pVal
[out] - binary value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMCard::SetBinaryProperty

The **IMCard::SetBinaryProperty** method is used with the IMCard interface.

Quick info

```
HRESULT SetIntegerProperty([in] long sProperty, [in] long sIndex, [in] long newVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property

newVal
[out, retval] - binary value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMCard::GetPropertiesXML

The **IMCard::GetPropertiesXML** method is used with the IMCard interface.

Quick info

```
HRESULT GetPropertiesXML(long* idArray, long cmax, BSTR* xmlProperties)
```

Parameters

idArray
[in] - an integer array which lists the property IDs that are to be returned. For indexed type properties all index values are returned
cmax
[in] - array length
xmlProperties
[out, retval] - populated XML property document. Each property that was requested is returned in the XML document.

Return values

The following value is returned when this method is called:

S_OK
Success status

IMCard::SetPropertiesXML

The **IMCard::SetPropertiesXML** method is used with the IMCard interface.

Quick info

```
HRESULT SetPropertiesXML(BSTR xmlProperties)
```

Parameters

xmlProperties
[in] - populated XML property document

Return values

The following value is returned when this method is called:

S_OK
Success status

IMCard::GetAllPropertiesXML

The **IMCard::GetAllPropertiesXML** method is used with the IMCard interface.

Quick info

```
HRESULT GetAllPropertiesXML(BOOL bRecurse, BSTR* xmlProperties)
```

Parameters

bRecurse

[in] - If false then only the properties of the object will be returned. If true then properties of related objects will also be returned. Specifically:

- If the object is an IMCard, then the properties of the IMCard and the related IMAdapter object will be returned.
- If the object is an IMMap, then the properties of the IMMap, all of its associated IMCard objects and the related IMAdapter objects will be returned.

xmlProperties

[out, retval] - populated XML property document. Each property that was requested is returned in the XML document.

Return values

The following value is returned when this method is called:

S_OK

Success status

IMCard properties

The IMCard object supports the following types of properties:

- [General](#)
- [Backup](#)

IMAdapter interface overview

The IMAdapter interface uses an adapter object from the TX Programming Interface that represents a resource adapter.

Defined methods allow the adapter properties to be modified.

- [IMAdapter virtual table order](#)
The IMAdapter virtual table (vtable) lists all the methods for this interface.
- [IMAdapter properties](#)
The IMAdapter object supports the following types of properties:

IMAdapter virtual table order

The IMAdapter virtual table (vtable) lists all the methods for this interface.

- [IMAdapter::GetCard](#)
The IMAdapter::GetCard method is used with the IMAdapter interface.
- [IMAdapter::GetStream](#)
The IMAdapter::GetStream method returns the stream object associated with the adapter object.
- [IMAdapter::GetInputStream](#)
The IMAdapter::GetInputStream method is used with the IMAdapter interface.
- [IMAdapter::GetOutputStream](#)
The IMAdapter::GetOutputStream method is used with the IMAdapter interface.
- [IMAdapter::GetIntegerProperty](#)
The IMAdapter::GetIntegerProperty method is used with the IMAdapter interface.
- [IMAdapter::SetIntegerProperty](#)
The IMAdapter::SetIntegerProperty method is used with the IMAdapter interface.
- [IMAdapter::GetTextProperty](#)
The IMAdapter::GetTextProperty method is used with the IMAdapter interface.
- [IMAdapter::SetTextProperty](#)
The IMAdapter::SetTextProperty method is used with the IMAdapter interface.
- [IMAdapter::GetBinaryProperty](#)
The IMAdapter::GetBinaryProperty method is used with the IMAdapter interface.
- [IMAdapter::SetBinaryProperty](#)
The IMAdapter::SetBinaryProperty method is used with the IMAdapter interface.
- [IMAdapter::GetPropertiesXML](#)
The IMAdapter::GetPropertiesXML method is used with the IMAdapter interface.
- [IMAdapter::SetPropertiesXML](#)
The IMAdapter::SetPropertiesXML method is used with the IMAdapter interface.
- [IMAdapter::GetAllPropertiesXML](#)
The IMAdapter::GetAllPropertiesXML method is used with the IMAdapter interface.

IMAdapter::GetCard

The **IMAdapter::GetCard** method is used with the IMAdapter interface.

Quick info

```
HRESULT GetCard(IMCard **pMCARD)
```

Parameters

pMCARD
[out, retval] - handle to card interface

Return values

The following value is returned when this method is called:

S_OK
Success status

IMAdapter::GetStream

The **IMAdapter::GetStream** method returns the stream object associated with the adapter object.

Quick info

```
HRESULT GetStream(long sProperty, long sIndex, IMStream **pIMStream)
```

Parameters

sProperty
[in] - property ID
sIndex
[in] - index of the property
pIMStream
[out,retval] - handle to stream object

Return values

The following value is returned when this method is called:

S_OK
Success status

IMAdapter::GetInputStream

The **IMAdapter::GetInputStream** method is used with the IMAdapter interface.

Quick info

```
HRESULT GetInputStream(IMStream **pIMStream)
```

Parameters

pIMStream
[out,retval] - handle to input stream object

Return values

The following value is returned when this method is called:

S_OK
Success status

IMAdapter::GetOutputStream

The **IMAdapter::GetOutputStream** method is used with the IMAdapter interface.

Quick info

```
HRESULT GetOutputStream(IMStream **pIMStream)
```

Parameters

pIMStream
[out, retval] - handle to output stream object

Return values

The following value is returned when this method is called:

S_OK
Success status

IMAdapter::GetIntegerProperty

The **IMAdapter::GetIntegerProperty** method is used with the IMAdapter interface.

Quick info

```
HRESULT GetIntegerProperty([in] long sProperty,  
                           [in] long sIndex, [out, retval] long *pVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property
pVal
[out, retval] - integer value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMAdapter::SetIntegerProperty

The **IMAdapter::SetIntegerProperty** method is used with the IMAdapter interface.

Quick info

```
HRESULT SetIntegerProperty([in] long sProperty, [in] long sIndex, [in] long newVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property
newVal
[in] - integer value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMAdapter::GetTextProperty

The **IMAdapter::GetTextProperty** method is used with the IMAdapter interface.

Quick info

```
HRESULT GetTextProperty(LONG sProperty, LONG sIndex, BSTR* pVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property

pVal
[out, retval] - text property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMAdapter::SetTextProperty

The **IMAdapter::SetTextProperty** method is used with the IMAdapter interface.

Quick info

```
HRESULT SetTextProperty(long sProperty, long sIndex, BSTR newVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property

pVal
[out, retval] - text value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMAdapter::GetBinaryProperty

The **IMAdapter::GetBinaryProperty** method is used with the IMAdapter interface.

Quick info

```
HRESULT GetBinaryProperty([in] long sProperty,  
                           [in] long sIndex, [out] VARIANT *pVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property

pVal
[out] - binary value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMAdapter::SetBinaryProperty

The **IMAdapter::SetBinaryProperty** method is used with the IMAdapter interface.

Quick info

```
HRESULT SetIntegerProperty([in] long sProperty, [in] long sIndex, [in] long newVal)
```

Parameters

sProperty
[in] - property ID

sIndex
[in] - index of the property
newVal
[out, retval] - binary value of the property

Return values

The following value is returned when this method is called:

S_OK
Success status

IMAdapter::GetPropertiesXML

The **IMAdapter::GetPropertiesXML** method is used with the IMAdapter interface.

Quick info

```
HRESULT GetPropertiesXML(long* idArray, long cmax, BSTR* xmlProperties)
```

Parameters

idArray
[in] - an integer array which lists the property IDs that are to be returned. For indexed type properties all index values are returned
cmax
[in] - array length
xmlProperties
[out, retval] - populated XML property document. Each property that was requested is returned in the XML document.

Return values

The following value is returned when this method is called:

S_OK
Success status

IMAdapter::SetPropertiesXML

The **IMAdapter::SetPropertiesXML** method is used with the IMAdapter interface.

Quick info

```
HRESULT SetPropertiesXML(BSTR xmlProperties)
```

Parameters

xmlProperties

[in] - populated XML property document

Return values

The following value is returned when this method is called:

S_OK
Success status

IMAdapter::GetAllPropertiesXML

The **IMAdapter::GetAllPropertiesXML** method is used with the IMAdapter interface.

Quick info

```
HRESULT GetAllPropertiesXML(BOOL bRecurse, BSTR* xmlProperties)
```

Parameters

bRecurse

[in] - If false then only the properties of the object will be returned. If true then properties of related objects will also be returned.

xmlProperties

[out, retval] - properties are specified in the form of an XML document. The XML Schema for this is mercpi_properties.xsd. Both the request document, which specifies which properties to return, and the returned document comply to this XML Schema.

Return values

The following value is returned when this method is called:

S_OK
Success status

IMAdapter properties

The IMAdapter object supports the following types of properties:

- [General](#)
- [On Success](#)
- [On Failure](#)
- [Retry](#)
- [Scope](#)
- [Warnings](#)
- [Aggregation](#)

IMStream interface overview

The IMStream interface uses a Stream object from the TX Programming Interface that represents an input or output card of a map in program memory.

- [IMStream virtual table order](#)
The IMStream virtual table (vtable) lists all the methods for this interface.

IMStream virtual table order

The IMStream virtual table (vtable) lists all the methods for this interface.

- [IMStream::Seek](#)
The **IMStream::Seek** method moves the stream cursor to the specified offset.
- [IMStream::Tell](#)
The **IMStream::Tell** method retrieves the current cursor absolute position (relative to the start).
- [IMStream::IsEnd](#)
The **IMStream::IsEnd** method checks if the cursor is at the stream end.
- [IMStream::GetSize](#)
The **IMStream::GetSize** method returns the current size of the stream.
- [IMStream::SetSize](#)
The **IMStream::SetSize** method sets the new stream size.
- [IMStream::Write](#)
The **IMStream::Write** method writes a portion of an array of bytes.

- [**IMStream::Modify**](#)
The **IMStream::Modify** method modifies stream settings.
- [**IMStream::Read**](#)
The **IMStream::Read** method reads bytes into a portion of a byte array.
- [**IMStream::Flush**](#)
The **IMStream::Flush** method forces the current data in memory to be written to file.
- [**IMStream::ReadPage**](#)
The **IMStream::ReadPage** method returns the **StreamPage** object associated with the specified stream.
- [**IMStream::NewStreamPage**](#)
The **IMStream::NewStreamPage** method creates a new stream page object.
- [**IMStream::DeletePage**](#)
The **IMStream::DeletePage** method deletes the stream page object associated with the stream.

IMStream::Seek

The **IMStream::Seek** method moves the stream cursor to the specified offset.

Quick info

```
HRESULT Seek(long lPos, long lOrigin)
```

Parameters

- lPos*
[in] - the offset from the origin
lOrigin
[in] - origin to which *iPos* is relative

Return values

The following value is returned when this method is called:

- S_OK
Success status

IMStream::Tell

The **IMStream::Tell** method retrieves the current cursor absolute position (relative to the start).

Quick info

```
HRESULT Tell([out, retval] long *pVal)
```

Parameters

- pVal*
[out, retval] - cursor position

Return values

The following value is returned when this method is called:

- S_OK
Success status

IMStream::IsEnd

The **IMStream::IsEnd** method checks if the cursor is at the stream end.

Quick info

```
HRESULT IsEnd(BOOL *pVal)
```

Parameters

- pVal*
[out, retval] - Is *true* if the cursor is at stream end. Is *false* if the cursor is not at stream end.

Return values

The following value is returned when this method is called:

S_OK

Success status

IMStream::GetSize

The **IMStream::GetSize** method returns the current size of the stream.

Quick info

```
HRESULT GetSize([out, retval] long *pVal)
```

Parameters

pVal

[out, retval] - stream size (in bytes)

Return values

The following value is returned when this method is called:

S_OK

Success status

IMStream::SetSize

The **IMStream::SetSize** method sets the new stream size.

If the new size is less than the old size, the stream is truncated to the specified size. If the new size is greater than the old one the stream is appended with the appropriate number of zeros to occupy the new size in bytes.

Quick info

```
HRESULT SetSize(long lVal)
```

Parameters

iVal

[in] - new size

Return values

The following value is returned when this method is called:

S_OK

Success status

IMStream::Write

The **IMStream::Write** method writes a portion of an array of bytes.

Quick info

```
HRESULT Write(VARIANT vData, long lSize)
```

Parameters

vData

[in] - array of bytes

lSize

[in] - number of bytes to write

Return values

The following value is returned when this method is called:

S_OK
Success status

IMStream::Modify

The **IMStream::Modify** method modifies stream settings.

The stream data is written to memory until it reaches a threshold and then it is written to a file. The created file can be temporary or explicit. A temporary file can be created in the system temp directory or in a specified one. If both the fileName and dir are empty strings or null, a temporary file is created in the system's temp dir. If only the fileName is empty (null), a temporary file is created in the specified directory. If the fileName is specified, dir is ignored.

Quick info

```
HRESULT Modify(long lMaxMem, BSTR bstrDirectory, BSTR bstrFileName,  
VARIANT_BOOL bKeepFile)
```

Parameters

lMaxMem
[in] - threshold size for stream. After the stream exceeds this size, it will begin to be flushed to file.
bstrDirectory
[in] - directory in which to create the temporary file
bstrFileName
[in] - explicit file name path
bKeepFile
[in] - If it is `true`, the file is preserved after the stream is destroyed. If it is `false`, the file is deleted.

Return values

The following value is returned when this method is called:

S_OK
Success status

IMStream::Read

The **IMStream::Read** method reads bytes into a portion of a byte array.

The maximum number of bytes that the method reads is specified by the *lsize* parameter.

Quick info

```
HRESULT Read(long lSize, VARIANT *pvData)
```

Parameters

lSize
[in] - number of bytes to read
pvData
[out] - buffer to receive bytes. The method reads as many bytes as will fit in the array. The actual number of bytes read is returned.

Return values

The following value is returned when this method is called:

S_OK
Success status

IMStream::Flush

The **IMStream::Flush** method forces the current data in memory to be written to file.

Quick info

```
HRESULT Flush()
```

Return values

The following value is returned when this method is called:

S_OK
Success status

IMStream::ReadPage

The **IMStream::ReadPage** method returns the **StreamPage** object associated with the specified stream.

Quick info

```
HRESULT ReadPage(IMStreamPage **pIStreamPage)
```

Parameters

pIStreamPage
[out, retval] - handle to the stream page

Return values

The following value is returned when this method is called:

S_OK
Success status

IMStream::NewStreamPage

The **IMStream::NewStreamPage** method creates a new stream page object.

Quick info

```
HRESULT NewStreamPage(VARIANT vData, long lSize, VARIANT_BOOL bCopy,  
IMStreamPage** pIStreamPage)
```

Parameters

vData
[in] - data to the stream in bytes
lSize
[in] - size of the new stream
bCopy
[in] - copies the data to the new stream page

Return values

The following value is returned when this method is called:

S_OK
Success status

IMStream::DeletePage

The **IMStream::DeletePage** method deletes the stream page object associated with the stream.

Quick info

```
HRESULT DeletePage(IMStreamPage* pIStreamPage)
```

Parameters

pIStreamPage
[in] - StreamPage interface handle

Return values

The following value is returned when this method is called:

S_OK
Success status

IMStreamPage interface overview

The IMStreamPage interface uses a StreamPage object from the TX Programming Interface that represents an input or output card of a map in program memory.

- [IMStreamPage virtual table order](#)
The IMStreamPage virtual table (vtable) lists all the methods for this interface.

IMStreamPage virtual table order

The IMStreamPage virtual table (vtable) lists all the methods for this interface.

- [IMStreamPage::GetSize](#)
The IMStreamPage::GetSize method returns the size of the stream.
- [IMStreamPage::GetData](#)
The IMStreamPage::GetData method returns the data in the stream page.
- [IMStreamPage::DeletePage](#)
The IMStreamPage::DeletePage method deletes the stream page object associated with the stream.

IMStreamPage::GetSize

The IMStreamPage::GetSize method returns the size of the stream.

Quick info

```
HRESULT GetSize(long *pVal)
```

Parameters

pVal
[out, retval] - stream size

Return values

The following value is returned when this method is called:

S_OK
Success status

IMStreamPage::GetData

The IMStreamPage::GetData method returns the data in the stream page.

Quick info

```
HRESULT GetData(VARIANT_BOOL bIntrep, VARIANT* pvData);
```

Parameters

bIntrep
[in]
pvData
[out] - return data in bytes

Return values

The following value is returned when this method is called:

S_OK
Success status

IMStreamPage::DeletePage

The **IMStreamPage::DeletePage** method deletes the stream page object associated with the stream.

Quick info

HRESULT DeletePage ()

Return values

The following value is returned when this method is called:

S_OK
Success status

COM API object hierarchy

The COM API objects exist in a defined hierarchy.

A map object can contain one or more card objects.

The object relationship is described in the following list:

- Each card object always has an adapter object associated with it.
- A map object has a number of card objects. The number is dependent on the number of input and output cards in a map.

Java API overview

The Java API interfaces enable you to create, edit, and run maps and schemas from a Java™ program.

IBM Transformation Extender provides a design-time Java API and a runtime Java API. The design-time Java API is different than the runtime Java API in that you can use the design-time Java API to create maps and type trees on Windows operating systems only.

For more information about the design-time Java API client interface, see the Javadocs by opening the overview-tree.html file located in *install_dir\docs\dtxds*.

For more information about the runtime Java API client interface, see the Javadocs by opening the overview-summary.html file located in *install_dir\docs\dtxpi*.

Java Tools overview

The Java™ Tools provide objects and JNI utilities that you can use to get information about your map instances.

For more information about the Java Tools client interfaces, see the Javadocs by opening the package-summary.html file located in *install_dir\docs\dtxpi\java\com\ibm\websphere\dtx\dtxpi\tools*.

Python API

Use the Python API to create, edit, and run maps and schemas from a Python program. For details, see the documentation installed in *install_dir\python\api\hip\docs\html\index.html*. Examples of the Python API are installed in *install_dir\python\api\examples*. Documentation for the Python API examples is available in *install_dir\python\api\docs\html\examples.html*.

IBM Transformation Extender REST API

IBM® Transformation Extender provides a REST API to run maps on a web server. An application can use virtually any programming language or technology to call the API, enabling transformation to be offered as a service from any web server or cloud platform.

- [Introduction](#)

- [Swagger documentation](#)

The APIs exposed by the ITX REST API are documented using Swagger.

- [Running a map directly](#)

- [REST API output](#)

When the map run completes, REST API output is text, only if a single card (and no other items) is returned. If two or more cards or any of the other optional items are added to a single (or multiple) card call, the output is a JSON data structure, with the actual card output being encoded with BASE64. Response is similar to the following example:

- [Cataloging a map](#)

- [Tutorial](#)

- [Important: Delete the artifacts from asynchronous map runs](#)
 - [Map caching](#)
 - [Map execution logs](#)
-

Introduction

An application can run an IBM® Transformation Extender map on a web server either synchronously or asynchronously. Use *synchronous* processing to run a map that must complete before it returns a response to the calling application. When you run a map *asynchronously*, the API returns URLs that an application can use to check the status of a long-running map and to retrieve output data and audit and trace logs when the map completes.

Running a map asynchronously requires a Redis server in addition to the web server. See the product [release notes](#) for details.

The servlet that implements the ITX REST APIs can run as a separate process from the web server process, in *fenced* run mode. Fenced mode ensures that an ITX failure does not affect the web server. Fenced mode is required to run a map asynchronously. In *unfenced* run mode, the servlet runs within the web server. Run maps in unfenced mode only for demos or during testing; do not use unfenced mode in production.

The HTTP request that invokes a map can pass data to one or more of the map's input cards. The HTTP response can return one or more map outputs. The API call can specify an adapter override that causes the map to receive input from an adapter or write output data to an adapter.

In addition, ITX provides a REST API that you can use to catalog maps and generate Swagger documentation for them. An application can run a cataloged map without specifying the URL of the map location or the cards to override, simplifying the web service call. This approach enables maps to be exposed as REST API endpoints without the need for the caller of the API to be aware of any ITX specifics.

The product [release notes](#) describe the prerequisites and required configuration to use the REST API and the tutorial.

Swagger documentation

The APIs exposed by the ITX REST API are documented using Swagger.

To access the Swagger documentation, enter the following URL in a browser. If the tx-rest.war file is installed on a server other than the local host, adjust the host name.

`http://localhost:8080/tx-rest/api-docs?url=/tx-rest/swagger.json`

You can invoke the APIs directly from the Swagger documentation by clicking Try it out under each API definition.

Running a map directly

Use curl to run a map from the command line.

- The HTTP PUT request runs the map synchronously.
- The HTTP POST request runs the map asynchronously.

Both requests use the same command parameters.

- [Synchronous direct calls](#)
 - [Asynchronous direct calls and map status queries](#)
-

Synchronous direct calls

The example below synchronously runs a map on a web server that's installed on the local host. The map has one input card and one output card. The command overrides the input card with the text string `test data` and requests the output data and audit log to be returned in the response:

```
> curl -X PUT -d "test data" "http://localhost:8080/tx-rest/v1/itx/maps/direct/OneInOneOut?input=1&output=1&return=audit"
```

<code>PUT</code>	Runs a map synchronously.
<code>-d "test data"</code>	Specifies the data to override a single card. To override multiple input cards, send the data for each card as multi-part form data, with the card number as the part name. For example: <code>"1=Card1 data" "2=Card2 data"</code>
<code>http://localhost:8080/tx-rest/v1/itx/maps/direct/</code>	The hostname and port of the web server where the tx-rest.war file is deployed, and the base URL for invoking maps directly.
<code>OneInOneOut</code>	The path to the compiled map file, relative to the <code>map.dirs=</code> path specified in the in the <code>install_dir/tx-rest.properties</code> file. The map file type (.mmc) is not required.

<code>input=1&output=1</code>	<p>The map input and output cards to override with data. The format of the parameters depends on whether a single card is overridden or multiple cards are overridden.</p> <p>Transfer data to or from a single card or a single audit or trace file as binary data. To override a single card, specify the card number as <code>input=cardnum</code> or <code>output=cardnum</code>.</p> <p>Transfer data to or from multiple cards or transfer multiple returns (such as a single output card with a trace file) as multi-part form data.</p> <ul style="list-style-type: none"> To override multiple input cards, send the data for each card as multi-part form data, with the card number as the part name. For example: <pre>"1=Card1 data" "2=Card2 data"</pre> <ul style="list-style-type: none"> To overwrite multiple output cards, specify: <pre>output=cardnum,cardnum</pre>
<code>return=[audit] [trace] [status] [auditonerror]</code> <code>[traceonerror] [statusonerror]</code>	<p>Specifies what to return from the map. Separate multiple values with commas, for example:</p> <pre>return=audit,trace</pre> <p>If you specify <code>auditonerror</code>, <code>traceonerror</code>, or <code>statusonerror</code>, the map returns audit, trace, or status only if the map does not complete successfully.</p>

Asynchronous direct calls and map status queries

The following command runs a map asynchronously and requests all outputs, the audit log, and the trace log to be returned from the map. To run a map asynchronously, you must set `rest.mode` in the `install_dir/config.yaml` configuration file.

```
> curl -X POST -F "1=Card1 data" -F "2=Card2 data" http://localhost:8080/tx-rest/v1/itx/maps/direct/TwoInTwoOut?
output=1,2&return=audit,trace
```

<code>POST</code>	Runs the map asynchronously.
<code>-F "1=Card1 data" -F "2=Card2 data"</code>	Overrides input card 1 and input card 2 with multi-part form data.
<code>http://localhost:8080/tx-rest/v1/itx/maps/direct</code>	The hostname and port of the web server where the tx-rest.war file is deployed, and the base URL for invoking maps directly.
<code>TwoInTwoOut</code>	The path to the compiled map file, relative to the <code>rest.persistence.maps</code> path specified in the in the <code>install_dir/config.yaml</code> file. The map file type (.mmc) is not required.
<code>output=1,2</code>	Overrides output cards 1 and 2 and returns a link to the data for both output cards in the response.
<code>return=audit,trace</code>	Returns a link to the audit log and trace log in the response when the map completes.

Running a map asynchronously immediately returns a response similar to the following. The response contains the URL that an application can use to query the status of a queued or long-running map.

```
{"id": "8b1f7e5e-5d16-480b-a972-03d66949cf7b", "href": "http://localhost:8080/tx-rest/v1/itx/maps/direct/8b1f7e5e-5d16-480b-a972-03d66949cf7b/status"}
```

Use a **GET** request and the URL from the response to query the map status:

```
> curl -X GET http://localhost:8080/tx-rest/v1/itx/maps/direct/8b1f7e5e-5d16-480b-a972-03d66949cf7b/status
```

The response from the **GET** request indicates whether the map execution is in progress or queued, the start time, and the number of milliseconds that the map has been queued or running. Call **GET** repeatedly until the map completes.

When the map completes, the status response is similar to the following example:

```
{
  "outputs": [
    {
      "href": "http://localhost:8080/tx-rest/v1/itx/maps/direct/8b1f7e5e-5d16-480b-a972-03d66949cf7b/outputs/1",
      "mime_type": "application/octet-stream",
      "card_number": 1
    },
    {
      "href": "http://localhost:8080/tx-rest/v1/itx/maps/direct/8b1f7e5e-5d16-480b-a972-03d66949cf7b/outputs/2",
      "mime_type": "application/octet-stream",
      "card_number": 2
    }
  ],
  "status": 0,
  "audit_href": "http://localhost:8080/tx-rest/v1/itx/maps/direct/8b1f7e5e-5d16-480b-a972-03d66949cf7b/audit",
  "trace_href": "http://localhost:8080/tx-rest/v1/itx/maps/direct/8b1f7e5e-5d16-480b-a972-03d66949cf7b/trace",
  "status_message": "Map completed successfully",
  "elapsed_time": 3,
  "start_timestamp": "2018-03-26T19:28:21.085+0000"
}
```

Use **GET** requests and the returned URLs to retrieve the output data, audit log, and trace log.

REST API output

When the map run completes, REST API output is text, only if a single card (and no other items) is returned. If two or more cards or any of the other optional items are added to a single (or multiple) card call, the output is a JSON data structure, with the actual card output being encoded with BASE64. Response is similar to the following example:

```
{
  "type": {
    "type": "multipart",
    "subtype": "related",
    "parameters": {},
    "wildcardType": false,
    "wildcardSubtype": false
  },
  "allAttachments": [
    {
      "headers": {
        "Content-ID": [
          "1"
        ],
        "Content-Type": [
          "application/octet-stream"
        ]
      },
      "object": null,
      "contentDisposition": null,
      "contentId": "1",
      "contentType": {
        "type": "application",
        "subtype": "octet-stream",
        "parameters": {},
        "wildcardType": false,
        "wildcardSubtype": false
      },
      "dataHandler": null
    },
    {
      "headers": {
        "Content-ID": [
          "2"
        ],
        "Content-Type": [
          "application/octet-stream"
        ]
      },
      "object": null,
      "contentDisposition": null,
      "contentId": "2",
      "contentType": {
        "type": "application",
        "subtype": "octet-stream",
        "parameters": {},
        "wildcardType": false,
        "wildcardSubtype": false
      },
      "dataHandler": null
    }
  ],
  "childAttachments": [
    {
      "headers": {
        "Content-ID": [
          "2"
        ],
        "Content-Type": [
          "application/octet-stream"
        ]
      },
      "object": null,
      "contentDisposition": null,
      "contentId": "2",
      "contentType": {
        "type": "application",
        "subtype": "octet-stream",
        "parameters": {},
        "wildcardType": false,
        "wildcardSubtype": false
      },
      "dataHandler": null
    }
  ],
  "rootAttachment": {
    "headers": {
      "Content-ID": [
        "1"
      ],
      "Content-Type": [
        "application/octet-stream"
      ]
    },
    "object": null,
    "contentDisposition": null,
    "contentId": "1",
    "contentType": {
      "type": "application",
      "subtype": "octet-stream",
      "parameters": {}
    }
  }
}
```

```
        "wildcardType": false,
        "wildcardSubtype": false
    },
    "dataHandler": null
}
```

Cataloging a map

Cataloging a map simplifies calls to the map and generates Swagger documentation that describes the APIs. The catalog provides a way to expose maps as services and to hide the implementation details of the services.

A map is defined in the catalog as a JSON document, similar to the `lin1out` map example that's included in the tutorial:

```
{
  "name": "lin1out",
  "summary": "Single input & single output",
  "description": "Uppercases the output from a single input",
  "tags": [ "Test" ],
  "inputs": [
    {
      "card_number": 1,
      "mime_type": "text/plain",
      "description": "Plain text"
    }
  ],
  "outputs": [
    {
      "card_number": 1,
      "mime_type": "text/plain",
      "description": "Uppercased input"
    }
  ],
  "url_path": "test/lin1out",
  "map_path": "OneInOneOut"
}
```

The Swagger documentation for the ITX REST API defines the structure of the JSON document and explains the purpose of each element.

You register a map in the catalog by posting the JSON document that defines it to the catalog directory specified on `rest.persistence.catalog` in the `install_dir/config.yaml` file. For example:

```
> curl -X POST "http://localhost:8080/tx-rest/v1/itx/catalog" -H "Content-Type: application/json" -d
@..\descriptors\lin1out.json
```

Use Swagger to display map details and to test-run maps. To see the Swagger documentation for the cataloged maps, enter the following URL in a browser:

```
http://localhost:8080/tx-rest/api-docs?url=/tx-rest/v1/itx/docs
```

If the tx-rest.war file is installed on a server other than the local host, adjust the host name.

You can run a cataloged map without specifying which cards to override or the name and path of the calling map. For example, the following command synchronously runs the cataloged version of the OneInOneOut map. Compare it to the direct call that runs the same map in [Synchronous direct calls](#):

```
> curl -X PUT -d "test data" "http://localhost:8080/tx-rest/v1/itx/maps/catalog/test/lin1out"
```

Tutorial

Transformation Extender installs a REST API tutorial in the `install_dir\examples\restapi` directory. The tutorial provides example maps, scripts, and README instructions that demonstrate how to catalog maps, access them from the Swagger interface, and call them using curl commands.

Before you use the tutorial, see the [release notes](#) for the REST API configuration requirements.

Important: Delete the artifacts from asynchronous map runs

The status, audit log, and trace log from an asynchronous map run are stored on the Redis server until you explicitly delete them. You must explicitly delete these artifacts when you run a map asynchronously, whether you run the map through a direct call, through the catalog, or from the Swagger interface.

To delete the artifacts of a map run, use a **DELETE** request and the URL of the map-run resource returned from the initial **POST** request. (Omit `/status` from the URL.) For example:

```
> curl -X DELETE "http://localhost:8080/tx-rest/v1/itx/maps/direct/8b1f7e5e-5d16-480b-a972-03d66949cf7b"
```

To verify that the map artifacts are deleted, use a **GET** request to request the map's status. For example:

```
> curl -X GET http://localhost:8080/tx-rest/v1/itx/maps/direct/8b1f7e5e-5d16-480b-a972-03d66949cf7b/status
```

After the artifacts of the map run are deleted, the **GET** request returns a response similar to the following:

```
{"code":404,"message":"No map run is in progress with id 8b1f7e5e-5d16-480b-a972-03d66949cf7b."}
```

Map caching

The ITX REST API caches maps in memory to avoid reloading them each time the map is executed.

To prevent maps that are used infrequently from consuming server resources, the REST API unloads a map that has not been accessed for a specified amount of time. The `rest.map.unloadTime` configuration parameter in the `install_dir/config.yaml` file specifies the amount of time (in minutes) that can elapse before an unaccessed map is unloaded.

You do not need to restart the web server when you change a map. The REST API detects when a map is updated, unloads it from memory, and reloads the map. Subsequent map runs use the updated map.

Map execution logs

Configure and enable map execution logging in the `install_dir/config.yaml` file.

Remote Method Invocation (RMI) API overview

Remote Method Invocation (RMI) is used when writing object-oriented programming so objects on different machines are able to communicate in a distributed network environment.

RMI is the Java™ version of a remote procedure call (RPC), however, it also includes the capability to pass one or more objects along with the request. The RMI API provides functionality for loading and running maps, overriding adapters in cards, setting and retrieving object properties, as well as feeding data to maps and obtaining data from maps. The remote feature in the RMI API makes maps available to be run outside of the client process space.

For more information about the RMI API client interfaces, see the Javadocs by opening the `package-summary.html` file located in `install_dir/docs/dtxpl/com/ibm/websphere/dtx/dtxpl/rmi`.

- [RMI server overview](#)
The RMI API is composed of two parts: client and server.
- [RMI server configurations](#)
You must configure the RMI server to run your maps.
- [RMI API configuration overview](#)
A fatal exception within the transformation logic that runs the map could cause the calling process to terminate. To mitigate against this, there are three configuration options available for the RMI API.

RMI server overview

The RMI API is composed of two parts: client and server.

The client interface component consists of Java™ classes used to load maps and override map settings. The server component, or RMI server, runs the maps.

- [RMI server implementation](#)
The RMI server runs maps in its own process and operates in one of three modes: single process, multi-process, and in-process.
- [RMI server error handling](#)
All error conditions generated by the IBM Transformation Extender Programming Interface are wrapped and re-thrown as RMI API exceptions.
- [RMI server process modes](#)
The RMI server can run in either a single or multi-process mode.

RMI server implementation

The RMI server runs maps in its own process and operates in one of three modes: single process, multi-process, and in-process.

The mode is specified when the server is started.

Related tasks

- [Starting the RMI server](#)

Related reference

- [RMI server mode property](#)

RMI server error handling

All error conditions generated by the IBM Transformation Extender Programming Interface are wrapped and re-thrown as RMI API exceptions.

These include various map, adapter, and internal failures. Errors generated by the RMI server are also thrown as RMI API exceptions as well as all unexpected error conditions. Low-level RMI and network-related exceptions are passed unchanged to the client. The MRmiApiException class has a list of RMI server-specific error conditions.

RMI server process modes

The RMI server can run in either a single or multi-process mode.

The different process modes control the way in which the RMI server runs the maps.

- [RMI server single process mode](#)
The RMI server can run in a single process mode.
 - [RMI server multi-process mode](#)
The RMI server can run in a multi-process mode.
 - [RMI server in-process mode](#)
The RMI server can run in an in-process mode. The in-process implementation is contained within a custom application process and is used when maps must be run within the client process.
-

RMI server single process mode

The RMI server can run in a single process mode.

Use the single process implementation to run maps in a single server process.

RMI server multi-process mode

The RMI server can run in a multi-process mode.

Use the multi-process implementation to run maps in multiple server processes. Each map runs in its own child process, referred to as the Map Process, of the main server process, referred to as the Control Process.

RMI server in-process mode

The RMI server can run in an in-process mode. The in-process implementation is contained within a custom application process and is used when maps must be run within the client process.

The in-process implementation is contained within a custom application process and is used when maps must be run within the client process. Though the in-process mode appears to an RMI API user as a client-server process, it is actually a single process. To run the RMI server in an in-process mode, the server must be installed on the same machine as the RMI API client component.

RMI server configurations

You must configure the RMI server to run your maps.

The configuration activities include setting the RMI server properties, starting the RMI server, and installing the RMI API client.

- [RMI server properties overview](#)
The RMI server has a set of properties that are defined in the rmiserver.properties file.
 - [Starting the RMI server](#)
You must start the RMI server from the command line before running the RMI API.
 - [RMI API client installation overview](#)
There are two configuration scenarios regarding the RMI API client component: installing the client component on the same machine running the RMI server, or on a separate machine.
-

RMI server properties overview

The RMI server has a set of properties that are defined in the rmiserver.properties file.

The rmiserver.properties file is read when the RMI server is started. However, a different property file can be specified at startup. The RMI server properties can be read from or persisted to the rmiserver.properties file using the **loadServerProperties()** and **storeServerProperties()** methods in the RMI API IMManager class. To read from or store these properties to a different file, use the **load()** and **store()** methods in java.util.Properties, and the **setServerProperties()** and **getServerProperties()** methods in the RMI API IMManager class.

The following table lists server properties and the mode they support.

- [RMI server properties](#)

The following table lists server properties and the RMI server process modes that they support.

RMI server properties

The following table lists server properties and the RMI server process modes that they support.

Property	Mode
RMI server mode property	single/multi
RMI server port property	single/multi
RMI server log mode full property	single/multi
RMI server pool.mode.managed property	multi-process
RMI server pool.max.process.count property	multi-process
RMI server pool.max.keep.idle.count property	multi-process
RMI server pool.max.idle.time property	multi-process
RMI server pool.acquire.process.timeout property	multi-process
RMI server pool.map.auto.unload.timeout property	multi-process

- [RMI server mode property](#)

The RMI server mode is specified through the server.mode.multi.process property defined in the rmiserver.properties file.

- [RMI server port property](#)

An instance of the RMI server is identified by specifying the TCP/IP server port using the server.port property defined in the rmiserver.properties file.

- [RMI server log.mode.full property](#)

The log.mode.full RMI server property specifies whether log information includes both server activity and errors, or error information only.

- [RMI server pool.mode.managed property](#)

The pool.mode.managed RMI server property turns pool management on or off.

- [RMI server pool.max.process.count property](#)

The pool.max.process.count specifies the maximum number of processes that the pool can create at any time.

- [RMI server pool.max.keep.idle.count property](#)

The pool.max.keep.idle.count specifies the maximum number of idle processes that are kept in the pool.

- [RMI server pool.max.idle.time property](#)

The pool.max.idle.time specifies the maximum amount of time, in seconds, that the pool will idle before disposing of the idle processes.

- [RMI server pool.acquire.process.timeout property](#)

The pool.acquire.process.timeout specifies the maximum amount of time the pool can block a request in order to acquire a process before it returns a failure.

- [RMI server pool.map.auto.unload.timeout property](#)

The pool.map.auto.unload.timeout specifies the maximum amount of time a map can stay loaded.

RMI server mode property

The RMI server mode is specified through the server.mode.multi.process property defined in the rmiserver.properties file.

The following table lists the valid values for the RMI server mode and their description.

Values	Description
--------	-------------

true	Makes the RMI server available to run in multiprocess mode.
------	---

false	Makes the RMI server available to run in single process mode.
-------	---

When multiprocess mode is enabled (server.mode.multi.process=true), map execution takes place in a separate JVM process. You set the startup options for this JVM process with the multi.process.jvm.options RMI option.

Related reference

- [RMI server implementation](#)

RMI server port property

An instance of the RMI server is identified by specifying the TCP/IP server port using the server.port property defined in the rmiserver.properties file.

The RMI server uses four consecutive port numbers starting with the specified port. For example, if you specify 2500 as the port number, the RMI server will actually use ports 2500-2503.

The following table lists the valid values for the RMI server port and their description.

Values	Description
--------	-------------

integer	Specifies TCP/IP server port.
---------	-------------------------------

RMI server log.mode.full property

The log.mode.full RMI server property specifies whether log information includes both server activity and errors, or error information only.

The following table lists the valid values for the log.mode.full RMI server property and their description.

Values	Description
true	Makes available both error and activity logging.
false	Makes available error logging only.

RMI server pool.mode.managed property

The pool.mode.managed RMI server property turns pool management on or off.

When it is turned off, there is no limit to the number of processes, and time idle processes are kept.

If this property is set to false, settings for all of the properties that control the process pool behavior are ignored.

The following table lists the valid values for the pool.mode.managed RMI server property and their description.

Values	Description
true	Turns pool management on.
false	Turns pool management off.

Related reference

- [Process pool management](#)

RMI server pool.max.process.count property

The pool.max.process.count specifies the maximum number of processes that the pool can create at any time.

When the limit is reached, new requests are queued and the client is blocked until either a process becomes available, or the request times out. If the request times out, the pool will return a failure.

The following table lists the valid values for the pool.max.process.count RMI server property and their description.

Values	Description
≥0	Maximum number of processes that the pool can create at any time. Zero or a negative value disables this feature.

Related reference

- [RMI server pool.acquire.process.timeout property](#)

RMI server pool.max.keep.idle.count property

The pool.max.keep.idle.count specifies the maximum number of idle processes that are kept in the pool.

All released processes above this number are destroyed.

The following table lists the valid values for the pool.max.keep.idle.count RMI server property and their description.

Values	Description
≥0	Maximum number of idle processes that are kept in the pool. A negative value disables this feature.

RMI server pool.max.idle.time property

The pool.max.idle.time specifies the maximum amount of time, in seconds, that the pool will idle before disposing of the idle processes.

The pool is idling if there are no active processes.

The following table lists the valid values for the pool.max.idle.time RMI server property and their description.

Values	Description
≥0	Maximum amount of time, in seconds, that the pool will idle before disposing of the idle processes. A negative value disables this feature.

RMI server pool.acquire.process.timeout property

The pool.acquire.process.timeout specifies the maximum amount of time the pool can block a request in order to acquire a process before it returns a failure.

This is used when a new request arrives, but the pool has already reached the maximum process count.

The following table lists the valid values for the pool.acquire.process.timeout RMI server property and their description.

Values	Description
≥0	Maximum amount of time the pool can block a request in order to acquire a process before it returns a failure. A negative value disables this feature.

Related reference

- [RMI server pool.max.process.count property](#)

RMI server pool.map.auto.unload.timeout property

The pool.map.auto.unload.timeout specifies the maximum amount of time a map can stay loaded.

When the time expires, the map is automatically unloaded and the associated process is released.

The following table lists the valid values for the pool.map.auto.unload.timeout RMI server property and their description.

Values	Description
≥0	Maximum amount of time a map can stay loaded. A negative value disables this feature.

Starting the RMI server

You must start the RMI server from the command line before running the RMI API.

The RMI server is started from the command line on both the Windows and UNIX operating systems.

To start the RMI server

1. Edit the *install_dir\startRMIServer.bat* file by setting the following variables:
 - JAVAHOME: Java 2 SDK installation directory (UNIX only)
 - MERCHOME: *tx_install_dir* (Windows only)
 - CONFIG_FILE: RMI server property filename and pathFor UNIX operating systems, modify the *install_dir/bin/startRMIServer.sh* file.
2. Save the file.
3. For UNIX operating systems only, enter the following command from a command prompt:
install_dir/setup
4. From a command prompt, enter the following command to start the RMI server:
 - Windows: *install_dir\startRMIServer.bat*
 - UNIX: *install_dir/startRMIServer.sh*

RMI API client installation overview

There are two configuration scenarios regarding the RMI API client component: installing the client component on the same machine running the RMI server, or on a separate machine.

The RMI API client component and the RMI server are included with the DK installation.

- [Installing the DK on the same machine](#)

If the DK is installed on the same machine running the RMI server, no additional installation steps are required because the client component is already installed.

- [Installing the DK on a separate machine](#)

If the DK is installed on a separate machine from the machine running the RMI server, you must provide additional configuration for the RMI API client component.

Installing the DK on the same machine

If the DK is installed on the same machine running the RMI server, no additional installation steps are required because the client component is already installed.

If the DK is installed on the same machine running the RMI server, no additional installation steps are required because the client component is already installed.

Installing the DK on a separate machine

If the DK is installed on a separate machine from the machine running the RMI server, you must provide additional configuration for the RMI API client component.

If the DK is installed on a separate machine from the one running the RMI server, the following additional steps are required to configure the RMI API client component.

To install the RMI API client component on a separate machine

Copy the following file to the machine hosting the RMI API client:

- Windows: `install_dir\dtxpi.jar`
- UNIX: `install_dir/libs/dtxpi.jar`

RMI API configuration overview

A fatal exception within the transformation logic that runs the map could cause the calling process to terminate. To mitigate against this, there are three configuration options available for the RMI API.

The configuration options are:

- [RMI API in-process configuration](#)
- [RMI API single process configuration](#)
- [RMI API multi-process configuration](#)

- [RMI API in-process configuration](#)

To prevent a fatal exception within the transformation logic that runs the map and causes the calling process to terminate, you can use the in-process configuration option.

- [RMI API single process configuration](#)

To prevent a fatal exception within the transformation logic that runs the map and causes the calling process to terminate, you can use the single process configuration option.

- [RMI API multi-process configuration](#)

To prevent a fatal exception within the transformation logic that runs the map and causes the calling process to terminate, you can use the multi-process configuration option.

RMI API in-process configuration

To prevent a fatal exception within the transformation logic that runs the map and causes the calling process to terminate, you can use the in-process configuration option.

The maps are run within the process of the calling program (in the same JVM). In this mode, there are no RMI calls - a call to the RMI API calls directly to the transformation logic that runs the map. This option is best-suited to a situation where you need optimal performance and the loss of the calling program is not catastrophic.

This option is not recommended for clients running on an application server, since a fatal exception could cause the server process to terminate.

Related reference

- [Comparison of the RMI API configuration options](#)

RMI API single process configuration

To prevent a fatal exception within the transformation logic that runs the map and causes the calling process to terminate, you can use the single process configuration option.

The maps are run within the RMI server process, with each map running in a separate thread. This protects the calling program from fatal map exceptions because the maps are running remotely from the calling program. However, if one map fails, the RMI server stops and all concurrent maps are terminated.

This option is well suited to programs running on an application server.

Related reference

- [Comparison of the RMI API configuration options](#)
-

RMI API multi-process configuration

To prevent a fatal exception within the transformation logic that runs the map and causes the calling process to terminate, you can use the multi-process configuration option.

The maps are run in processes created from the RMI Server process.

This option offers the best protection, since a fatal exception in one map will not adversely affect other maps.

The downside of this approach is that adapter connections are not shared across map processes. This means that a connection that is started in one process for a particular map can be reused only by maps that run in that same process. This might be an issue if many different maps are run that connect to a wide array of resources, such as different databases.

Web Services

Web Services includes the SOAP Adapter and WSDL (Web Services Definition Language) Importer. You can use these tools to provide or consume Web services.

SOAP (WSDL) Adapter

SOAP defines the XML-based message format that applications use to communicate and inter-operate with each other over the Web.

The heterogeneous environment of the Web demands that applications support a common data encoding protocol and message format.

SOAP is a standard for encoding messages in XML that invoke functions in other applications running on any hardware platform regardless of different operating systems or programming languages. It is analogous to Remote Procedure Calls (RPC) used in many technologies such as Distributed Component Object Model (DCOM), but eliminates some of the complexities of using these interfaces.

The SOAP (WSDL) Adapter supports the SOAP 1.1 protocol as defined by <http://www.w3.org/TR/SOAP/>.

Use the SOAP (WSDL) Adapter to help to create SOAP request messages and to interpret response messages. The SOAP (WSDL) Adapter does not handle the delivery of messages and should be used with a transport adapter, such as HTTP, to deliver the request and receive the response message.

When you send a SOAP-based HTTP request, the default encoding of the content of the HTTP request is ISO-8859-1. The SOAP adapter requires a UTF-8 encoded response from the HTTP server, but the request can be in any Western or UTF-8 encoded format. See the description of the **-TYPE** command in the HTTP adapter documentation for details about how to specify the encoding.

The adapter has the following capabilities:

- Adds SOAP envelopes if they are not provided
- Parses the response message to extract scalar data elements
- Removes envelope and simplifies the form of SOAP responses to aid mapping of the response data
- Understands fault codes and interprets them as map failures

The SOAP (WSDL) Adapter does not provide a listener. The transport adapter provides this functionality.

- [System requirements](#)
 - [Command alias](#)
 - [SOAP Adapter commands](#)
 - [Syntax summary](#)
 - [Using the adapter](#)
 - [Return codes and error messages](#)
-

System requirements

The minimum system requirements and operating system requirements for the SOAP (WSDL) Adapter are detailed in the release notes.

Command alias

Adapter commands can be specified by using a command string on the command line or by creating a command file that contains adapter commands. The execution command syntax is:

```
-IA[alias] card_num  
-OA[alias] card_num
```

where **-IA** is the Input Source Override execution command and **-OA** is the Output Target Override execution command, alias is the adapter alias, and **card_num** is the number of the input or output card. The following table shows the adapter alias and its execution command.

Adapter	Alias	As Input	As Output
SOAP	SOAP	-IASOAPcard_num	-OASOAPcard_num

SOAP Adapter commands

This documentation describes the functions and use of the SOAP (WSDL) Adapter commands and their options.

- [List of commands](#)

List of commands

The following table lists valid commands for the SOAP (WSDL) Adapter, the command syntax, and whether the command is supported (✓) for use with data sources, targets, or any other combination.

Commands can be specified on the adapter's command line or through adapter properties. Note that the commands are not case sensitive but that each value is case sensitive.

Command	Syntax	Source	Target
Decode (-DECODE)	-DECODE	✓	
Encode (-ENCODE)	-ENCODE		✓
Header (-HDR)	-HDR	✓	
Raw (-RAW)	-RAW	✓	
Return (-RETURN)	-RETURN element	✓	
SOAPAction (-SA)	-SA soap_action		✓
Trace (-T)	-T[E][NX][+] [filename]	✓	✓
Transport (-TRANSPORT)	-TRANSPORT 'adapter_name (adapter_command_line)'	✓	✓

- [Decode \(-DECODE\)](#)
- [Encode \(-ENCODE\)](#)
- [Header \(-HDR\)](#)
- [Raw \(-RAW\)](#)
- [Return \(-RETURN\)](#)
- [SOAPAction \(-SA\)](#)
- [Trace \(-T\)](#)
- [Transport \(-TRANSPORT\)](#)

Decode (-DECODE)

Use the Decode adapter command (-DECODE) to instruct the adapter to decode the SOAP message, which involves stripping the envelope and SOAP envelope header, and handling SOAP faults.

-DECODE

For example, to decode a message received over HTTP:

```
GET ("SOAP", "-DECODE -TRANSPORT 'HTTP (-URL http://myurl/)'")
```

The **-DECODE** option is optional since it is implied by the invocation of the SOAP (WSDL) Adapter in an input card or GET function.

For more information on encoding and decoding data, see *Encoding and Decoding Data* in the Resource Adapters documentation.

Encode (-ENCODE)

Use the Encode adapter command (-ENCODE) to instruct the adapter to encode the SOAP message, which involves adding a SOAP envelope if none is provided.

-ENCODE

For example, to encode a SOAP message before transporting over HTTP:

```
PUT ("SOAP", "-ENCODE -TRANSPORT 'HTTP (-URL http://myurl/)'  
SoapRequest")
```

The **-ENCODE** option is optional since it is implied by the invocation of the SOAP (WSDL) Adapter in an output card or PUT function.

For more information on encoding and decoding data, see *Encoding and Decoding Data* in the Resource Adapters documentation.

Header (-HDR)

Use the Header adapter command (-HDR) to specify that the SOAP envelope header be returned. This is an optional command. The default is to not return the SOAP header.

-HDR

See [Source Options Behavior](#) for more information on the behavior of the SOAP (WSDL) Adapter and its combinations of available options.

Raw (-RAW)

Use the Raw adapter command (-RAW) to specify that the response message be returned unmodified, except the SOAP envelope header is removed.

-RAW

If the -RAW command is specified, the only processing of the response data is:

The SOAP envelope header is stripped out. To keep the header specify -HDR.

Fault codes are interpreted

For example, using the -RAW command results in the data being returned as follows (intact, but without SOAP envelope header):

```
<?xml version="1.0" encoding="UTF-8" standalone="no" ?>
- <SOAP-ENV:Envelope SOAP-
  ENV:encodingStyle=http://schemas.xmlsoap.org/soap/encoding/
  xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">
- <SOAP-ENV:Body>
  - <SOAPSSDK1:AddResponse
    xmlns:SOAPSSDK1="http://tempuri.org/message/">
    <Result>290</Result>
  </SOAPSSDK1:AddResponse>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

If the -RAW command is not specified, then the following is returned:

- The body of the request without the enclosing **<Body>...</Body>** tags
- Any namespace prefixes are removed
- Any attributes are removed

For example, the message shown above is returned as follows:

```
- <AddResponse>
  <Result>290</Result>
</AddResponse>
```

See [Source Options Behavior](#) for more information on the behavior of the SOAP (WSDL) Adapter and its combinations of available options.

Return (-RETURN)

Use the Return adapter command (-RETURN) to return a single scalar value from the response message. In many cases, a map only has interest in a single value. This option simplifies mapping in these types of cases. This command can only be used if the value of the element is a scalar value.

This command is incompatible with the -HDR command.

This is an optional command. The default is a null reply.

-RETURN element

Option

Description

element

Specify the path and the element to be returned using XPath syntax.

XPath is a language for addressing parts of an XML document. For more information on the XPath language, go to www.w3.org/TR/xpath.

For example, to specify /cat/dog as the XML element to be returned:

```
-RETURN /cat/dog
```

See [Source Options Behavior](#) for more information on the behavior of the SOAP (WSDL) Adapter and its combinations of available options.

- [Return option and XPath](#)

Return option and XPath

The element to return is specified using an XPath subject to the following limitations:

- The element to return must be a scalar type. That is, it cannot be an array or contain another element.
- Only fully qualified paths are accepted, for example:
/Message/StockQuote/Price
- Attributes of elements can be specified using the standard XPath '@' notation, for example:
/Message/StockQuote/@currency

While the SOAP standard does not forbid the use of attributes, it recommends not using them.

No other XPath syntax is supported

The limitations in the previous examples are taken into consideration in the following sample message:

```
<Message>
  <StockQuote>
    <Symbol>XYZ</Symbol>
    <Price currency="dollar">20</Price>
  </StockQuote>
</Message>
```

The names of the elements in the path correspond to the name in the returned data. Therefore, if the `-RAW` command is used, the names correspond to the element names in the raw response message. In this case, the elements are often qualified by namespace prefixes.

Consider the following example return message:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/">
<SOAP-ENV:Body SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<NS1:BabelFishResponse xmlns:NS1="urn:BorlandBabelIntf-IBorlandBabel">
<return xsi:type="xsd:string">Freeend</return>
</NS1:BabelFishResponse>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

If we want to return only the `<return>` element, the following command(s) should be used:

```
-RAW -RETURN /SOAP-ENV:Envelope/SOAP-ENV:Body/
NS1:BabelFishResponse/return
```

Or, if the `-RAW` command is not specified:

```
-RETURN /BabelFishResponse/return
```

SOAPAction (-SA)

When the transport is HTTP, many Web services require the SOAPAction field to be added to the HTTP header of a SOAP request. Use the SOAPAction adapter command (`-SA`) to indicate to the server the intent of the request.

Use one of the following values:

- `NULL` (`-SA` with no argument), means that there is no indication of the intent
- `Empty string` (`-SA ""`), means that the intent of the request is provided by the HTTP request URI or Uniform Resource Identifier (no value is specified between the single quotes)
- `URI` (`-SA 'http://www.me.com/'`), where the intent is provided by the URI

The presence and content of the SOAPAction header field can be used by servers to appropriately filter SOAP request messages.

This is an optional command. The default is no SOAPAction.

```
-SA soap_action
```

Option	Description
<code>soap_action</code>	Specify the intent of the request for the SOAP message.

When using the HTTP adapter as the transport, the HTTP adapter command `-HDR1+` must be used to instruct the HTTP adapter to add the specified SOAPAction to the HTTP header.

For example, to specify urn:BorlandBabelIntf-IBorlandBabel#BabelFish as the SOAPAction:

```
GET ("SOAP", "-SA 'urn:BorlandBabelIntf-  
IBorlandBabel#BabelFish' -TRANSPORT 'http(-HDR+ -HDIR+ -URL  
http://ww6.borland.com/webservices/BorlandBabel/  
BorlandBabel.exe/soap/IBorlandBabel -T)'", RequestData)
```

If the WSDL Importer is used to create the schemas for the SOAP request messages, the value that should be assigned to the SOAP action command can be found in the description of the corresponding operation.

See the Schema Importers documentation for more information on the WSDL Importer.

Trace (-T)

Use the Trace adapter command (-TRACE or -T) to produce a diagnostics file that contains detailed information about SOAP (WSDL) Adapter SOAP (WSDL) Adapter activity.

The default filename is **m4soap.mtr** and the file is created in the map directory unless otherwise specified.

```
-T [E] [NX] [+ ] [filename]
```

Option	Description
E	Produce a trace file containing only the adapter errors that occurred during map execution.
NX	Excludes information about XML data from the trace file.
+	Append trace information to the existing trace file.
filename	Creates a trace file with the specified name in the specified directory.

You can override the adapter command line trace options dynamically using the Management Console.

Transport (-TRANSPORT)

Use the Transport adapter command (-TRANSPORT) to specify which transport adapter to use and the command line for the transport adapter.

The syntax of the command must include the single quotes and parentheses as shown below.

```
-TRANSPORT 'adapter_name (adapter_command_line)'
```

Option	Description
adapter_name	Specify which transport adapter to use.
adapter_command_line	Specify the command line for the transport adapter. You must enclose this option within parentheses () .

For example, to specify the HTTP adapter as the transport adapter, and to send the SOAP request to the http://localhost/WebService/test URL, enter the following command:

```
-TRANSPORT 'http (-URL http://localhost/WebService/test -T)'
```

Syntax summary

This documentation discusses the SOAP syntax summary and how it is used.

- [Data sources](#)
- [Data targets](#)
- [Source options behavior](#)

Data sources

The following is the command syntax for the SOAP (WSDL) Adapter commands used for data sources:

```
-TRANSPORT 'adapter_name (adapter_command_line)'  
[-DECODE]  
[-RAW]  
[-HDR]  
[-RETURN element]  
[-T [E] [NX] [+ ] [filename]]
```

- [Example](#)

Example

For the GET Source setting in an input card, select SOAP. In the **GET > Source > Command** field, enter:

```
-T -RAW -TRANSPORT 'http (-URL http://www.myws.com/DoWS) '
```

This command specifies that the SOAP message:

- Received data from the HTTP URL `http://www.myws.com/DoWS` using the HTTP adapter (`-TRANSPORT`)
- Returned data in full (`-RAW`)
- Adapter trace is enabled (`-T`) and a diagnostics file is produced

Data targets

The following is the command syntax for the SOAP adapter commands used for data targets:

```
-TRANSPORT 'adapter_name (adapter_command_line)'
[-ENCODE]
[-SA soap_action]
[-T[E] [NX] [+| [filename]]]
```

- [Example](#)

Example

For the PUT Target setting in an output card, select SOAP. In the **PUT > Target > Command** field, enter:

```
-SA " -T -TRANSPORT 'http (-URL http://www.myws.com/DoWS) '
```

This command specifies that the SOAP message:

- Sent data over HTTP to the URL `http://www.myws.com/DoWS` using the HTTP adapter (`-TRANSPORT`)
- SOAPAction is provided by the HTTP request URL (`SA "`)
- Adapter trace is enabled (`-T`) and a diagnostics file is produced

Source options behavior

The following table defines the behavior of the SOAP (WSDL) Adapter based upon combinations of available options.

Commands	Behavior
No formatting commands	Only the contents of the body of the message are returned (this is the default). No attributes are returned and namespace prefixes are removed.
-RAW alone	If a header is in the message's envelope, it is removed, but the envelope and body are returned intact.
-HDR alone	Equivalent to -RAW and -HDR , since an envelope is required to ensure the well-formedness of the XML document. For more information on XML document standards go to www.w3.org/TR/1998/REC-xml-19980210 .
-RAW and -HDR	The SOAP request is returned in its entirety.
-RETURN XPath	Only the single scalar value is returned. See Return Option and XPath for more information.

Using the adapter

Use the SOAP (WSDL) Adapter to either invoke a Web service by sending a request message and processing the response, or in the implementation of a Web service.

Note that two adapters are used in communicating between the map and the Web service:

- The SOAP (WSDL) Adapter
- A transport adapter, such as an HTTP adapter

There are two primary usage scenarios for the SOAP (WSDL) Adapter:

- As a consumer of Web services

- As a provider of Web services
 - [Consumer scenario](#)
 - [Provider scenario](#)
 - [Example files](#)
-

Consumer scenario

A common scenario is the flow of a request from a map, through SOAP and HTTP adapters to the Web Service, and the flow of the response back to the map from the Web Service.

The adapter is designed to be called in a GET map function call. The third parameter of the GET is the request message. For example:

```
Response = GET("SOAP", "-HDR -TRANSPORT 'HTTP(-URL http://  
www.stuff.com -T)', PACKAGE(Request))
```

Adapter Action Sequence

The following describes the sequence of actions that occur in the consumer scenario.

- The request message is first passed to the SOAP (WSDL) Adapter.
 - The request message might or might not have a SOAP envelope. If the envelope is not provided, the adapter adds it.
 - The request message might or might not have a SOAP envelope header. The adapter does nothing with the header. If it is not provided in the request, then no header is sent.
 - The adapter specified in the -TRANSPORT command is invoked to issue the request and receive a reply. Typically, this is the HTTP adapter that will then send an HTTP request and return the HTTP response.
 - The SOAP (WSDL) Adapter is invoked a second time to process the reply.
 - The adapter looks in the body to see if there is a Fault tag. If there is, the SOAP (WSDL) Adapter returns an error message that is comprised of the faultstring and the faultcode.
 - The SOAP envelope is removed unless the -RAW command is specified.
 - If the adapter is called with the -HDR command, and there is a SOAP envelope header, the header data will be returned.
 - If the adapter is called with the -RETURN command, then all XML tags are removed and only the specified datum from the response message is returned. If the response message returns more than one datum, then the whole XML response message is returned with a warning code. This command is mutually exclusive with the -HDR command.
-

Provider scenario

The following descriptions explain using the SOAP (WSDL) Adapter with the HTTP adapter.

- [Response](#)
-

Response

The HTTP Adapter is invoked to send the response message.

Example files

The `install_dir\examples\web_services` directory contains sample files to be used with Web Services components, including the WSDL Importer, SOAP and HTTP adapters, to implement Web services strategies.

See `readme.txt` located in the example directory for more information about the examples.

Return codes and error messages

Return codes and messages are returned when the particular activity completes. Return codes and messages might also be recorded as specified in the audit logs, trace files and execution summary files.

- [Messages](#)
-

Messages

The following is a listing of all the codes and messages that can be returned as a result of using the SOAP (WSDL) Adapter for sources or targets.

Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Return Code

Message	
-2001	General internal adapter error
-2002	Invalid command line option
-2003	Missing argument in command line option
-2004	Missing command line option
-2005	Invalid argument in command line option
-2006	FC A fault code has been generated.
-2007	Xpath data not found
-2008	Xpath duplicate data found
-2009	Stream error
-2010	XML invalid

WSDL Importer

The Web Services Description Language (WSDL) Importer is a utility for generating type trees from message definitions contained within WSDL documents.

Tuning Importer behavior

The WSDL Importer has a Java™ native interface and uses the JVM options specified in the dtx.ini file to create a Java virtual machine (JVM). For information about configuring JVM options to tune the importer's behavior, see ["Configuring JVM options from the dtx.ini file"](#).

Import options

The WSDL import process can create a classic type tree or a native XML schema (.xsd) file from the WSDL document. You select the type of output in the WSDL Importer wizard.

- When the WSDL document structure requires support for derived types (such as through the xsi:type attribute), create a native XML schema.
- When the WSDL document structure does not require support for derived types, create a classic XML type tree. Classic type trees are smaller than native XML schemas.

Classic type tree processing

The importer reads a WSDL document and assembles lists of port types, operations, services, messages, and bindings. When the parsing is complete, the importer creates a map for each web service operation and adds it to the resulting XML map source file. During this process, the XML Schema Importer is used to create the types defined in the input WSDL document.

After the WSDL Importer imports the WSDL document, it creates a WSDL type tree (.mtt) file and an XML (*_map.xml) file. Use File > Import > Map from XML in the Design Studio to import the XML file to create a map. The import process creates a map (*WSDLname.map.mms*) that uses the new WSDL type tree in the output cards.

Native XML schema processing

When you select native XML schema validation in the wizard, the WSDL Importer imports the WSDL document and creates two XML schemas:

WSDLname.xsd
Contains the XSD and WSDL-based schema types.
WSDLname_soap.xsd
Contains the SOAP envelope, header, and body types.

Use the *WSDLname_soap.xsd* as the card's native type tree.

z/OS Configuration overview

The z/OS® Configuration documentation provides additional configuration information for the IBM® Transformation Extender for z/OS features that you have already installed. This information will help you customize IBM Transformation Extender for z/OS for your site.

The z/OS Configuration information applies to the following IBM Transformation Extender for z/OS features:

- IBM Transformation Extender - Common Components
- IBM Transformation Extender with Command Server
- IBM Transformation Extender with Launcher
- IBM Transformation Extender for Application Programming

The z/OS Configuration documentation also contains information that applies to specific products, as well as across products. They provide additional configuration instructions to assist you in using the installed features for:

- deploying the installed features to your runtime environment
 - setting environmental variables
 - running examples
 - other post-installation information
- [Related publications for z/OS](#)
This topic lists Transformation Extender for z/OS functions and related documentation.
- [SMP/E installation](#)
IBM Transformation Extender for z/OS features are installed through System Modification Program Extended (SMP/E).

- [z/OS Configuration overview](#)

SMP/E installation

IBM® Transformation Extender for z/OS® features are installed through System Modification Program Extended (SMP/E).

For instructions about installing the IBM Transformation Extender for z/OS features, see the *Program Directory for IBM Transformation Extender for Use with z/OS* (order number: GI13-5666-01).

IBM Transformation Extender - Common Components

One of the features of the IBM® Transformation Extender for z/OS® product is the IBM Transformation Extender - Common Components.

The files that are installed with the IBM Transformation Extender - Common Components base feature are programs and JCL that are used with the other IBM Transformation Extender for z/OS optional features that you have installed.

- [Configuring the common components](#)

These are the required configuration steps for the IBM Transformation Extender - Common Components.

Configuring the common components

These are the required configuration steps for the IBM® Transformation Extender - Common Components.

- [Accessing DB2 databases in CICS and IMS environments](#)

To access DB2 databases in CICS and IMS environments, there are configuration steps that you must follow.

- [Accessing DB2 databases in Batch and USS environments](#)

To access DB2 databases in Batch and UNIX System Services (USS) environments, there are configuration steps that you must follow.

- [Allocating an zFS on USS environments](#)

To allocate an zFS on UNIX System Services (USS) environments, there are configuration steps that you must follow.

- [Defining programs to CICS region for IBM Transformation Extender CICS Adapter server-side components](#)

To define programs to CICS region for CICS® Adapter server-side components, there are configuration steps that you must follow.

Accessing DB2 databases in CICS and IMS environments

To access DB2 databases in CICS and IMS environments, there are configuration steps that you must follow.

When you are running the IBM® Transformation Extender in your CICS and IMS environments and need to access and manipulate data in your DB2 database, you must use the DB/2 (z/OS®) Call Attachment Facility (CAF) Adapter.

To use the DB/2 (z/OS) CAF Adapter, follow the steps described in [Binding the Data Base Request Module \(DBRM\)](#).

Related reference

- [Binding the Data Base Request Module \(DBRM\)](#)

Accessing DB2 databases in Batch and USS environments

To access DB2 databases in Batch and UNIX System Services (USS) environments, there are configuration steps that you must follow.

When you are running the IBM® Transformation Extender with Command Server feature in your Batch environment or the IBM Transformation Extender for Application Programming feature in your UNIX System Services (USS) runtime environment and need to access and manipulate data in your DB2 databases, you can use either the DB/2 (z/OS®) Call Attachment Facility (CAF) Adapter or the DB2 (z/OS ODBC) Adapter.

To use the DB/2 (z/OS) CAF Adapter, follow the steps described in [Binding the Data Base Request Module \(DBRM\)](#).

The prerequisite for using the DB2 (z/OS ODBC) Adapter is that the ODBC support is set up in the DB2 subsystem. For more information about installing and configuring ODBC, see the *DB2 UDB for z/OS ODBC Guide and Reference*. There are no additional configuration steps required to use the DB2 (z/OS ODBC) Adapter.

Allocating an zFS on USS environments

To allocate an zFS on UNIX System Services (USS) environments, there are configuration steps that you must follow.

Define a unique mount point on your UNIX System Services (USS) environment for the deployed runtime environment for the IBM® Transformation Extender USS features that you have installed. Run the DTXDHFS JCL that is installed in the DTX.SDTXSAMP PDS. The DTXDHFS JCL will allocate a Hierarchical File System (HFS) data set on your USS environment, mount it, and set the owner and file permissions.

HFS is deprecated and not supported on the newest z/OS systems. It is supported with ITX and can be used if required.

To allocate an HFS on UNIX System Services (USS) environments, there are configuration steps that you must follow.

Define a unique mount point on your UNIX System Services (USS) environment for the deployed runtime environment for the IBM Transformation Extender USS features that you have installed. Run the DTXDHFS JCL that is installed in the DTX.SDTXSAMP PDS. The DTXDHFS JCL will allocate a Hierarchical File System (HFS) data set on your USS environment, mount it, and set the owner and file permissions.

Defining programs to CICS region for IBM Transformation Extender CICS Adapter server-side components

To define programs to CICS region for CICS® Adapter server-side components, there are configuration steps that you must follow.

The programs can be defined to CICS by adding statements to the CICS CSD definitions. To update the CSD, use the definitions in the DTXCRDEF member of the DTX.SDTXSAMP PDS included in the installation. The DTXCRDEF file contains example RDO commands.

Add the DTX.SDTXLOAD load library to the DFHRPL concatenation for the CICS region that will be running the CICS Adapter server-side components.

IBM Transformation Extender with Command Server

One of the features of the IBM® Transformation Extender for z/OS® product is the IBM Transformation Extender with Command Server.

- [Configuring IBM Transformation Extender with Command Server](#)

These are the required configuration steps for the IBM Transformation Extender with Command Server.

Configuring IBM Transformation Extender with Command Server

These are the required configuration steps for the IBM® Transformation Extender with Command Server.

- [Binding the DB2 plan](#)
- [Examples](#)

There are several examples that are described in the readme files installed in the DTX.SDTXSAMP PDS and are used to demonstrate the various feature components.

Binding the DB2 plan

For the configuration steps for the Data Base Request Module (DBRM) that is included with the installation files, see [Binding the Data Base Request Module \(DBRM\)](#).

Examples

There are several examples that are described in the readme files installed in the DTX.SDTXSAMP PDS and are used to demonstrate the various feature components.

For your Batch environment:

DTXBMRME
 Burst Map example
DTXDMRME
 DB2 Map example
 run only if you will be using the DB2 Adapter
DTXMQRME
 WebSphere MQ example
 run only if you will be using the IBM MQ Adapter
DTXMSRME
 Resource Registry example
 run only if you want to try the Resource Registry alias feature

IBM Transformation Extender with Launcher

One of the features of the IBM® Transformation Extender for z/OS® product is the IBM Transformation Extender with Launcher.

- [Configuring IBM Transformation Extender with Launcher](#)

These are the required configuration steps for the IBM Transformation Extender with Launcher.

Configuring IBM Transformation Extender with Launcher

These are the required configuration steps for the IBM® Transformation Extender with Launcher.

- [Configuring UNIX System Services \(USS\)](#)

Configuring UNIX System Services (USS)

For additional configuration steps that are common to other IBM® Transformation Extender features installed on UNIX System Services (USS), see [Additional configuration on UNIX System Services \(USS\)](#) that is in [Information common to all features](#).

IBM Transformation Extender for Application Programming

One of the features of the IBM® Transformation Extender for z/OS® product is the IBM Transformation Extender for Application Programming.

The IBM Transformation Extender for Application Programming feature supports the following runtime environments:

- CICS®
- IMS/TM
- z/OS Software Development Kit
- UNIX System Services Software Development Kit
- [CICS environment](#)
The IBM Transformation Extender for Application Programming includes the CICS Execution Option through which you can run maps in your CICS environments.
- [IMS environment](#)
The IBM Transformation Extender for Application Programming includes the IMS/DC Execution Option through which you can run maps in your IMS environments.
- [UNIX System Services \(USS\) Software Development Kit](#)
The IBM Transformation Extender for Application Programming includes the UNIX System Services (USS) SDK through which you can run maps in your USS environments.

CICS environment

The IBM® Transformation Extender for Application Programming includes the CICS® Execution Option through which you can run maps in your CICS environments.

Prior to the 8.1 release, this functionality was provided in the CICS Command Server product.

- [CICS configuration requirements](#)
You must modify your CICS configuration to use IBM Transformation Extender for Application Programming.
- [Examples for the CICS environment](#)
There are several examples that are described in the readme files installed in the DTX.SDTXSAMP PDS and are used to demonstrate the various feature components.

CICS configuration requirements

You must modify your CICS configuration to use IBM® Transformation Extender for Application Programming.

The following modifications are described in this documentation:

- DFHRPL changes differ from prior releases.
- XPLINK requires an XPLINK Language Environment (LE) Library.
- [Updating CICS CSD definitions and DFHRPL](#)
The IBM Transformation Extender for Application Programming for the CICS runtime environment installs the DTXCTBL file in the DTX.SDTXSAMP PDS, which contains the RDO definitions.
- [XPLINK and non-XPLINK](#)
The CICS Execution Option takes advantage of the C/C++ Extra Performance Linkage (XPLINK) compiler optimization introduced in CICS Transaction Server for z/OS V 3.1.
- [Loading Maps](#)
To use the IBM Transformation Extender for Application Programming feature on CICS runtime environments, and to successfully complete the IVP, you must load the IBM Transformation Extender for Application Programming executable maps into a VSAM keyed-sequential data set (KSDS).
- [Language Environment \(LE\) requirement](#)
The transformation server is ported to CICS using the IBM "C/C++" compiler and requires the z/OS Language Environment runtime libraries.
- [\(Optional\) Setting up the DB2 \(z/OS\) Adapter to use the CICS CAF](#)
To use the DB2 (z/OS) Adapter, you will need to set it up to use the CICS DB/2 Attachment Facility.
- [Multiple versions of the IBM Transformation Extender for Application Programming for the CICS runtime environment in a single CICS region](#)
You can run multiple versions of the IBM Transformation Extender for Application Programming for the CICS runtime environment in a single CICS region.
- [Additional updates to CICS CSD definitions](#)
If you plan to run multiple, concurrently executing IBM Transformation Extender for Application Programming for the CICS runtime environment tasks that share

the map keyed-sequential data sets (KSDS), set the CSDSTRNO parameter for the map KSDS equal to the maximum number of concurrently executing tasks you want to allow in the z/OS CICS region.

- **Sizing temporary storage**
Temporary Storage Queue (TSQ) is used to back up IBM Transformation Extender for Application Programming work spaces required to run a map.
- **(Optional) Defining and loading the Resource Name file**
Optionally define and load the VSAM entry-sequenced data set (ESDS) that stores the DTXCRMNR resource name file.

Updating CICS CSD definitions and DFHRPL

The IBM® Transformation Extender for Application Programming for the CICS runtime environment installs the DTXCTBL file in the DTX.SDTXSAMP PDS, which contains the RDO definitions.

Use the supplied RDO definitions to update the CICS CSD definitions, defining transactions, programs and data sets for the region or regions where you will be using the IBM Transformation Extender for Application Programming for the CICS runtime environment.

XLINK and non-XLINK

The CICS® Execution Option takes advantage of the C/C++ Extra Performance Linkage (XLINK) compiler optimization introduced in CICS Transaction Server for z/OS V 3.1.

IBM® Transformation Extender for z/OS® includes two load libraries, DTX.SDTXLOAD and DTX.SDTXLOD2. The DTX.SDTXLOAD load library contains files that support the use of XLINK. If you want to use XLINK, you must add the DTX.SDTXLOAD load library to the DFHRPL concatenation.

- **DTXCTBL CSD definitions**
The IBM Transformation Extender for z/OS installation includes a DTXCTBL file containing the program definitions.

DTXCTBL CSD definitions

The IBM® Transformation Extender for z/OS® installation includes a DTXCTBL file containing the program definitions.

The DTXCTBL file is divided into the following program definition categories:

- program definitions for various components such as the mapper, resource manager, adapters and ICU
- transaction resource definitions
- file resource definitions

The DTXCTBL CSD is used for standard linkage. The DTXCTBL file contains the program definitions for the same product components, but the program names and the specific definitions are different.

The program definitions for the CICS drivers, DTXnnnCI (XLINK version) and DTXnnnKI (non-XLINK version) are used for the current version of IBM Transformation Extender for z/OS. The *nnn* variable represents the version number. An example is DTX820CI. The aliases for MERCCICS and DSTXCICS are provided for backwards compatibility when migrating from the Mercator or DSTX/CICS Command Server products in older releases.

- **DTXCTBL CSD definitions for XLINK**
The default settings in the DTXCTBL file are for the XLINK versions of the program definitions for IBM Transformation Extender for z/OS.
- **DTXCTBL CSD definitions for non-XLINK**
You will need to change the default settings in the DTXCTBL file for non-XLINK versions of the program definitions for IBM Transformation Extender for z/OS.

DTXCTBL CSD definitions for XLINK

The default settings in the DTXCTBL file are for the XLINK versions of the program definitions for IBM® Transformation Extender for z/OS®.

To use the XLINK versions of the program definitions, use the file the way it is delivered, with the default settings.

To use the non-XLINK versions of the program definitions, comment and uncomment the sections as described in [DTXCTBL CSD definitions for non-XLINK](#).

DTXCTBL CSD definitions for non-XLINK

You will need to change the default settings in the DTXCTBL file for non-XLINK versions of the program definitions for IBM® Transformation Extender for z/OS®.

Comment and uncomment the sections in the DTXCTBL file that is delivered with the IBM Transformation Extender for z/OS as described here:

- program definitions
 - comment the driver definitions in the XLINK section

```
* DEFINE PROGRAM(MERCCICS)

```

To use the non-XPLINK versions of the program definitions, comment and uncomment the sections as described above.

To use the XPLINK versions of the program definitions, use the file the way it is delivered, with the default settings as described in [DTXCTBL CSD definitions for XPLINK](#).

Loading Maps

To use the IBM® Transformation Extender for Application Programming feature on CICS runtime environments, and to successfully complete the IVP, you must load the IBM Transformation Extender for Application Programming executable maps into a VSAM keyed-sequential data set (KSDS).

To load the maps, do the following steps:

1. Define the VSAM cluster used to store IBM Transformation Extender for Application Programming executable maps. You can use the sample DTXCIJCL JCL to define the VSAM KSDS.
2. Extract, format, and load IBM Transformation Extender for Application Programming maps into the VSAM map KSDS. You can use the sample DTXCMJCL JCL that will extract, format, and load the maps into the VSAM KSDS that was defined by the DTXCIJCL JCL.

Language Environment (LE) requirement

The transformation server is ported to CICS using the IBM "C/C++" compiler and requires the z/OS Language Environment runtime libraries.

The z/OS IBM® Transformation Extender for Application Programming for the CICS runtime environment is compatible with all supported releases of Language Environment (LE).

This will require that LE support be installed in CICS.

(Optional) Setting up the DB2 (z/OS) Adapter to use the CICS CAF

To use the DB2 (z/OS) Adapter, you will need to set it up to use the CICS® DB/2 Attachment Facility.

You will be updating the CSD. For information about updating the CSD, see the *IBM CICS System Definition Guide*.

To set up the adapter to use the CICS DB/2 Attachment Facility:

1. Bind the Data Base Request Module (DBRM).
See [Binding the Data Base Request Module \(DBRM\)](#).
2. Create a DB2ENTRY in the CICS CSD for the DBUTILE plan.

3. Create DB2TRAN entries in the CICS CSD for each CICS transaction that will call the IBM Transformation Extender for Application Programming for the CICS runtime environment and invoke a DB2 map.
4. Create a DB2TRAN entry in the CICS command line for the DTXI (used for backward compatibility to a previous release) and DTXT transactions.
5. If your site uses the RCT macro, DSNCRCT, to define the entries for the CICS DB/2 Attachment Facility, you will need to code and assemble the DSNCRCT TYPE=ENTRY macro instruction to add the entry for the DBUTILE plan.

Multiple versions of the IBM Transformation Extender for Application Programming for the CICS runtime environment in a single CICS region

You can run multiple versions of the IBM® Transformation Extender for Application Programming for the CICS runtime environment in a single CICS region.

If you are installing this feature for the first time, continue with [Additional updates to CICS CSD definitions](#).

- **Description**
This feature enables people who use the IBM Transformation Extender for Application Programming for the CICS runtime environment or the Mercator Integration Broker or Ascential DataStage TX to run multiple versions of these products concurrently in a single CICS region.
- **Installing multiple versions**

Description

This feature enables people who use the IBM® Transformation Extender for Application Programming for the CICS runtime environment or the Mercator Integration Broker or Ascential DataStage TX to run multiple versions of these products concurrently in a single CICS region.

The benefit of this feature is the ability to do a staged migration to IBM Transformation Extender for Application Programming while being able to run your existing product release in the same CICS region.

This feature is only available starting with Ascential DataStage TX version 7.5. As of Ascential DataStage TX 7.5, only one prior release of Ascential DataStage TX can be used at the same time as this version.

For more information, see the topic about *Multiple Command Server versions* in the *z/OS CICS* section of the Command Server documentation in the IBM Transformation Extender information center that is published on the WebSphere Transformation Extender Library web page (<http://www.ibm.com/software/integration/wdatastagetx/library/index.html>). For other locations where you can find the Command Server documentation and additional documentation related to z/OS, see [Related publications for z/OS](#).

If you are not installing multiple versions of these products in the same CICS region, continue with [Additional updates to CICS CSD definitions](#).

Installing multiple versions

To install multiple versions, do the following steps:

1. Complete the feature installation steps as described in this documentation.
 - a. Install IBM® Transformation Extender for Application Programming for the CICS runtime environment in a region that has an existing version of the Mercator Integration Broker or Ascential DataStage TX.
Both versions will be separate instances of the product for the CICS execution environment that can run concurrently.
2. The CICS RDO definitions supplied with this release contain resource definitions that provide backwards compatibility for existing users of the product for the CICS runtime environment. These definitions will create conflicts and render the prior release unusable. Before installing the RDO definitions for this release, either comment out or delete the following items:
 - a. program entry: MERCCICS or DSTXCICS
 - b. transaction definitions:

MERC or DSTX
for the start CICS transaction
MERT, DSTT or DSTX
for the start the test sample transaction

If you do not comment out or delete the above items, these RDO definitions will create conflicts between an older release and the new release and as a result, you will not be able to use the prior release.
There are multiple program entry and transaction definitions options depending on which release of the product for the CICS runtime environment you currently have installed.
3. Do not delete the CICS RDO group, TSIMERC or ASCLDSTX.
4. Place the data set definition of the IBM Transformation Extender for Application Programming load library for the CICS runtime environment for this release after the load library of the existing release in the DFHRPL concatenation.

Additional updates to CICS CSD definitions

If you plan to run multiple, concurrently executing IBM® Transformation Extender for Application Programming for the CICS runtime environment tasks that share the map keyed-sequential data sets (KSDS), set the CSDSTRNO parameter for the map KSDS equal to the maximum number of concurrently executing tasks you want to allow in the z/OS CICS region.

If you are adding the IBM Transformation Extender for Application Programming to an existing IBM Transformation Extender for Application Programming installation (meaning, that this is not a new installation), you must update the CSD. Unless you are planning on running multiple versions of IBM Transformation Extender for Application Programming in a single CICS region, remove the ASCLDSTX group from the CSD and add the new system definitions.

The use of CICS Temporary Storage Queues might increase if you upgrade from Mercator Integration Broker or Ascential Datastage TX. The VSAM-based work space manager has been replaced with a TSQ-based work space manager.

The benefits of using a TSQ-based work space manager is that it simplifies the installation process and improves the performance of your map execution. The storage requirements for TSQ might be impacted. You must ensure that there is enough available TSQ.

For more information about how to size temporary storage, see [Sizing temporary storage](#).

Sizing temporary storage

Temporary Storage Queue (TSQ) is used to back up IBM® Transformation Extender for Application Programming work spaces required to run a map.

Work space refers to a physical store that is used to shadow input and output data. Shadow data is usually created when the map uses an adapter or Transient Data Queues, or the map is expecting the data to contain record separators. Work spaces are also used by the core transformation services to store information about the data that is being mapped.

Because you can develop a map with no inputs and outputs, work spaces might not be used in some situations.

The minimum number of possible work spaces for a map execution is 1. The maximum possible number is $1 + (2 * \text{number of inputs}) + (2 * \text{number of outputs})$.

TSQ will not be used by a map if the map's source and targets are passed as memory buffers and the workspace in memory option (-WM) is used.

Each work space is keyed by a unique TSQ qname. The format of the qname is TXnnnnNdddddd, where nnnn is the CICS task id and ddddddd is a sequence number.

In theory, the maximum size of a single work space is 1,073,545,221 bytes.

To calculate the TSQ space requirements for a particular map, you need to determine the maximum data size of each input and each output.

The formula for a specific input is:

```
TSQ size = (max data size * 5)
```

The criteria for the multiplier of 5 is 1 for the shadow file and 4 for the work space used by the core transformation service. The amount of space required by the core transformation service might actually be less. It depends on a number of factors such as the number of objects being validated. Four (4) is typical for a complex type tree with lots of types defined.

- [Sizing temporary storage example](#)

This is an example of how the temporary storage for a map is sized.

Sizing temporary storage example

This is an example of how the temporary storage for a map is sized.

Assume that your map has two inputs and one output. Input 1 is a WebSphere MQ message. Input 2 is a lookup from a DB/2 table. The target destination for the output is to DB/2.

The MQ message is 100,000 bytes. The DB/2 lookup is 1,200 bytes. The target destination for the output is to DB/2 and is 25,000 bytes.

Work space estimates:

Input

```
500,000 = 100,000 + (100,000 * 4)
```

Input 2

```
6,000 = 1,200 + (1,200 * 4)
```

Output 1

```
25,000 = 25,000
```

Map total size is: 531,000.

In this example, the actual amount of TSQ used will be greater based on the fact that the size of the TSQ records used by the work space manager is 32,763. Also, the map's page size setting will determine the minimum amount of space used by the core.

Assuming a 64K page size setting, the estimate would be:

Input 1

```
622,497 = ((100,000 / 32,763) + 32,763) +
((400,000 / 65,535) + 65,535) / 32,763 + 32,763
```

Input 2

```
131,052 = 32,763 + ((65,535 / 32,763) + 32,763)
```

Output 1

32,763

New map total size is 786,312.

The actual required amount will depend on how many 64K pages are necessary to validate the input. An additional factor for which you need to account when sizing temporary storage is the maximum number of concurrent transactions that will be running the map.

Assuming there can be 3 concurrent tasks, the total temporary storage would be:

$$2,358,936 = 3 * 786,312$$

(Optional) Defining and loading the Resource Name file

Optionally define and load the VSAM entry-sequenced data set (ESDS) that stores the DTXCRMNRN resource name file.

The step should be done only if you want to use the IBM® Transformation Extender for Application Programming resource name file, and successfully complete the IVP for the Resource Registry example described in the DTXCRRME readme file.

To define and load the resource name file (.mrn), run the DTXRRJCL example JCL that is in the DTX.SDTXSAMP PDS.

To use the resource name file on CICS, create the resource name file. For information about creating the resource name file (.mrn) on Windows, see the IBM Transformation Extender Resource Registry documentation. The DTXCRMNRN example resource name file is provided in the IBM Transformation Extender for Application Programming installation in the DTX.SDTXSAMP PDS.

Examples for the CICS environment

There are several examples that are described in the readme files installed in the DTX.SDTXSAMP PDS and are used to demonstrate the various feature components.

For the required configuration steps, see [Loading Maps](#).

DTXVRMME

Burst Map example

DTXCDRMME

DB2 Map example

run only if you will be using the DB2 Adapter and the DB2 plan

DTXCRMME

WebSphere MQ example

run only if you will be using the IBM MQ Adapter

DTXCRREME

Resource Registry example

run only if you will be using the Resource Registry

for configuration requirements, see [\(Optional\) Defining and loading the Resource Name file](#).

IMS environment

The IBM® Transformation Extender for Application Programming includes the IMS/DC Execution Option through which you can run maps in your IMS environments.

- [Configuration steps for the IMS environment](#)

There might be configuration steps required for you to do before you can use the IBM Transformation Extender for Application Programming feature, depending on your business needs and if specific system administration and set up prerequisites have not yet been done in your IMS environment.

Configuration steps for the IMS environment

There might be configuration steps required for you to do before you can use the IBM® Transformation Extender for Application Programming feature, depending on your business needs and if specific system administration and set up prerequisites have not yet been done in your IMS environment.

For more information, see the IMS/DC Execution Option documentation. For other locations where you can find the IMS/DC Execution Option documentation and additional documentation related to z/OS, see [Related publications for z/OS](#).

- [\(Optional\) Binding the DB2 plan](#)

(Optional) Binding the DB2 plan

For configuration steps for the Data Base Request Module (DBRM) that is included with the installation files, see [Binding the Data Base Request Module \(DBRM\)](#).

UNIX System Services (USS) Software Development Kit

The IBM® Transformation Extender for Application Programming includes the UNIX System Services (USS) SDK through which you can run maps in your USS environments.

For additional configuration steps that are common to other IBM Transformation Extender for Application Programming features installed on UNIX System Services (USS), see [Additional configuration on UNIX System Services \(USS\)](#), that is in [Information common to all features](#).

For information about using the API on USS, see the Platform API documentation in the IBM Transformation Extender information center that is published on the WebSphere Transformation Extender Library web page (<http://www.ibm.com/software/integration/wdatastagetx/library/index.html>). For other locations where you can find the Platform API documentation and additional documentation related to z/OS, see [Related publications for z/OS](#).

Information common to all features

There is configuration information that is common across the different IBM® Transformation Extender features.

- [Binding the Data Base Request Module \(DBRM\)](#)

These are the steps for binding the Data Base Request Module (DBRM) that are common across the different IBM Transformation Extender features.

- [Additional configuration on UNIX System Services \(USS\)](#)

To use IBM Transformation Extender features in your USS environments, there are additional configuration activities that you might need to do.

- [Preserving the encoding of XML files](#)

To preserve the encoding of XML files that were created on an ASCII platform, transfer the files (including files such as the Resource Registry .mrc and .mrn files) in BINARY mode (for example, by using FTP or IND\$FILE). Note that ASCII files that are transferred in BINARY mode are still ASCII-encoded, and therefore are not readable on the mainframe platform.

- [Support for Getting Started Sub-capacity Pricing \(GSSP\)](#)

All IBM Transformation Extender runtime environments on z/OS systems support Getting Started Sub-capacity Pricing (GSSP).

- [Support for z/OS XML System Services processing](#)

The IBM Steling Transformation Extender for z/OS Batch, API, IMS, and CICS can use z/OS XML System Services to parse and, optionally, validate XML documents.

Binding the Data Base Request Module (DBRM)

These are the steps for binding the Data Base Request Module (DBRM) that are common across the different IBM® Transformation Extender features.

- [Upgrading from an earlier version](#)

If you are using the DB2 (z/OS) Adapter with your current release of the IBM Transformation Extender and with a prior release or prior releases of the IBM Transformation Extender concurrently, it is recommended that you bind the application plans as a package.

- [Binding the DBUTILE application plan package](#)

You must bind the DBRM to use the DB/2 (z/OS®) Call Attachment Facility (CAF) Adapter.

Related reference

- [Accessing DB2 databases in CICS and IMS environments](#)

Upgrading from an earlier version

If you are using the DB2 (z/OS) Adapter with your current release of the IBM® Transformation Extender and with a prior release or prior releases of the IBM Transformation Extender concurrently, it is recommended that you bind the application plans as a package.

This will allow multiple releases of the IBM Transformation Extender to be bound to the same application plan.

Binding the DBUTILE application plan package

You must bind the DBRM to use the DB/2 (z/OS®) Call Attachment Facility (CAF) Adapter.

There is only one Data Base Request Module (DBRM), named DBUTILE. It is contained in the DTXDBUTE member of the DTX.SDTXSAMP PDS that is included with the installation files. It can be bound as the DBUTILE plan by running the DTXBIND JCL that is included in the feature installation.

The DBUTILE plan name is used when the DB2 Adapter connects to the DB2 subsystem where its DB request module was bound.

For more instructions on binding the application plan by using the sample DTXBIND JCL, see the readme files DTXCDRME and DTXDMRME that are installed with DTX.SDTXSAMP PDS.

Additional configuration on UNIX System Services (USS)

To use IBM® Transformation Extender features in your USS environments, there are additional configuration activities that you might need to do.

- [Modifying the DTXINST JCL](#)

The DTXINST JCL job is used to create the IBM Transformation Extender UNIX System Services (USS) runtime environment.

- [Setting USS environment variables](#)

There are several UNIX System Services (USS) environment variables that you need to set.

- [Using IBM Transformation Extender for Application Programming on USS](#)

IBM Transformation Extender for Application Programming contains Java™ interface components that run the UNIX System Services (USS) SDK on z/OS® operating systems in a UNIX environment. Because the native character-encoding of USS differs from the native character-encoding of JVM, you must set type tree properties to accommodate the difference in encoding.

- [\(Optional\) Defining DB2 system load library](#)

When you use either the DB2 (z/OS) Adapter or DB2 (z/OS ODBC) Adapter in your UNIX System Services (USS) runtime environment, you need to define the DB2 system load library to the system linklist.

- [\(Optional\) Defining IBM MQ system load libraries](#)

When you use the IBM MQ Adapter in your UNIX System Services (USS) runtime environment, you need to define the IBM MQ system load libraries to the system linklist.

- [\(Optional\) Accessing Oracle 9i database](#)

The Oracle 9i Client Adapter is available for you to use in maps on your UNIX System Services (USS) runtime environment.

- [\(Optional\) Using Language Environment parameters](#)

The IBM Transformation Extender UNIX System Services (USS) runtime environment is a 31-bit application. The Language Environment (LE) parameters at many sites are optimized for COBOL programs and 24-bit applications.

- [\(Optional\) Defining port numbers when using the E-mail Adapter](#)

The E-mail Adapter is available for use in maps run on your UNIX System Services (USS) runtime environment.

Modifying the DTXINST JCL

The DTXINST JCL job is used to create the IBM® Transformation Extender UNIX System Services (USS) runtime environment.

Run this job if you have not yet run it to deploy the installed files on USS and only after you have installed one or more of the following features:

- JDTXnn2 IBM Transformation Extender for Application Programming
- JDTXnn3 IBM Transformation Extender for Integration Servers
- JDTXnn4 IBM Transformation Extender with Launcher

where *nn* is the release number. An example is JDTX904, the IBM Transformation Extender with Launcher V9.0 feature.

Before you run the DTXINST JCL, make the following modifications:

1. Modify the **SET INSTHOME** statement in the JCL to define the location of your IBM Transformation Extender - Common Components base feature installation if it is different than the default location settings. The default location is: /usr/lpp/dtx/VnRnMn/IBM/common.
2. Update the JAVA_HOME_DIR environment variable in the STDENV DD statement of the INSTALL job step. Change the *javahome* variable to the directory location of the IBM Runtime Environment, Java™ Technology Edition for your system. See the product [release notes](#) for the required version of IBM Runtime Environment, Java Technology Edition.

For example, change

```
JAVA_HOME_DIR=javahome
```

to

```
JAVA_HOME_DIR=/usr/lpp/java/IBM/J1.6
```

3. Update the BIT_PREFERENCE keyword in the STDENV DD statement of the INSTALL job step. Change the *BITS* variable to the word length of the installation runtime library and binary file selections. The *BITS* variable is one of the following:

Option	Description
64	64-bit library and binary files

4. Modify the **SET CRTHOME** statement in the JCL to define the location of the directory structure where you want the UNIX System Services (USS) runtime environment for the optional features you installed to be created if it is different than the default location settings. The default location is: /u/dtxuser/dtx.

When you run the DTXINST JCL, it will run the **SET** commands, and then run the following two steps: **MAKEDIR** and **INSTALL**.

- [MAKEDIR step](#)

The **MAKEDIR** step of the DTXINST JCL runs the BPXBATCH MVS™ utility program, which uses a **MKDIR** command to create the IBM Transformation Extender home directory.

- [INSTALL step](#)

The **INSTALL** step of the DTXINST JCL runs the BPXBATCH MVS utility program, which runs the createuser shell script from the bin directory of the IBM Transformation Extender - Common Components base feature.

Related reference

- [MAKEDIR step](#)
- [INSTALL step](#)

MAKEDIR step

The **MAKEDIR** step of the DTXINST JCL runs the BPXBATCH MVS™ utility program, which uses a **MKDIR** command to create the IBM® Transformation Extender home directory.

Related tasks

- [Modifying the DTXINST JCL](#)

INSTALL step

The **INSTALL** step of the DTXINST JCL runs the BPXBATCH MVS™ utility program, which runs the createuser shell script from the bin directory of the IBM® Transformation Extender - Common Components base feature.

The createuser shell script creates the following subdirectories in the IBM Transformation Extender home directory (DTX_HOME_DIR) location, specified in the **CRTHOME** setting, and installs the files from the location specified in the **INSTHOME** setting into these subdirectories:

- bin
- config
- data
- dump
- libs
- logs
- maps
- OSGI Bundle
- src
- systems
- tmp
- wmqi

Note: The wmqi and OSGI Bundle subdirectories are created if you have installed the IBM Transformation Extender for Integration Servers optional feature.

The createuser script creates symbolic links to the bin, libs, and config directories of the installed IBM Transformation Extender features. It also creates the setup shell script and optionally creates the deploy shell script for the IBM Transformation Extender for Integration Servers if you have installed this optional feature.

The **INSTALL** step uses the **INSTHOME** symbolic parameter to identify the installed location of the common components directory and the **CRTHOME** symbolic parameter to identify the location of the user runtime directory.

Related tasks

- [Modifying the DTXINST JCL](#)

Setting USS environment variables

There are several UNIX System Services (USS) environment variables that you need to set.

1. Export the **_CEE_RUNOPTS** environment variable.

If you are using IBM® Runtime Environment, Java™ Technology Edition on a z/OS® operating system and you want to use the IBM Transformation Extender in your UNIX System Services (USS) runtime environment, you must add **XPLINK** to the **_CEE_RUNOPTS** USS environment variable. For example:

```
export _CEE_RUNOPTS=$_CEE_RUNOPTS,"XPLINK(ON)"
```

2. Modify the setup script in the current directory to set the **DISPLAY**, **JAVAHOME** environment variable.

The setup script defines the environment variables required to run the IBM Transformation Extender. The **DISPLAY**, **JAVAHOME** environment variable are defined in the following way:

```
DISPLAY  
      Address of the X Server  
JAVAHOME  
      Installation directory of JRE on the z/OS environments
```

The **DISPLAY** and **JAVAHOME** variables are commented out in the script. Either uncomment these environment variables in the setup script or include them in your profile (.profile). If you include these settings in your profile in your UNIX System Services (USS) home directory, you can avoid having to reset these variables each time you install the IBM Transformation Extender in your USS environment.

3. Set the environment variables for IBM Transformation Extender.

Enter " . ./setup" at the command prompt from the directory where you deployed the runtime environment under UNIX System Services (USS) for the IBM Transformation Extender features that you have installed.

Now you can begin to run the IBM Transformation Extender that you installed on your UNIX System Services (USS) execution environment.

Using IBM Transformation Extender for Application Programming on USS

IBM® Transformation Extender for Application Programming contains Java™ interface components that run the UNIX System Services (USS) SDK on z/OS® operating systems in a UNIX environment. Because the native character-encoding of USS differs from the native character-encoding of JVM, you must set type tree properties to accommodate the difference in encoding.

The USS environment uses EBCDIC encoding, and the Java JVM uses UTF-8 encoding. LATIN-1 data is the most appropriate data type to exchange with the JVM.

When you write a map to call a Java-based adapter on USS, set the following properties:

- In the type tree, set the Data language property to LATIN-1 for all character text data items that are to be passed to the adapter.
- The Java-based adapter typically returns a LATIN-1 encoded byte stream. In most cases, use the following type tree properties to set the format of output results that are to be passed from the adapter to the map:
 - Set the Item Subclass property to Text.

- o Set the Interpret as property to Binary.

These settings are especially important if the results are to be used as input into another map or adapter.

For additional information about the Java programming code page considerations, see the reference information for Java on z/OS on the IBM web site.

(Optional) Defining DB/2 system load library

When you use either the DB2 (z/OS) Adapter or DB2 (z/OS ODBC) Adapter in your UNIX System Services (USS) runtime environment, you need to define the DB2 system load library to the system linklist.

To define the DB2 system load library to the system linklist, do one of the following steps:

1. Define the hlq.SDSNLOAD DB2 system load library to the system linklist or
2. Export the STEPLIB variable with the location of the DB2 load library by using the following command:

```
export  
STEPLIB=hlq. SDSNLOAD
```

where hlq is the high-level qualifier for the DB2 installation.

Each time you run the IBM® Transformation Extender, you can do one of the following steps:

- use this export statement at the shell prompt or
- add the export statement to the /etc/profile or the .profile file of the specific user of the feature

(Optional) Defining IBM MQ system load libraries

When you use the IBM® MQ Adapter in your UNIX System Services (USS) runtime environment, you need to define the IBM MQ system load libraries to the system linklist.

To define the IBM MQ system load libraries to the system linklist, do one of the following steps:

1. Define the IBM MQ system load libraries to the system linklist or
2. Export the STEPLIB variable with the location of the IBM MQ load library by using the following command:

```
export STEPLIB=hlq..SCSQANLE:hlq..SCSQAUTH
```

where hlq is the high-level qualifier for the IBM MQ installation.

Each time you run the IBM Transformation Extender, you can do one of the following steps:

- use this export statement at the shell prompt or
- add the export statement to the /etc/profile or the .profile file of the specific user of the feature

(Optional) Accessing Oracle 9i database

The Oracle 9i Client Adapter is available for you to use in maps on your UNIX System Services (USS) runtime environment.

This adapter allows access to data stored in Oracle 9i databases on remote systems.

To be able to access data using the Oracle 9i Client Adapter:

1. Install and configure Oracle 9i.
2. Be sure that Oracle 9i is included in the PATH= environment variable and that other environment variables required by the Oracle 9i database are set appropriately. Environment variables required by the Oracle 9i database that are involved with translation from ASCII to EBCDIC require particularly close attention.

Support is not currently provided for direct connection to an Oracle database on the same z/OS system on which the IBM® Transformation Extender is executing.

(Optional) Using Language Environment parameters

The IBM® Transformation Extender UNIX System Services (USS) runtime environment is a 31-bit application. The Language Environment (LE) parameters at many sites are optimized for COBOL programs and 24-bit applications.

To prevent the application from running out of memory because it lacked storage below the 16 megabyte (MB) line, and then terminating abnormally with an abend code such as 80A, the LE parameters listed later in this section are recommended.

Note: These LE parameters are documented in the *z/OS: Language Environment Programming Reference* publication.

Put the following LE parameters in an export statement to be added to the .profile file of the specific user of the feature.

Memory Management

```
STACK(128K,64K,ANY,FREE)  
HEAP(256K,64K,ANY,FREE)  
HEAPPOLS(ON)
```

Error Management

```
TER(UADUMP) or TER(UAIMM)
```

Examples:

(The following LE parameters must be placed all on one line, without any space between them.)

```
_CEE_RUNOPTS="TER(UADUMP),STACK(128K,64K,ANY,FREE),HEAPPOOLS(ON),  
HEAP(256K,64K,ANY,FREE)"
```

(Optional) Defining port numbers when using the E-mail Adapter

The E-mail Adapter is available for use in maps run on your UNIX System Services (USS) runtime environment.

To ensure correct operation of the E-mail Adapter, you need to define the port numbers for SMTP and pop3 in the TCPIP.ETC.SERVICES or /etc/services files.

1. Define the well-known port number for SMTP as 25.
2. Define the well-known port number for pop3 as 110.

For a complete list and discussion of well-known port numbers, see the Internet Assigned Numbers Authority (IANA) website at <http://www.iana.org>.

Preserving the encoding of XML files

To preserve the encoding of XML files that were created on an ASCII platform, transfer the files (including files such as the Resource Registry .mrc and .mrn files) in BINARY mode (for example, by using FTP or IND\$FILE). Note that ASCII files that are transferred in BINARY mode are still ASCII-encoded, and therefore are not readable on the mainframe platform.

An XML instance document might contain an encoding attribute that identifies the code page of its content. If you transfer an XML file to your mainframe in ASCII mode or convert it to EBCDIC, you must manually change the encoding setting in the resulting XML instance document to the correct code page in order to ensure that the XML parser correctly processes the file. In most cases, change UTF-8 encoding to IBM-1047 encoding.

Support for Getting Started Sub-capacity Pricing (GSSP)

All IBM® Transformation Extender runtime environments on z/OS systems support Getting Started Sub-capacity Pricing (GSSP).

After IBM Transformation Extender registers with the hosting subsystem, GSSP system management facility (SMF) accounting records are collected continuously on behalf of IBM Transformation Extender for the hosting subsystem's address space.

Support for z/OS XML System Services processing

The IBM Sterling Transformation Extender for z/OS Batch, API, IMS, and CICS can use z/OS XML System Services to parse and, optionally, validate XML documents.

However, due to new compiler restrictions, IBM Sterling Transformation Extender for z/OS on USS can no longer use z/OS XML System Services to parse and validate XML documents.

- [Invoking z/OS System Services parsing](#)

IBM Transformation Extender for z/OS® uses z/OS XML System Services parsing when you supply an input schema in OSR format.

- [z/OS XML System Services parsing limitations](#)

Invoking z/OS System Services parsing

IBM® Transformation Extender for z/OS® uses z/OS XML System Services parsing when you supply an input schema in OSR format.

To use z/OS XML System Services to parse an XML document, supply the input schema as a binary Optimized Schema Representation (OSR) file. Use the z/OS **xsdorg** command to generate the OSR file. Specify the path to the OSR file in the Schema.>Type.>Metadata property of the input card. See [z/OS XML System Services User's Guide and Reference](#) for a description of the **xsdorg** command and the list of data encodings that z/OS XML System Services supports.

- To parse an OSR file without validation, set the input card DocumentVerification.>Xerces property to Well formed.
- To parse an OSR file with validation, set the input card DocumentVerification.>Xerces property to Schema Validation.

When the Schema.>Type.>Metadata property points to an XSD file instead of an OSR file, IBM Transformation Extender uses its internal native-schema parsing to parse the file.

z/OS XML System Services parsing limitations

The following limitations apply to z/OS XML System Services processing:

- Because the z/OS XML System Services parser stops parsing when it encounters an error, native-schema-enabled maps that use z/OS XML System Services parsing do not support the REJECT function.
- The z/OS XML System Services parser and the **xsdorg** command flag null characters at the end of a file as invalid data. To use z/OS XML System Services processing, specify variable-length record format for the input data set. Fixed-length records pad the data set with nulls to the specified block size.
- Native-schema-enabled maps that use the z/OS XML System Services parser do not support CDATA.

In addition, these limitations that are common to native-schema-enabled maps also apply to native-schema-enabled maps that are parsed by z/OS XML System Services:

- IBM® Transformation Extender maps do not handle XML schema sequences that contain elements with the same name. When an XML schema contains a sequence of elements that do not have unique names, a map creates the output correctly only for the first element. The map creates the output with empty values for all the subsequent elements that have the same name.
- A map that runs successfully in versions of WebSphere Transformation Extender earlier than version 8.2.0.4 might fail to run in version 8.2.0.4 and later versions. The process of mapping items from the schema changed in version 8.2.0.4, and you might have to revise the map.

IBM Transformation Extender for Integration Servers overview

IBM® Transformation Extender for Integration Servers packages extenders to IBM products.

It provides installation and integration support when combining IBM Transformation Extender with additional IBM products. It includes IBM Transformation Extender components that are ready to deploy in message flows, mediation flows, and business processes. IBM Transformation Extender complements the native capabilities of these products, and can process large documents and messages with more complex formats that are not based on XML.

The following IBM Transformation Extender products are packaged as IBM Transformation Extender for Integration Servers:

- IBM Transformation Extender for IBM Integration Bus
- IBM Transformation Extender for Sterling B2B Integrator
- IBM Transformation Extender for IBM Business Process Manager Advanced

System requirements

IBM® Transformation Extender for Integration Servers requirements are detailed in the [system requirements](#).

IBM Transformation Extender for Sterling B2B Integrator

IBM Transformation Extender for Sterling B2B Integrator combines the business process management features of IBM® Sterling B2B Integrator with the universal transformation capability of IBM Transformation Extender. This integration of business-to-business (B2B) gateway and universal transformation solution gives you new options for solving B2B and application-to-application (A2A) integration problems.

- **[Product uses for Sterling B2B Integrator customers](#)**
IBM Transformation Extender includes a transformation engine, a graphical map editor, and industry packs that provide pre-defined support for multiple document standards, and a range of technology adapters.
- **[Product uses for IBM Transformation Extender customers](#)**

The WTX Map service combines the data transformation power of IBM Transformation Extender with the business integration capabilities of Sterling B2B Integrator.
- **[Services that support IBM Transformation Extender maps](#)**
In addition to the WTX Map service, certain Sterling B2B Integrator services can run IBM Transformation Extender maps.
- **[Business process concepts](#)**
A *business process* is a goal-driven, ordered flow of activities that accomplishes a business objective. A *service* is a set of instructions that Sterling B2B Integrator uses to perform an activity in a business process. *Process data* is data that a process stores in an XML document when the process runs. For example, process data that a service extracts from a document can be used to determine which service runs next in the process.
- **[Sterling B2B Integrator user interface permissions](#)**
You must explicitly set specific permissions to use many of the interfaces in the Sterling B2B Integrator dashboard.
- **[Developing a business process that uses the WTX Map service](#)**
You can develop a business process that uses a IBM Transformation Extender map to transform data.
- **[Deploying IBM Transformation Extender maps](#)**
The location where you store a IBM Transformation Extender map determines which services can use the map.
- **[Testing IBM Transformation Extender maps](#)**
You can use IBM Transformation Extender Design Studio to manually test the IBM Transformation Extender map on the Sterling B2B Integrator server.
- **[Running a business process](#)**
A business process can run on a predefined schedule, in response to an activity, or manually.
- **[Configuring the Translation service to use IBM Transformation Extender maps](#)**
When the Sterling B2B Integrator Translation service uses a IBM Transformation Extender map, set the `exhaust_input` setting to YES to enable the service to process all of the input records.

- **Problem determination**

You can enable trace and audit logs to diagnose WTX Map service errors. You can configure the WTX Map service to extract data from a document or a process for tracking purposes.

- **Performance tuning**

The `tx_install_dirconfig.yaml` file contains the `runtime/stream/MaxMemLimit` property and the `runtime/stream/MaxMemDirectory` property. When data passed to or from an adapter exceeds the size (in MB) that is configured on the `StreamMaxMemLimit` property, the data is paged to a temporary file to limit the memory consumption of the process. The `StreamMaxMemDirectory` property specifies the directory where the temporary files are located.

Product uses for Sterling B2B Integrator customers

IBM Transformation Extender includes a transformation engine, a graphical map editor, and industry packs that provide pre-defined support for multiple document standards, and a range of technology adapters.

You can embed IBM Transformation Extender within an application or run it in parallel to an application. With different engine configurations, you can use the transformation capabilities of IBM Transformation Extender through:

- Direct integration with specific IBM® products
- The API
- The command line
- Event-based triggers

IBM Transformation Extender has these unique features:

- Transformation of multiple inputs and multiple outputs in a single translation process
- High throughput execution
- Code-free design and deployment
- Robust design and testing functions through the Eclipse IDE
- Ontological data model for all data types
- Support for industry standards such as HL7, SEPA, NCPDP, and ACORD

IBM Transformation Extender addresses the business needs that are common to both application-to-application (A2A) and business-to-business (B2B) integration. Integration with Sterling B2B Integrator adds these capabilities:

- Trading partner management
- Enveloping and de-enveloping or bulking and debulking
- Document management and archive
- Automated acknowledgment generation
- Reporting
- Managed file transfer with Sterling File Gateway

IBM Transformation Extender maps can run in existing or new business processes. Within a business process, Sterling B2B Integrator logging, alerts, and error messages are active. IBM Transformation Extender has additional logging and management facilities that can provide product-specific detail. If you have experience with either product, you can use the troubleshooting tools that you know.

Business needs determine whether to use the adapters that are available with IBM Transformation Extender or the adapters that are available with Sterling B2B Integrator.

Product uses for IBM Transformation Extender customers

If you already use IBM Transformation Extender, you can invoke your existing IBM Transformation Extender maps in predefined business processes for business-to-business (B2B) processing, or create new processes that use Sterling B2B Integrator functionality to address your specific needs.

As a B2B gateway, Sterling B2B Integrator provides:

- Integrated communications
- Trading partner management
- Message enveloping and de-enveloping
- Automated acknowledgment generation
- A set of pre-defined EDI and B2B processes

Advantages of IBM Transformation Extender for Sterling B2B Integrator

The integration of IBM Transformation Extender with Sterling B2B Integrator provides map reuse, support for industry standards, and support for complex maps.

- Reuse existing maps
If you already use IBM Transformation Extender for A2A or B2B transformation, you can combine existing business processes (or the sample EDI translation business processes) in Sterling B2B Integrator with your existing IBM Transformation Extender maps.
- Industry standards support
IBM Transformation Extender supports financial services and healthcare industry standards in a Sterling B2B Integrator business process. Maps that you create with either IBM Transformation Extender or Sterling B2B Integrator can coexist within Sterling B2B Integrator.
- Implementation of complex many-to-many maps
Business needs can require the transformation of one source document into multiple target documents, or many-source-to-many-target transformation. With IBM Transformation Extender, a single process can address these transformation requirements without the need for multiple translation processes.

Examples

You can learn about IBM Transformation Extender for Sterling B2B Integrator by running the examples that are provided with the product. The examples illustrate how to use IBM Transformation Extender for Sterling B2B Integrator to accomplish specific tasks. The examples and readme files that describe them are located in the `tx_install_dir/examples` directory.

Standards, globalization, and data-type support

Sterling B2B Integrator services are developed using industry-accepted specifications for data formats, communication protocols, workflow modeling, and security in order to maximize interoperability between systems and trading partners.

Sterling B2B Integrator supports standards for:

- Internet transports
- Cryptographic services
- Document formats
- Document-enveloping formats
- Business-process sequencing
- Web services

Sterling B2B Integrator is built on a Java™ code base. Because Java supports Unicode, the universal character-encoding scheme, your business processes can interact with data that is written in nearly any language. Virtually any file-based, message-based, or stream-based data type is also supported.

Related concepts

Transforming data

When a sender and receiver have different message format specifications, you can design your business process to transform the data in a document before delivering it. You can design a business process to reformat a document, enrich a message, or perform numeric and string calculations based on the value of certain fields.

Sterling B2B Integrator provides built-in services for you to use in your business processes. IBM Transformation Extender for Sterling B2B Integrator extends these data transformation and validation capabilities by enabling you to use IBM Transformation Extender maps and type trees within the Sterling B2B Integrator environment. You can create IBM Transformation Extender type trees that model complex data and use component rules to validate the syntax and semantics of the data in your messages.

For information about the services, see the related topics in the [Sterling B2B Integrator documentation](#).

WTX Map service overview

The WTX Map service is a component of IBM Transformation Extender for Sterling B2B Integrator. The WTX Map service provides the ability to run a IBM Transformation Extender map within a Sterling B2B Integrator business process. The WTX Map service combines the data transformation power of IBM Transformation Extender with the business integration capabilities of Sterling B2B Integrator.

Within Sterling B2B Integrator, you can use the Graphical Process Modeler (GPM) to configure a business process. When IBM Transformation Extender for Sterling B2B Integrator is installed on a Sterling B2B Integrator server, the WTX Map service icon is available in the GPM palette for you to include in the business process. Alternatively, you can directly edit the Business Process Modeling Language (BPML) meta-language of a business process to add the WTX Map service.

In a business process, a series of steps process a document. A service performs each step. The WTX Map service receives input from Sterling B2B Integrator, runs the IBM Transformation Extender map that is configured in the map service settings, and creates one or more Sterling B2B Integrator documents as output. The map can have multiple input cards and multiple output cards. Each input card and output card can be associated with a Sterling B2B Integrator document.

When an input card does not receive a document, the card pulls data from the adapter that is specified on the card. If an output card is associated with a document, the map service creates or overwrites the document. If an output card is not associated with a document, the map services sends the data to the adapter that is specified on the output card. Maps can also read and create documents dynamically. You can create a dynamic document by using the IBM Transformation Extender PUT rule.

The WTX Map service can load a compiled IBM Transformation Extender map from the Sterling B2B Integrator map repository or from a local file system on the Sterling B2B Integrator server. The WTX Map service also can dynamically load a map at runtime when the map is specified as a workflow variable.

Related tasks

Services that support IBM Transformation Extender maps

In addition to the WTX Map service, certain Sterling B2B Integrator services can run IBM Transformation Extender maps.

These Sterling B2B Integrator services can run IBM Transformation Extender maps that are checked into the Sterling B2B Integrator map repository:

- EDIFACT Enveloping
- EDIFACT De-enveloping
- Translation
- X12 Envelope
- X12 De-envelope

The Sterling B2B Integrator X12 Envelope, X12 De-envelope, and EDIFACT De-enveloping services can use the compliance checkers that are built into the IBM Transformation Extender X12, HIPAA, and EDIFACT Packs as an alternative to the native compliance-check functionality in Sterling B2B Integrator.

See the IBM Transformation Extender Packs documentation for information about compliance-checking and services.

Business process concepts

A *business process* is a goal-driven, ordered flow of activities that accomplishes a business objective. A *service* is a set of instructions that Sterling B2B Integrator uses to perform an activity in a business process. *Process data* is data that a process stores in an XML document when the process runs. For example, process data that a service extracts from a document can be used to determine which service runs next in the process.

IBM Transformation Extender for Sterling B2B Integrator installs the WTX Map service into Sterling B2B Integrator. The WTX Map service and certain Sterling B2B Integrator services can run a IBM Transformation Extender map as part of a business process.

See the [Sterling B2B Integrator documentation](#) for details about business processes, services, and process data.

Related reference

- [Services that support IBM Transformation Extender maps](#)

Sterling B2B Integrator user interface permissions

You must explicitly set specific permissions to use many of the interfaces in the Sterling B2B Integrator dashboard.

For details, see the description of the permissions needed to access UI resources in the Security documentation in the [Sterling B2B Integrator documentation](#).

Developing a business process that uses the WTX Map service

You can develop a business process that uses a IBM Transformation Extender map to transform data.

To use a IBM Transformation Extender map in a business process:

1. Create a IBM Transformation Extender map.
2. Compile the map and deploy it to Sterling B2B Integrator.
3. Create the business process by using the Sterling B2B Integrator Graphical Process Modeler (GPM) or by editing the Business Process Modeling Language (BPML).
4. Edit the business process to add the WTX Map service.
5. Edit the WTX Map service to identify the IBM Transformation Extender map that you want to run.

In the GPM service editor, use the Message To Service tab to identify the map to run and use either:

MapServerLocation

Specifies a map on the local file system of the Sterling B2B Integrator server. If you configure MapServerLocation, you must also configure the LocalMap field if you want to retrieve and edit the map settings from the file system.

MapName

Specifies a map in the Sterling B2B Integrator map repository.

If you configure both MapName and MapServerLocation, the WTX Map services uses the MapName value.

6. Deploy the business process to Sterling B2B Integrator.

- [WTX Map service](#)

Sterling B2B Integrator users who are familiar with the format of Sterling B2B Integrator service descriptions can use this overview of the WTX Map service. Details

about configuring, deploying, running, and debugging the WTX Map service are covered by the other topics in this information unit.

- **[Specifying the map for the WTX Map service](#)**

The WTX Map service can run a map that is in the file system on the Sterling B2B Integrator server or in the Sterling B2B Integrator map repository. At runtime, a service that runs before the WTX Map service can dynamically override the map that is configured on the WTX Map service.

- **[Map caching](#)**

Map caching can improve the runtime performance of the WTX Map service. You enable map caching at design time. You can cache any map except for dynamic maps.

- **[Resource Registry](#)**

The resource configuration file defines resources and aliases that are available to all WTX Map services that run on the Sterling B2B Integrator.

- **[Input and output cards](#)**

The IBM Transformation Extender map editor represents map input data and output data as map *cards*. The WTX Map service can host maps that have any number of input and output cards. Optionally, you can associate each card with a Sterling B2B Integrator document.

- **[Overriding map and card properties by using map settings](#)**

You can override the settings of a IBM Transformation Extender map that is configured for the WTX Map service. The map can be stored in either the map repository or in the file system of the Sterling B2B Integrator server.

- **[Accessing the Sterling B2B Integrator data harness from maps](#)**

Any service that runs IBM Transformation Extender maps reads and writes to the underlying database of Sterling B2B Integrator through a data harness. The data harness interacts with the Sterling B2B Integrator engine to perform functions such as getting data and setting correlations.

- **[Sending output data from a map to a Sterling B2B Integrator document](#)**

You configure the WTX Map service to send output data to a Sterling B2B Integrator document by configuring the PUT map rule on the Sterling adapter. The IBM Transformation Extender PUT map rule can create a Sterling B2B Integrator document immediately, or based on the success or failure of the map.

WTX Map service

Sterling B2B Integrator users who are familiar with the format of Sterling B2B Integrator service descriptions can use this overview of the WTX Map service. Details about configuring, deploying, running, and debugging the WTX Map service are covered by the other topics in this information unit.

System name

WTX Map service

Graphical Process Modeler (GPM) category

IBM Transformation Extender

Description

Runs a IBM Transformation Extender map in a Sterling B2B Integrator business process to transform data.

Business usage

Performs translation of the input document within a business process.

Usage example

See the examples and readme files located in the `tx_install_dir\examples` directory.

Preconfigured?

No

Requires third-party files?

No

Platform availability

All supported application platforms.

Related services

No

Application requirements

The IBM Transformation Extender map that the WTX Map service runs must be located in the Sterling B2B Integrator or on the file system of the Sterling B2B Integrator server.

The connection to the Sterling B2B Integrator server must be configured by using the IBM Transformation Extender Design Studio. See the Map Designer documentation.

Initiates business processes?

No

Invocation

Runs as part of a business process.

Business process context considerations

The well-known `dynamicMap` work flow context variable points to a document object that stores a compiled map that the WTX Map service can load at runtime.

Returned status values

See the problem determination topics in this information unit.

Restrictions

No

Persistence level

None

Testing considerations

See the examples and readme files located in the `TX_install_directory\examples` directory.

Related concepts

- [WTX Map service overview](#)
-

Specifying the map for the WTX Map service

The WTX Map service can run a map that is in the file system on the Sterling B2B Integrator server or in the Sterling B2B Integrator map repository. At runtime, a service that runs before the WTX Map service can dynamically override the map that is configured on the WTX Map service.

- [Using maps from the map repository](#)
Maps that are checked into the Sterling B2B Integrator map repository can be used by the WTX Map service and any Sterling B2B Integrator service that supports IBM Transformation Extender maps. You can check in a map to the Sterling B2B Integrator map repository by using the Sterling B2B Integrator administrative console or the IBM Transformation Extender Design Studio.
- [Using maps on the server file system](#)
You can configure the WTX Map service in your business process to use a IBM Transformation Extender map on the Sterling B2B Integrator server.
- [Dynamically specifying maps at runtime](#)
At run time, you can override the compiled map that you specified in the WTX Map service with a compiled map that is specified in process data.
- [Dynamically loading RUN maps from the Sterling B2B map repository](#)
You can store a RUN map in the Sterling B2B Integrator map repository. A RUN map can be dynamically loaded by the WTX Map service and by other Sterling B2B Integrator services.

Related concepts

- [WTX Map service overview](#)
-

Using maps from the map repository

Maps that are checked into the Sterling B2B Integrator map repository can be used by the WTX Map service and any Sterling B2B Integrator service that supports IBM Transformation Extender maps. You can check in a map to the Sterling B2B Integrator map repository by using the Sterling B2B Integrator administrative console or the IBM Transformation Extender Design Studio.

Before you can use Design Studio to check a map into the map repository, you must:

- Install IBM Transformation Extender for Integration Servers on the computer where Design Studio is installed.
- Use Design Studio to configure the connection to the Sterling B2B Integrator server. See the IBM Transformation Extender Map Designer documentation for details.

To use Design Studio to check a map into the map repository, right-click a source map and select Deploy Map to Sterling B2B Integrator. Design Studio automatically compiles the map before storing it in the repository.

See the [Sterling B2B Integrator documentation](#) for details about checking in maps by using the administrative console.

To configure the WTX Map service to run a map in the Sterling B2B Integrator repository, right-click the WTX Map service in the Graphical Process Modeler and click Properties. Specify the name of the map in the repository in the MapName field.

Using maps on the server file system

You can configure the WTX Map service in your business process to use a IBM Transformation Extender map on the Sterling B2B Integrator server.

In the Sterling B2B Integrator Graphical Process Modeler, right-click the WTX Map service and click Properties. Use the MapServerLocation field to specify a compiled map on the file system of the Sterling B2B Integrator server.

Dynamically specifying maps at runtime

At run time, you can override the compiled map that you specified in the WTX Map service with a compiled map that is specified in process data.

A business process can derive either the map name or the map itself from process data. For example, the /ProcessData/here document can contain the name of another ProcessData document, /ProcessData/there:

```
/ProcessData/here="ProcessData/there"  
/ProcessData/there="hello"
```

- When /ProcessData/here is used as an XPATH expression, it resolves to hello.
- When /ProcessData/here is not used as an XPATH expression, it resolves to /ProcessData/there.

A business process searches for the map to execute in this order:

1. A map from a document

A compiled map can be stored in process data and passed to the WTX Map service.

Source
Process data

Location
A document called dynamicMap

Purpose
To run the compiled map that is supplied as an array of bytes in the process data.

Result
The WTX Map service runs the supplied map.

Storing large maps in the dynamicMap property can affect performance and memory usage. In general, write a large map to disk and reference it from the MapServerLocation property.

2. A map in the Sterling B2B Integrator repository

Source
WTX Map service
Location
/ProcessData/MapName

Purpose
To run a compiled map that is stored in the Sterling B2B Integrator Map Repository.
Result
The specified map runs, unless it is overridden by MapServerLocation or dynamicMap.

3. A map from a file system on the Sterling B2B Integrator server

At runtime, override the map server location with the map server location that was placed in the process data by a prior service in the business process:

Source
The file system
Location
/ProcessData/MapServerLocation

Purpose
To run a compiled map that is in a location other than the location that is configured on the WTX Map service.
Result
The Sterling B2B Integrator business process overrides the map server location with the location that you specified in the process data, and the WTX Map service runs the map from this location instead.

To specify a map in the map repository, omit the file extension from the MapName. To specify a map in the file system on the server, include the file extension in the map name.

When a map name includes a file extension, IBM Transformation Extender for Sterling B2B Integrator searches for the map on the file system of the Sterling B2B Integrator server. If the map is not in the file system, IBM Transformation Extender for Sterling B2B Integrator strips the file extension from the map name and searches for the map name in the Sterling B2B Integrator map repository.

When a map name omits a file extension, IBM Transformation Extender for Sterling B2B Integrator searches the map repository first, then searches the file system.

For more information about process data, see the [Sterling B2B Integrator documentation](#).

Dynamically loading RUN maps from the Sterling B2B map repository

You can store a RUN map in the Sterling B2B Integrator map repository. A RUN map can be dynamically loaded by the WTX Map service and by other Sterling B2B Integrator services.

When a RUN map is in the map repository, the RUN function call must reference its name in the repository. For example:

```
RUN ("map_name_in_repository", ....)
```

Map caching

Map caching can improve the runtime performance of the WTX Map service. You enable map caching at design time. You can cache any map except for dynamic maps.

Map caching can improve performance because the WTX Map service does not load the compiled map every time the map runs. The WTX Map service loads the compiled map only on the first invocation of the map.

When map caching is enabled, changes that you make to the compiled map are not loaded until the Sterling B2B Integrator server is restarted. When map caching is disabled, any changes that you make to the compiled map are loaded the next time the WTX Map service runs.

Map caching can be enabled or disabled for each instance of the WTX Map service. In the Graphical Process Modeler, set the CacheMap property in the Message to Service tab. Alternatively, configure the BPMN with one of the following assignments:

```
<assign to="CacheMap">YES</assign>
<assign to="CacheMap">NO</assign>
```

You can enable RUN map caching in the [RUN Maps] section of the config.yaml configuration file. Set /runtime/Run Maps/RunMapMaxCacheNum to the maximum number of RUN maps to cache.

 - [Running multiple concurrent instances of maps](#)
 - [Performance tuning](#)
-

Resource Registry

The resource configuration file defines resources and aliases that are available to all WTX Map services that run on the Sterling B2B Integrator.

For detailed information about the Resource Registry, see the IBM Transformation Extender documentation.

- [Modifying resource names](#)
Use the IBM Transformation Extender editor to create resource aliases to be used with IBM Transformation Extender resources in Sterling B2B Integrator.
 - [Specifying the Resource Registry location](#)
Configure the Resource Registry location on the ResourceFile= property in the *Sterling_installation_dir\properties\translator.properties_wtx_ext.in* file.
-

Modifying resource names

Use the IBM Transformation Extender editor to create resource aliases to be used with IBM Transformation Extender resources in Sterling B2B Integrator.

You can use resource aliases only on a WTX Map service. You can create aliases for these IBM Transformation Extender resources that are used in WTX Map services:

- Unwired source and target resources that are specified in map cards
- GET and PUT functions in map rules
- RUN map overrides
- Audit file names
- Trace file names
- Back up file names
- Work space locations

For a complete list of the resources, see the IBM Transformation Extender Resource Registry documentation.

Specifying the Resource Registry location

Configure the Resource Registry location on the ResourceFile= property in the *Sterling_installation_dir\properties\translator.properties_wtx_ext.in* file.

Input and output cards

The IBM Transformation Extender map editor represents map input data and output data as map *cards*. The WTX Map service can host maps that have any number of input and output cards. Optionally, you can associate each card with a Sterling B2B Integrator document.

Relative paths on input and output cards resolve to the *Sterling_installation_dir\logs* directory.

- [Wired and unwired cards](#)
Input and output cards are considered to be *wired* when the card receives data from or sends data to a Sterling B2B Integrator document. An *unwired* card receives data from or sends data to the IBM Transformation Extender adapter that is specified on the card.
- [Configuring input and output cards in maps](#)
The WTX Map service can host a map that has any number of input and output cards. Optionally, you can associate an input or output card with a Sterling B2B Integrator document.
- [XML entities](#)
There are three ways to read from or write to an XML document: by using a classic type tree, by using a Xerces type tree, or by using a native schema. Optionally, a Xerces or native type tree can validate against any XML schema.

Related reference

- [XML entities](#)
-

Wired and unwired cards

Input and output cards are considered to be *wired* when the card receives data from or sends data to a Sterling B2B Integrator document. An *unwired* card receives data from or sends data to the IBM Transformation Extender adapter that is specified on the card.

Sterling B2B Integrator services associate only the first input card and the last output card with the primary document.

Configuring input and output cards in maps

The WTX Map service can host a map that has any number of input and output cards. Optionally, you can associate an input or output card with a Sterling B2B Integrator document.

You use the Sterling B2B Integrator Service Editor in the Graphical Process Modeler (GPM) to define input and output cards and to associate a card with a document.

1. Right-click the WTX Map service icon and click Properties to open the Service Editor.
 2. In the Message To Service tab, click Advanced.
 3. Click Add to create a new row in the table.
 4. In the Name column, specify the card that is to be associated with a document.
 - The name `in1` specifies input card 1, `in19` specifies input card 19, and so on.
 - The name `out1` specifies output card 1, `out11` specifies output card 11, and so on.
 5. Optional: In the Value column, specify the Sterling B2B Integrator document that is to be associated with the card.
- For example:
- `/ProcessData/PrimaryDocument` associates the document called PrimaryDocument that is located in ProcessData with the selected card. If the Value is an XPath location that points to another location, select Use XPATH.
 - `/ProcessData/SomeDocument/@SCIObjectID` accesses the document called SomeDocument by using the SCI ObjectID.
 - `/ProcessData/Document ID/text()` accesses the document by using the Document ID. For example, when the Document ID is `67797813f405b8237node1`, the path is `/ProcessData/67797813f405b8237node1/text()`

XML entities

There are three ways to read from or write to an XML document: by using a classic type tree, by using a Xerces type tree, or by using a native schema. Optionally, a Xerces or native type tree can validate against any XML schema.

When you use a native schema (instead of a type tree) to define a wired card, use the root of the schema (XSD) to define the card type. The native schema must be in the Sterling B2B Integrator repository.

If the map is specified by MapServerLocation, the schema can be on the file system. If a map is a dynamic map or a map in the repository, the schema must be in the Sterling B2B Integrator repository.

- [Input and output cards](#)

Overriding map and card properties by using map settings

You can override the settings of a IBM Transformation Extender map that is configured for the WTX Map service. The map can be stored in either the map repository or in the file system of the Sterling B2B Integrator server.

You use the Service Editor in the Sterling B2B Integrator Graphical Process Modeler (GPM) to retrieve and modify the configured map settings. You can override the settings only by using the GPM. You cannot override the adapter settings of an unwired card.

1. In GPM, right-click the WTX Map service and click Properties to open the Service Editor.
 2. In the MapSettings field, click Map Settings to retrieve the map settings and populate the field:
 - If the MapName field is configured in the Service Editor, the map settings are retrieved from the specified map in the map repository.
 - If the MapServerLocation field and the LocalMap field are configured in the Service Editor, the map settings are retrieved from the specified map on the Sterling B2B Integrator server.To override the properties of a map that is stored in the file system of the Sterling B2B Integrator server, the IBM Transformation Extender Design Studio must be installed on the computer where you are running GPM.
 3. In the Map Settings window, edit the map settings and click OK to save the new settings or Reset to clear the settings.
The revised settings are saved as an XML string and used at runtime.
- [**Required property for secure Map Test HTTP Server adapter**](#)
When the Sterling B2B Integrator Map Test HTTP Server adapter is configured to use the secure socket layer (SSL), the client computer must use a secure connection to retrieve map settings from the Sterling B2B Integrator map repository.

Required property for secure Map Test HTTP Server adapter

When the Sterling B2B Integrator Map Test HTTP Server adapter is configured to use the secure socket layer (SSL), the client computer must use a secure connection to retrieve map settings from the Sterling B2B Integrator map repository.

To use a secure connection to retrieve map settings from the Sterling B2B Integrator map repository:

1. On the client computer, go to `C:\Documents and Settings\Administrator\pmodeler\host_IP_address\dashboard_port_number\gbm.properties`.
2. Set the following property:

```
WTXMapSettings_SecureConnection = true
```

When the Map Test HTTP adapter setting and the client configuration do not match, an error message displays. To resolve the problem, correct the WTXMapSettings_SecureConnection property in the gbm.properties file and restart the GPM.

Table 1. Incompatible Adapter and Client Configurations and Error Messages

Map-Test HTTP Adapter Setting	Client Configuration	Error Message
Use SSL	WTXMapSetting s_SecureConnection = false	Unable to send SOAP Request to Host: http://hostName:adapter_port/MapServices. The following exception occurred: Unexpected end of file from server Possible protocol error (http/https). Contact server administrator. Map settings retrieval operation was not successful.
Do not use SSL	WTXMapSetting s_SecureConnection = true	Unable to send SOAP Request to Host: https://hostName:adapter_port/MapServices. The following exception occurred: Unrecognized SSL message, plaintext connection? Map settings retrieval operation was not successful.

Accessing the Sterling B2B Integrator data harness from maps

Any service that runs IBM Transformation Extender maps reads and writes to the underlying database of Sterling B2B Integrator through a data harness. The data harness interacts with the Sterling B2B Integrator engine to perform functions such as getting data and setting correlations.

The WTX Map service can invoke the data harness functions by configuring either:

- The PUT and GET rules in the map
- An input card or output card command line that specifies the Sterling adapter.

By using the Sterling adapter, maps can read Sterling B2B Integrator data on input cards and from GET rules, and write to tables from output cards and PUT rules. To execute the harness function as soon as the PUT rule is processed, use the -NOW argument. The -NOW executes the function even if the map fails.

When the PUT rule does not include the -NOW argument, the function executes when the map completes.

When the map runs successfully, the output from the adapter is associated with a Sterling B2B Integrator document for use by normal stream adapters.

- **Data harness functions**

The WTX Map service supports data harness functions that operate on Sterling B2B Integrator correlations, process data, code lists, delimiters, and the transaction register. You can use data harness functions in map rules and type trees.

Data harness functions

The WTX Map service supports data harness functions that operate on Sterling B2B Integrator correlations, process data, code lists, delimiters, and the transaction register. You can use data harness functions in map rules and type trees.

Command	Description
getBinaryDocument	Retrieves the specified binary document.
getEnvelope	Retrieves the specified field from an envelope.
setCorrelation	Updates the Sterling B2B Integrator correlation table with the specified name/value pair for the document or business process.
getProcessData	Retrieves process data from the XML document object model (DOM) specified by the XPath. A business process can store and retrieve process data in order to access the data during process execution. See the Sterling B2B Integrator documentation for details about process data.
setProcessData	Stores process data from the current field into the XML DOM that is specified by the XPath. A business process can store and retrieve process data in order to access the data during process execution. See the Sterling B2B Integrator documentation for details about process data.
getCodeListItemBySenderCode	Retrieves a trading-partner code-list entry from Sterling B2B Integrator by sender code. A <i>trading partner code list</i> consists of one or many pairs of code values containing a sender code and a receiver code. Sterling B2B Integrator uses code pairs in code lists to identify items in transactions between two or more trading partners. See the Sterling B2B Integrator Trading Partner documentation for details about code lists.
getCodeListItemByReceiverCode	Retrieves a trading-partner code list from Sterling B2B Integrator by receiver code. A <i>trading partner code list</i> consists of one or many pairs of code values containing a sender code and a receiver code. Sterling B2B Integrator uses code pairs in code lists to identify items in transactions between two or more trading partners. See the Sterling B2B Integrator Trading Partner documentation for details about code lists.
getTransactionRegister	Compares the fields that you loaded into the Transaction Register with the input data, returns a code, and clears the Transaction Register.
0	Success; no duplicate data found.
1	Failure; duplicate data found.
8	No updates performed to this transaction register yet. Cannot perform a select before an update. The Transaction Register is empty. You must invoke setTransactionRegister to load the Transaction Register before you can invoke getTransactionRegister .

The following example:

```
PUT("Sterling", "-t+ -c setTransactionRegister -k 1", "Reg 1")
GET("Sterling", "-t+ -c getTransactionRegister")
GET("Sterling", "-t+ -c getTransactionRegister")
```

1. Loads Transaction Register field 1 with the literal value Reg 1.
2. Compares the input document data to the content of the Transaction Register and returns 0 or 1.
3. Attempts to invoke **getTransactionRegister** again without loading the Transaction Register, resulting in return code 8.

The following example loads Transaction Register field 3 with the contents of the specified input data field:

```
PUT("Sterling", "-t+ -c setTransactionRegister -k 3", PONumber Field:In1)
```

setTransactionRegister

Loads the specified Transaction Register field with the specified data. You can load up to six fields of data into memory for the Transaction Register. See the [See the Sterling B2B Integrator documentation](#) for details about the size limits of the fields.

After you run the **setTransactionRegister** command, you can run the **getTransactionRegister** command to check for duplicate input data.

getDelimiter

Gets a delimiter from an X12 or EDIFACT envelope.

This example **PUT** rule uses the Sterling adapter to create an element under process data that is called "getmap." The -NOW option creates the key even if the map fails:

```
=PUT("Sterling", "-t+ -c setProcessData -k getmap -now", "data")
```

This example GET rule uses the Sterling adapter to read the value of a key called "getmap" from the process data:

```
=GET rule " + VALID( GET("Sterling", "-t+ -c getProcessData -k getmap")
```

This example of a Sterling adapter command line on a card creates a correlation that is called "adapter" when the card completes. The correlation includes all of the data that was built on the card:

```
-c setCorrelation -k adapter -t+
```

The Sterling adapter supports the harness functions with the following command line arguments:

Table 1. Sterling adapter command line arguments

Command Long Form	Command Short Form	Description
-Command	-C	Command
-Key	-K	Key
-Now	-N	Executes the harness function as soon as the PUT rule is processed, even if the map fails
-T	-T	Adapter trace (overwrite)
-T+	-T+	Adapter trace (append)
-TE	-TE	Adapter trace error (overwrite)
-TE+	-TE+	Adapter trace error (append)
-TV	-TV	Adapter trace verbatim (overwrite)
-TV+	-TV+	Adapter trace verbatim (append)
-Code	-D	Sender/Receiver code
-Table	-B	Code table name

This table describes the data harness functions and key values that you can use on the Sterling adapter:

Table 2. Sterling adapter commands and key values

Command	Key
getBinaryDocument	The name of the document to retrieve.
setCorrelation	The name of the correlation to update.
getProcessData	The XPATH to select.
setProcessData	The XPATH to update.
getCodeListItemBySenderCode	The sender value for the code-list entry to retrieve. The command requires a sender code, codeListTable name, and column.
getCodeListItemByReceiverCode	The receiver value for the code-list entry to retrieve. The command requires a receiver code, codeListTable name, and column.
getEnvelope	The envelope field name.
getTransactionRegister	There are no keys for this command.
setTransactionRegister	Each entry is a number between 1 and 6 that indicates the field to update. See the Sterling B2B Integrator documentation for details about the field-size limits.
getDelimiter	An array of numbers that indicates the fields to select. The list is defined in Table 4 .

This table lists the sender and receiver keys and values to use with the getCodeListItemBySenderCode and getCodeListItemByReceiverCode functions.

Table 3. Sender and receiver keys and values

Key	Value
COL_SENDER	0
COL_RECEIVER	1
COL_DESC	2
COL_TEXT1	4

Sending output data from a map to a Sterling B2B Integrator document

You configure the WTX Map service to send output data to a Sterling B2B Integrator document by configuring the PUT map rule on the Sterling adapter. The IBM Transformation Extender PUT map rule can create a Sterling B2B Integrator document immediately, or based on the success or failure of the map.

- [Sending output data by using a PUT wire](#)
The IBM Transformation Extender map PUT rule sends output data from a WTX Map service to a document, either immediately, or based on the outcome of the map. When the output terminal is wired, the data is propagated to the next service in the business process.
- [WTX Map service BPML](#)
You can customize this WTX Map service Business Process Modeling Language (BPML) example to call your own maps. However, to edit map settings, use the Graphical Process Modeler (GPM).
- [Validating the business process modeling language](#)
When you save a business process model in the Graphical Process Modeler (GPM), by default the GPM automatically verifies that the Business Process Modeling Language (BPML) is valid and well-formed. The validation does not verify the configuration of the services within the business process.

Sending output data by using a PUT wire

The IBM Transformation Extender map PUT rule sends output data from a WTX Map service to a document, either immediately, or based on the outcome of the map. When the output terminal is wired, the data is propagated to the next service in the business process.

- [Configuring the WTX Map service PUT rule](#)
To send output data from the WTX Map service to a document, you create a map that uses the PUT rule and create a business process that includes a WTX Map service.
- [PUT rule syntax](#)
To dynamically create a document from a IBM Transformation Extender map, configure a map rule to use the PUT function and the WIRE keyword. Optionally, you can use the -NOW argument to create the document as soon as the PUT function is processed, rather than when the map completes.

Configuring the WTX Map service PUT rule

To send output data from the WTX Map service to a document, you create a map that uses the PUT rule and create a business process that includes a WTX Map service.

PUT rule syntax

To dynamically create a document from a IBM Transformation Extender map, configure a map rule to use the PUT function and the WIRE keyword. Optionally, you can use the -NOW argument to create the document as soon as the PUT function is processed, rather than when the map completes.

The map rule must use the PUT function and specify WIRE as the adapter name:

```
=PUT("WIRE", "output_document",data)
```

Optionally, you can specify that the document is to be created immediately. The -NOW argument creates the output document as soon as the PUT rule is processed. When you omit the -NOW argument, the WTX Map service creates the document when the map completes, and a RUN map creates the document when the parent map completes. When you specify the -NOW argument, the document is created even if the map or RUN map fails.

```
=PUT("WIRE", "output_document -NOW",data)
```

The WIRE and -NOW keywords are not case-sensitive.

WTX Map service BPML

You can customize this WTX Map service Business Process Modeling Language (BPML) example to call your own maps. However, to edit map settings, use the Graphical Process Modeler (GPM).

This BPML example illustrates how you might configure a WTX Map service. It assumes you are familiar with coding in BPML.

```
<process name="default">
  <operation name="WTXSIMapService">
    <participant name="wtxmap"/>
    <output message="WTXSIMapServiceInputMessage">
      <assign to=". " from="*"></assign>
      <assign to="CacheMap">NO</assign>
      <assign to="LocalMap">C:\test\map1.mmc</assign>
      <assign to="MapServerLocation">D:\Sterling\samples\test\map1.mmc</assign>
      <assign to="Threshold"></assign>
      <assign to="MapSettings"><![CDATA[<!-- map settings go here --&gt;]]&amp;gt;&lt;/assign&gt;
      &lt;assign to="in9"&gt;C:\test\GolfCountryClub.xml&lt;/assign&gt;
      &lt;assign to="out4"&gt;C:\test\output.xml&lt;/assign&gt;
    &lt;/output&gt;
    &lt;input message="inmsg"&gt;
      &lt;assign to=". " from="*"></assign>
    </input>
  </operation>
</process>
```

Where:

operation name

Must be WTXSIMapService.

participant name

The name of the IBM Transformation Extender map that the service is to run.

CacheMap

Specifies whether the map should be cached (YES) or loaded each time the service runs (NO). See the description of map caching.

LocalMap

The path to the compiled map in a local file system on the Sterling B2B Integrator server.

MapServerLocation

The path to the compiled map on the Sterling B2B Integrator server.

MapSettings

The map settings in the form of an XML string. Use the Graphical Process Modeler (GPM) to edit the map settings.

Threshold

The input data size limit that determines whether the WTX map service runs in a separate JVM.

in9

The name of the ninth input card.

out4

The name of the fourth output card.

Related tasks

- [Developing a business process that uses the WTX Map service](#)

Related reference

Validating the business process modeling language

When you save a business process model in the Graphical Process Modeler (GPM), by default the GPM automatically verifies that the Business Process Modeling Language (BPML) is valid and well-formed. The validation does not verify the configuration of the services within the business process.

See the [Sterling B2B Integrator documentation](#) for details about business process model validation.

Deploying IBM Transformation Extender maps

The location where you store a IBM Transformation Extender map determines which services can use the map.

You can store a compiled IBM Transformation Extender map:

- In the Sterling B2B Integrator map repository
A map that is stored in the Sterling B2B Integrator map repository is available to the WTX Map service and to all Sterling B2B Integrator services that are enabled for IBM Transformation Extender.
- In a file system on the computer where Sterling B2B Integrator is installed
The WTX Map service can load and run maps from the file system.

- In a Sterling B2B Integrator document object that is to be loaded dynamically at runtime
Another service in the business process can pass a map in the form of a document to the WTX Map service.
- **Deploying to the map repository**
You can store a compiled IBM Transformation Extender map in Sterling B2B Integrator by using IBM Transformation Extender Design Studio or by using Sterling B2B Integrator. Any Sterling B2B Integrator service that is enabled for IBM Transformation Extender can browse for a IBM Transformation Extender map that is stored in the repository.
- **Deploying to a file system**
You can manually transfer a compiled IBM Transformation Extender map to a file system on the Sterling B2B Integrator server. Ensure that the map is compiled for the correct platform, and then use FTP to transfer the map in binary mode. You must manually check in any required schema files by using the Sterling B2B Integrator dashboard.

Deploying to the map repository

You can store a compiled IBM Transformation Extender map in Sterling B2B Integrator by using IBM Transformation Extender Design Studio or by using Sterling B2B Integrator. Any Sterling B2B Integrator service that is enabled for IBM Transformation Extender can browse for a IBM Transformation Extender map that is stored in the repository.

You must compile a source IBM Transformation Extender map before you can store the map in Sterling B2B Integrator.

Before you can use Design Studio to check a map into the map repository, you must:

- Install IBM Transformation Extender for Integration Servers on the computer where Design Studio is installed.
- Use Design Studio to configure the connection to the Sterling B2B Integrator server. See the IBM Transformation Extender Map Designer documentation for details.

To use Design Studio to store a compiled IBM Transformation Extender map in Sterling B2B Integrator, right-click the map in the Design Studio navigator window and click Deploy Map to Sterling B2B Integrator.

To use the Sterling B2B Integrator dashboard to store a IBM Transformation Extender map in Sterling B2B Integrator:

1. In the Administration Menu, click Deployment > Maps.
2. Select Check in new map from Map Editor.

See the description of checking in maps in the [Sterling B2B Integrator documentation](#) for the procedure to check in maps by using the Sterling B2B Integrator Map Editor.

Deploying to a file system

You can manually transfer a compiled IBM Transformation Extender map to a file system on the Sterling B2B Integrator server. Ensure that the map is compiled for the correct platform, and then use FTP to transfer the map in binary mode. You must manually check in any required schema files by using the Sterling B2B Integrator dashboard.

For details about using the Sterling B2B Integrator dashboard, see the [Sterling B2B Integrator documentation](#).

Testing IBM Transformation Extender maps

You can use IBM Transformation Extender Design Studio to manually test the IBM Transformation Extender map on the Sterling B2B Integrator server.

Before you can use Design Studio to test a map, you must:

- Install IBM Transformation Extender for Integration Servers on the computer where Design Studio is installed.
- Use Design Studio to configure the connection to the Sterling B2B Integrator server. See the IBM Transformation Extender Map Designer documentation for details.

To run a map in Design Studio, right-click the map and click Run Map on Sterling B2B Integrator. See the IBM Transformation Extender Map Designer documentation for details.

Running a business process

A business process can run on a predefined schedule, in response to an activity, or manually.

Each step in a business process performs one of these activities:

- A service runs within the system.
- An adapter calls a third-party application to perform activities outside of the system.
- Sterling B2B Integrator performs the BPML activities that are configured in the business process.

For example, the BPML might start or stop the process flow, assign a specified value in the data, or run specified activities simultaneously.

A map runs when the service that invokes it is triggered by the business process.

See the [Sterling B2B Integrator documentation](#) for details about defining business process schedules, bootstrapping, and manually running a business process.

- **Running multiple concurrent instances of maps**

When you run multiple concurrent instances of maps, enable map caching and set unique work file names and audit file names for maps that perform I/O.

- [Running maps locally or in a separate JVM](#)

You can configure a service to run in a separate JVM based on the size of the input data. You also can create a service configuration to use the WTXRMIAAdapter and configure an adapter container to run the service in a separate JVM. Services that run in separate JVMs are isolated from certain failures, which improves the availability of the service.

Running multiple concurrent instances of maps

When you run multiple concurrent instances of maps, enable map caching and set unique work file names and audit file names for maps that perform I/O.

When multiple instances of a map are running in multiple services or multiple business processes, traces are recorded in the designated file for the first business process thread that runs, but other business processes and other threads fail to trace. The map does not fail or cause an exception.

For optimal performance, configure the map settings to use unique work files and audit files as follows:

- When the Map Settings enable map audit, set MapAudit.>.AuditLocation to File and set the audit FileName to Unique.
- In the Map Settings set WorkSpace to File and set WorkFilePrefix to Unique.
- When the Edit Input Card or Edit Output Card settings enable backup for a card, set Backup.>.BackupLocation.>.FileName to Unique. The map does not fail, and it does not throw an exception.

See the IBM Transformation Extender Map Designer documentation for more information about running multiple instances of a map.

- [Performance tuning](#)

Running maps locally or in a separate JVM

You can configure a service to run in a separate JVM based on the size of the input data. You also can create a service configuration to use the WTXRMIAAdapter and configure an adapter container to run the service in a separate JVM. Services that run in separate JVMs are isolated from certain failures, which improves the availability of the service.

- [Based on input-data-size threshold](#)

The Threshold property and the size of the input file determine whether all map instances run locally within the same Java™ Virtual Machine (JVM) or each instance of a map service runs in a separate JVM. When the input data exceeds the input-data-size threshold, each map instance runs in its own JVM and accesses the IBM Transformation Extender Translation Engine through the Sterling RMI adapter.

- [Using service configurations and an adapter container JVM](#)

A *service configuration* is a set of saved configuration properties for a specific type of service, such as the WTX Map service. With Sterling B2B Integrator, you can create and manage multiple service configurations. You can configure a service in a business process to use a particular service configuration. You can create an *adapter container JVM* to run services and adapters in a separate Java virtual machine (JVM).

- [Assigning the WTX Map service to a container node](#)

You can enable the WTX Map service to run in a separate Java Virtual Machine (JVM) when input data exceeds a maximum input-data-size threshold. You create a Sterling B2B Integrator adapter container node and configure the WTX Map service properties to run on the node.

Related reference

- [Performance tuning](#)

Based on input-data-size threshold

The Threshold property and the size of the input file determine whether all map instances run locally within the same Java™ Virtual Machine (JVM) or each instance of a map service runs in a separate JVM. When the input data exceeds the input-data-size threshold, each map instance runs in its own JVM and accesses the IBM Transformation Extender Translation Engine through the Sterling RMI adapter.

You configure the default input-data-size threshold on the Threshold= property in the *Sterling_installation_dir\properties\translator.properties_wtx_ext.in* file. The Threshold value is measured in bytes of data. The default threshold is 0, meaning that all maps run in the same JVM.

Related reference

- [WTX Map service BPML](#)

Using service configurations and an adapter container JVM

A *service configuration* is a set of saved configuration properties for a specific type of service, such as the WTX Map service. With Sterling B2B Integrator, you can create and manage multiple service configurations. You can configure a service in a business process to use a particular service configuration. You can create an *adapter container JVM* to run services and adapters in a separate Java™ virtual machine (JVM).

These steps present an overview of the procedures to create a service configuration and adapter container. See the [Sterling B2B Integrator documentation](#) for details about the procedures.

1. Create and enable one or more service configurations. See the [Sterling B2B Integrator services and adapters documentation](#).
2. Open a business process in the Graphical Process Modeler (GPM) and specify which configuration you want a service to use to run a IBM Transformation Extender map:
 - a. Right-click the service and click Properties.
 - b. Click Advanced.
 - c. Click Add to create a new row in the table.
 - d. In the Name column, enter WTXRMIAAdapter.
 - e. In the Value column, specify the name of the service configuration that you want the service to run.
 - f. Click OK.
3. Set up and start the adapter container JVM. See the [Sterling B2B Integrator services and adapters documentation](#).

Assigning the WTX Map service to a container node

You can enable the WTX Map service to run in a separate Java Virtual Machine (JVM) when input data exceeds a maximum input-data-size threshold. You create a Sterling B2B Integrator adapter container node and configure the WTX Map service properties to run on the node.

1. Configure the adapter container JVM node as described in the Sterling B2B Integrator services and adapters documentation. Run the Sterling B2B Integrator `setupContainer.cmd containerNumber` command, where `containerNumber` is the adapter container node number.
For example, run `setupContainer.cmd 1` to create a container node named `Node1AC1`. See the [Sterling B2B Integrator documentation](#) for additional details.
2. Set the Threshold property in the `Sterling_installation_dir\properties\translator.properties_wtx_ext.in` file.
3. Run the Sterling B2B Integrator `setupFiles.cmd` command.
4. Run the Sterling B2B Integrator `startWindowsService.cmd` command to start the JVM instance.
This command brings up the node and all containers on the node.
5. Edit the WTX Map service and set the environment to the node name, for example, `Node1AC1`:
 - a. Log into the Sterling B2B Integrator dashboard as an administrator.
 - b. Go to Deployment>Services>Configuration and search for the WTX Map service.
 - c. Click Edit. The first page contains the option to select a node. For example, select `Node1AC1` to specify container 1 on node 1.
 - d. Save the changes.

The WTX Map service translates any file that exceeds the input-data-size threshold value against the specified container node, for example, `Node1AC1`. When the file size is less than the threshold value, or when `Threshold=0`, the file is not translated on the container.

Configuring the Translation service to use IBM Transformation Extender maps

When the Sterling B2B Integrator Translation service uses a IBM Transformation Extender map, set the `exhaust_input` setting to YES to enable the service to process all of the input records.

When the `exhaust_input` setting is set to YES, the Sterling B2B Integrator Translation service consumes all of the input records during translation. When the `exhaust_input` parameter is set to NO, the IBM Transformation Extender map processes the entire input, but it returns the output from only the first burst of data. Other processing still occurs, such as calls to the data harness to track duplicate records.

To simulate the `exhaust_input=NO` capabilities of the Sterling B2B Integrator maps, you can define the input type tree on the IBM Transformation Extender map to process only the first block of input data and ignore the remaining input data.

Note: When the Translation service runs a IBM Transformation Extender map, only the first input card and the last output card are associated with the primary document. For more information about the `exhaust_input` setting, see the description of the Translation Service in the [Sterling B2B Integrator documentation](#).

Problem determination

You can enable trace and audit logs to diagnose WTX Map service errors. You can configure the WTX Map service to extract data from a document or a process for tracking purposes.

- **WTX Map service correlations**
A *correlation* is a name/value pair that is extracted from a document or a business process for the purpose of tracking the document or process. The WTX Map service collects a static set of well-known correlations.
- **Diagnostic tools**
Both IBM Transformation Extender and Sterling B2B Integrator provide tools to diagnose an instance of a WTX Map service.

WTX Map service correlations

A *correlation* is a name/value pair that is extracted from a document or a business process for the purpose of tracking the document or process. The WTX Map service collects a static set of well-known correlations.

Correlation data is stored in a Sterling B2B Integrator correlation table. You can use the Sterling B2B Integrator Correlation Search to locate a document or business process by using the data you extracted from it, such as a purchase-order number.

The WTX Map service creates the following correlations with a scope of Translation on the input document:

Map
 Map name
MapVersion
 Version of the map.

The WTX Map service creates the following correlations with a scope of Translation on the output document:

Map
 Map name
MapVersion
 Version of the map
TranslationDateTime
 Current date and time

The well-known correlations are saved in the correlation table, along with any custom correlations that you set by using the data harness function on the map rules or component rules.

See the [Sterling B2B Integrator documentation](#) for details about configuring and searching for correlations.

Diagnostic tools

Both IBM Transformation Extender and Sterling B2B Integrator provide tools to diagnose an instance of a WTX Map service.

You can use these mechanisms for problem determination:

- Sterling B2B Integrator service translation reports
- IBM Transformation Extender trace and audit files
- Sterling B2B Integrator log files
- Sterling B2B Integrator exception handling

You configure map trace and audit files by using the map settings of the WTX Map service.

To enable Sterling B2B Integrator logging and tracing, see the description of setting up event logging in the [Sterling B2B Integrator documentation](#).

- [**Sterling B2B Integrator service translation report**](#)
If a Sterling B2B Integrator service runs a IBM Transformation Extender map and the map fails, the Sterling B2B Integrator translation report contains the results of the map run.
- [**Configuring IBM Transformation Extender logging properties in Sterling B2B Integrator**](#)
In Sterling B2B Integrator, a log file name, location, logging level, and other characteristics are controlled by properties files. You configure IBM Transformation Extender logging by overriding the properties in the log.properties_wtx_ext file with customized settings that you configure in the customer_overrides.properties file.
- [**IBM Transformation Extender logging properties**](#)
The `Sterling_install_dir\properties\log.properties_wtx_ext.in` file defines the properties for IBM Transformation Extender map logs. You can customize the properties of IBM Transformation Extender logs on Sterling B2B Integrator by adding the properties to the `Sterling_install_dir\properties\customer_overrides.properties` file.
- [**Map trace, audit log, and work space directories**](#)
The location of the work space, trace file, and audit file for a map depends on the map settings and the location from which the map is loaded.

Sterling B2B Integrator service translation report

If a Sterling B2B Integrator service runs a IBM Transformation Extender map and the map fails, the Sterling B2B Integrator translation report contains the results of the map run.

Use the Sterling B2B Integrator Administration menu to configure the translation report, such as whether to email the report or save it to a file system. See the [Sterling B2B Integrator documentation](#) for more information.

For each call to the translation service of the map, the translation report includes:

- Translation object name
- Translation service start time
- Translation service end time
- Total map execution time in milliseconds
- IBM Transformation Extender map status code and status message
- Audit data, if enabled in a IBM Transformation Extender map

Unlike other Sterling B2B Integrator services, the WTX Map service does not produce a translation report. For audit data from a IBM Transformation Extender map to be written to the translation report, the map must have audit enabled, the AuditLocation must be `Memory`, and the appropriate data audit settings must be enabled.

When the map enables auditing and the AuditLocation is `File`, the map execution produces an audit log on the file system. The audit log contains additional details.

Configuring IBM Transformation Extender logging properties in Sterling B2B Integrator

In Sterling B2B Integrator, a log file name, location, logging level, and other characteristics are controlled by properties files. You configure IBM Transformation Extender logging by overriding the properties in the `log.properties_wtx_ext` file with customized settings that you configure in the `customer_overrides.properties` file.

In Sterling B2B Integrator, properties files are stored in the `Sterling_install_dir\properties` directory. The `log.properties_wtx_ext.in` file initializes the default properties of the `log.properties_wtx_ext` file. At runtime, the `Sterling_install_dir\log.properties_wtx_ext` file controls IBM Transformation Extender logs that are created in the Sterling B2B Integrator log directory. The `\properties\customer_overrides.properties` file overrides the settings in any properties file when Sterling B2B Integrator is installed or when you run the setup script. To customize the properties of IBM Transformation Extender map logs, you add IBM Transformation Extender logging properties to the `customer_overrides.properties` file.

IBM Transformation Extender logging properties

The `Sterling_install_dir\properties\log.properties_wtx_ext.in` file defines the properties for IBM Transformation Extender map logs. You can customize the properties of IBM Transformation Extender logs on Sterling B2B Integrator by adding the properties to the `Sterling_install_dir\properties\customer_overrides.properties` file.

At runtime, the properties that are configured in the `customer_overrides.properties` file override the default properties defined in the `Sterling_install_dir\properties\log.properties_wtx_ext.in` file. You can override any default property except the `wtxlogger.logkey` property and the `wtxlogger.displayname` property.

Map trace, audit log, and work space directories

The location of the work space, trace file, and audit file for a map depends on the map settings and the location from which the map is loaded.

When the map settings specify that trace, audit or work files are written to the map directory:

- When the map is stored in a file system on the Sterling B2B Integrator server, files are written to the directory where the map is stored.
- When the map is stored in the Sterling B2B Integrator map repository, files are written to the Sterling B2B Integrator `Sterling_install_dir\logs\` directory.
- When a compiled map is dynamically loaded from a document object, files are written to the Sterling B2B Integrator `Sterling_install_dir\logs\` directory.

When the map settings specify that trace, audit or work files are written to a custom directory, they are written to the specified location.

When the map settings specify that the audit data is sent to memory, the audit data is written to the translation status report and instance data of the WTX Map service.

Performance tuning

The `tx_install_dirconfig.yaml` file contains the `runtime/stream/MaxMemLimit` property and the `runtime/stream/MaxMemDirectory` property. When data passed to or from an adapter exceeds the size (in MB) that is configured on the `StreamMaxMemLimit` property, the data is paged to a temporary file to limit the memory consumption of the process. The `StreamMaxMemDirectory` property specifies the directory where the temporary files are located.

Configure these properties in conjunction with the threshold for running maps in separate Java™ Virtual Machines (JVMs).

Introduction

IBM® Transformation Extender for IBM Integration Bus is one of the extenders packaged as IBM Transformation Extender for Integration Servers.

Use this extender to trigger and run IBM Transformation Extender transformation maps from within a IBM Integration Bus message flow. Use IBM Transformation Extender for IBM Integration Bus to transform and distribute different messages across your various systems and applications, because this product enhances the enterprise service bus features of IBM Integration Bus with the universal transformation capability of IBM Transformation Extender.

IBM Transformation Extender for IBM Integration Bus complements the native message transformation and message parsing capabilities of IBM Integration Bus. With IBM Integration Bus, not only can you use the set of parsers and transformation options that are ready for you to use as is, but you can also use custom parsers and transformations through a plug-in facility. IBM Transformation Extender for IBM Integration Bus includes a plug-in node, called the TX Map node, for running IBM Transformation Extender maps in your message flows.

For information about IBM Integration Bus, see the [IBM Integration Bus library page](#).

-

Product uses

IBM® Transformation Extender for IBM Integration Bus extends the functionality of IBM Integration Bus so that when you use IBM Integration Bus, you have access to IBM Transformation Extender's universal transformation capabilities through maps and type trees.

Also, IBM Transformation Extender for IBM Integration Bus enhances the functionality of IBM Transformation Extender so that when you use IBM Transformation Extender, you have access to IBM Integration Bus Enterprise Service Bus capabilities.

- [For IBM Integration Bus users](#)
If you already use IBM Integration Bus, you can develop message flows that use IBM Transformation Extender maps and type trees to complement IBM Integration Bus built-in transformation functionality.
 - [For IBM Transformation Extender users](#)
If you already use IBM Transformation Extender, you can develop message flows that use IBM Integration Bus Enterprise Service Bus functionality to complement IBM Transformation Extender maps and type trees.
-

For IBM Integration Bus users

If you already use IBM® Integration Bus, you can develop message flows that use IBM Transformation Extender maps and type trees to complement IBM Integration Bus built-in transformation functionality.

As a IBM Integration Bus user, use IBM Transformation Extender maps and type trees in the following ways:

- Use IBM Transformation Extender maps if you need transformation features that are not available with native ESQL, Java, Mapping, and XSL transformations such as:
 - Pulling data from sources such as files and queues within a map.
 - Calling external programs and services from within a map.
 - Splitting and routing batches of messages.

- Use IBM Transformation Extender type trees if you need message modeling features that are not available with native message sets such as:
 - Modeling complex binary or text message formats that the MRM is unable to model.
 - Complex validation without having to write code, using component rules on type trees.
 - Use IBM Transformation Extender Industry Packs to integrate a range of industry standard data formats with your enterprise infrastructure through predefined type tree templates and maps that the packs provide.
-

For IBM Transformation Extender users

If you already use IBM® Transformation Extender, you can develop message flows that use IBM Integration Bus Enterprise Service Bus functionality to complement IBM Transformation Extender maps and type trees.

As a IBM Transformation Extender user, use IBM Integration Bus built-in functionality in the following ways:

- Use existing IBM Transformation Extender skills.
 - Use a single transformation technology and skill set across your entire organization.
- Reuse existing IBM Transformation Extender maps and type trees within an Enterprise Service Bus environment.
- Combine IBM Transformation Extender maps with IBM Integration Bus facilities, such as:
 - Message routing, including publish/subscribe applications.
 - Event-driven processing, such as message aggregation and fan-in flows.
 - Complex event processing, which can use configurable patterns of event sequences to trigger maps to run.
 - Integration with Web Services through IBM Integration Bus's support for SOAP, WS-Addressing and WS-Security, and WebSphere® Service Registry and Repository.
 - An integrated environment to move transactional data throughout your organization.
 - Implementation of a complete application integration solution.
 - Enterprise Service Bus-enabled adapters and services.
 - Integrated runtime security model.
 - Built-in accounting, statistics, and monitoring functionality.
- Run maps in a robust, scalable and highly available environment.
 - Use for your applications that have high-availability or failover requirements.
 - Use IBM Integration Bus clustering.

Transforming data

A message sender and receiver might have different message format specifications, requiring you to design your message flow to transform the data in the message before delivering it. You might need to design your message flow to reformat your message, enrich your message, or do numeric and string calculations based on the value of certain fields.

IBM® Integration Bus provides the following four built-in transformation nodes that are ready for you to use as is, in your message flows:

- Compute
- XSLTransform
- Mapping
- JavaCompute

IBM Transformation Extender for IBM Integration Bus extends these data transformation and validation capabilities by enabling you to use these IBM Transformation Extender maps and type trees within the broker environment. You can create IBM Transformation Extender type trees that model complex data, complete with component rules that do syntax and semantic validation of the data in your messages. These type trees can be used in maps, which might have multiple input and output cards, and reused in different message flows, as well as in other applications across your enterprise besides IBM Integration Bus.

For information about the IBM Integration Bus transformation nodes, see the related topics in the IBM Integration Bus product documentation.

TX Map node overview

The TX Map node is a component of the IBM® Transformation Extender for IBM Integration Bus.

Within a IBM Integration Bus message flow, a series of steps is used to process a message. A message flow node performs each step. The TX Map node is a message flow node that you use in message flows. It runs a IBM Transformation Extender map within a message flow. The TX Map node uses one or more broker message trees as its input, runs a IBM Transformation Extender map that you specify, and creates one or more broker message trees as its output.

The map that the TX Map node runs can either be a compiled map that is predeployed to the broker, or a source map that is compiled when the message flow is added to a broker archive (.bar) file and deployed as part of broker archive deployment. The map can have multiple input cards, but the TX Map node only has a single input terminal.

If the message tree that arrives at the input terminal consists of a single message, select which input card receives the message. If the message tree that arrives at the input terminal is a message collection, containing multiple messages, each message in the collection is delivered to the appropriate input card. Then the TX Map node runs the map.

Any cards that did not receive a message obtains data from the adapter that is specified on them. The map can have multiple output cards. Select which output cards to connect to other nodes in the message flow. If the output terminal for an output card is connected, a message tree is built, and propagated down the message flow. If the output terminal for an output card is not connected, the data is sent to the adapter that is specified on the card.

IBM Integration Bus processes many different classes of message, such as fixed-length binary, delimited text, and XML. Each class is known as a message domain. The TX Map node can handle input and output messages belonging to several different message domains. See [Supported message domains](#).

The TX Map node is contained in the IBM Transformation Extender for IBM Integration Bus drawer of the IBM Integration Toolkit message flow node palette. Use the message flow node palette to add TX Map nodes in the message flows you are creating in the Message Flow editor. Drag node objects from the palette onto the IBM Integration Toolkit canvas, and create connections, also called wires, between two nodes.

The TX Map node is not an input node, and can not be used to trigger the execution of the message flow.

Using the TX Map node within a message flow

When you develop a message flow, you can set up a TX Map node that runs a map that has a single input card or multiple input cards.

The activities for using a TX Map node within a message flow include:

- Creating a map.
- Creating a message flow that uses the TX Map node.
- Deploying the message flow.
 - Creating and building a broker archive (bar) file.
 - Deploying the broker archive (bar) file.
 - Deploying the map only if you are using a precompiled map.
- Running your message flow.

After the message flow is deployed, IBM® Integration Bus starts the message flow automatically, and the following actions result:

- The message flow runs when an input node receives an input message bit stream.
 - A parser parses the input bit stream into an input message tree.
 - A TX Map node receives the input message tree and runs the map.
 - The map transforms the data in the input message tree, and creates one or more output message trees.
 - The output message trees can be processed by other nodes in the message flow.
- [Using the TX Map node with a source map and a single input](#)
Develop a message flow with a TX Map node specified with a source map, that, at run time, is triggered to run by a single input.

Related tasks

- [Running your message flow](#)

Using the TX Map node with a source map and a single input

Develop a message flow with a TX Map node specified with a source map, that, at run time, is triggered to run by a single input.

The map could have many input cards. Only one nominated card receives data from the message flow, while each of the other cards pull data directly from their adapter.

The map could have many output cards. Cards that are connected to the message flow propagate data to the flow, while each of the unconnected cards send data directly to their adapter.

To develop a simple message flow that demonstrates this scenario, do the following steps. They are based on the assumption that you used Map Designer to create a source map (.mms) file containing an executable map with one or more input cards, and one or more output cards.

1. Create a new message flow project in the IBM® Integration Development perspective.
2. Create a new message flow in the project. Select Use default broker schema, or provide your own schema name to qualify the message flow name.
3. Drag a TX Map node from the palette onto the canvas for your message flow.
The node initially has no output terminals, and one failure terminal.
4. Navigate to the Properties view.
5. On the Basic tab of the TX Map node, select the [source map](#).
6. On the Input tab of the TX Map node, select the map card that receives the input.
7. Drag an input node, for example, a FileInput node or MQInput node, to the canvas, and connect the out terminal of the input node to the in terminal of the TX Map node.
The message from the input node overrides the adapter of the map's selected input card.
8. Configure the input node with the necessary transport-related properties.
9. On the Input Message Parsing tab of the input node, configure the message template properties to describe the format of the input message. Select the domain from the list of [supported message domains](#).
10. Drag an output node, for example, a FileOutputStream node or MQOutput node, to the canvas, and connect one of the output terminals of the TX Map node to the in terminal of the output node.
Connecting the output terminal overrides the adapter of the corresponding output card.
11. Configure the output node with the necessary transport-related properties.
12. On the Outputs tab of the TX Map node, configure properties to describe the format of the output message propagated by the output card.
 - a. Click Add to add a set of properties.
The Add Properties entry dialog appears.
 - b. Enter values for Card Number, Message Domain, Message Set, and Message Type, and click OK.
Message Domain must be one of the [supported message domains](#).
13. Repeat steps 10 through 12 for each output terminal that you want to connect.
14. Press Ctrl+S to save the message flow.

Manually create and build the broker archive (bar) file, and then deploy it to the broker.

When the message flow runs, the message from the input node is passed to the TX Map node, and the TX Map node runs the map. The message overrides the adapter specified on the selected input card. For example, if the input card uses the File adapter, the map does not read from the file; it uses the message from the message flow. Connected output terminals override the adapters of the corresponding output cards. For example, if an output card uses the File adapter, the map does not write to the file; it propagates the message to the message flow.

The map could have many output cards. Cards that are connected to the message flow propagate data to the flow, while each of the unconnected cards send data directly to their adapter.

To develop a simple message flow that demonstrates this scenario, do the following steps. They are based on the assumption that you used Map Designer to create a source map (.mms) file, containing an executable map with one or more input cards, and one or more output cards, and that you compiled the map for a target platform, creating a compiled map (.mmc) file.

1. Create a new message flow project in the IBM® Integration Development perspective.
2. Create a new message flow in the project. Select Use default broker schema, or provide your own schema name to qualify the message flow name.

3. Drag a TX Map node, from the palette onto the canvas for your message flow.
The node initially has no output terminals and one failure terminal.
4. Navigate to the Properties view.
5. On the Basic tab of the TX Map node, select the [precompiled map](#).
6. On the Input tab of the TX Map node, select the map card that receives the input.
7. Drag an input node, for example, a FileInput node or MQInput node, to the canvas, and connect the out terminal of the input node to the in terminal of the TX Map node.
The message from the input node overrides the adapter of the map's selected input card.
8. Configure the input node with the necessary transport-related properties.
9. On the Input Message Parsing tab of the input node, configure the message template properties to describe the format of the input message. Select the domain from the list of [supported message domains](#).
10. Drag an output node, for example, a FileOutputStream node or MQOutput node, to the canvas, and connect one of the output terminals of the TX Map node to the in terminal of the output node.
Connecting the output terminal overrides the adapter of the corresponding output card.
11. Configure the output node with the necessary transport-related properties.
12. On the Outputs tab of the TX Map node, configure properties to describe the format of the output message propagated by the output card.
 - a. Click Add to add a set of properties.
The Add Properties entry dialog appears.
 - b. Enter values for Card Number, Message Domain, Message Set, and Message Type, and click OK.
Message Domain must be one of the [supported message domains](#).
13. Repeat steps 10 through 12 for each output terminal that you want to connect.
14. Press Ctrl+S to save the message flow.

Manually create and build the broker archive (bar) file, and then deploy it to the broker. You must also manually deploy the compiled map (.mmc) file to the broker's file system.

When the message flow runs, the message from the input node is passed to the TX Map node, and the TX Map node runs the map. The message overrides the adapter specified on the selected input card. For example, if the input card uses the File adapter, the map does not read from the file; it uses the message from the message flow. Connected output terminals override the adapters of the corresponding output cards. For example, if an output card uses the File adapter, the map does not write to the file; it propagates the message to the message flow.

Using the TX Map node with a source map and multiple inputs

Develop a message flow with a TX Map node specified with a source map, that, at run time, is triggered to run by multiple inputs.

The TX Map node is used with a native Collector node, which gathers the multiple inputs and, when specified event criteria are satisfied, propagates the messages to the TX Map node in the form of a message collection. For information about the Collector node and message collection, see the specific IBM® Integration Bus product documentation.

The map could have many input cards. Any number of cards can receive data from the message collection, while any cards that do not receive data pull data directly from their adapter.

The map could have many output cards. Cards that are connected to the message flow propagate data to the flow, while each of the unconnected cards send data directly to their adapter.

To develop a simple message flow that demonstrates this scenario, do the following steps. They are based on the assumption that you used Map Designer to create a source map (.mms) file containing an executable map with two input cards, and one or more output cards.

1. Create a new message flow project in the IBM Integration Development perspective.
2. Create a new message flow in the project. Select Use default broker schema, or provide your own schema name to qualify the message flow name.
3. Drag a TX Map node from the palette onto the canvas for your message flow.
The node initially has no output terminals and one failure terminal.
4. Navigate to the Properties view.
5. On the Basic tab of the TX Map node, select the [source map](#).
6. Drag a Collector node to the canvas.
7. Drag an input node, for example, a FileInput node or MQInput node, to the canvas.
8. Configure the input node with the necessary transport-related properties.
9. On the Input Message Parsing tab of the input node, configure the message template properties to describe the format of the input message. Select the domain from the list of [supported message domains](#).
10. Right-click the Collector node, and select Add Input Terminal. Enter the name of a new input terminal, which must match the card name of the input card in the map that receives the input message. The new input terminal is added to the Collection Definition table on the Basic tab.
11. On the Basic tab, configure the required event criteria properties for the new input terminal, namely Quantity, Timeout, Correlation Path, and Correlation Pattern.
12. Connect the out terminal of the input node to the new input terminal on the Collector node.
13. Repeat steps 7 through 12 for each different input the map requires from the message flow.
14. On the Basic tab of the Collector node, configure the Collection Name and Collection Expiry properties. In particular, you should specify a Collection Expiry value.
15. Connect the out terminal from the Collector node to the in terminal of the TX Map node.
Messages from the propagated message collection override the adapters of the map's input cards.
16. Connect the expiry terminal from the Collector node to the in terminal of the TX Map node, to handle incomplete message collections.

17. Drag an output node, for example, a FileOutput node or MQOutput node, to the right of the TX Map node, and connect one of the output terminals of the TX Map node to the in terminal of the output node.

Connecting the output terminal overrides the adapter of the corresponding output card.

18. Configure the output node with the necessary transport-related properties.

19. On the Outputs tab of the TX Map node, configure properties to describe the format of the output message propagated by the output card.

a. Click Add to add a set of properties.

The Add Properties entry dialog appears.

b. Enter values for Card Number, Message Domain, Message Set, and Message Type, and click OK.

Message Domain must be one of the [supported message domains](#).

20. Repeat steps 17 through 19 for each output terminal that you want to connect.

21. Press Ctrl+S to save the code.

An Unconnected catch terminals warning message appears, which you can ignore.

Manually create and build the broker archive (bar) file, and then deploy it to the broker.

When the message flow runs, the Collector node gathers messages into message collections. As each collection completes, it is propagated to the TX Map node, and the TX Map node runs the map. Each message in the collection is delivered to the matching input card. For example, if a message in the collection arrived at the invoice Collector node input terminal, it would be delivered to the invoice input card. The messages in the collection override the adapter specified on the input cards. For example, if the input cards use the File adapter, the map does not read from the file; it uses the message from the message collection. Connected output terminals override the adapters of the corresponding output cards. For example, if an output card uses the File adapter, the map does not write to the file; it propagates the message to the message flow.

3. Drag a TX Map node from the palette onto the canvas for your message flow.
The node initially has no output terminals and one failure terminal.
4. Navigate to the Properties view.
5. On the Basic tab of the TX Map node, select the [precompiled map](#).
6. Drag a Collector node to the canvas.
7. Drag an input node, for example, a FileInput node or MQInput node, to the canvas.
8. Configure the input node with the necessary transport-related properties.
9. On the Input Message Parsing tab of the input node, configure the message template properties to describe the format of the input message. Select the domain from the list of [supported message domains](#).
10. Right-click the Collector node, and select Add Input Terminal. Enter the name of a new input terminal, which must match the card name of the input card in the map that receives the input message. The new input terminal is added to the Collection Definition table on the Basic tab.
11. On the Basic tab, configure the required event criteria properties for the new input terminal, namely Quantity, Timeout, Correlation Path, and Correlation Pattern.
12. Connect the out terminal of the input node to the new input terminal on the Collector node.
13. Repeat steps 7 through 12 for each different input the map requires from the message flow.
14. On the Basic tab of the Collector node, configure the Collection Name and Collection Expiry properties. In particular, you should specify a Collection Expiry value.
15. Connect the out terminal from the Collector node to the in terminal of the TX Map node.
Messages from the propagated message collection override the adapters of the map's input cards.
16. Connect the expiry terminal from the Collector node to the in terminal of the TX Map node, to handle incomplete message collections.
17. Drag an output node, for example, a FileOutput node or MQOutput node, to the right of the TX Map node, and connect one of the output terminals of the TX Map node to the in terminal of the output node.
Connecting the output terminal overrides the adapter of the corresponding output card.
18. Configure the output node with the necessary transport-related properties.

19. On the Outputs tab of the TX Map node, configure properties to describe the format of the output message propagated by the output card.
 - a. Click Add to add a set of properties.
The Add Properties entry dialog appears.
 - b. Enter values for Card Number, Message Domain, Message Set, and Message Type, and click OK.
Message Domain must be one of the [supported message domains](#).
20. Repeat steps 17 through 19 for each output terminal that you want to connect.
21. Press Ctrl+S to save the code.
An Unconnected catch terminals warning message appears, which you can ignore.

Manually create and build the broker archive (bar) file, and then deploy it to the broker. You must also manually deploy the compiled map (.mmc) file to the broker's file system.

When the message flow runs, the Collector node gathers messages into message collections. As each collection completes, it is propagated to the TX Map node, and the TX Map node runs the map. Each message in the collection is delivered to the matching input card. For example, if a message in the collection arrived at the invoice Collector node input terminal, it would be delivered to the invoice input card. The messages in the collection override the adapter specified on the input cards. For example, if the input cards use the File adapter, the map does not read from the file; it uses the message from the message collection. Connected output terminals override the adapters of the corresponding output cards. For example, if an output card uses the File adapter, the map does not write to the file; it propagates the message to the message flow.

Deploying your message flow

These topics provide you with the information you need to deploy message flows that contain TX Map nodes.

Message flows are hosted in execution groups. An execution group is a process. On System z environments, it is an address space. A broker can have one or more execution groups. Message flows are deployed to execution groups in broker archive (.bar) files.

When you deploy your message flow, select the execution group into which the broker archive (bar) file is deployed.

After you deploy your message flow, it is started automatically.

For details about IBM® Integration Bus concepts, see the IBM Integration Bus documentation.

- [Deploying IBM Transformation Extender maps](#)

When you deploy message flows that contain TX Map nodes, you must also deploy the associated IBM Transformation Extender maps, and any files that the maps require.

Deploying IBM Transformation Extender maps

When you deploy message flows that contain TX Map nodes, you must also deploy the associated IBM® Transformation Extender maps, and any files that the maps require.

There are two alternative map deployment mechanisms when you use the TX Map node in a message flow.

For all deployments:

1. Create a broker archive (bar) file.
This opens the bar file editor.
2. Switch to the Prepare tab, and check the box against your message flow.
3. Click Build broker archive to build the bar file, confirm that the build operation was successful, and click Save to save the updated bar file.
After you click Build broker archive, you might be prompted to respond in the Override configurable properties dialog as to whether or not you want to continue to allow the build process to override the configurable properties in the bar file.
4. If you need to set any message flow configurable properties, switch to the Manage tab, and set the properties accordingly in the Configure tab of the Properties view.

The steps that you do next, depend on the kind of map you are using:

- [source](#)
- [precompiled](#)
- [Using a source map with a TX Map node](#)
- [Using a precompiled map with a TX Map node](#)

Related tasks

- [Using the TX Map node with a source map and a single input](#)
 - [Using the TX Map node with a precompiled map and a single input](#)
 - [Using the TX Map node with a source map and multiple inputs](#)
 - [Using the TX Map node with a precompiled map and multiple inputs](#)
-

Using a source map with a TX Map node

To use a source map with a TX Map node:

1. In the Prepare tab, click Build broker archive.
When IBM® Integration Bus builds the bar file, it compiles the message flow, and adds it to the bar file. As part of this compilation, the source map is compiled automatically, and the resulting compiled maps, and [other resources](#) in the project, are added to a map archive (mar) file, which is then added to the bar file. When a source map is compiled, IBM Integration Bus adds three compiled maps to the map archive (mar) file, one each for Windows, UNIX, and z/OS operating systems. This means that the resulting bar file can be deployed to any supported IBM Integration Bus runtime environment.
2. When the bar file is complete, deploy it using one of the typical IBM Integration Bus deployment techniques.
Deployment unpacks the bar file and forwards the content to the broker runtime environment. Any mar files are placed into locations from where they are loaded when the TX Map node requires them.

Related tasks

- [Deploying map resources](#)
-

Using a precompiled map with a TX Map node

To use a precompiled map with a TX Map node:

1. In the Prepare tab, click Build broker archive.
When the IBM® Integration Bus builds the bar file, it compiles the message flow. The compiled map does not get deployed in the bar file.
2. Compile the map for the IBM Integration Bus runtime environment that you want.
3. Manually deploy the map, and [other required resources](#), to the runtime directory specified by the Map Server location property of the TX Map node.
4. When the bar file is complete, deploy it using one of the typical IBM Integration Bus deployment techniques.
Deployment unpacks the bar file and forwards the content to the broker runtime environment.

Running your message flow

You can run your message flow by sending one or more messages through the flow.

The message flow receives a message in an input node. The input node parses the message bit stream using the specified parser, creating a broker message tree. The resulting message tree is propagated down the flow. When a TX Map node receives a propagated message tree, it runs the associated map and creates output messages.

If your map is expecting multiple inputs, use a Collector node to gather those inputs. In this case, you must send as many messages as are needed to complete the message collection that the Collector node defined.

The body of a message tree, propagated from an output terminal of a TX Map node, is owned by the message domain that you specified on the output terminal. Any headers present in the input message tree that the map received, such as MQMD, will be preserved into the propagated message tree, unchanged. If the map received a message collection as its input, the propagated headers will be those of the first message in the collection. Headers from other messages in the collection are discarded. The Environment, Local Environment and Exception List trees from the input message are also propagated, unchanged.

If a failure occurs when running a map, the failure is added to the Exception List, and the input message, Environment, Local Environment and Exception List are propagated from the failure terminal, if connected. Otherwise, an exception is thrown.

When the message tree reaches an output node, it is serialized into a bit stream by the owning parser.

You can override the name of the map to be run by a TX Map node, dynamically at run time, using the message flow's LocalEnvironment. See [Overriding map properties at run time](#).

To run your message flow:

1. If your message flow has a TX Map node with a single input:
 - a. Put a message on the queue.
The TX Map node passes the message to the map, and the map writes it to the output.
2. If your message flow has a Collector node:
 - a. Put a message on the first queue.
 - b. Put a message on the second queue.
The Collector node passes both messages to the map, and the map writes them to the output.

Problem determination

Exceptions occur for map failures, TX Map node data errors, or when messages from both input and output are missing or malformed. IBM® Transformation Extender passes error messages to IBM Integration Bus to write to its log and trace files.

- [IBM Transformation Extender map failures](#)

When IBM Integration Bus runs your message flow that uses the TX Map node to run your map, and the map fails, there are tools that you can use to troubleshoot the problem.

- [TX Map node exceptions](#)

When IBM Integration Bus runs your message flow that uses the TX Map node, and it fails, there are tools that you can use to troubleshoot the problem.

- [Using IBM Integration Bus log and trace files](#)

When the TX Map node detects a problem and raises an exception, it sends information to event log and trace files through the IBM Integration Bus logging and tracing mechanisms.

- [Sending audit data to output and failure terminals through the local environment tree](#)

You can configure a IBM Transformation Extender map to send audit-log data across IBM Transformation Extender message flow wires by using the IBM Integration Bus local environment (LocalEnvironment) tree. When the IBM Integration Bus message flow runs successfully, the message flow sends the audit-log data to the output terminal of the IBM Integration Bus node. When the IBM Integration Bus message flow fails, the audit log data is sent to the failure terminal of the IBM Integration Bus node (if a failure terminal is wired to the map node).

Related reference

- [Using IBM Integration Bus log and trace files](#)

IBM Transformation Extender map failures

When IBM® Integration Bus runs your message flow that uses the TX Map node to run your map, and the map fails, there are tools that you can use to troubleshoot the problem.

As a result of running a map, if the audit log map settings are set to ON, IBM Transformation Extender writes information about the map run, including the map return codes and messages, to the log file. For the list of all the return codes and messages, see the topic about error and warning messages that is in the IBM Transformation Extender Map Designer documentation.

If the trace map settings are set to ON, IBM Transformation Extender writes the map run steps to the trace file. For information about the trace file, see the specific topics in the IBM Transformation Extender Map Designer documentation.

All log and trace entries include time stamps.

By default, IBM Transformation Extender generates unique log and trace file names at run time, equivalent to when you use the Unique setting for the log and trace file names. You can also select the Custom setting to specify a custom file name and location.

If you specified Use external map in the TX Map node, IBM Transformation Extender creates the log and trace files with the same names and in the same directory locations as specified in the external map.

If you specified Use map from project in the TX Map node, and selected Default for the audit log or trace file name map setting, IBM Transformation Extender creates the log file as *map_name.log*, and the trace file as *map_name.mtr*, where *map_name* is the name of the executable map. If you selected Default for Directory, which specifies the audit log or trace file location, IBM Transformation Extender creates the files in the IBM Integration Bus's deployment directory.

Use the information that is in the IBM Transformation Extender log and trace files to help you troubleshoot the problem.

For information about the log and trace files, and troubleshooting maps, see the IBM Transformation Extender Map Designer documentation.

- [TX Map node exceptions](#)

TX Map node exceptions

When IBM® Integration Bus runs your message flow that uses the TX Map node, and it fails, there are tools that you can use to troubleshoot the problem.

If any of the data that the TX Map node receives from an input message is missing or malformed, the node raises an exception.

If a Map Node failure terminal is connected to the message flow, IBM Transformation Extender for IBM Integration Bus propagates the following information through the failure terminal when the Map node fails:

- A message that contains NodeErrorInfo
- The exception list

In addition, IBM Integration Bus sends the original input message through the failure terminal as a separate message.

If the terminal is not connected, the exception is thrown back up the message flow, according to standard IBM Integration Bus failure behavior.

If the TX Map node fails, IBM Integration Bus logs the failure exception, including the standard error message, in the broker's event log and, optionally, trace files. For details about the standard error message, see the topic about problem determination.

Use the information that is in the IBM Integration Bus log and trace files to help you troubleshoot the problem.

Related reference

- [Using IBM Integration Bus log and trace files](#)
 - [IBM Transformation Extender map failures](#)
-

Using IBM Integration Bus log and trace files

When the TX Map node detects a problem and raises an exception, it sends information to event log and trace files through the IBM® Integration Bus logging and tracing mechanisms.

It sends information to local error log files through the IBM Integration Bus logging mechanism, which is the Event Viewer on Windows, the system log on UNIX, and the console log on z/OS® operating systems. Logging information includes event status, and node return code, which is either the map return code or the node failure code.

If you activated the user trace options, IBM Integration Bus sends information to trace files through the IBM Integration Bus tracing mechanism. Tracing information includes more information than the event log files provide, such as formatted messages.

All log and trace entries include time stamps.

Use the information that is in these IBM Integration Bus log and trace files to help you troubleshoot the problem.

For information about the IBM Integration Bus logging and tracing mechanisms, see the specific IBM Integration Bus product documentation.

Sending audit data to output and failure terminals through the local environment tree

You can configure a IBM® Transformation Extender map to send audit-log data across IBM Transformation Extender message flow wires by using the IBM Integration Bus local environment (LocalEnvironment) tree. When the IBM Integration Bus message flow runs successfully, the message flow sends the audit-log data to the output terminal of the IBM Integration Bus node. When the IBM Integration Bus message flow fails, the audit log data is sent to the failure terminal of the IBM Integration Bus node (if a failure terminal is wired to the map node).

To enable this feature, set the Audit Location to Memory in the IBM Transformation Extender map settings. Click Map > Map Settings > MapAudit > AuditLocation > Memory. The Sized setting can be either ON or OFF.

Map audit information is propagated to the LocalEnvironment.WTX.Audit.MapInst_x location in the IBM Integration Bus local environment tree, where x is the instance of the map run from the IBM Integration Bus. Map instances start at 1, are unique, and are sequential.

The type of audit data information that is propagated to the local environment tree depends on the IBM Transformation Extender Map settings. For example, to send the map execution summary, set MapAudit Switch setting to ON, and set the SummaryAudit Execution setting to Always.

Product requirements

IBM® Transformation Extender for IBM Integration Bus is packaged with the IBM Transformation Extender for Integration Servers product installation.

To use IBM Transformation Extender for IBM Integration Bus, other products must be installed and running. Product requirements are detailed in the [release notes](#).

Supported message domains

A *parser* is a program that interprets the bit stream of an incoming message and creates an internal representation of the message in a tree structure. The parser also regenerates a bit stream from the internal message tree representation for an outgoing message. Each parser is suited to a particular message domain. A *message domain* is class of messages, such as fixed-length binary messages or XML messages. IBM® Integration Bus supplies a range of parsers to parse and write message formats.

The following table lists the domain that you should use for the specified scenario.

Table 1. Message scenarios and domain types

Scenario	Domain
Message is modeled by type tree (.mtt), or XML Schema (.xsd), or broker message definition (.mxsd). Only the map processes the message content. The message is opaque to native broker nodes in the message flow.	BLOB
Message is a business object from a WebSphere® adapter, and is modeled by broker message definition (.mxsd).	DataObject
Message is not XML or a business object, and is modeled by Data Format Description Language (DFDL) schema.	DFDL
Message is not XML or a business object, and is modeled by broker message definition (.mxsd).	MRM
Message is XML, and is modeled by XML Schema (.xsd) or broker message definition (.mxsd).	XMLNSC

The TX Map node handles messages that belong in the following message domains, and these messages can be used as input to, and output from, map cards. The steps you take to create your message flow, and the runtime behavior of the TX Map node, depend on the domain that you selected.

- **[BLOB domain](#)**
IBM Integration Bus uses the BLOB parser to process messages that belong to the BLOB domain.
- **[DataObject domain](#)**
IBM Integration Bus uses the DataObject parser to read and write messages that belong to the DataObject domain.
- **[DFDL domain](#)**
IBM Integration Bus uses the DFDL parser to read and write messages that belong to the DFDL domain.
- **[MRM domain](#)**
IBM Integration Bus uses the MRM parser to read and write messages that belong to the MRM domain.
- **[XMLNSC domain](#)**
IBM Integration Bus uses the XMLNSC parser to read and write messages that belong to the XMLNSC domain.
- **[Other domains](#)**
IBM Integration Bus provides several other domains, such as XMLNS, MIME, JMSMap and JMSStream, and accompanying parsers to parse and serialize messages that belong to them.

BLOB domain

IBM® Integration Bus uses the BLOB parser to process messages that belong to the BLOB domain.

A BLOB message is handled as a single string of bytes, and although you can manipulate it, you cannot identify specific pieces of the byte string in the way that you can with messages in other domains. The BLOB parser does not create a message tree structure in the same way that other parsers do. It creates a simple tree with a root element BLOB that has a child element, also called BLOB, that contains the message bit stream.

The TX Map node can consume and create messages in the BLOB domain. However, the message must be modeled using a type tree so the map can interpret the structure of the BLOB message.

To create a message flow that uses the TX Map node to create or consume messages in the BLOB domain, do the following steps within the IBM Integration Toolkit:

1. In the Transformation Extender Development perspective, use Type Designer to model the message format as a type in a type tree (.mtt) file.
2. In the Transformation Extender Development perspective, use Map Designer to create a map, and add input or output cards as required. In the New Card dialog, select the type tree (.mtt) file as the Type tree, and the type as the Type.
3. Switch to the IBM Integration Development perspective, and create a message flow containing a TX Map node that uses your map.

- a. If the message is consumed by an input card, configure the input node of the message flow to specify the Message Domain as **BLOB**.
 - b. If the message is created by an output card, configure the corresponding TX Map node output terminal to specify the Message Domain as **BLOB**, complete the Message Set property, and set the Encoding and Coded Char Set ID properties to match the byte order (endianness) and character set of the output data from the map.
4. Complete the message flow, and deploy it to the broker.

At run time, if the message is to be consumed by an input card, the input node of the message flow starts the BLOB parser, which creates a simple message tree from the message bit stream. The TX Map node receives the BLOB message tree, extracts the BLOB bit stream element, and passes it to the input card. When the map runs, it parses the bit stream using the type tree.

At run time, if the message is to be created by an output card, when the map runs, it creates a bit stream. The TX Map node starts the BLOB parser to create a simple message tree from the bit stream, and propagates it to the next node in the message flow. The output node of the message flow starts the BLOB parser, which extracts the BLOB bit stream element.

The map is built using the type tree, and at run time, the map itself parses the message bit stream on input, and serializes it on output, using the type tree.

- [Configuring connected output terminals](#)

DataObject domain

IBM® Integration Bus uses the DataObject parser to read and write messages that belong to the DataObject domain.

You must use the DataObject domain when you use the WebSphere® Adapter nodes in your message flow. IBM Integration Bus uses the DataObject parser to read and write messages, or business objects, from Enterprise Information Systems (EIS) such as SAP. The DataObject parser uses either XML schema files (.xsd) from an IBM Integration Bus library, or message definitions in a message set when reading and writing messages. A message definition (.mxsd) file is an annotated XML schema file.

The TX Map node can consume and create messages in the DataObject domain.

To create a message flow that uses the TX Map node to create or consume messages in the DataObject domain, do the following steps within the IBM Integration Toolkit:

1. In the IBM Integration Development perspective, use the Adapter Connection wizard to model the business object as either:
 - A global element in an XML schema file (.xsd) within a broker library
 - A message in a message definition (.mxsd) file, within a broker message set
- For detailed instructions, see the IBM Integration Bus product documentation.
2. In the Transformation Extender Development perspective, use Map Designer to create a map, and add input or output cards as required. In the New Card dialog, select the message definition (.mxsd) file or the XML schema (.xsd) file as the Type tree, and the group corresponding to the business object message as the Type.
 3. Switch to the IBM Integration Development perspective. Create a message flow that contains a TX Map node that uses your map.
 - a. If the message is consumed by an input card, configure the input node of the message flow to specify the Message Domain as **DataObject**.
 - b. If the message is created by an output card, configure the corresponding TX Map node output terminal to specify the Message Domain as **DataObject**. Set the Encoding and Coded Char Set ID properties to match the byte order (endianness) and the character set of the output data from the map.
 4. Complete the message flow and deploy it to the broker, along with the message set.

If the message is to be consumed by an input card, at run time the input node of the message flow starts the DataObject parser. The DataObject parser uses the XML schema or the message set to create a message tree from the EIS business object. The TX Map node receives the DataObject domain message tree and passes it to the input card. The map uses the tree directly when it runs.

If the message is to be created by an output card, at run time the map creates the DataObject domain message tree directly. The TX Map node propagates the message tree to the next node in the message flow. The output node of the message flow starts the DataObject parser, which uses the XML schema or the message set to create the EIS business object.

You do not have to create an equivalent type tree for the business object message. The map is built with the message definition file. At run time, the map operates directly on the DataObject domain message tree, and not on a bit stream.

- [Configuring connected output terminals](#)

DFDL domain

IBM® Integration Bus uses the DFDL parser to read and write messages that belong to the DFDL domain.

Use the DFDL domain to parse and write a wide variety of message formats. The DFDL domain is intended for text and binary message formats that are described by Data Format Description Language (DFDL) schema files. The DFDL parser uses DFDL schema files (.xsd) from an IBM Integration Bus library when it parses and serializes messages. A DFDL schema (.xsd) file is an annotated XML Schema file. The TX Map node can consume and create messages in the DFDL domain.

Use the IBM Integration Toolkit to create a message flow that uses the TX Map node to create or consume messages in the DFDL domain.

1. In the Integration Development perspective, model the message format as a message in a DFDL (.xsd) file, within a broker library. See the IBM Integration Bus product documentation for details.
2. In the Transformation Extender Development perspective:
 - a. Use Map Designer to create a map and add input or output cards as required.
 - b. In the New Card dialog, select the DFDL (.xsd) file as the Type tree, and select XSD as the Type.
3. Switch to the Integration Development perspective, and create a message flow containing a TX Map node that uses your map.
 - If the message is consumed by an input card, configure the input node of the message flow to specify the Message Domain property as DFDL, and the Message property as the name of the message in the DFDL schema.

- If the message is created by an output card, configure the corresponding TX node output terminal to specify the Message Domain as DFDL, and the Message property as the name of the message in the DFDL schema. Set the Encoding and Coded Char Set ID properties to match the byte order (endianness) and character set of the output data from the map.
4. Complete the message flow and deploy it to the broker along with the message set.

When the message is to be consumed by an input card, at run time the input node of the message flow starts the DFDL parser. The DFDL parser uses the DFDL schema to create a message tree from the message bit stream. The TX Map node receives the DFDL domain message tree and passes it to the input card. When the map runs, it uses the tree directly.

When the message is to be created by an output card, when the map runs, it creates the DFDL domain message tree directly. The TX Map node propagates the message tree to the next node in the message flow. The output node of the message flow starts the DFDL parser. The DFDL parser uses the DFDL schema to serialize the message tree.

You do not have to create an equivalent type tree for the message. The map is built using the DFDL schema. At run time, the map operates directly on the DFDL domain message tree, and not on a bit stream.

MRM domain

IBM® Integration Bus uses the MRM parser to read and write messages that belong to the MRM domain.

Use the MRM domain to parse and write a wide variety of message formats. It is primarily intended for non-XML message formats, but it can also parse and write XML. The MRM parser always uses message definitions in a message set when parsing and serializing messages. A message definition (.mxsd) file is an annotated XML Schema file.

The TX Map node can consume and create messages in the MRM domain.

To create a message flow that uses the TX Map node to create or consume messages in the MRM domain, do the following steps within the IBM Integration Toolkit:

1. In the IBM Integration Development perspective, model the message format as a message in a message definition (.mxsd) file, within a broker message set. For detailed instructions, see the specific IBM Integration Bus product documentation.
2. In the Transformation Extender Development perspective, use Map Designer to create a map, and add input or output cards as required. In the New Card dialog, select the message definition (.mxsd) file as the Type tree, and the group corresponding to the message as the Type.
3. Switch to the IBM Integration Development perspective, and create a message flow containing a TX Map node that uses your map.
 - a. If the message is consumed by an input card, configure the input node of the message flow to specify the Message Domain as `MRM`, and complete the Message Set, Type, and Format properties.
 - b. If the message is created by an output card, configure the corresponding TX Map node output terminal to specify the Message Domain as `MRM`, complete the Message Set, Type and Format properties, and set the Encoding and Coded Char Set ID properties to match the byte order (endianness) and character set of the output data from the map.
4. Complete the message flow, and deploy it to the broker along with the message set.

At run time, if the message is to be consumed by an input card, the input node of the message flow starts the MRM parser, which creates a message tree from the message bit stream, using the message set. The TX Map node receives the MRM domain message tree, and passes it to the input card. When the map runs, it uses the tree directly. At run time, if the message is to be created by an output card, when the map runs, it creates the MRM domain message tree directly. The TX Map node propagates the message tree to the next node in the message flow. The output node of the message flow starts the MRM parser, which serializes the message tree, using the message set.

You do not have to create an equivalent type tree for the message. The map is built using the message definition file, and at run time, the map operates directly on the MRM domain message tree, and not on a bit stream.

- [Configuring connected output terminals](#)

XMLNSC domain

IBM® Integration Bus uses the XMLNSC parser to read and write messages that belong to the XMLNSC domain.

The XMLNSC parser is a flexible, general-purpose XML parser that offers high performance XML parsing and optional XML schema validation. The XMLNSC parser has a range of options that make it suitable for most XML processing requirements. The XMLNSC parser uses either XML schema files (.xsd) from an IBM Integration Bus library, or message definitions in a message set to parse and serialize messages. A message definition (.mxsd) file is an annotated XML schema file.

The TX Map node can consume and create messages in the XMLNSC domain.

To create a message flow that uses the TX Map node to create or consume messages in the XMLNSC domain, do the following steps within the IBM Integration Toolkit:

1. In the IBM Integration Development perspective, model the message format as either:
 - A global element in an XML schema file (.xsd) within a broker library
 - A message in a message definition (.mxsd) file within a broker message set, typically by importing an XML schema (.xsd) file.
 For detailed instructions, see the IBM Integration Bus product documentation.
2. In the Transformation Extender Development perspective, use Map Designer to create a map and add input or output cards as required. In the New Card dialog, select either the message definition (.mxsd) file or the XML schema (.xsd) file as the Type tree. Select the group that corresponds to the message as the Type.
3. Switch to the IBM Integration Development perspective, and create a message flow that contains a TX Map node that uses your map.
 - a. If the message is consumed by an input card, configure the input node of the message flow to specify the Message Domain as `XMLNSC`.
 - b. If the message is created by an output card, configure the corresponding TX Map node output terminal to specify the Message Domain as `XMLNSC`. Set the Encoding and Coded Char Set ID properties to match the byte order (endianness) and character set of the output data from the map.
4. Complete the message flow, and deploy it to the broker along with the message set.

If the message is to be consumed by an input card, at run time the input node of the message flow starts the XMLNSC parser. The XMLNSC parser uses the XML schema or the message set to create a message tree from the message bit stream. The TX Map node receives the XMLNSC domain message tree and passes it to the input card. When the map runs, it uses the tree directly.

If the message is to be created by an output card, at run time the map creates the XMLNSC domain message tree directly. The TX Map node propagates the message tree to the next node in the message flow. The output node of the message flow starts the XMLNSC parser. The XMLNSC parser uses the XML schema or the message set to serialize the message tree.

You do not have to create an equivalent type tree for the XML message. The map is built with the message definition file or XML schema. At run time, the map operates directly on the XMLNSC domain message tree, and not on a bit stream.

-

Other domains

IBM® Integration Bus provides several other domains, such as XMLNS, MIME, JMSMap and JMSStream, and accompanying parsers to parse and serialize messages that belong to them.

The TX Map node can consume and create messages in these domains.

To create a message flow that uses the TX Map node to create or consume messages in these domains, do the following steps within the IBM Integration Toolkit:

1. In the Transformation Extender Development perspective, use Type Designer to model the message format as a type in a type tree (.mtt) file.
2. In the Transformation Extender Development perspective, use Map Designer to create a map, and add input or output cards as required. In the New Card dialog, select the type tree (.mtt) file as the Type tree, and the type as the Type.
3. Switch to the IBM Integration Development perspective, and create a message flow containing a TX Map node that uses your map.
 - a. If the message is consumed by an input card, configure the input node of the message flow to specify the selected Message Domain.
 - b. If the message is created by an output card, configure the corresponding TX Map node output terminal to specify the selected Message Domain. Set the Encoding and Coded Char Set ID properties to match the byte order (endianness) and character set of the output data from the map.
4. Complete the message flow, and deploy it to the broker.

If the message is to be consumed by an input card, at run time the input node of the message flow starts the selected parser. The parser creates a message tree from the message bit stream. The TX Map node receives the message tree, serializes it back to a bit stream, and passes it to the input card. The map runs and uses the type tree to parse the bit stream.

If the message is to be created by an output card, at run time the map creates a bit stream. The TX Map node starts the selected parser to create a message tree from the bit stream, and propagates it to the next node in the message flow. The output node of the message flow starts the selected parser, which serializes the message tree.

The map is built by using the type tree. At run time, the map uses the type tree to parse the message bit stream on input, and serialize it on output.

Deploying map resources

When you deploy message flows that contain TX Map nodes, you must also deploy the associated IBM® Transformation Extender maps, and any files that the maps require.

If the map is deployed to the broker in a map archive (mar) file, you must make sure that any required files reside in the same project as the map, so they are automatically included in the mar file.

If the map is manually deployed to the broker, you must also manually deploy any required files to the broker.

The two alternative map deployment mechanisms are described in [Deploying IBM Transformation Extender maps](#).

In particular, if your data is XML, and you have imported an XML Schema (.xsd file) when creating a type tree validated using Xerces, or used an XML Schema directly when creating a map card, the .xsd file is required by the map and must be deployed to the broker for use at run time in either of the following cases:

- if the data is being received from the message flow in the BLOB domain
- if the data is being received from a IBM Transformation Extender adapter

Triggering maps to run

When a message is propagated to the TX Map node from the preceding node in a message flow, the TX Map node responds to this event by triggering the map to run.

The run unit within a IBM® Integration Bus execution group is a message flow. A message flow contains one or more input nodes that wait for input. After the nodes receive the input, they run the rest of the message flow.

When you use a IBM Transformation Extender map with IBM Integration Bus, the map can only be triggered to run within the context of a message flow, by a TX Map node. The message flow must also contain one or more input nodes. The TX Map node is not an input node, and can not start a message flow.

To configure a message flow that triggers a map to run, using the Message flow editor of the IBM Integration Toolkit, connect a TX Map node into a message flow, and then connect the input terminal of the TX Map node to the output terminal of a preceding node. Connections between objects in your message flows are called wires.

When the message flow is running, a message, which was propagated from the output terminal of the preceding node, arrives at the input terminal of the node in the form of a broker message tree. The TX Map node uses the content of the message tree to run the map.

Input nodes and events

Input nodes and events trigger a message flow to run.

You can use the following input nodes and events as triggers to run your message flow containing a TX Map node:

Input node or event	Trigger
FileInput	a file that appears in a file system folder or from an FTP server
MQInput	a message that arrives on a WMQ queue
HTTPInput	a message that arrives at an HTTP URI
SOAPInput	a Web Services SOAP that arrives at an HTTP URI
JMSInput	a message that arrives at a JMS destination
TCPIPCClientInput	a message that arrives at a TCPIP port
TCPIPServerInput	a message arriving at a TCPIP port
SCADAInput	a message that arrives from a SCADA input device
SAPInput	a business object that arrives from the WebSphere® Adapter for SAP
TimeoutNotification	a timer event that is signaled

Triggering maps to run by a single event

A single event can trigger a IBM Transformation Extender map to run.

When you have a message flow that contains a TX Map node that is preceded by a node other than a Collector node, a single event can trigger the IBM Transformation Extender map to run.

A single event can be a message that arrives at its destination. The node sends the message, in the form of a broker message tree, to the IBM Transformation Extender map input card that you configured on the Card number to wire property of the TX Map node.

The TX Map node runs the map. If the map has other input cards, it pulls data from each card's adapter.

Triggering maps to run by multiple events

Multiple events can trigger a IBM Transformation Extender map to run.

When you have a message flow that contains a TX Map node that is preceded by a Collector node, multiple events can trigger the IBM Transformation Extender map to run.

The Collector node in a message flow groups together multiple messages that arrive at its input terminals, and runs the rest of the flow when triggering criteria that you have defined are met. It performs event triggering functions similar to the IBM Transformation Extender with Launcher product.

The node propagates all the messages it receives in a message collection, which is a type of broker message tree. Each message is contained within a folder in the message collection. The folder names are taken from the names of the input terminals of the Collector node. When you use the Collector node and TX Map nodes together in your message flow, you must add Collector input terminals with names that match the card names, not the card numbers, of the map's input cards.

If the IBM Transformation Extender map has an input card with a card name that matches the name of a folder in the message collection, the Collector node delivers the message in that folder to that input card. After the Collector node delivers the messages within all of the folders in the collection to the map's input cards with matching names, the TX Map node runs the map.

If the IBM Transformation Extender map has other input cards that do not match any folder names in the message collection, these input cards do not receive messages, and the map pulls data from each of these card's adapter.

Triggering maps to run in complex message flows

A message flow can trigger systems of IBM® Transformation Extender maps to run under complex triggering conditions.

A more complex example of a message flow might contain multiple Connector and TX Map nodes connected together. For example, it can contain several input nodes that are connected to a Collector node, which is configured to trigger the rest of the message flow after it receives a message from all the input nodes. The Collector node generates the message collection, propagates it to a TX Map node, which triggers a IBM Transformation Extender map that has multiple output cards to run. Each output card propagates an output message to a separate branch of the flow, each of which contains additional Collector and TX Map nodes.

Through this network of message flows containing complex triggering conditions, systems of maps can be triggered to run.

Input cards in maps

The input cards of a map are all associated with a single input terminal of a TX Map node.

When you drag a blank TX Map node from the IBM® Integration Toolkit palette onto the canvas for your message flow, it contains a single input terminal. All cards that require data from the message flow will receive their data through this single input terminal.

- [Map triggered by multiple inputs](#)

If your map is triggered to run by multiple inputs, you must use a Collector node in your message flow before the TX Map node.

- [Wired input cards](#)

Wired input card is the term used when a map input card receives its data from another node in the message flow. The TX Map node receives the data in the form of a broker message tree.

- [Unwired input cards](#)

Unwired input card is the term used when a map input card does not receive its data from another node in the message flow, but instead gets its data from the IBM Transformation Extender adapter specified on the input card.

Map triggered by multiple inputs

If your map is triggered to run by multiple inputs, you must use a Collector node in your message flow before the TX Map node.

Configure the Collector node to gather the required inputs together in a message collection. When the conditions that you set for the message collection have been met, the message collection is complete, and the inputs are propagated as a message collection tree. When a broker message collection tree arrives at the input terminal of the TX Map node, the individual messages it contains are passed to the corresponding input cards, and the map runs. Any input cards that did not receive data get data from their adapter.

Any card number specified on the Input tab of the TX Map node properties is ignored when using a message collection tree.

If you need to wire, or connect, only a single input card to run the map, use a non-Collector node type. Wire the input node directly to the input terminal of the TX Map node, and specify the card to wire in the node's properties. This is a case where you have a map with multiple input cards, but only one of the cards is required for the message to trigger the map to run.

IBM® Transformation Extender for IBM Integration Bus adds input card properties for the TX Map node, based on the number of input cards in the compiled map. If the input terminal is wired to a Collector node, the Collector node determines which input cards are physically wired in the TX Map node. The TX Map node input card property determines which input card is wired for a non-Collector node message. For compatibility to previous versions, the default is the first input card.

- [Collector node](#)

You can use a Collector node to gather multiple input messages from IBM Integration Bus into a single TX Map node. This is also known as fan-in.

Collector node

You can use a Collector node to gather multiple input messages from IBM® Integration Bus into a single TX Map node. This is also known as fan-in.

Use a Collector node where multiple messages are required to trigger the map to run.

The Collector node gathers input messages, and when specified event criteria have been met, propagates the input messages in the form of a message collection tree. Each message is contained in a folder in the tree. The name of the folder is the same as the name of the Collector node input terminal that received that message.

The TX Map node interprets broker message collection trees. At run time, when a message collection arrives at the input terminal of a TX Map node, it disassembles it, and passes the individual input messages to the input cards of the IBM Transformation Extender map. The name of the folder in the message collection determines the input card that receives that message.

For example, a map has two input cards. The name of card #1 is PurchaseOrder, and the name of card #2 is AddressDetails. You want the map to run only when both cards have data. Configure the Collector node at design time to create message collections that consist of one purchase order message, and one address details message. If you dynamically add two input terminals to the Collector node, one named PurchaseOrder, and one named AddressDetails, to match the map input card names, the propagated message collection will contain folders named PurchaseOrder and AddressDetails.

Input cards, which do not have associated folders in the message collection, get their data from the IBM Transformation Extender adapter specified on the card.

The Collector node input terminal names and the map input card names are case sensitive. If you do not name them the same, the message collection will have a folder name that does not match the name of the input card. This condition causes the message in the folder to be discarded, and the input card to get its data from the IBM Transformation Extender adapter specified on the card. The name of the Collector node input terminal can not contain dots (.). Therefore, if you create a map that is used in a IBM Integration Bus message flow, the names of the map input cards that are wired to the previous Collector node in the flow can not contain dots (.).

The Collector node provides a comprehensive set of controls that enable you to set complex event criteria.

For more information about the Collector node, and message collection, see the specific IBM Integration Bus product documentation.

Wired input cards

Wired input card is the term used when a map input card receives its data from another node in the message flow. The TX Map node receives the data in the form of a broker message tree.

If the tree represents a single message, the TX Map node passes the message to a single, specified input card.

If the tree is a message collection, containing several messages, the TX Map node passes each message to the appropriate input card.

Unwired input cards

Unwired input card is the term used when a map input card does not receive its data from another node in the message flow, but instead gets its data from the IBM® Transformation Extender adapter specified on the input card.

This occurs when the broker message tree arriving at the input terminal of the TX Map node does not contain a message for the input card.

Output cards in maps

The output cards of a map are associated with the output terminals of a TX Map node.

When you drag a blank TX Map node from the IBM® Integration Toolkit palette onto the canvas for your message flow, it contains only a failure terminal. After you associate the node with a map, terminals appear on the node icon.

- [Creating the output terminals](#)
The TX Map node creates the output terminals dynamically, where possible. Otherwise, you create them manually.
 - [Connecting output terminals to nodes](#)
You can connect an output terminal to a subsequent node, although not all output terminals need to be connected.
 - [Configuring connected output terminals](#)
You can configure additional properties for any output terminals that you connect to nodes when you want to override the default behavior.
 - [Wired output cards](#)
Wired output card is the term used when the TX Map node output terminal corresponding to a map output card is connected, or wired, to another node in the message flow.
 - [Unwired output cards](#)
Unwired output card is the term used when the TX Map node output terminal corresponding to a map output card is not connected, or wired, to another node in the message flow.
-

Creating the output terminals

The TX Map node creates the output terminals dynamically, where possible. Otherwise, you create them manually.

The TX Map node creates the output terminals dynamically when the TX Map node in your message flow is configured, in the Basic tab of the Properties view, to reference a map on your local system:

- For a precompiled map, click Browse to set the Local compiled map property.
- For a source map, click Browse to set the Executable and Source map properties.

The node creates one output terminal for each output card of the map.

The node cannot create the output terminals dynamically when you select a precompiled map, which is located remotely. IBM® Integration Toolkit cannot determine how many output cards the map has. You have to manually add the correct number of output terminals by right-clicking the TX Map node, and selecting the Add Output Terminal option.

-

Connecting output terminals to nodes

You can connect an output terminal to a subsequent node, although not all output terminals need to be connected.

Where the output terminal is connected, the data flows from the map output card to the output terminal, and is propagated down the connection to the next node in the message flow. Where the output terminal is not connected, the data flows from the map output card to the IBM® Transformation Extender adapter specified on the card.

The Terminal Selection dialog is displayed when you right-click and select Create connection, or if the node has so many terminals that they have been grouped together in the user interface, for example, a Compute node or TX Map node with many output cards.

When you connect a TX Map node output terminal to a subsequent node, IBM Integration Toolkit displays the Terminal Selection dialog if the map has four or more output cards. The Terminal Selection dialog displays the output terminals, plus an additional failure terminal, for you to select. As an example, if your map has four output cards, the following terminals are available for you to select from the list of terminals:

- failure
- out1
- out2
- out3
- out4

Configuring connected output terminals

You can configure additional properties for any output terminals that you connect to nodes when you want to override the default behavior.

You must configure the message domain. The domain that you use determines which message template properties, message set, message type, and message format, you need to configure. See [Supported message domains](#). Configure the message template properties for the output terminals through the Outputs tab in the Properties view.

You must configure the Encoding and Coded Char Set ID properties. These properties must match the byte order (endianness) and character set of the output data from the map. Configure these properties for the output terminals through the Outputs tab in the Properties view. The values you need to use follow IBM Integration Bus conventions, described in the help topic about converting data with message flows in the IBM Integration Bus documentation.

If you do not configure these properties for an output terminal, IBM Transformation Extender for IBM Integration Bus uses the corresponding properties from the input tree. As an example, if the input belongs to the XMLNSC message domain, and you do not configure the message template properties for the output terminal, TX Map node creates the output message using the XMLNSC domain. If the message flow uses a Collector node, TX Map node creates the output message using the domain to which the tree on the first input message belongs.

When the Outputs tab initially opens, there are no entries in the Properties table. Add the properties for each of the connected output terminals. After you configure additional properties for a connected output terminal, the Properties table displays the card's number in the following format:

card-number

Examples are:

1
2

Wired output cards

Wired output card is the term used when the TX Map node output terminal corresponding to a map output card is connected, or wired, to another node in the message flow.

The data from that card is propagated to the connected node in the form of a broker message tree.

Related reference

- [Sending output data from a map to an IBM Integration Bus node](#)

Unwired output cards

Unwired output card is the term used when the TX Map node output terminal corresponding to a map output card is not connected, or wired, to another node in the message flow.

The data from that card is propagated to the IBM® Transformation Extender adapter specified on the output card. No data is propagated to the message flow.

Sending output data from a map to an IBM Integration Bus node

You can use a IBM Transformation Extender PUT map rule to send output data to another IBM® Integration Bus node, either immediately, or based on the outcome of the map.

To send the output data, wire an output terminal to a IBM Transformation Extender map node or RUN map that uses the PUT rule. You wire a map node to the output terminal specified in the map's message flow. The map must use the PUT rule and specify WIRE as the adapter name:

```
=PUT("WIRE", "output_terminal_name", data)
```

Optionally, you can specify that the message is to be sent immediately. The -NOW argument sends the message to the output terminal as soon as the PUT rule is processed. When you omit the -NOW argument, a map node sends a message to the output terminal when the map completes, and a RUN map sends a message to the output terminal when the top map completes. If you omit the -NOW argument and the map node or RUN map fails, the message is not sent.

```
=PUT("WIRE", "output_terminal_name -NOW", data)
```

Specifying the map for the TX map node

There are several different ways to specify the map that a TX Map node runs.

At design time, you can specify the following map information on the TX Map node:

- Name of an executable map within a source map (.mms) file.
 - When IBM® Integration Bus adds the message flow containing the TX Map node to a broker archive (.bar) file, the specified executable map is compiled automatically to create a compiled map (.mmc) file.
 - The compiled map, and other files in the project, are zipped into a map archive (.mar) file, which is added to the broker archive file. The map is, therefore, automatically deployed to the broker when you deploy the message flow.
- Location of a precompiled map (.mmc) file on the file system of the broker's machine.
 - When IBM Integration Bus adds the message flow containing the TX Map node to a broker archive (.bar) file, the map is not automatically compiled, and is not added to the broker archive file.
 - You must manually deploy the map to the location that you specified.

At deploy time, you can specify the location of a compiled map by using the Configure tab in the Properties view, which is under the Manage tab in the Broker Archive editor. This overrides the map that you specified at design time.

At run time, your message flow can dynamically specify the location of a compiled map, and pass this to the TX Map node, by using the Local Environment message tree. This takes precedence over any of the other methods.

- [Using source maps](#)
Configure a TX Map node in your message flow to use a source map.
- [Using precompiled maps](#)
Configure the TX Map node in your message flow to use a precompiled map.
- [Changing a source map compared to changing a compiled map](#)
When you design a message flow to use either a source map or a compiled map, consider whether you might want to change the map later. There are fewer steps required to change a compiled map than to change a source map.
- [Changing a message flow to point to a different map](#)
When you design a message flow to use either a source map or a compiled map, consider whether you might change the message flow later to point to a different map. There are fewer steps required to point to a different a compiled map than to point to a different source map. To dynamically change a message flow to point to a different map, design the message flow to use compiled maps.
- [Deploy-time TX Map node configuration](#)
You can modify certain properties of a TX Map node, when the containing message flow has been added to a bar file, using the Configure tab of the Broker Archive editor.
- [Overriding map properties at run time](#)
Override map properties at run time by using the IBM Integration Bus LocalEnvironment.

- [Dynamically overriding a map with a compiled map](#)

An upstream node in a message flow can dynamically override a map that is configured in the properties of a TX Map node. The upstream node can populate the IBM Integration Bus local environment tree with the binary data of a compiled map. The map bytes in the local environment tree override the map that is configured on the TX Map node. Ensure that the map in the local environment tree is compiled for the appropriate operating system platform.

Using source maps

Configure a TX Map node in your message flow to use a source map.

To use a source map:

1. Switch to the IBM® Integration Development perspective, and open your message flow in the project.
2. Select a TX Map node, and navigate to the Basic tab of the Properties view.
3. Select Use map from project.
4. Browse for the source map (.mms) file by clicking Browse, and use the wizard to locate the source map.
5. Select an executable map from the source map.

If you do not see your map inside the source map file, it might be set up as a functional map. For detailed information about functional maps, see the Map Designer documentation.

6. The number of output cards in the executable map determines the number of output terminals that are automatically added to the TX Map node.
7. To override any of the map or card settings, switch to the Map Settings tab, and click Map Settings.

Automatically, the map is compiled when IBM Integration Bus adds the message flow to a broker archive (bar) file. A map archive (mar) file is created containing compiled map (.mmc) files, which is added to the current project in the workspace and to the bar file. Then you deploy the bar file to the broker.

Related reference

- [Changing a source map compared to changing a compiled map](#)
- [Changing a message flow to point to a different map](#)

Using precompiled maps

Configure the TX Map node in your message flow to use a precompiled map.

To use a compiled map:

1. Switch to the IBM® Integration Development perspective, and open your message flow in the project.
2. Select a TX Map node, and navigate to the Basic tab of the Properties view.
3. To select the compiled map when it is located on an external file system, which is on the same machine as where you develop the message flow and where the broker runs:
 - a. Select Use external map.
External maps are compiled outside any projects. They must exist at design time for the map node to determine the number of output cards, and create the output terminals. They would not be transferred to the server because this scenario is using compiled maps that are on the same machine.
 - b. Enter the fully qualified path to the compiled map that is located on your local machine in the Local compiled map field, or click Browse [...], select the compiled map from the file system in the Browse Compiled Map dialog, and click OK.
IBM Integration Toolkit creates one output terminal for each output card in the map on the TX Map node.
The TX Map node is configured to use the compiled map from an external location.
4. To select the compiled map when you have a copy of the map in the machine where you are developing the message flow, and have to import it into your workspace project:
 - a. Import the map and type trees into your workspace project.
 - i. Select File > Import. The Import wizard starts.
 - ii. Expand the Other folder, select Project Interchange, and click Next.
 - iii. Navigate to the directory in which your map and type trees are located, select them, and click Open.
 - iv. Select the check box next to the displayed project, and click Finish. The map and type trees are imported into your workbench project.
 - b. Select Use map from project.
 - c. Enter the map in the Executable map field, or click Browse [...], select the executable map from the file system in the Select executable map dialog, and click OK.
This populates the Executable map and Source map edit fields. The source map is read only and is derived from the executable map selection. IBM Integration Toolkit also creates output terminals automatically for each output card of the map on the TX Map node.
The TX Map node is configured to use the compiled map from your workspace.
5. To select the compiled map when you do not have a copy of the map in the machine where you are developing the message flow, and the map and broker are both on the same remote machine:
 - a. Select Use external map.
External maps are compiled outside any projects. An external map must exist at design time and be compiled for the correct platform. If the server is a different machine, you must manually transfer the map to the server.
 - b. Enter the fully qualified name of the compiled map in the Map Server Location field.
The TX Map node is configured to use the compiled map from a remote location.

The TX Map node does not use the bar file mechanism to deploy the map. You deploy the map outside of the bar file deployment. You must manually create and build the bar file, without a mar file, and then deploy it to the broker. At run time, IBM Integration Bus finds and runs the compiled map.

If you want to use a different compiled map than the one you specified in the TX Map node, specify it in the LocalEnvironment. At run time, the compiled map specified in the LocalEnvironment overrides the map that you specified in the TX Map node. For more information about the LocalEnvironment, see the specific IBM Integration Bus product documentation.

Changing a source map compared to changing a compiled map

When you design a message flow to use either a source map or a compiled map, consider whether you might want to change the map later. There are fewer steps required to change a compiled map than to change a source map.

To change a source map:

1. Use IBM® Transformation Extender Design Studio or the IBM Transformation Extender perspective of IBM Integration Bus to make the map changes.
2. Recompile the broker archive (BAR) file.
3. Deploy the new BAR file.

To change a compiled map:

1. Use IBM Transformation Extender Design Studio or the IBM Transformation Extender perspective of IBM Integration Bus to make the map changes.
2. Replace the original map with the revised map in the database or file system where the BAR file is deployed.

Map Type	Edit Map	Recompile BAR File	Deploy New BAR File
Source map	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
Compiled map	<input checked="" type="checkbox"/>		

See the IBM Integration Bus documentation for additional information about compiling and deploying a broker archive file.

When you design a message flow to use either a source map or a compiled map, consider whether you might change the message flow later to point to a different map. There are fewer steps required to point to a different a compiled map than to point to a different source map. To dynamically change a message flow to point to a different map, design the message flow to use compiled maps.

To change a message flow to point to a different source map:

1. In the TX map node, select a new source map or executable map.
2. Recompile the broker archive (BAR) file.
3. Deploy the new BAR file.

You cannot dynamically change the TX map node's executable map or source map properties by using the the BAR file override properties in IBM® Integration Toolkit or by using the IBM Integration Bus **mqsiapplybaroverride** command.

To change a message flow to point to a different compiled map, you can do one of the following:

- Change the map server location property:
 1. In the TX map node, change the Map Server Location property to point to a different compiled map.
 2. Recompile the broker archive (BAR) file.
 3. Deploy the new BAR file.
- Override the BAR file:
 1. Use the BAR file override properties in IBM Integration Toolkit or the IBM Integration Bus **mqsiapplybaroverride** command to change the map server location.
 2. Redeploy the BAR file. You do not have to recompile the BAR file.
- Specify a dynamic binary map or a dynamic path to a map in the IBM Integration Bus local environment tree
This method takes precedence over the map name or map location specified in the IBM Integration Toolkit or by the BAR file. When you use the local environment tree to specify the map, you do not have to recompile or redeploy the BAR file.

Related reference

- [Changing a source map compared to changing a compiled map](#)

Deploy-time TX Map node configuration

You can modify certain properties of a TX Map node, when the containing message flow has been added to a bar file, using the Configure tab of the Broker Archive editor.

The properties you can override are the Map Server Location for a precompiled map that you specified outside of a project, the Card Number To Wire, and the Cache Map.

In the Broker Archive editor, select the Manage tab, and in the Configure tab of the Properties view, modify the properties of the TX Map node. If you override the map with an invalid configuration with other node properties, such as a wired input or output that does not exist, the node fails.

Overriding map properties at run time

Override map properties at run time by using the IBM® Integration Bus LocalEnvironment.

The message flow derives the map properties from different sources, and searches for the properties in the order listed:

1. Run time
 - Source: LocalEnvironment
 - Override the map server location and input card to wire map properties at run time in the LocalEnvironment.
 - For information about how the LocalEnvironment works, see the related topics in the IBM Integration Bus product documentation.
2. Deploy time
 - Source: broker archive (bar) file
 - Override the cache map, map server location, and input card to wire map properties at deploy time in the bar file using the Configure tab of the Properties view, which is under the Manage tab in the Broker Archive editor.
3. Design time
 - Source: TX Map node
 - Override the map and card properties at design time in the Map Settings tab of the TX Map node.

At run time, override the following map properties by using the IBM Integration Bus LocalEnvironment tree from a prior node in the message flow, such as a Compute node, which can change the LocalEnvironment to override parameters in the tree that is passed to the TX Map node:

MapServerLocation property

LocalEnvironment tree path: LocalEnvironment.WTX.MapServerLocation

Purpose: To run the compiled map located in a different location than the location configured on the TX Map node.

Result: IBM Integration Bus overrides the map server location with the location you specified in the LocalEnvironment tree, and the TX Map node runs the map from this location instead.

CardNumberToWire property

LocalEnvironment tree path: LocalEnvironment.WTX.InputCardNumberToWire

Purpose: To specify which input card of the map should be wired.

Result: The specified map input card receives its data from the prior node in the message flow.

Related tasks

- [Using precompiled maps](#)

Dynamically overriding a map with a compiled map

An upstream node in a message flow can dynamically override a map that is configured in the properties of a TX Map node. The upstream node can populate the IBM® Integration Bus local environment tree with the binary data of a compiled map. The map bytes in the local environment tree override the map that is configured on the TX Map node. Ensure that the map in the local environment tree is compiled for the appropriate operating system platform.

LocalEnvironment subtree

LocalEnvironment.WTX.DynamicMap

Contains the binary data of a compiled map. The map bytes dynamically override the map that is configured on a downstream TX Map node.

LocalEnvironment.WTX.DynamicMapName

Assigns a name to the binary data of the compiled map in the local environment tree. This name identifies the binary map for purposes such as map caching.

LocalEnvironment.WTX.MapServerLocation

Specifies the path to a map on the file system. This map runs instead of the map that is configured in the TX Map node.

Order of precedence

The order of precedence for map overrides is:

1. A dynamic binary map in the local environment tree (`LocalEnvironment.WTX.DynamicMap`)
2. A dynamic path to a map in the local environment tree (`LocalEnvironment.WTX.MapServerLocation`)
3. A map that is configured through the TX Map node properties, whether it is configured through the map settings interface or by a WebSphere® IBM Integration Bus broker archive (BAR) editor.

Default directory locations for dynamic maps

The default location of a dynamic map's log, trace, and work files is:

`MQSI_WORKPATH/common/log/WTX/ExeGrpName/FlowName/NodeName/DynamicMapName`

If you do not provide a dynamic map name by using `LocalEnvironment.WTX.DynamicMapName`, the dynamic map bytes are in the directory:

`MQSI_WORKPATH/common/log/WTX/ExeGrpName/FlowName/NodeName/NodeName`

You can find the value of `MQSI_WORKPATH` in a WebSphere IBM Integration Bus command shell environment.

If the dynamic map requires static files or RUN maps, put them in the same directory as the dynamic map's log, trace, and work files.

Related concepts

- [Map caching](#)

Related tasks

-

Map caching

At design time, set map caching to optimize runtime performance.

Map caching optimizes the runtime performance because the process does not load the compiled map for every iteration of the running of the map. The compiled map is loaded only on the first invocation of the map.

When map caching is set on, any changes that you make to the compiled map are used by the message after you stop and restart the execution group. When map caching is set off, any changes that you make to the compiled map are used by the next message that passes through the message flow.

Set up map caching for each TX Map node to enable individual control for each map node instance. Set map caching on in the Basic tab under Properties in the IBM® Integration Toolkit.

Even after a map is cached, the physical file in the path for the cached map must exist at run time.

A TX Map node can use a map that is cached by a different node if the TX Map node specifies the exact path and name of the cached map.

You can enable RUN map caching in the `/runtime/RUN Maps/RunMapMaxCacheNum` path of the `config.yaml` configuration file. Set `RunMapMaxCacheNum` to the maximum number of maps to cache.

LocalEnvironment DynamicMap and MapServerLocation caching

When the TX Map node Cache map property is enabled, the TX Map node caches the path to a map and the dynamic map bytes that are configured in the local environment tree.

Dynamic map caching

When Cache map is enabled and a dynamic map has a name (`LocalEnvironment.WTX.DynamicMapName`), the node caches the bytes of a dynamic map (`LocalEnvironment.WTX.DynamicMap`). The node cannot cache dynamic map bytes that do not have a dynamic map name.

After you cache a dynamic map, a TX Map node that invokes the dynamic map name does not need to retrieve the map bytes from the local environment tree. If the TX Map node receives the dynamic map name (`LocalEnvironment.WTX.DynamicMapName`) together with at least one placeholder byte in `LocalEnvironment.WTX.DynamicMap`, the node runs the cached map.

For example, if you cache a map named PreProcessEDI and a TX Map node receives the following input from the local environment tree on a subsequent invocation, the TX Map node runs the cached PreProcessEDI map:

```
SET OutputLocalEnvironment.WTX.DynamicMapName = 'PreProcessEDI';
SET OutputLocalEnvironment.WTX.DynamicMap = X'00';
```

To enable the TX Map node to detect changes to a cached dynamic map, use a new map name (`LocalEnvironment.WTX.DynamicMapName`) to trigger the node to load the map bytes (`LocalEnvironment.WTX.DynamicMap`).

MapServerLocation caching

When you set the TX Map node Cache map property, the TX Map node caches each unique MapServerLocation path in the local environment tree. The TX Map node does not need to load a cached map path for subsequent invocations of the map, but the map must exist.

To enable the TX Map node to detect changes to a cached map path, use a new map server location (`LocalEnvironment.WTX.MapServerLocation`) to trigger the node to load a new map path.

Wildcards

Wildcards are represented by the asterisk (*) and question mark (?) characters, and are used to substitute specific portions of the file name property of the FileInput node, and the FileOutput node when you want to use a pattern instead of a specific name.

The FileInput node is the only input node that handles wildcards.

The wildcard character represented by the asterisk (*) is used to substitute 0 or more characters. The wildcard character represented by the question mark (?) is used to substitute 1 character.

For information about how wildcards are resolved on the Collector node, the FileInput node, and the FileOutput node, see the related topics in the IBM® Integration Bus product documentation.

- [Using wildcards](#)

You can use the wildcard characters for IBM Transformation Extender resources that are not wired, which includes non-wired sources and targets, only if you use wildcards on the IBM Integration Bus FileInput node that you selected as the input to the TX Map node.

Using wildcards

You can use the wildcard characters for IBM® Transformation Extender resources that are not wired, which includes non-wired sources and targets, only if you use wildcards on the IBM Integration Bus FileInput node that you selected as the input to the TX Map node.

The FileInput node resolves any wildcards in its file name or pattern properties, and places the evaluated wildcard expression at \$LocalEnvironment/Wildcard/WildcardMatch. The TX Map node uses this result for non-wired input and output cards that contain a wildcard to evaluate the correct source and target name, for example, filename and command line.

If you want more than one input card of the IBM Transformation Extender map to receive data from IBM Integration Bus, you need to use the Collector node. The Collector node can pass wildcard values from the FileInput node to the TX Map node when you set the Correlation path property of the Collector node to \$LocalEnvironment/Wildcard/WildcardMatch in the Basic tab of the Properties view.

One way to use wildcards is to represent a portion of a name for an output file that you want IBM Transformation Extender to create, so that it includes the corresponding characters from a message correlation ID that IBM Transformation Extender receives.

One example is if you configured a FileInput node with the c:*inputdata.txt file name, and a IBM Transformation Extender non-wired output file with the DATA*.txt name. If the FileInput node receives an input file with the 123inputdata.txt name, the wildcard expression evaluates to 123, and the result is that IBM Transformation Extender produces an output file with the DATA123.txt name.

Another example is if you configured a FileInput node with the c:*input??data.txt file name, and a IBM Transformation Extender non-wired output file with the DATA*.txt name. If the FileInput node receives an input file with the 123inputHQdata.txt name, the wildcard expression evaluates to 123inputHQ, and the result is that IBM Transformation Extender produces an output file with the DATA123inputHQ.txt name.

Map Settings interface

Use the Map Settings interface to override map and card properties when you configured your TX Map node properties in the Basic tab with either Use map from project selected, or both Use external map and Local compiled map selected.

If you configured your TX Map node properties with Use external map selected, and only Map server location selected, without Local compiled map selected as well, the map settings are disabled.

Override the map and card settings in the Map Settings tab of the TX Map node.

Through the Map Settings tab, override card settings, such as audit, trace, paging, and so forth, for all sources and targets of the map. Only unwired cards from IBM® Integration Bus use the card settings that you changed in the Map Settings interface.

Resource Registry

In IBM® Integration Bus, you can dynamically modify and configure the location of the IBM Transformation Extender resource configuration file by using the IBM Transformation Extender property in the execution group to which the bar file is deployed.

The Resource Registry can be used only with IBM Transformation Extender resources. See the Resource Registry documentation for details.

- [Modifying resource names](#)

Use the IBM Transformation Extender editor to create resource aliases to be used with IBM Transformation Extender resources in IBM Transformation Extender for IBM Integration Bus running under IBM Integration Bus.

- [Setting resource registry on execution groups](#)

Configure IBM Transformation Extender for IBM Integration Bus to use the IBM Transformation Extender Resource Registry by setting the resource configuration (.mrc) file on the IBM Integration Bus execution groups.

Modifying resource names

Use the IBM® Transformation Extender editor to create resource aliases to be used with IBM Transformation Extender resources in IBM Transformation Extender for IBM Integration Bus running under IBM Integration Bus.

You can use resource aliases only on TX Map nodes. The IBM Transformation Extender resources used in TX Map nodes that can be aliased include:

- non-wired source and target resources that are specified in map cards
- GET and PUT functions in map rules
- RUN map overrides
- audit file names
- trace file names
- back up file names
- work space locations

For a complete list of the resources, see the Resource Registry documentation.

Setting resource registry on execution groups

Configure IBM® Transformation Extender for IBM Integration Bus to use the IBM Transformation Extender Resource Registry by setting the resource configuration (.mrc) file on the IBM Integration Bus execution groups.

Update the default settings of the execution groups to use the Resource Registry. All command properties that are listed in the following steps are case-sensitive. The sample commands are shown for the Windows operating system.

To set the resource configuration file on execution groups:

1. Verify that the broker is running.
2. Open a Command Console that has the IBM Integration Bus environment configured for your current installation. Select Start>IBM Integration Bus *n.n>* Command Console, where *n.n* represents the product version number.
3. To find out where the current execution group's resource configuration file is located, use the IBM Integration Bus **mqswireportproperties** command:

```
C:\Program Files\IBM\MQSI\n.n>
mqswireportproperties brokername
-e executiongroup
-o ComIbmWTXManager
-n resourceConfigFile
```

An example of what your default setting might be:

```
C:\Program Files\IBM\MQSI\6.1>
mqswireportproperties WBRK61_DEFAULT_BROKER
-e default
-o ComIbmWTXManager
-n resourceConfigFile
```

The Command Console returns the following response:

```
resource.mrc
BIP8071I: Successful command completion.
```

4. To set the location of the resource configuration file for an execution group, use the IBM Integration Bus **mqsicchangeproperties** command:

```
C:\Program Files\IBM\MQSI\n.n>
mqsicchangeproperties brokername
-e executiongroup
-o ComIbmWTXManager
-n resourceConfigFile
-v locaton_of_your_resource_registry_configuration_file
```

An example of what your default setting might be:

```
C:\Program Files\IBM\MQSI\6.1>
mqsicchangeproperties WBRK61_DEFAULT_BROKER
-e default
-o ComIbmWTXManager
-n resourceConfigFile
-v C:\myfile.mrc
```

The Command Console returns the following response:

```
C:\myfile.mrc
BIP8071I: Successful command completion.
```

5. To have the changes take effect, stop and restart the execution group.

For information about these commands, see the specific IBM Integration Bus product documentation.

Samples

Use the samples that are included in the IBM® Transformation Extender for IBM Integration Bus installation to demonstrate how you use the product.

For the latest information about where the samples are installed, and how you use them, see the IBM Transformation Extender for Integration Servers [release notes](#).

The following table lists the Application samples that are available for IBM Transformation Extender for IBM Integration Bus.

Sample name	Description
IVT	A sample that uses a message flow, which runs a IBM Transformation Extender map. You can run this sample as an installation verification test (IVT) of the IBM Transformation Extender product components.
Node	A sample that shows how the TX Map node runs a IBM Transformation Extender map within a message flow.

Containers Overview

Containers are executable units of software that package application code along with its libraries and dependencies. IBM Sterling Transformation Extender (ITX) product offers a runtime container image for running ITX maps and flows through a REST API. The runtime server container image is distributed as, IBM Sterling Transformation Extender for Red Hat OpenShift.

Runtime Server Container

This section describes the IBM Sterling Transformation Extender Runtime Server Container.

Introduction

IBM Sterling Transformation Extender for Red Hat OpenShift, formerly known as IBM Sterling Transformation Extender Runtime Server, is a packaging of the IBM Sterling Transformation Extender (ITX) runtime product in the form of a Linux container image. The container image, ibm-itx-rs, is an IBM distributed container image that exposes REST API endpoints to deploy and invoke ITX compiled maps and packaged flows.

This document describes deploying the container to a Red Hat OpenShift cluster through a Helm Chart. It also describes using the image to run in a container runtime such as Docker or Podman.

This document supplements the information provided in the CASE (Container Application Software for Enterprises) bundle documentation for ITX Runtime Server (ITX-RS).

Information about Industry and Enterprise Packs distributed by the product and setting up those Packs for the ITX Runtime Server has been provided for Packs users.

For additional high-level overview of the ITX Runtime Server product, see [IBM Support page](#).

The following is a list of high-level features provided by the ITX Runtime Server:

- Uploading, listing, downloading, and deleting compiled ITX maps and other files.
- Listing and downloading generated REST API server and map execution engine log files.
- Fenced (REST API server and map execution engine running in separate processes) and unfenced (REST API server and map execution engine running in same process) run modes.
- Synchronous and asynchronous map executions.
- Cataloging support for the maps, with the REST API endpoints automatically generated for the produced map catalog entries.
- Direct map execution and execution via cataloged map REST APIs.
- Ability to override map inputs and outputs with the REST API request and response data.

In addition to the previous features, which are specific to Version 1 (V1) of the ITX Runtime REST API, the following is a list of additional capabilities that are provided by the ITX Runtime Server:

- Integration with Design Server. Using the Design Server graphical interface, both maps and flows can be deployed to a Runtime Server installation and monitored.
- Flow and map executions are supported by using Version 2 of the ITX Runtime REST API.
- The watch functionality of flows allows listeners to be deployed to a Runtime Server.
- Automated map and flow deployments are available via Cloud Object Storage (COS).
- Synchronous and asynchronous map and flow executions.
- Horizontal pod autoscaling with support for custom metrics and behavior policies.

Installing ITX Runtime Server

- [Prerequisites](#)
- [System Requirements](#)
- [Installing ITX Runtime Server from Command Line](#)

- [Configuration](#)
 - [Storage](#)
 - [SecurityContextConstraints Requirements](#)
-

Prerequisites

ITX Runtime Server requires Red Hat OpenShift cluster version 4.14. It is supported on Linux 64 clusters only. ITX maps can be designed and compiled for the Linux 64 platform by using either ITX Design Studio or Design Server. ITX Design Studio and Design Server are available as separate download options and must be installed locally. Design Studio is only supported on Windows. Design Server is supported on Linux and Windows. Refer to the information provided with your entitlement for instructions to download and install ITX Design Studio and Design Server. Refer to the [ITX Documentation](#) for startup instructions and technical guidelines on using both ITX Design Studio and Design Server. For more information about the product release, see [IBM Sterling Transformation Extender for Red Hat OpenShift 11.0.1](#).

When compiling maps in ITX Design Studio, you must choose the option to compile them for Linux 64 platform. Alternatively, you can use multi-platform composite maps, which will increase the size of the map while enabling the same map to run on both Windows and Linux platforms.

A Redis installation is required to use the ITX Runtime Server in fenced mode, to invoke REST APIs for asynchronous map invocations, or to use the V2 REST API. Flow execution is part of the V2 REST API. For more information, see the [Redis Configuration](#) section.

Two filesystem-based persistent volumes must be provisioned for the ITX Runtime Server to be operational. For a Kubernetes installation, if you plan for the ITX Runtime Server pods to be distributed across multiple nodes, the volumes must support the ReadWriteMany access mode option so that they can be bound by all pods in the installation. For more information, see the [Storage](#) section.

In those cases where only maps need to be run, the two file-based persistent volumes are not required as long as S3 or GCP Cloud Object Storage (COS) is accessible. The ITX Runtime Server can leverage COS for both V1-based map executions and V2-based flow executions. When running V1-based map executions, however, the deployment no longer requires these persistent volumes. By decoupling from persistent volumes, the REST service can become highly available and fault tolerant without any dependencies on one single file system.

System Requirements

- When configuring an ITX Runtime Server instance, specify the requested and the maximum Memory and CPU size, as well as the storage capacity.

The following requested values are selected by default:

Memory (Gi)	CPU (milliscores)	Disk (Gi)	Nodes
4	1000	10	1

- Note that if you choose to run an instance of the ITX Runtime Server in **fenced** mode, the REST service process will run separately from the map execution worker process. Therefore, two Java Virtual Machine (JVM) processes will be created, which should be taken into account when planning system resources, especially memory.
- The storage class that you choose to use for persistent volumes must be of filesystem type.
- Following table shows different configuration profiles, the minimum configuration advisable to set up for the ITX Runtime Server:

Profile	Memory (Gi)	CPU (milliscores)	Disk (Gi)	Nodes
Starter	4	1000	10	1 (master and worker node)
Development	4	2000	25	3 (1 master, 2 worker nodes)
Production	16	4000	50	5 (2 master, 3 worker nodes)

Adjust the above suggested configuration based on your transformation needs, by updating the **resources** and **persistence** sections in `values.yaml`.

Installing ITX Runtime Server from Command Line

ITX Runtime Server can be installed in an online (connected) cluster or offline (air-gapped) cluster using command line tools.

- Download and install **cloudctl**, **oc**, and **helm** command line tools. In case of offline installation, download the tools to the bastion server (if using bastion), or to the portable device (if not using bastion). The CASE needs to be saved to the same machine to which the tools are downloaded.
 - **oc**: To interact with the OpenShift Cluster
 - **cloudctl**: To interact with the CASE
 - **helm**: To install and configure the embedded chart
- Open a Linux shell on the machine with the downloaded tools and the CASE.
- Go to the directory containing the **case** directory for the CASE. All **cloudctl** commands must be run from that directory.

Note: **cloudctl case** usage is deprecated. **cloudctl case** usage when discontinued should be replaced with **oc ibm_pak** in the below command lines after **ibm_pak** plugin for **oc** command line tool has been installed.

- [Installing in an Online Cluster through CASE](#)
- [Installing in an Online Cluster through Native helm CLI Commands](#)
- [Installing in Air-Gapped \(Offline\) OpenShift Cluster](#)
- [Verifying Installation](#)

Installing in an Online Cluster through CASE

Run the following command to install the catalog source to the ibm-itx namespace in your cluster. You may choose a namespace different from ibm-itx.

```
cloudctl case launch \
  --case case/ibm-itx-rs \
  --namespace ibm-itx \
  --inventory itxRsProd \
  --args "-accept unknown" \
  --action install
```

Use the --args "" parameter to pass additional arguments to the helm installer. For example, --args "--set persistence.data.capacity=40Gi" expands the default size of 10Gi specified in values.yaml.

Also, the -accept value must be passed in the --args string once you have read and agreed to the product licensing. The product will not operate until this value is set to true.

Installing in an Online Cluster through Native helm CLI Commands

Run the following command, after replacing the <target_namespace> placeholder with the name of the namespace to which you wish to install the Helm chart. The v11 designation prefixes the release name of the ITX-RS instance. You can change this to another value that better describes your installation.

```
helm install v11 \
  --namespace <target_namespace> \
  --set license=false \
  charts/ibm-itx-rs-prod
```

Note: You must read and accept the product licensing terms and then change --set license=false in the above command line to --set license=true. The product will not operate until the value of the license setting is set to true.

Installing in Air-Gapped (Offline) OpenShift Cluster

- [Prepare Bastion Host or Portable Device](#)
- [Prepare CASE](#)
- [Configure Registry Auth](#)
The following `cloudctl case launch` commands all include <target_namespace> argument. The `ConfigureCredsAirgap`, `mirror-images`, and `ConfigureClusterAirgap` actions do not operate on the target cluster and this argument can be omitted.
- [Mirror Images](#)
- [Configure Cluster for Airgap](#)
- [Install ITX definitions to the cluster](#)

Prepare Bastion Host or Portable Device

Log on to the bastion machine, and verify that it has access to:

- the public Internet (to download images from the source image registry)
- the target image registry (where the images will be mirrored)
- the target OpenShift cluster, to install the Helm chart

If a bastion machine is not available, you can use a portable device (such as laptop) instead, which you must be able to carry into the air-gapped environment to connect to the target cluster.

The remaining steps should be run from the bastion machine (portable device).

Open Linux shell and go to the directory that contains the `case` folder for this CASE. All the remaining `cloudctl` commands must be run from this directory.

Prepare CASE

Procedure

1. Prepare the CASE files used by the process. Create a temporary directory used during the process:

```
$ mkdir /tmp/cases
```

2. Run the following command:

```
$ cloudctl case save --case case/ibm-itx-rs --outputdir /tmp/cases Downloading and extracting the CASE ...
Success
Retrieving CASE version ...
Success
Validating the CASE ...
Success
Creating inventory ...
Success
Finding inventory items
Success
Resolving inventory items ...
```

```
Parsing inventory items
Success
```

A set of .tgz and .csv files will be created under the /tmp/cases folder.

Configure Registry Auth

The following **cloudctl case launch** commands all include <target_namespace> argument. The **ConfigureCredsAirgap**, **mirror-images**, and **ConfigureClusterAirgap** actions do not operate on the target cluster and this argument can be omitted.

Procedure

1. Authenticate with the source image registry (Entitled Registry).
2. Run the following command after replacing the <target_namespace> placeholder with the name of the namespace to which you wish the secret to be created, and after replacing <password> placeholder with the password (API key) you have received with your entitlement.

```
$ cloudctl case launch \
  --case case/ibm-itx-rs \
  --namespace <target_namespace> \
  --inventory itxRsProd \
  --action configureCredsAirgap \
  --args "--registry cp.icr.io --user <user> --pass <password>"
```

The credentials will be saved to ~/.airgap/secrets/cp.icr.io.json

3. Authenticate with the target image registry.

Note: This step can be skipped if the target registry does not require authentication.

4. Run the following command, after replacing the <target_namespace> placeholder with the name of the namespace to which you wish the secret to be created, and after replacing <target_registry>, <user> and <password> placeholders with the registry, user and password for the target image registry.

```
$ cloudctl case launch \
  --case case/ibm-itx-rs \
  --namespace <target_namespace> \
  --inventory itxRsProd \
  --action configureCredsAirgap \
  --args "--registry <target_registry> --user <user> --pass <password>"
```

The credentials will be saved to ~/.airgap/secrets/<target_registry>.json

Mirror Images

In this step, the container image for ITX Runtime Server is copied to the target registry in the air-gap environment. This generates calls to the **oc image mirror** command which copies the images over. Run the following command after replacing the <target_namespace> placeholder with the name of the target namespace for the image, and after replacing the <target_registry> placeholder with the name of the target image registry.

```
$ cloudctl case launch \
  --case case/ibm-itx-rs \
  --namespace <target_namespace> \
  --inventory itxRsProd \
  --action mirror-images \
  --args "--registry <target_registry> --inputDir /tmp/cases"
```

Configure Cluster for Airgap

If the portable device was used instead of the bastion server, carry the device to the air-gapped environment with the target OpenShift cluster, and make sure it has connection to the cluster.

This step does the following:

- Creates a global image pull **Secret** for the target registry (skipped if target registry is unauthenticated).
- Creates an **ImageSourceContentPolicy** object with mirror settings.

Warning: Cluster resources must adjust to the new pull secret, which can temporarily limit the usability of the cluster. Authorization credentials are stored under \$HOME/.airgap/secrets and /tmp/airgap* to support this action.

Warning: Applying ImageSourceContentPolicy causes cluster nodes to recycle. Run the following command after replacing the <target_namespace> placeholder with the name of the target namespace for the Helm chart, and after replacing the <target_registry> placeholder with the name of the target image registry.

```
cloudctl case launch \
  --case case/ibm-itx-rs \
  --namespace <target_namespace> \
  --inventory itxRsProd \
  --action ConfigureClusterAirgap \
  --args "--registry <target_registry> --inputDir /tmp/cases"
```

Install ITX definitions to the cluster

Follow the instructions in **Installing in an Online Cluster through CASE** section, or the instructions in **Installing in an Online Cluster through Native helm CLI Commands** section.

With either method, provide the `--set image.repository=<target_registry>` command argument.

Verifying Installation

Once you have installed the ITX Runtime Server, you can test accessing the instance by invoking the version and configuration REST API endpoints, after replacing `<location>` with the location of the **Route** resource deployed with the instance:

`<location>/tx-rest/v1/itx/version`

`<location>/tx-rest/v1/itx/configuration`

The version endpoint returns a JSON document with information about the product name and version. The configuration endpoint returns a JSON document with the configuration options and values that you specified when you deployed the instance, which you can consider as additional confirmation that the instance was configured as expected.

Configuration

This section describes the configuration parameters of the Runtime Server when Helm is used for installation. An alternate configuration method is used for an installation of the Runtime Server as a single container in a container runtime such as Docker or Podman. See the section on the `ibm-itx-rs` container image for information about configuring a single-container installation.

When Helm is used for installation, the Runtime Server supports two installation modes as follows:

- V1 installation mode
- V2 installation mode

The V1 mode only supports the V1 API, which is enabled by the `restV1.deploy` parameter. The V2 mode supports the V2 and V1 APIs, both of which are activated by the `rest.deploy` parameter. The V2 mode requires an external Redis installation because the V2 API requires map and flow execution requests and results to be stored in Redis. The V1 mode does not require an external Redis installation if the server is unfenced. The V1 mode can be used simultaneously with the V2 mode only if the V1 installation is unfenced (`restV1.runMode`).

The V1 mode supports scaling the number of REST servers (`restV1.replicas`). The V2 mode uses an alternate form of scaling where a single REST server provides messages to one or more execution pods (`executor.replicas`). Horizontal pod autoscaling (HPA) is supported for both modes (`restV1.autoscaling.enabled`, `executor.autoscaling.enabled`).

The configuration settings of the Helm chart `values.yaml` file for the Runtime Server can be broken down into the following logical groups:

- REST settings (V1 or V2 API installation, image details, service account, custom environment variables, replica count)
- Probe settings (liveness, readiness)
- Map and Flow settings (map threads, file extension, etc.)
- Logging (log severity, log name uniqueness, log targets, etc.)
- Resource utilization (memory, CPU, storage, replica count)
- Redis configuration (host, port, password, etc.)
- Storage settings (storage class, capacity, dynamic vs. static binding, etc.)
- TLS configuration (certificates, keys, etc.)
- Cloud Object Storage settings

The following configuration settings are a subset of the total settings available to the ITX Runtime Server. For more information, see the installation's `values.yaml` and `README.md` files. The config section of the `values.yaml` file enables the ITX configuration settings in the `config.yaml` file to be overridden. Each `config.yaml` setting is referenced under the config section according to camel case convention, whereby the first letter of a named setting is lowercase while any remaining words in the name start with a capital letter.

Whenever changes are made to the below properties during a Helm upgrade, the pods that are associated with the existing installation will not automatically restart - unless the change affects the actual deployment manifest. For example, an update to the image name or resource metrics will change the deployment manifest of the installation, which in turn will trigger an automatic restart of the pods. However, a basic change to a property that is linked to the ITX `config.yaml` file, such as the logging level, will not trigger an automatic restart. The restart would need to take place manually, as provided by the Kubernetes scale command.

values.yaml property	Description
Licensing	
license	Switch with true/false values for accepting the terms and conditions of the license agreement. The default is false.
REST V1 - Map Executions via Version 1 of the REST API	
restV1.deploy	Deploy the REST V1-based service, which only supports map executions. The default is true.
restV1.replicas	Number of ITX Runtime Server replica pods to deploy and run. The default is 1.
restV1.runMode	Selection of mode (fenced/unfenced). In fenced mode the REST service process and the worker map execution process are separate processes, and in unfenced mode they run in the same process. The default is unfenced.
restV1.serviceAccount.existingName	Name of the ServiceAccount object to use for the installation. If left empty, the default service account is used.
restV1.extraEnvConfigMap	Name of an optional ConfigMap containing key/value pairs to set as environment variables when creating the pods.
restV1.nodeSelector	Name and value of the label of the worker nodes to which the pods must be deployed.
restV1.affinity	The node affinity and anti-affinity preferences when selecting a node for a pod.
REST V2 - Map and Flow Executions via Version 2 of the REST API	
rest.deploy	Deploy the REST V2-based service, which supports map and flow executions. The default is false.

values.yaml property	Description
executor.replicas	Number of ITX Runtime Server replica pods to deploy and run. The default is 1.
rest(existingName	Name of the ServiceAccount object to use for the installation. If left empty, the default service account is used.
rest.extraEnvConfigMap	Name of an optional ConfigMap containing keys/ value to set as environment variable names/values when creating the pods.
rest.nodeSelector	Name and value of the label of the worker nodes to which the pods must be deployed.
rest.affinity	The node affinity and anti-affinity preferences when selecting a node for a pod.
Image Settings	
rest.image.repository	Image registry and repository location.
rest.image.digest	Image digest value, which takes priority over image tag value.
rest.image.tag	Image tag value.
rest.image.pullPolicy	Image pull policy, one of Always, Never and IfNotPresent.
itxImagePullSecret	Name of the pull image Secret object with which to configure the ServiceAccount for pulling images.
Probes Settings	
restV1 rest executor.probes.liveness.enabled	Switch with true/false values to enable/disable liveness probe. The default is true.
restV1 rest executor.probes.liveness.initialDelaySeconds	Number of seconds to wait before making the initial liveness probe call. The default is 35.
restV1 rest executor.probes.liveness.periodSeconds	Number of seconds between liveness probe calls. The default is 20.
restV1 rest executor.probes.readiness.enabled	Switch with true/false values to enable/disable readiness probe. The default is true.
restV1 rest executor.probes.readiness.initialDelaySeconds	Number of seconds to wait before making the initial readiness probe call. The default is 35.
restV1 rest executor.probes.readiness.periodSeconds	Number of seconds between readiness probe calls. The default is 20.
Map and Flow Run Settings	
rest.map.fileExtension	File extension for compiled maps. The default is mmc.
config.rest.map.uploadTime	Time in minutes to keep loaded maps in memory. The default is 1.
config.rest.resources.mapThreads	Maximum number of threads to spawn for running maps concurrently. The default is 10.
config.rest.resources.flowThreads	Maximum number of threads to spawn for running flows concurrently. The default is 10.
restV1 rest.synchronousTimeout	Synchronous map and flow execution timeout in seconds. The default is 300.
config.runtime.runMaps.runMapMaxCacheNum	Controls run map caching in the Runtime Server. The default is -1, which disables run map caching.
config.rest.multipartbody.allAttachment	Switch to include/exclude all attachments in the multi-part body response. The default is false.
Logging	
config.rest.logging.level	Severity level for REST and map/flow execution logs (ALL,TRACE,INFO,ERROR,NONE). The default is ERROR.
config.rest.logging.rotation.fileAge	Number of days to keep logs. The default is 30.
config.rest.logging.rotation.fileCount	Number of log files. The default is 5.
config.rest.logging.rotation.fileSize	Size in bytes of each log file. The default is 20000.
config.runtime.trace	Switch with "stdout" and "" values to enable logging to Kubernetes versus files located in the /data folder. The default is "stdout".
config.runtime.jniLayerTrace.level	Severity level for the Java Native Interface (JNI) component (10=Critical, 20=Error, 30=Warning, 40=Info, 50=Verbose). The default is 20.
config.rest.logging.addWebServerConsoleLogging	A boolean-valued property which, when true, causes web server logs to be sent to the container stderr stream. The default is true.
Resource Registry	
config.rest.resourceRegistryFile	Full path, starting with /data, of the optional ITX resource registry file, if it was previously uploaded or mounted via a Kubernetes ConfigMap.
Redis Settings	
itxRedis.host	Redis host name. Must be a resolvable name on the current network. The default is redis-master.
itxRedis.port	Redis port number. The default is 6379.
itxRedis.password.secret	Name of the Secret object containing the Redis password, when accessing a password-enabled Redis service.
itxRedis.password.key	The key in the Secret object that contains the redis password.
itxRedis.tls	A mapping which contains keys related to client TLS configuration. Used when a Redis server requires TLS.
restV1.redisStem	Key prefix to use for Redis V1 keys produced and consumed by the server. The default is tx-rest-v1.
Resource Constraints	
restV1 rest executor.resources.requests.cpu	Requested number of CPU cores or millicores (using m suffix). The default is 250m.
restV1 rest executor.resources.requests.memory	Requested memory in bytes (with optional base-10 suffix like M or G, or base-2 suffix, like Mi or Gi. The default is 700mi.
restV1 rest executor.resources.limits.cpu	Upper limit number of CPU cores or millicores (using m suffix). The default is 4000m.
restV1 rest executor.resources.limits.memory	Upper limit for memory in bytes (with optional base-10 or base-2 suffix, like Gi for gigabytes). The default is 8Gi, except for the executor setting which is 4Gi.
Persistent Volumes	
rest.persistence.data logs.size	Capacity to request for data persistent volume. Base-10 suffixes like M and G, or base-2 suffixes like Mi and Gi can be used. The default is 20Gi for data and 100Mi for logs.
rest.persistence.data logs.accessMode	Access mode to specify for the data/logs persistent volume. It can be set to ReadWriteMany or ReadWriteOnce. The default is ReadWriteOnce.

values.yaml property	Description
rest.persistence.data logs.useDynamicProvisioning	Switch with true/false values to enable/disable dynamic provisioning for the data/logs persistent volume. The default is false.
rest.persistence.data logs.storageClassName	Name of the storage class supported by the cluster to use for dynamic provisioning the data/logs persistent volumes.
rest.persistence.data logs.enabled	Switch with true/false to enable/disable persistence. Consider setting it to true if COS is used with REST V1 synchronous, “unfenced” deployments. The default is false.
TLS Settings	
restV1 rest.inbound.https.enabled	Switch with true/false values to enable/disable use of HTTPS protocol on the ITX Runtime Server REST pods. The default is false.
restV1 rest.inbound.https.serviceServingCertificates	Switch with true/false values to enable/disable OpenShift service serving certificates for securing service traffic. The default is false.
restV1 rest.inbound.https.clientAuth	Switch with true/false values to enable/disable validation of certificates presented by the REST API callers (mutual authentication). The default is false.
restV1 rest.inbound.https.secret	Name of the Secret object containing CA certificate, Server certificate and Server private key, in PEM format.
Service Settings	
restV1 rest.service.type	Type of the network service to provision, one of ClusterIP, NodePort, LoadBalancer or ExternalName. Defaults to ClusterIP.
restV1 rest.service.port.http	Port to expose for the HTTP traffic, when SSL is not enabled. The default is 8080.
restV1 rest.service.port.https	Port to expose for the HTTPS traffic, when SSL is enabled. The default is 8443.
Cloud Object Storage (COS) Settings	
external.cos.enabled	Enables maps and flows to get downloaded from COS. The default is false.
external.cos.name	Name of ZIP object to download and unzip. The default is maps.zip.
external.cos.bucket	Name of bucket that contains the ZIP object.
external.cos.targetDir	Target directory that ZIP file gets extracted to. The default is /data/maps.
external.cos.platform	Set to s3 for S3-based platform or gcp for Google-based platform. The default is s3.
external.cos.s3.accessKey secretKey region endpoint	Credentials and location information for S3-based platform. The accessKey and secretKey are the keys of the secret, as specified under Secret Settings.
external.cos.gcp.cf	The key of the secret which contains the Credentials file, as specified under Secret Settings.
Secret Settings	
external.secrets[].name data	An array of secret names and keys, which are mounted under the /xdata/sec folder with a filename that uses the value of the data setting.
external.mq.secret	The secret that contains the MQ channel definition table, which is mounted by default under the /xdata/sec folder.
ConfigMap Settings	
external.configMaps[].name key path	An array of ConfigMap objects that get mounted by default under the /xdata/cfg folder.
Auto Scaling Settings	
restV1 executor.autoscaling.enabled	Switch with true/false values to enable/disable auto scaling of ITX Runtime Server pods. The default is false.
restV1 executor.autoscaling.maxReplicas	Maximum number of ITX Runtime Server pods to auto scale.
restV1 executor.autoscaling.minReplicas	Minimum number of ITX Runtime Server pods with which to start.
restV1 executor.autoscaling.cpu.averageUtilization	Threshold CPU utilization percentage to scale a new ITX Runtime Server pod.
restV1 executor.autoscaling.memory.averageUtilization	Threshold memory utilization percentage to scale a new ITX Runtime Server pod.
restV1 executor.autoscaling.custom.enabled	Switch with true/false values to enable/disable custom metrics. The default is false.
restV1 executor.autoscaling.custom.types[]	An array of custom metric type definitions, as defined by Kubernetes v2 API version.
restV1 executor.autoscaling.custom.behavior	Behavior policies for scaling up and scaling down the deployment, as defined by the Kubernetes v2 API version.

- [Redis Configuration](#)
- [SSL/TLS Configuration](#)

Redis Configuration

If you are planning to run ITX Runtime Server instances in fenced mode (which includes the V2 mode) or run maps asynchronously, you must install Redis prior to installing ITX Runtime Server.

A Redis server installation is not included and must be obtained separately. Ensure that the Redis server which you install comes from a reputable source that you trust. Redis server version 7.0.11 was validated with this version of ITX Runtime Server. This version or later is the recommended version to use. Older Redis server versions may not function as expected when combined with this product and may need to be upgraded before they can be used.

The installed Redis server must be accessible to all ITX Runtime Server pods, at the same host URL and port, which means it must be accessible to all worker nodes to which ITX Runtime Server pods are deployed.

If the selected Redis server installation requires a password for authentication, you must create a Kubernetes Secret object with the password to use for connecting to Redis. The name of the secret is given by `itxRedis.password.secret`. The key within the secret which contains the password is given by `itxRedis.password.key`. See the documentation of your Kubernetes platform for information on creating Secret objects and configuring secure cluster secret storage.

Communication with a Redis server which uses TLS is supported. Both mutual and non-mutual TLS are supported. TLS is enabled by setting `itxRedis.tls.enabled` to true. The configuration of the external Redis server determines if mutual authentication is required.

For non-mutual and mutual TLS, a Kubernetes ConfigMap must be used to provide the trust store that is used by the ITX Redis clients to authenticate the Redis server. The name of the ConfigMap is given by `itxRedis.tls.clientCaConfigMap`. The key within the ConfigMap which provides a PEM trust store is given by `itxRedis.tls.certCafilename`. See the documentation of your Kubernetes platform for information on creating ConfigMap objects.

For mutual TLS, a Kubernetes Secret must be used to provide a client certificate and private key. The name of the Secret is given by `itxRedis.tls.clientSecret`. The key which provides the client certificate PEM file is given by `itxRedis.tls.certFilename`. The key which provides the client private key PEM file is given by `itxRedis.tls.certKeyFilename`.

SSL/TLS Configuration

Two options are available for enabling SSL/TLS communication (HTTPS) with the ITX Runtime Server.

With either option, the Runtime Server can be configured to perform client authentication. This is enabled by setting `restV1.inbound.https.clientAuth` or `rest.inbound.https.clientAuth` to true for the V1 and V2 deployment modes, respectively. Client authentication is disabled by default.

- With the first option, a Kubernetes Secret object needs to be provided. This object contains the server certificate and the server certificate key for the Runtime Server. Both are in PEM format. If you wish to enable client authentication, then you also need to provide a CA certificate file, again in PEM format, that can be used to authenticate clients.

See the mappings `restV1.inbound.https` and `rest.inbound.https` for HTTPS TLS configuration. The keys that you use in the Secret object for certificate authority, server certificate and server key must be named `ca.crt`, `tls.crt`, and `tls.key` respectively.

You can define and manage the Secret object directly and deploy it to the namespace prior to installing ITX Runtime Server, or you can use a cert-manager tool in your cluster to generate the secret automatically and to manage the certificates and keys stored in the secret, including their expiry and rotation. The name of the secret needs to be provided when deploying ITX Runtime Server.

- With the second option, the built-in Service Serving Certificates feature of OpenShift is utilized to provide a server certificate, server private key, and a CA trust store. Use of the Service Serving Certificates feature is indicated by setting `restV1.inbound.https.serviceServingCertificates` or `rest.inbound.https.serviceServingCertificates` to true for the V1 and V2 deployment modes, respectively.

When the Runtime Server is deployed, a Secret object is created for a Service whose backend uses the Service Serving Certificates feature. For example, if the Service Serving Certificates feature is used for the V2 deployment option, a Secret is created for the Service which exposes the HTTPS port of the REST server for the V2 deployment option. Naming and use of this Secret is handled automatically.

A ConfigMap object is automatically created which contains a CA certificate for the Service Serving Certificates CA. The CA certificate of this ConfigMap is used when the ITX Runtime Server performs client authentication. In other words, use of the Service Serving Certificates feature together with client authentication implies that only clients who can be authenticated relative to the Service Serving Certificates CA will be able to access the Runtime Server over HTTPS.

For more information about the OpenShift Service Serving Certificates feature, see [OpenShift documentation](#).

In both the V1 and V2 modes, HTTP connections are enabled by default. To disable HTTP connections, set `restV1.inbound.http.enabled` or `rest.inbound.http.enabled` to false, respectively.

- [**Option 1 - Produce Secret with ca.crt, tls.crt and tls.key PEM values**](#)

Option 1 - Produce Secret with ca.crt, tls.crt and tls.key PEM values

If you have CA certificate, server certificate, and server key values in PEM format, you can create **Secret** object manually and deploy it to the namespace where you plan to install ITX Runtime Server. Note that if you choose to manually create **Secret** object, you assume responsibility for its lifecycle, including management of the key and certificate values they store, and restarting the pods to pick up any updates made to the Secret content.

The following is an example of a **Secret** object with the name `itx-rs-ssl-secret`. Before applying it, replace the three indicated base64 value placeholders with the base64 encoded PEM certificates and keys:

```
apiVersion: v1
kind: Secret
metadata:
  name: itx-rs-ssl-secret
  type: Opaque
data:
  ca.crt: "base64_ca_cert"
  tls.crt: "base64_server_cert"
  tls.key: "base64_server_key"
```

To base64 encode a PEM file and display the value in a single line for inclusion in this manifest, you can use the following command:

```
base64 --wrap=0 <file_name>
```

After applying the manifest, if you deployed it from the command line from a yaml file, you may want to delete the file after applying it, since it will contain the server certificate's private key.

In addition to providing a custom **Secret** object, you can also utilize a certificate management tool to automatically create and manage the Secret. For example, IBM Cloud® [Secrets Manager](#) could be used.

Storage

ITX Runtime Server requires two file system based persistent volumes for its default operation:

- data
- logs

The volumes may be provisioned dynamically during the product installation, or created and installed prior to installing the product, as supported by your cluster.

If you wish to use static volume binding and you wish to initialize the data volume with all the maps you want to make available to the ITX Runtime Server pods immediately upon the installation, note that you must organize the file directories in the volume as shown here:

/data/maps - directory for compiled maps

/data/catalog - directory for map catalog

/data/config - directory for configuration files

/data/extras - directory for any additional JARs and shared libraries

/data/tmp - directory for temporary files used by maps

- [Access Modes](#)
- [Cloud Object Storage](#)
- [Extra Content](#)
- [Backup](#)
- [Encryption](#)

Access Modes

Two access modes are supported:

- ReadWriteMany (RWX)
- ReadWriteOnce (RWO)

The default access mode is ReadWriteOnce.

Since all ITX Runtime Server pods are considered equal for handling client requests, they need to be able to process requests that reference the same maps, logs and other data artifacts in the shared data persistent volume. The storage class used for the **data** and **logs** persistent volume must support ReadWriteMany access mode and this mode must be selected in order for the data persistent volume claim to be satisfied and for the data storage to be successfully bound to all running pods.

In cases when all the pods are always deployed to the same worker node, such as the case with development environments, the ReadWriteOnce access mode may be selected, particularly if a storage class in the environment supports this mode and no other storage classes are available that support ReadWriteMany mode.

ITX Runtime Server has been tested with the following storage providers:

- Google Persistent Disk (RWO)
- Rook CephFS (RWO & RWX)
- NFS (RWO & RWX)

ITX Runtime Server supports the following storage provisioning options:

- Dynamic provisioning using a storageClass
- Pre-created PV's (Persistent Volumes)

Cloud Object Storage

ITX Runtime Server can download maps and flows from a Cloud Object Storage (COS) location. The Amazon S3 and GCP APIs are supported (see `external.cos.platform` in `values.yaml`). When deploying a REST V1 or V2-based installation, all the compiled maps and/or packaged flows can be zipped up in a file with a .zip extension and uploaded to COS for subsequent downloading and automatic setup by the REST V1 or REST V2 pods. The automatic download of both maps and flows is done before the REST pod even starts. The REST pod will only become available once all the maps and/or flows are ready to be executed, thereby avoiding any need for manual deployment and streamlining the overall startup process.

In the case of a REST V1-based deployment whereby maps are only invoked in a synchronous and unfenced configuration, the persistent volume requirement is optional. The REST V1 deployment must be configured for unfenced mode, which is the default. Otherwise, a fenced configuration would require incoming REST data to be stored on a shared persistent volume for subsequent processing by one of the executing pods. In the case of unfenced mode, however, each and every pod that is spun up for map execution runs independently of the others - since the maps are loaded in the ephemeral storage location of the running pod. As long as log files are sent to the Kubernetes log and map logs to the REST API invocation when needed, persistent volumes are no longer required and the REST V1-based deployment can be run in a cloud-native capacity that has no single point of failure and a higher degree of availability.

Extra Content

The extra folder is used to host any JAR files, Java classes, or shared libraries that are required for running the maps but that are not included with the product and you will be providing it separately. An example is JDBC and ODBC drivers to be utilized with JDBC and ODBC adapters. Since these components will be loading and executing in the ITX Runtime Server pods, it is critical that you ensure that they come from reputable sources that you trust, and that you validate them before enabling them for use with the ITX Runtime Server.

Backup

If you are using dynamically provisioned persistent volumes for data and logs, be aware that these volumes will be claimed when the ITX Runtime Server instance is installed, but will be recycled after the product has been uninstalled, since at that time the persistent volume claims created by the product when it was installed will be removed as well. For dynamically provisioned persistent volumes, the assumption is that the maps, flows, and associated artifacts will continue to be available in your source systems from which you originally uploaded or deployed them to the ITX Runtime Server environment.

For example, ITX Runtime Server operates on compiled maps (mmc files) which must have all originated from source maps on on-prem systems where they have been produced by compiling the map source definitions (.mms files) with tools like ITX Design Studio. The compiled maps are then uploaded to ITX Runtime Server. In order to be able to upload the maps again if that need arises, they need to continue to remain available at their origin. This is especially critical for the map definitions (.mms files) since they are required to be able to make updates in the future, and can always be compiled again to be uploaded to ITX Runtime Server. Backing up the original storage for those maps, especially the map sources (.mms files) is therefore of utmost importance, and is outside the scope of ITX Runtime Server deployment.

When using persistent volumes, you can choose to configure them with the Retain policy. The content of the persistent volume will then be preserved and can be subsequently retrieved - even after uninstalling ITX Runtime Server. The exact Kubernetes steps for accomplishing this task is documented under the **Storage** section in the README file of the Helm Chart Examples. After configuring the persistent volume with the Retain policy, the **existingClaim** setting in the values.yaml file can be used to identify the persistent volumes, thereby ensuring that deployment of maps and flows need not be repeated after re-installation.

If you need to back up any files in the persistent volumes that were produced by the maps or flows running under ITX Runtime Server, you must download those files individually using the provided data and logs GET APIs. Alternatively, you may choose to backup the persistent volume storage directly, if your cluster environment provides for direct access to the backing storage. Note that the data GET APIs work on subfolders as well, in which case the response will contain the names of all subfolders and files in that folder. This can be utilized to implement scripts which will recursively pull all the files in a given directory.

Encryption

ITX Runtime Server does not itself perform encryption and decryption of the data at rest. To ensure the data in your persistent volumes is encrypted at rest, when defining persistent volume claims for the ITX Runtime Server, you must specify a filesystem-based storage class that is available in your cluster and supports encryption. For some storage classes, the data may be encrypted automatically by their respective storage providers, but in some cases additional manual configuration may be necessary, such as definition and enablement of encryption keys. For more information, see documentation for the storage classes available in your environment.

In those cases where filesystem-based encryption is not available or only needed in select circumstances, the ITX cipher adapter may be used in maps, flows and configuration files to encrypt data that is stored to disk and decrypt the same data that is retrieved from disk. This capability is documented in the ITX Design Studio examples and online help. The data is encrypted with a highly secure symmetric AES-256 cipher. The key that is used for encryption and decryption can be stored as a secret in the cluster. By mounting the secret key via the external.secrets section of the values.yaml file, the data at rest on disk remains securely encrypted.

SecurityContextConstraints Requirements

ITX Runtime Server requires a SecurityContextConstraints resource to be applied to the namespace to which the instance will be deployed. To define and apply it, follow the instructions provided in the [support page](#).

Custom SecurityContextConstraints definition:

```
apiVersion: security.openshift.io/v1
kind: SecurityContextConstraints
metadata:
  annotations:
    kubernetes.io/description: "This policy allows a single, non-root user"
    name: ibm-itx-rs-scc
  allowHostDirVolumePlugin: false
  allowHostIPC: false
  allowHostNetwork: false
  allowHostPID: false
  allowHostPorts: false
  allowPrivilegedContainer: false
  allowPrivilegeEscalation: false
  allowedCapabilities: null
  allowedFlexVolumes: null
  allowedUnsafeSysctls: null
  defaultAddCapabilities: null
  defaultAllowPrivilegeEscalation: false
  forbiddenSysctls:
    - "*"
  fsGroup:
    type: MustRunAs
    ranges:
      - max: 65535
        min: 1
  readOnlyRootFilesystem: false
  requiredDropCapabilities:
    - ALL
  runAsUser:
    type: MustRunAsRange
    uidRangeMin: 1000
    uidRangeMax: 65535
  seccompProfiles:
    - docker/default
  selinuxContext:
    type: RunAsAny
  supplementalGroups:
    type: MustRunAs
```

```

ranges:
- max: 65535
  min: 1
volumes:
- configMap
- downwardAPI
- emptyDir
- persistentVolumeClaim
- projected
- secret
priority: 0

```

From the command line, save the YAML object to a file and run the following command to apply the file content to your namespace.

```
oc apply -f <file_name> -n <namespace_name>
```

ibm-itx-rs Container Image

- [ibm-itx-rs Image and Container](#)
The image is named ibm-itx-rs, where rs stands for Runtime Server. The ibm-itx-rs image can be used to create a container in a container runtime such as Docker or Podman. This is in contrast to the use of the image as the image for a container in a pod in a Kubernetes deployment of the Runtime Server.
- [Configuring a single-container deployment of ibm-itx-rs](#)
- [Example override file](#)
- [ibm-itx-rs REST API](#)
- [ibm-itx-rs Usage Example](#)
The following example demonstrates how to import the ibm-itx-rs image, how to create a running container and how to execute example map OneInOneOut.mmc. This example map takes the input string, converts it to uppercase string and returns that string.
- [ibm-itx-rs V2 Usage Example](#)
The following example demonstrates how to deploy a flow into the ibm-itx-rs container and then invoke it with input overrides. The example Timesheet flow is described further under the Flow section of the Examples Readme, which is located in the examples sub-directory of the ITX Runtime Server Helm chart. The Timesheet flow enables employee work hour information to be extracted from a list of employee timesheets.

ibm-itx-rs Image and Container

The image is named ibm-itx-rs, where rs stands for Runtime Server. The ibm-itx-rs image can be used to create a container in a container runtime such as Docker or Podman. This is in contrast to the use of the image as the image for a container in a pod in a Kubernetes deployment of the Runtime Server.

To design ITX maps to be used by this container, ITX Design Studio or ITX Design Server must be used. To design flows, ITX Design Server must be used.

For the V1 API, the compiled maps must be saved to a volume or a host directory which is bound to the /data/maps location in the container file system.

For the V2 API, packages must be created in Design Server. A package is deployed to an installation of the Runtime Server using the package deployment endpoint of the V2 API.

The image is comprised of the following main components:

- Red Hat Universal Base Image 9 (ubi9 minimal) operating system as the base image
- Tomcat 10 application server
- REST API service running under Tomcat
- ITX runtime for running maps
- IBM MQ Client

The directories which are the values of the rest.persistence mapping in config.yaml are created at runtime if they do not exist.

The following directories have special significance for the Runtime Server:

/data/maps

Contains compiled maps. By default, the maps must have .mmc file extension. If a map references a file relative to the map directory, that file must reside in the directory relative to this directory. Likewise, if a map creates a file without specifying a directory, that file will be created in the map directory. If a map runs other maps, those maps must reside in the same directory, and must be saved under the exact names, including file extension, under which they are referenced in the main map. To ensure that all instances of the container have access to the same maps when those instances are running on different hosts, this location must be accessible on all hosts, for example, it can be an NFS share.

/data/tmp

Contains temporary execution files.

/logs

Contains log files produced by the ITX runtime, Tomcat application server and REST API service deployed to Tomcat.

/data/catalog

Directory used for cataloged maps.

/data/config

Directory used for holding configuration files, for example, key store file for MQ purposes. The configuration of a single-container deployment can be customized with a file at /data/config/config.yaml.

/data/extr

Contains any additional shared libraries and JAR files to make available to the running container, such as for example JDBC driver JARs for use with JDBC adapter.

The above locations must be mounted to volumes, or host machine directories, when creating a container. Alternatively, a single volume or a local host directory that contains maps, tmp and extra sub-directories can be mounted to the /data location in the container and a single volume or host directory for logs that can be mounted to the /logs location in the container.

Configuring a single-container deployment of ibm-itx-rs

A deployment of the ITX Runtime Server as a single container is configured with a YAML file which provides overrides to the default Runtime Server configuration file. This file must be provided at /data/config/config.yaml. It is recommended to separately add this override file to the volume which is used for the /data directory in the container. This file must be readable by the Runtime Server user which is used inside of the container (UID 1001, itxuser). The directory /data/config should be writable by this user. This mechanism is not used with Helm installations of the Runtime Server.

The override file follows the format of the ITX product configuration file config.yaml. Only the properties for which overrides are desired need to be in the override file. Several configuration parameters which are specific to the Runtime Server may be placed in the override file. These are described below.

The environment variables which were used for configuration in previous releases are not supported with one exception. The environment variable **ITX_RS_LICENSE_ACCEPT** must be set with value true to accept the license and use the container image. For example, the Docker command line option **-e ITX_RS_LICENSE_ACCEPT=true** could be used.

The following config.yaml properties are only used with the Runtime Server:

config.yaml property	Description
Logging	
rest.logging.addWebServerConsoleLogging	A boolean property which, when true, causes the REST server to send logging information to the container stderr stream. The default value is false. This property is analogous to the formerly supported environment variables ITX_RS_LOG_SERVICE_LOG_STD_ERR and ITX_RS_LOG_EXEC_LOG_STD_ERR .
rest.logging.disableWebServerAccessLogging	A boolean property which, when true, disables the Runtime Server access log file. The default value is false (access log enabled). This property is analogous to the formerly supported environment variable ITX_RS_LOG_ACCESS_LOG_LEVEL .
rest.logging.useHostname	A boolean property which, when true, causes the hostname to be added to Runtime Server log files. The default value is false for the single-container deployment. This property is analogous to the formerly supported environment variable ITX_RS_LOG_INCLUDE_HOST_IN_LOG_NAME .
SSL/TLS	
rest.inbound.mutualTls	A boolean property which, when true, causes the Runtime Server to authenticate clients. A CA certificate file must be provided in this case. The default value is false. This property is analogous to the formerly supported environment variable ITX_RS_SSL_CLIENT_AUTH .
Redis TLS [valid for single-container deployments only when an external Redis server is used (redis.deploy is false)]	
redis.port	A value of 0 should be used when the external server uses TLS. The value must be non-zero when the external Redis server does not use TLS.
redis.tlsPort	The listening port for TLS connections of the external Redis server. The value must be zero if redis.port is non-zero. By default, TLS is not used.
redis.client.ssl.enabled	A boolean value which, when true, indicates that TLS should be used when connections are made to the Redis server. TLS parameters are ignored if this value is false. The default value is false.
redis.client.ssl.ca	The absolute path in the container of a PEM trust store file which is used to authenticate the Redis server. The default value is empty.
redis.client.ssl.cert	The absolute path in the container of a PEM certificate chain file which will be provided to the Redis server when it performs client authentication. The default value is empty.
redis.client.ssl.key	The absolute path in the container of a PEM private key file which will be used by the client when the Redis server performs client authentication. The default value is empty.
redis.client.ssl.sni	A hostname string which will be used by the client for the TLS SNI extension when the Redis server requires use of this extension. The default value is empty.

Other configuration is provided through the regular ITX configuration options.

For the Runtime Server, HTTP and HTTPS are enabled or disabled with the rest.inbound.ports mapping. A value of 0 disables the scheme. A non-zero value provides the listening port for the scheme. By default, HTTP uses port 8080, and HTTPS is disabled. The tomcat.inbound.ports mapping is not used.

TLS is enabled for the Runtime Server by providing a non-zero value for the rest.inbound.ports.https property as mentioned above. The server certificate is provided as a PEM file at /opt/server/ssl/cert.pem in the container. The server private key is provided as a PEM file at /opt/server/ssl/key.pem in the container. If mutual authentication is used by setting rest.inbound.mutualTls to true, then a CA trust store is provided as a PEM file at /opt/server/ssl/ca.pem in the container. These files must be readable by the Runtime Server user (UID 1001, itxuser).

Authentication is provided in a single-container deployment of the Runtime Server through mutual TLS. The property rest.inbound.authentication.enabled is false for the Runtime Server.

By default, a single-container deployment of the Runtime Server is unfenced (rest.mode). If fenced mode is used, a Redis server will be created within the container by default. An external Redis server is not needed in this case. The default directory in the container for the Redis server database file redis.rdb is /data/catalog.

If an external Redis server is used for a single-container deployment, then communication with the Redis server over TLS is supported. An external Redis server is used if redis.deploy is false. By default, as mentioned above, an internal Redis server is used. Redis TLS parameters are provided in the table above. By default, TLS is not used when an external Redis server is used. The files must be readable by the Runtime Server user. The parameter for the non-TLS port, redis.port, must be 0 when TLS is used. The TLS port of the Redis server is given by redis.tlsPort.

Logging is configured through the properties of the rest.logging mapping such as rest.logging.level and rest.logging.rotation.fileAge. Also, the rest.executor.trace property can be used to send flow executor logging to stdout or stderr instead of being sent to a file.

Example override file

The following YAML content is an example of the content of a YAML file which can be provided at /data/config/config.yaml in a single-container deployment to customize the Runtime Server. These overrides will enable fenced mode, set the logging level to INFO, send web server logs to stderr in addition to file logging, and enable HTTPS on port 8443. In this example, a server certificate and private key would be provided through file mounts in the container as described above.

```
rest:
  mode: "fenced"
  logging:
    level: "INFO"
    addWebServerConsoleLogging: true
  inbound:
    ports:
      https: 8443
```

ibm-itx-rs REST API

The ibm-itx-rs container exposes a Swagger UI web page which documents the supported APIs. This web page can be displayed by pointing your web browser to:

```
http://CONTAINER_HOSTNAME:8080/tx-rest/api-docs?url=/tx-rest/docs
```

Where **CONTAINER_HOSTNAME** is the IP address or hostname assigned to the running container. If the container is running under a cluster environment like Red Hat OpenShift, use ingress or route name of the ITX Runtime Server. Replace the default text v2/docs or v1/itx/docs in the search box with openapi.json and select the Explore button in the Swagger UI web page.

By default, all the deployed map and flow endpoints for V2 REST API are displayed in the Swagger UI web page. If the rest.defaultSwagger property is set to v1, then all cataloged map endpoints for V1 REST API are displayed in the Swagger UI page.

The following REST APIs are supported:

Version

```
GET http://CONTAINER_HOSTNAME:8080/tx-rest/v1/itx/version
```

Where **CONTAINER_HOSTNAME** is the IP address or hostname assigned to the running container.

The return value is JSON in the format:

```
{
  "version": "11.0.1.0",
  "name": "IBM Sterling Transformation Extender for Red Hat OpenShift",
  "up_time": "1 days, 4 hours, 18 minutes, 44 seconds",
  "date": "20240927",
  "revision": "0"
}
```

This API call can be used as a heartbeat mechanism for ensuring the container is up and running.

Configuration

```
GET http://CONTAINER_HOSTNAME:8080/tx-rest/v1/itx/configuration
```

Where **CONTAINER_HOSTNAME** is the IP address or hostname assigned to the running container.

The return value is JSON in the format:

```
{
  "map_dirs": [
    "/data/maps"
  ],
  "work_dir": "/data/tmp",
  "catalog_dir": "/data/catalog",
  "redis_host": "localhost",
  "redis_key_stem": "tx-rest",
  "is_fenced": true,
  "unload_time": 60000,
  "max_map_threads": 10,
  "exec_log_dir": "/logs"
}
```

Direct Map Invocation

```
PUT http://CONTAINER_HOSTNAME:8080/tx-rest/v1/itx/maps/direct/PATH
```

```
POST http://CONTAINER_HOSTNAME:8080/tx-rest/v1/itx/maps/direct/PATH
```

Where **CONTAINER_HOSTNAME** is the IP address or hostname or ingress/route name assigned to the running container and PATH is the path to the compiled map file, relative to the location corresponding to the maps mount point, and with the .mmc file extension omitted.

POST method runs the map asynchronously. Redis is required to be setup to run maps in this mode of execution to find the status of the map execution, fetching outputs, map trace and map audit from the Runtime Server. Environment variables for running map in fenced mode, Redis server host and port options listed in previous page must be passed when launching the Runtime Server container. Fenced mode ensures that an ITX failure does not affect the web server. Fenced mode is required to run a map asynchronously. In unfenced run mode, the servlet runs within the web server.

The following query parameters are supported:

- **input**

The input query parameter is used for overriding source data settings in input cards. Multiple input overrides can be specified by a comma-separated list, or by specifying multiple input parameters. Each value is either an input card number (if the card data is being provided in the request body), or an adapter specification in the form:

```
card-num;adapter-alias;adapter-command
```

For example, to specify that the data for card 2 should be from a file:

```
input=2;FILE;mydata.txt
```

- **output**

The output query parameter is used to specify which output cards should be returned. Multiple output overrides can be specified by a comma-separated list, or by specifying multiple output parameters. Each value is either an output card number (if the card data should be returned in the response body), or an adapter specification in the form:

```
card-num;adapter-alias;adapter-command
```

For example, to specify that the data for card 2 should be written to a file:

```
output=2;FILE;results.txt
```

- **return**

The return query parameter is used to specify the type of information to return about the executed map. Permitted values are **status**, **statusonerror**, **audit**, **auditonerror**, **trace**, and **traceonerror**. Multiple values can be specified, as a comma-separated list in a single return query parameter, or by using multiple return query parameters.

ibm-itx-rs Usage Example

The following example demonstrates how to import the ibm-itx-rs image, how to create a running container and how to execute example map OneInOneOut.mmc. This example map takes the input string, converts it to uppercase string and returns that string.

About this task

To import the ibm-itx-rs image, create a running container and execute example system, complete the following steps:

Procedure

1. Start by logging into the IBM Entitled Registry (cp.icr.io) to pull the ibm-itx-rs image:

```
docker login -u <username> -p <password> cp.icr.io
```

Note: Login credentials, username and password, are provided with the entitlement of the product. Internet access to download the image from the IBM Entitled Registry is a prerequisite for saving the image in the local docker registry or to the local image server.

- a. Pull the docker image by image tag or image digest from the IBM Entitled Registry:

```
docker image pull cp.icr.io/cp/ibm-itx-rs:11.0.1.0.20240927
```

```
docker image pull cp.icr.io/cp/ibm-itx-rs@sha256:9bc80dd8f0cb2db8a35f17f10a11b2eea9b21ec497b3ccae9729fce919475661
```

Note: Image tag and digest change when a refreshed container image is published to the IBM Entitled Registry. Replace proper image tag/digest accordingly in the commands listed in this document.

- b. If you have downloaded the docker image from the IBM Entitled Registry in a docker archive, for example, **ibm-itx-rs_11.0.1.0.20240927.tar.gz**, load the ibm-itx-rs docker image archive to the local docker registry:

```
docker load -i ./ibm-itx-rs_11.0.1.0.20240927.tar.gz
```

- c. List the images to ensure ibm-itx-rs image was imported:

```
docker images
```

The command returns the list of images, which includes image with the name ibm-itx-rs and the tag **11.0.1.0.20240927**.

Note: The **11.0.1.0.20240927** tag value is assigned to the ibm-itx-rs image. It represents the image version and you will use it later to start the container based on this image.

2. Create directories on the host to serve as bind mounts for the container (Docker managed volumes could be used instead of host managed directories as well). For example, as a test, to create them under /tmp on the host system:

```
mkdir -p /tmp/itx-rs/logs
```

```
mkdir -p /tmp/itx-rs/data/maps
```

```
mkdir -p /tmp/itx-rs/data/tmp
```

```
mkdir -p /tmp/itx-rs/data/extra
```

3. Optionally, you can also create a config directory. You can store config.yaml and other runtime configuration files in it if you wish to modify them from the defaults used by the container. To start with the default configuration files deployed with the image, you can perform the following steps to create a temporary container and extract the config directory from it to use it as the starting point:

```
docker create --name itx-rs-tmp ibm-itx-rs:11.0.1.0.20240927
```

```
docker cp itx-rs-tmp:/opt/runtime/config/tmp/
```

```
docker rm itx-rs-tmp
```

- a. You can then edit /tmp/config/config.yaml file and customize the settings in it. Refer to the documentation included in the configuration file for details about the individual settings. No customization is necessary to complete this example.

4. Save the compiled map OneInOneOut.mmc to /tmp/itx-rs/data/maps directory. This map is a simple transformation map that converts the provided string to uppercase. The string is provided in a request and passed to the input card. The result is collected from the output card and returned in the response:

```
cp ./OneInOneOut.lnx /tmp/itx-rs/data/maps
```

5. Run the container by invoking the following command (as one line):

```
docker run --name itx-rs -it -d -p 8080:8080 -v /tmp/config:/opt/runtime/config -v /tmp/itx-rs/data:/data -v /tmp/itx-rs/logs:/logs ibm-itx-rs:11.0.1.0.20240927
```

Note: The **-v /tmp/config:/opt/runtime/config** argument is optional and is needed only if you customized configuration files on the host and have made changes to them that you wish to be used by the runtime in the container.

Note: The **-p 8080:8080** argument is used to bind port 8080 on the local host to port 8080 in the container. This will allow you to submit REST calls via a **curl** command to localhost:8080, which in turn will be served by Tomcat running in the container.

a. Ensure that the itx-rs container is running:

```
docker ps
```

The command should return a list of running containers, which should include a container with name itx-rs.

6. Check that the container is serving traffic by obtaining the version:

```
curl -X GET "http://localhost:8080/tx-rest/v1/itx/version"
```

It returns a JSON document in this format:

```
{"version":"11.0.1.0","name":"IBM Sterling Transformation Extender for Red Hat OpenShift","up_time":"1 days, 4 hours, 34 minutes, 58 seconds","date":"20240927","revision":"0"}
```

7. Run the map synchronously by invoking the following command (as one line):

```
curl -X PUT -d "This is a test" "http://localhost:8080/tx-rest/v1/itx/maps/direct/OneInOneOut?input=1&output=1"
```

It returns the value:
THIS IS A TEST

Note: The map source file OneInOneOut.mms is also provided. If you open it in Design Studio or Design Server, you will observe that it has one input card of File type, reading from file in.txt, and one output card of File type, writing to file out.txt.

Note: In the previous invocation of the map, the input and output cards were overridden to use the request and response data of the REST API call. If you create file in.txt in the same maps directory as the OneInOneOut.mmc compiled map and invoke the map without specifying the overrides, the map will run and produce out.txt file in the same maps directory, with the same text as in.txt file, except it will be changed to uppercase:

```
echo "This is a file test" > /tmp/itx-rs/data/maps/in.txt
curl -X PUT -d "" "http://localhost:8080/tx-rest/v1/itx/maps/direct/OneInOneOut"
cat /tmp/itx-rs/data/maps/out.txt
```

It should display the value:

```
THIS IS A FILE TEST
```

Note: The locations of the files in the provided sample map are specified as relative file names only, which means that they must reside in the same directory as the compiled map. If you specify absolute locations of the files in the maps, note that those locations must be valid locations in the container file system. For example, if you specified **-v /tmp/itx-rs/data:/data** argument when you started the container as in this example, you can store a file somewhere under the /tmp/itx-rs/data directory, and you should refer to it in the maps as if it was under /data directory, since /tmp/itx-rs/data directory in the host file system is mapped to /data directory in the container file system.

8. To run the map asynchronously, the Runtime Server must run in fenced mode and be able to connect to the Redis server to get the execution status of a (long) running map, fetch the map output(s), map trace and audit. The Redis host and port number may have to be configured accordingly and specify the fenced mode when running the Runtime Server instance as following:

```
docker run --name itx-rs -it -d -p 8080:8080 -v /tmp/config:/opt/runtime/config -v /tmp/itx-rs/data:/data -v /tmp/itx-rs/logs:/logs ibm-itx-rs:11.0.1.0.20240927
```

a. Following command returns a JSON response with a link to check the map execution status.

```
curl -X POST -d "This is a test" "http://localhost:8080/tx-rest/v1/itx/maps/direct/OneInOneOut?input=1&output=1"
```

A sample snippet as following:

```
{"id":"5e8fabfc-4da5-4e22-9bff-27db13827f43",
"href":"http://localhost:8080/tx-rest/v1/itx/maps/direct/5e8fabfc-4da5-4e22-9bff-27db13827f43/status"}
```

b. A long running map execution status can then be fetched using the link provided in the JSON response.

```
curl -X GET "http://localhost:8080/tx-rest/v1/itx/maps/direct/5e8fabfc-4da5-4e22-9bff-27db13827f43/status"
```

The map execution status would look something like as shown below with the link(s) for map output(s).

```
{"status":0,"outputs":[{"href":"http://localhost:8080/tx-rest/v1/itx/maps/direct/9690ed3b-0804-4bda-a076-b336bd0cc733/outputs/1","card_number":1,"mime_type":"application/octet-stream"}],"start_timestamp":"2020-12-18T02:41:50.943+0000","elapsed_time":1,"status_message":"Map completed successfully"}
```

c. To fetch the map output from the Runtime Server, the output link in the map execution status JSON response must be utilized as following:

```
curl -X GET "http://localhost:8080/tx-rest/v1/itx/maps/direct/9690ed3b-0804-4bda-a076-b336bd0cc733/outputs/1"
```

It should return the value:

```
THIS IS A TEST
```

9. To perform cleanup, remove the image, container, and local host directories used as bind mounts, run the following commands:

```
docker stop itx-rs
```

```
docker rm itx-rs
docker rmi ibm-itx-rs:11.0.1.0.20240927
rm -rf /tmp/itx-rs
rm -rf /tmp/config
```

- [Cataloged Map Invocation](#)

Cataloging a map simplifies calls to the map and generates Swagger documentation that describes the APIs. The catalog provides a way to expose maps as services and to hide the implementation details of the services.

Cataloged Map Invocation

Cataloging a map simplifies calls to the map and generates Swagger documentation that describes the APIs. The catalog provides a way to expose maps as services and to hide the implementation details of the services.

A map is defined in the catalog as a JSON document, like the 1in1out map example that is defined as following:

```
{
  "name": "1in1out",
  "summary": "Single input & single output",
  "description": "Uppercases the output from a single input",
  "tags": [ "Test" ],
  "inputs": [
    {
      "card_number": 1,
      "mime_type": "text/plain",
      "description": "Plain text"
    }
  ],
  "outputs": [
    {
      "card_number": 1,
      "mime_type": "text/plain",
      "description": "Uppercased input"
    }
  ],
  "url_path": "test/lin1out",
  "map_path": "OneInOneOut"
}
```

The Swagger documentation for the Runtime Server defines the structure of the JSON document and explains the purpose of each element. You register a map in the catalog by posting the JSON document that defines it to the catalog directory. The following commands assume Runtime Server running on localhost (port 8080):

```
curl -X POST "http://localhost:8080/tx-rest/v1/itx/catalog" -H "Content-Type: application/json" -d @1in1out.json
```

Use Swagger to display map details and to test-run maps. To see the Swagger documentation for the catalogued maps, enter the following URL in a browser:

```
http://localhost:8080/tx-rest/api-docs?url=/tx-rest/v1/docs
```

By default, all the deployed map and flow endpoints for V2 REST API are shown in the Swagger web UI page, since the rest.defaultSwagger property defaults to v2. To see the catalogued map endpoints for V1 REST API, replace the text v2/docs in the search box with v1/itx/docs and select the Explore button in the Swagger web UI page.

You can run a catalogued map without specifying which cards to override or the name and path of the calling map. For example, the following command synchronously runs the catalogued version of the OneInOneOut map.

```
curl -X PUT -d "This is a test" "http://localhost:8080/tx-rest/v1/itx/maps/catalog/test/lin1out"
```

It should return the value:

```
THIS IS A TEST
```

ibm-itx-rs V2 Usage Example

The following example demonstrates how to deploy a flow into the ibm-itx-rs container and then invoke it with input overrides. The example Timesheet flow is described further under the Flow section of the Examples Readme, which is located in the examples sub-directory of the ITX Runtime Server Helm chart. The Timesheet flow enables employee work hour information to be extracted from a list of employee timesheets.

About this task

To load the ibm-itx-rs image, create a container, and execute the flow, complete the following steps:

Procedure

1. Load the ibm-itx-rs image into Podman.

```
podman load -i ibm-itx-rs_11.0.1.0.20240927.tar.gz
```

2. Configure the V2 Runtime REST API.

```
echo -e "rest:\n  mode: fenced" >/tmp/config.yaml
```

3. Install the ITX Runtime Server.

```
podman run --name itx-rs-v2 -it -d -p 8080:8080 -e ITX_RS_LICENSE_ACCEPT=true -v /tmp/config.yaml:/data/config/config.yaml  
ibm-itx-rs:11.0.1.0.20240927
```

4. Deploy the flow.

```
curl -X POST "http://localhost:8080/tx-rest/v2/packages" -H "accept: */*" -H "Content-Type: application/octet-stream" --  
data-binary @Timesheet_linux.sqlite
```

5. Run the flow.

```
curl -X PUT -F "1=@allemps1f.txt" -F "2=@employee1.txt" "http://localhost:8080/tx-rest/v2/run/WorkHours"  
curl -X PUT -F "1=@allemps1f.txt" -F "2=@employee2.txt" "http://localhost:8080/tx-rest/v2/run/WorkHours"
```

The first flow invocation returns 50 hours for employee1 while the second returns 90.45 hours for employee2.

Note: The sqlite package and input files are available in the ITX Runtime Server Helm chart under the examples\flow sub-directory. Once the container is stopped, no mapping and logging artifacts are retained because external mount points were not used in the example. If external mount points are used during the **Install**, the **Deploy** need not be run again. The ITX Design Server provides a graphical way to re-deploy changes and monitor flow executions.

Packs

General Notes:

- IBM Sterling Transformation Extender for Red Hat OpenShift must be installed and configured as above, with appropriate permissions provided to any users that will be deploying and executing maps from a Pack.
- The selected Pack (Healthcare, Supply Chain, Financial Payments, SAP) Version for IBM Sterling Transformation Extender for Red Hat OpenShift must be installed on a Windows machine with the existing Transformation Extender Design Studio installed for use of V1 API. For use of V2 API, the specific Pack project to be used should be imported into Design Server.
- As the container is UNIX based, any files transferred as input to a pack map that has Windows-based, line endings (for example, CR/LF) should be converted to UNIX base line endings (LF) before, or during file transfer. Similarly, any paths within maps that are part of the Pack, or that you implement with components of a path, need to use the UNIX expected slash (/) instead of backslash (\) in paths to data files in input or output cards.
- All executable maps must be built for the Linux platform. Design Studio should be used with the container V1-based map executions. The compiled map extension in the container config.yaml is set to .mmc. Using Design Studio to build maps for the Linux target platform gives the map extension .lnx. (see the individual pack tips for details).
- There are several options to synchronize the map extension. Select one of the options below:
 - Modify the container config.yaml and change the setting file Extension mmc to lnx to match the extension with Design Studio compile. The new config.yaml would need to be copied to the <rs_mount> location under /config folder.
 - Modify preferences in Design Studio and select Transformation Extender > Compiled Map Extensions (Linux change to .mmc).
 - Modify preferences in Design Studio and select Transformation Extender > Map > Build Options. Selecting Windows and Linux will build the map for both Windows and Linux (without identifying target platform) and give the file extension .mmc

Docker Tips:

- To restart the container:

```
docker restart itx-rs
```

- Out of space conditions can show unusual errors (for example, java errors and dumps). Try cleaning up the system using the following commands:
 - To clean up unused local volumes, run the command: **docker volume prune**
 - To clean up unused images, run the command: **docker image prune**
 - To clean up stopped containers, run the command: **docker container prune**
 - To clean up all unused containers, networks, images (both dangling and unused), and optionally images, run the command: **docker system prune**

Healthcare

- [HIPAA Compliance Check or HIPAA Data Compliance](#)

To run HIPAA Compliance check or HIPAA Data Compliance, perform the following steps:

- [HL7 Compliance Check](#)
- [Other Healthcare Components](#)

HIPAA Compliance Check or HIPAA Data Compliance

To run HIPAA Compliance check or HIPAA Data Compliance, perform the following steps:

- [Setup for Design Studio V1-based map executions](#)
- [Setup for Design Studio V2-based map executions](#)

Setup for Design Studio V1-based map executions

Procedure

1. Open map compliance_check.mms or hipaa_data_compliance under hipaa/maps.
2. Build all maps for specific platform Linux. All maps will be created with a .lnx extension.
3. With the exception of the compliance_check.lnx or hipaa_data_compliance.lnx, rename all other maps from .lnx to .mmc.
4. Under the container /tmp/itx-rs/data/maps directory, create a directory structure, and copy compiled maps to /maps directory and data files (with UNIX based line endings):

```
/tmp/itx-rs/data/maps/hipaa
/tmp/itx-rs/data/maps/hipaa/maps
/tmp/itx-rs/data/maps/hipaa/data
```
5. Additional steps needed for running Type 5 validation in hipaa data compliance include updates and references to the resource registry files found in hipaa/examples/code_sets.
 - a. Ensure that the host value in the hipaa_code_set.mrn file points to a MongoDB server that is accessible from the container, and that server includes the hipaa_code_sets database with external code set collections/values that are to be validated (these can be loaded with the maps in hipaa/examples/code_sets).
 - b. Copy both files to an accessible directory, such as /tmp/itx-rs/data/maps/code_sets.
 - c. Add the .mrc file to the config.yaml, similar to the following:

```
rest:
  inbound:
    ports:
      http: 8080
      https: 8443
  mode:
    fenced
  resourceRegistryFile: "/data/maps/code_sets/hipaa_code_set.mrc"
```

6. To execute compliance_check through command line:

- a. With the default input files:

```
curl -X PUT -d "" "http://localhost:8080/tx-rest/v1/itx/maps/direct/ hipaa.maps.compliance_check"
```

- b. To override input card 2:

```
curl -X PUT -d "" "http://localhost:8080/tx-rest/v1/itx/maps/direct/ hipaa.maps.compliance_check?
input=2;FILE;../data/inputfile.dat"
```

7. To execute compliance_check using Swagger UI:

- a. In the path field, enter the path: .hipaa.maps.compliance_check
- b. In the input field, specify the input data for card 2 from the file: input=2;FILE;../data/all_hippa_5010_transaction
- c. In the return field, specify audit

Note:

If you need to apply configurable rules to the HIPAA compliance process, be aware that this step can only be done on Windows prior to building the compliance_check maps, and the configurable_rules map does not need to be ported.

Setup for Design Studio V2-based map executions

Procedure

1. Import hipaaCompliance or hipaaDataCompliance.zip
2. Create a package that includes all the run maps, but only need to define an endpoint for the main map: Compliance_check or hipaa_data_compliance
3. In addition to the specific parameters you wish to run with, the compliance_check_5010_parameter.dat or hipaa_data_compliance_parameter.json must include a path for the **Base_Map_Directory**=“..//maps” (dat) or “**BaseMapDirectory**”: “..//maps/” (json)
4. Build and deploy the package to the container.
5. Use the v2/run API to run the map from the endpoint defined through Swagger or Curl command.

HL7 Compliance Check

About this task

To run HL7 Compliance check, perform the following steps:

Procedure

1. Edit file compilemaps.bat under hl7/maps. Replace **.mmc** in the **%MCOMPILER%** lines with .lnx -P LINUX. Make sure the variable “**%DTX_HOME%**” is pointing to the TransformationExtender_11.0.1 directory.
2. Run the compilemaps.bat. Verify .lnx files were created in the hl7/maps directory.
3. Using Design Studio, open maps ncpdp_script_to_hl7.mms and hl7_to_ncpdp_script.mms in the \hl7\examples\hl7_ncpdp_script subdirectory and build all for Linux platform.
4. Under the container /tmp/itx-rs/data/maps directory, create directory structure, and copy compiled maps, schemas and data files to /hl7/maps, /hl7/hl7schemas and /hl7/data subdirectories (with UNIX based line endings).
5. To execute HL7 Compliance, the hl7main map through command line:

```
curl -X PUT -d "" "http://localhost:8080/tx-rest/v1/itx/maps/direct/hl7.maps.hl7main"
```

- a. To override input card 1:

```
curl -X PUT -d "" "http://localhost:8080/tx-rest/v1/itx/maps/direct/hl7.maps.hl7main?
input=1;FILE;../data/sample_hl7_edi_v2_7_adt_a01.dat"
```

Other Healthcare Components

The HIPAA, HL7 and NCPDP passthrough, conversion maps included in the Pack for Healthcare can be run similarly, by building for Linux and making sure any appropriate directory structure is set up under the container maps directory.

If running NCPDP Validation map, the ncpdp_jexit.jar file must be copied from the ncpdp/jars folder to the /data/extra directory.

Supply Chain EDI

- [EDI Compliance check](#)
- [Setup for Design Studio V1-based map executions](#)
Design Studio should be used with the container V1-based map executions. The compiled map extension in the container config.yaml is set to .mmc. Using Design Studio to build maps for the Linux target platform gives the map extension .lnx. The map extension between the config.yaml and the map Design Studio compiled must correspond.
- [Setup for Design Server V2-based flow executions](#)
- [Supply Chain Examples](#)

EDI Compliance check

The main execution maps for the EDI Compliance Checking follow similar naming conventions. For example, component EDIFACT main execution map name is ccdef and with component X12 the main execution map is cx12. By design, Supply Chain compliance checking includes configurations for additional validations, acknowledgments, runtime features, default input and output destinations. The output destinations can be structured for file and card outputs with paths identified in xml or json configuration files requiring the output structure to be defined for the container.

The compiled maps along with input and output folder structures must be saved to the volume, or a host directory, bound to the /data/maps location in the container file system. Configuration files are located (relative to the map location) with the default output file location for the file system defined.

Setup for Design Studio V1-based map executions

Design Studio should be used with the container V1-based map executions. The compiled map extension in the container config.yaml is set to .mmc. Using Design Studio to build maps for the Linux target platform gives the map extension .lnx. The map extension between the config.yaml and the map Design Studio compiled must correspond.

Before you begin

- Build the following maps in Design Studio on Windows, with Linux selected as the target platform, in the <DTXHOME>\packs\supplychain_edi_v10.2.3\x12\compliance\mapsandschemas folder: ccx12, x12segment, x12tval.
- The configuration file is identified on input card three, ConfigInfo, for the main execution map for each pack component. Each pack component uses the default configuration (*defaultconfig.xml or *defaultconfig.json.dat). The x12u and tt-x12 components use the *defaultconfig.json.dat file. With container mount location /tmp/itx-rs/data, the x12defaultconfig.xml file location:

```
/tmp/itx-rs/data/maps/x12/compliance/data/x12defaultconfig.xml
<FileOutput>
    <FileDirectory>.../data/output</FileDirectory>
</FileOutput>
```
- Create the compliance folder structure like the one in Windows. Either copy the entire x12, edifact, or rail folder from the Design Studio pack install (step a.) or create and copy folders and files individually (steps b and c).

Procedure

1. Copy the entire x12 folder to the <rs_mount> location under /maps for example:

```
<rs_mount> = /tmp/itx-rs/data
cp -R x12 /tmp/itx-rs/data/maps
```

Note: Make sure the folders have Write permission. If not, use **chmod +777** to change the permission.
2. Create folders individually <rs_mount> = /tmp/itx-rs/data:

```
mkdir -p /tmp/itx-rs/data/maps/x12/compliance/data/output/x12/reject
mkdir -p /tmp/itx-rs/data/maps/x12/compliance/data/output/fa/inbound
mkdir -p /tmp/itx-rs/data/maps/x12/compliance/data/output/fa/outbound
mkdir -p /tmp/itx-rs/data/maps/x12/compliance/data/output/ta1/inbound
mkdir -p /tmp/itx-rs/data/maps/x12/compliance/data/output/ta1/outbound
mkdir -p /tmp/itx-rs/data/maps/x12/compliance/mapsandschemas
```

Note: Make sure the folders have Write permission. If not, use **chmod +777** to change the permission.
3. Copy files from the Windows mapsandschemas to the Linux mapsandschemas folder:
 - a. Copy all the compiled maps from the Windows mapsandschemas to the Linux mapsandschemas folder.

- b. Copy all the xsd files to the Linux mapsandschemas folder.
 - c. Transfer edicc file to the Linux mapsandschemas folder to ensure CR/LF end of line character is converted to NL character of the target system.
 - d. Copy the files that begin with x12 to the data folder.
 - e. Copy the files that end with xml to the data folder.
-

Setup for Design Server V2-based flow executions

Design Server packages are used to deploy to the V2 based flow executions and are defined using the maps and files in a project. When the package is deployed or compiled, it is saved to the volume, or a host directory, bound to the /data/catalog location in the container file system.

The following information is related to the Design Server project x12Compliance.zip. The main execution map is ccx12. Modify the ccx12 map and input card three, ConfigInfo, to use the x12rsconfig.xml file or the x12fullconfig.xml file. The x12fullconfig.xml file contains additional configuration settings for the compliance checking process. The *config.xml file selected will need to be downloaded, modified, and replaced in the Design Server project. The FileDirectory needs to be updated to follow the container mount location.

```
<FileOutput>
<!-- This section will send output to files. Reference file x12rsconfig.sh -->
  <FileDirectory>/data/data/x12Compliance</FileDirectory>
</FileOutput>
```

The FileDirectory defined in the x12 configuration file should point to the container file system and mount location.

With container mount location /tmp/itx-rs/data and package name x12Compliance.

```
<FileOutput>
  <!-- This section will send output to files. Reference file x12rsconfig.sh -->
    <FileDirectory>/data/x12Compliance</FileDirectory>
</FileOutput>
```

The compliance check output folder structure must also be defined for the container file system and mount location /data.

A script file is located in the x12Compliance project, relative to the map location. The script contains example commands to create the output file structure for the container package deployment to the rest container depending on the server definition in Design Server for deployment.

With container mount location /tmp/itx-rs/data.

```
/tmp/itx-rs/data/maps/x12Compliance/compliance/data/x12rsconfig.sh
```

```
mkdir -p /tmp/itx-rs/data/x12Compliance/x12/reject
```

```
mkdir -p /tmp/itx-rs/data/x12Compliance/fa/inbound
```

```
mkdir -p /tmp/itx-rs/data/x12Compliance/fa/outbound
```

```
mkdir -p /tmp/itx-rs/data/x12Compliance/ta1/inbound
```

```
mkdir -p /tmp/itx-rs/data/x12Compliance/ta1/outbound
```

As an alternative to using the predefined output structure, you can remove the <FileOutput> component from the *config.xml file. This will cause compliance checking to default to card output. Using card output requires that each output card of interest be identified with the map execution. The example below would override output card 5 in the ccx12 map for valid data and card 9 for the x12 acknowledgement.

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/ccx12?output=5;FILE;/data/x12compliance/x12ValidData.out,
output=9;FILE;/data/x12compliance/x12Ack.out"
```

After deploying the package and modifications, restart the container.

- [Compliance Check Execution](#)

Compliance Check Execution

Procedure

1. Test the map with valid data by issuing this command:

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/ccx12"
```

If you get a message Map completed successfully, go to /tmp/itx-rs/data/x12Compliance/x12 and locate a file that ends with .in extension. If not, check the map folders to make sure they are created in the correct location.

2. Test the map with invalid data by issuing this command:

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/ccx12?input=1;FILE;../data/x12_invalid.txt"
```

If you get a message Map completed successfully, go to /tmp/itx-rs/data/x12Compliance/x12/reject folder and locate a file that ends with .log.

3. If you see the following message in the container JSON response, there could be issues with the output file structure.

```
"message": "FAIL function aborted map: Map terminated due to map framework problem"
```

With this situation, the compliance check maps will generate a map framework trace in the mapsandschemas folder. With V2 execution, this is found within the container and will need to be retrieved. One way is to use the docker cp command.

- a. Find the link in the container JSON response. For example, "Settings": "/tmp/6c64-f72a-1350-b233/compliance/mapsandschemas/
- b. Create a folder to copy the files from the container. For example, /home/x12Results
- c. Issue the docker copy command:

```
docker cp itx-rs:/tmp/6c64-f72a-1350-b233 x12Results
```

d. Navigate to the /home/x12Results/6c64-f72a-1350-b233 and the mapsandschemas folder.
e. Open the edilog.xml and search on sendoutput to verify output locations. With the example below the output folder structure /data/x12u/ta1/output is not defined.

```
<SendOutput>
<Send>
    <Command>/data/x12u/ta1/outbound/20240918-192651_ta1.out</Command>
    <Execute>FILE adapter called to process output type TA1OUT - Result: E9000 The TX File adapter was unable to
locate the target output directory structure. Ensure that the configuration input has the correct location and that
directory exists.
    ** SEND FAILURE ** </Execute>
    <FrameworkErrorOccurred>Send output to file failed</FrameworkErrorOccurred>
</Send>
</SendOutput>
```

4. If you see the following message, that means there is something wrong with the edisvu shared library location.
Return code/text: -99999/Adapter not found structure failed. DLL path: ./ Check the edicc.ini file to make sure that it correctly specifies the edisvu shared library
 - a. Make sure the edicc.ini is transferred in ASCII mode. The removal of extra carriage-return when transferring the file is required.
 5. Finally, if you are still experiencing problems, try to restart the container by issuing the command:

```
docker restart itx-rs
```

Supply Chain Examples

Design Server projects are also available for examples. The outputs for most of the examples do not follow any output file structure and can be easily identified with the output override in the curl command.

Exception: edifactExampleBlockChain.zip which contains an output file structure. The project contains two maps that can be executed to retrieve the final output results.

When creating the package for the edifactExampleBlockChain project, select aViewOrderChain, aBuyerNewOrder, and aViewOrderChainInfo and identify the URL for each map. The main execution map is aBuyerNewOrder. The aViewOrderChain map will return the complete order chain and the aViewOrderChainInfo will return a summary of execution.

Example commands:

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/aBuyerNewOrder"
curl -X PUT "http://localhost:8080/tx-rest/v2/run/aViewOrderChain?output=1;FILE;/data/edifactblockchain/orderchain.out"
```

Flow Example: x12isxTransform.zip which contains 2 Flows, x12ToJsonFlow and xmlToX12Flow. The project contains both flows. The example is designed to execute out of the box using the Flow Designer. With container execution, modifications to the flow output terminals will be needed.

The x12ToJsonFlow contains 2 possible output terminals depending on the Flow variable setting in the decision node of the flow. Terminal 2 generates xml output. The decision node of the flow uses the flow variable convToJson to generate either json output with output terminal 1 or xml output with output terminal 2. Using Design Server and creating the package, select all maps and files and clear URL. Add the URL to maps x12toxml and xmlo tox12. Under the Flow, select x12ToJsonFlow with URL and under default Flow, select mapsandschemas/x12ToJsonFlow. Under files, select all files. Deploy the package to the container and restart the container.

Example command:

```
curl -X PUT "http://172.17.0.1:8090/tx-rest/v2/run/x12ToJsonFlow"
```

Results:

```
{"status": -73, "run_details": {"host": "172.17.0.1", "port": 8090}, "platform": "Linux", "product_version": "11.0.1.0(54)", "name": "x12ToJsonFlow", "id": "66ed7ecb2afbfcc634c7e072a", "timestamp": "2024-09-20T14:08:11.588Z", "elapsed_time": 12, "code": -74, "status": "Flow instance Executed", "message": "Commit output flow terminal failed Terminal=2"}
```

Using Flow Designer, modify the action property setting for output terminal xmloput from create to create unless empty. The same modification is needed for the output terminal jsonOutput. Next, open the flow variables under settings and use the Discover button. Set the flow variable convToJson value to Y. Save the flow, analyze, and run.

Re-deploy the package for the x12ToJsonFlow and re-execute the curl command. Execution should be successful but we need to override the output to be written to the container mount location /tmp/itx-rs/data.

Example command:

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/x12ToJsonFlow?output=1;FILE;/data/x12ToJson.out"
```

To execute the x12ToJsonFlow to get XML output, you can issue the following command which sets the flow variable to the value N.

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/x12ToJsonFlow?convToJson=N&output=2;FILE;/data/x12ToXml.out"
```

The xmlToX12Flow contains 1 output terminal. Create a package for this flow, selecting the xmlToX12Flow similar to the X12ToJsonFlow. Deploy the package to the container. Override output 1 similar to the X12ToJsonFlow, using a similar execution command.

SAP Applications

- [Install and run SAP maps](#)
- [Run SAP example maps using endpoint for V1 REST API](#)

- [Run SAP example maps using endpoint for V2 REST API](#)

Install and run SAP maps

About this task

Perform the following steps to install and run SAP maps:

Procedure

1. On Windows machine with Design Studio installed, install IBM Sterling Transformation Extender Pack for SAP Applications V10.2.0.1 for Certified Containers (itxsap_10201_1101_rs.exe).
2. On Linux machine with container installed, ensure you have directories like:
/tmp/itx-rs/logs
/tmp/itx-rs/data/extra
/tmp/itx-rs/data/maps
/tmp/itx-rs/data/tmp
/tmp/itx-rs/data/mqdata
3. Copy file C:\Program Files\IBM\TransformationExtender_11.0.1\sap_pack_libs.tar from Windows to Linux. On Linux, extract contents into /tmp/itx-rs/data/extra directory.
4. Obtain the following user provided libraries from SAP JCo 3.1.10 or later:
libsapjco3.so
sapjco3.jar
5. Copy these files to /tmp/itx-rs/data/extra and ensure they have execute permissions.
/tmp/itx-rs/data/extra should now contain:
.sapjco3.jar
.m4r3ale.jar
.dssap.jar
.m4r3bapi.jar
.libsapjco3.so
.p4saphana.jar

Run SAP example maps using endpoint for V1 REST API

About this task

Perform the following steps to run the SAP example maps:

Procedure

1. For SAP examples installed to C:\ProgramData\IBM\TransformationExtender_11.0.1\examples\sap, edit the maps in Design Studio to use JALE and JBAPI command lines specific to your SAP installation.
2. Build all maps for Linux and copy maps\input files to Linux under /tmp/itx-rs/data/maps/sap.
3. Special notes for executing these example maps on Linux:
 - a. For any text input files (like legacy.txt), you must run **dos2unix** on the file to convert it to Unix line endings.
 - b. Note that the BAPI example's xSingleStyle map calls xBapiInput.mmc by name, so even on Linux, the compiled map needs to have an .mmc extension. Rename xBapiInput.lnx to xBapiInput.mmc.
 - c. The PEPPOL example maps use input and output files including a path name and a backslash as a path separator. These need to be updated with a Linux path separator, and remove any spaces. That is, change input\PEPPOL Invoice example1.xml to input/example1.xml and rename the file itself before copying it to Linux.
 - d. The S4HANA_REST example has an absolute path in the output card's GET call to the configuration file SAP_HANA_REST.json. This path needs to be updated to a Linux path such as /tmp/itx-rs/data/maps/sap/S4HANA_REST/SAP_HANA_REST.json
4. You should then have the following files under /tmp/itx-rs/data/maps:
.JBAPI/xSingleStyle.lnx
.JBAPI/xBapiInput.mmc
.DXOB/LegacyToDXO050.lnx
.DXOB/legacy.txt
.DXOB/leg_dxob.txt
.PEPPOL/from_ubl_invoice.lnx
.PEPPOL/input/example1.xml
.PEPPOL/input/SAPInvoice_mod.dat
.PEPPOL/to_ubl_invoice.lnx
.JALE/JALEOutboundToLegacy.lnx
.JALE/LegacyToInboundJALE.lnx

```

./JALE/legacy.txt
./EDI/invoice02_to_810/InvoicePackets.lnx
./EDI/invoice02_to_810/SAPIInvoice_mod.dat
./EDI/invoice02_to_810/validate_output.lnx
./EDI/850_to_orders05/x12_po.txt
./EDI/850_to_orders05/850_to_Orders.lnx
./S4HANA_REST/GetS4HANA.lnx
./S4HANA_REST/PostToS4HANA.lnx
./S4HANA_REST/ProcOrdConf2_postdata.txt
./S4HANA_REST/SAP_HANA_REST.json

```

5. You can then execute the maps with the following commands:

```

curl -X PUT -d "Testing" http://localhost:8080/tx-rest/v1/itx/maps/direct/sap/DXOB/LegacyToDX0050
curl -X PUT -d "Testing" http://localhost:8080/tx-rest/v1/itx/maps/direct/sap/JALE/LegacyToInboundJALE
curl -X PUT -d "Testing" http://localhost:8080/tx-rest/v1/itx/maps/direct/sap/JALE/JALEOutboundToLegacy
curl -X PUT -d "Testing" http://localhost:8080/tx-rest/v1/itx/maps/direct/sap/JBAPI/xSingleStyle
curl -X PUT -d "Testing" http://localhost:8080/tx-rest/v1/itx/maps/direct/sap/EDI/850_to_orders05/850_to_Orders
curl -X PUT -d "Testing" http://localhost:8080/tx-rest/v1/itx/maps/direct/sap/EDI/invoice02_to_810/InvoicePackets
curl -X PUT -d "Testing" http://localhost:8080/tx-rest/v1/itx/maps/direct/sap/PEPPOL/to_ubl_invoice
curl -X PUT -d "Testing" http://localhost:8080/tx-rest/v1/itx/maps/direct/sap/PEPPOL/from_ubl_invoice
curl -X PUT -d "Testing" http://localhost:8080/tx-rest/v1/itx/maps/direct/sap/S4HANA_REST/GetS4HANA
curl -X PUT -d "Testing" http://localhost:8080/tx-rest/v1/itx/maps/direct/sap/S4HANA_REST/PostToS4HANA

```

Run SAP example maps using endpoint for V2 REST API

Prerequisites

1. Import the example .zip projects on <WINDOWS_pack_install_dir>/examples/sap/SAP_pack_examples_windows.zip into Design Server.
2. Create a package for the project including all maps and files.
3. Deploy package into ITX-RS server instance.
4. Set config.yaml property rest.mode to fenced.

Below are examples of REST calls using `curl` commands to execute Pack for SAP example maps:

- **JALE Inbound example**

```
curl -X 'PUT' 'http://localhost:8080/tx-rest/v2/run/LegacyToInboundJALE?
input=1;FILE;legacy.txt&return=log&audit_file=always' -H 'accept: */*'
```

- **JALE Outbound example**

```
curl -X 'PUT' 'http://localhost:8080/tx-rest/v2/run/JALEOutboundToLegacy?input=1%3BJALE%3B-a%20<program_id>%20-g%20<gateway_host>%20-x%20<gateway_port>%20-tv%20-ar3&return=log&audit_file=always' -H 'accept: */*'
```

- **JBAPI**

Note: You must edit the GET rule with adapter command line prior to exporting.

```
curl -X 'PUT' 'http://localhost:8080/tx-rest/v2/run/xSingleStyle?return=log&audit_file=always' -H 'accept: */*'
```

- **DXOB example**

```
curl -X 'PUT' 'http://localhost:8080/tx-rest/v2/run/LegacyToDX0050?return=log&audit_file=always' -H 'accept: */*'
```

- **EDI examples**

```
curl -X 'PUT' 'http://localhost:8080/tx-rest/v2/run/850_to_Orders?return=log&audit_file=always' -H 'accept: */*'
```

```
curl -X 'PUT' 'http://localhost:8080/tx-rest/v2/run/InvoicePackets?return=log&audit_file=always' -H 'accept: */*'
```

```
curl -X 'PUT' 'http://localhost:8080/tx-rest/v2/run/validate_output?return=log&audit_file=always' -H 'accept: */*'
```

Pack for Financial Payments (FINPAY)

- [Prerequisites](#)
- [Configuring SWIFT MT JVC](#)
- [Building maps for Linux](#)

- [Porting artifacts to UNIX host](#)
 - [Example map execution on ITX-RS using endpoint for V1 REST API](#)
 - [Overrides on input, output cards due to backward slashes](#)
 - [Example map execution on ITX-RS using endpoint for V2 REST API](#)
 - [Not available for execution on ITX-RS](#)
-

Prerequisites

Procedure

1. Install the finpay_n.n.n.n_v1101_4c.zip on Windows.

Example:

```
<bind_mount_dir>/maps/finpay
where <bind_mount_dir> = /tmp/itx-rs/data
```

2. Define the similar directories and subdirectories under <bind_mount_dir>/maps/finpay as defined under the following:

```
<WINDOWS_pack_install_dir>/financial_payments_vn.n.n.n/fix
<WINDOWS_pack_install_dir>/financial_payments_vn.n.n.n/nacha
<WINDOWS_pack_install_dir>/financial_payments_vn.n.n.n/sepa
<WINDOWS_pack_install_dir>/financial_payments_vn.n.n.n/swift
```

Where n represents the current version of the Pack for Financial Payments.

Note:

- No need to define a directory for type trees.
- <bind_mount_dir> refers to directory specified in volume (-v) option on the docker run command, that is,

```
docker run --name itx-rs -it -d -p 8080:8080 -v /tmp/itx-rs/data:/data -v /tmp/itx-rs/ logs:/logs ibm-itx-rs:11.0.1.0.20240927
```

Configuring SWIFT MT JVC

Procedure

1. On <WINDOWS_pack_install_dir>/financial_payments_vn.n.n.n/swift/mt/jvc/maps, update the jvalccyy.prop, replacing the WINDOWS directory references with the corresponding equivalent on ITX-RS docker container mounted data volume: /data/maps/finpay
2. Using Design Studio, update the map rule on the validate_message map, on output card #1 item JvalPropPath. Change the map rule from =NONE to the location of the jvalccyy.prop on the corresponding equivalent on the ITX-RS docker container mounted data volume: ="/data/maps/finpay/swift/mt/jvc/maps".
3. Copy the following JVC jars to the <bind_mount_dir>/extra directory by extracting from <WINDOWS_pack_install_dir>/financial_payments_vn.n.n.n/UIProjectImports/swiftMTjvcConfig.tar.gz
 - jvcwrap.jar
 - jvalccyy.jar
4. Restart the ITX-RS container, by issuing the following command:

```
docker restart itx-rs
```

Building maps for Linux

Procedure

1. Compile all maps for the Linux platform, with a file extension that matches the property rest.map.fileExtension specified in config.yaml. Default file extension for compile maps is set to mmc.
2. Prior to executing any of the following build scripts,
 - a. Using a text editor, open build_deploy_jvc.bat under <WINDOWS_pack_install_dir>/financial_payments_vn.n.n.n/swift/mt/jvc/maps and search for this, **set mcompileOptions= -P %PLATFORM% -A -E -O "%DeployDir%\maps*.mmc"** and change to **set mcompileOptions= -P %PLATFORM% -A -E -O "%DeployDir%\maps*.<rest.map.fileExtension>"**.
 - b. Save file and execute on command prompt, that is, build_deploy_jvc.bat LINUX.
 - c. Using a text editor, open build_deploy_lmf.bat under <WINDOWS_pack_install_dir>/financial_payments_vn.n.n.n/swift/mt/lmf and search for this, **set mcompileOptions= -P %PLATFORM% -A -E -O "%DeployDir%\maps*.mmc"** and change to **set mcompileOptions= -P %PLATFORM% -A -E -O "%DeployDir%\maps*.<rest.map.fileExtension>"**.
 - d. Save file and execute on command prompt, i.e. build_deploy_lmf.bat LINUX.
 - e. Using a text editor, open build_mt_mx_translator.bat under <WINDOWS_pack_install_dir>/financial_payments_vn.n.n.n/swift/mx/examples/mt_mx_translation/maps on a text editor and search for this, **set mcompileOptions= -A -E** and change to **set mcompileOptions= -P LINUX -A -E -O "*.<rest.map.fileExtension>"**.
 - f. Save file and execute on command prompt, i.e. build_mt_mx_translator.bat.
3. When running the mt950_split example, ensure the following run maps are built for Linux but with an extension .mmc:
split_mt950
v2_mt950_runmap_balance

Porting artifacts to UNIX host

- Port compiled maps, schemas, data files to the corresponding <bind_mount_dir>/finpay directories.
- All compiled maps must be ported as BINARY.
- All XML schemas must be ported as BINARY.
- All data files must be ported as BINARY except for the following:
 - In the mt_mx_translation example, mt_mx_errorcodes.txt must be ported as ASCII.

Example map execution on ITX-RS using endpoint for V1 REST API

Below are examples of REST calls using **curl** commands to execute compliance maps:

SWIFT

```
curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/ direct/.finpay.swift.mt.jvc.maps.validate_messages?
input=1;FILE;mt101.mt" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"

curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finpay.swift.mx.maps.swiftval?
input=1;FILE;../data/pacs_008_001_08.xml" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"
```

SEPA

```
curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finpay.sepa.mapsandschemas.sepvalid" -H "accept:
application/json" -H "Content-Type: application/json" -d "{}"
```

NACHA

```
curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/ direct/.finpay.nacha.examples.ach_validation.maps.achval01" -H "accept:
application/json" -H "Content-Type: application/json" -d "{}"
```

Overrides on input, output cards due to backward slashes

Note: Due to some maps reference to directories with Windows specific backward slashes (\), the following maps will require input, output card overrides.
Map isoccd01 on ACH to ISO 20022 Payment Initiation Credit Transfer example

```
curl -X PUT "http://localhost:8080/tx-
rest/v1/itx/maps/direct/.finpay.nacha.examples.ach_iso20022.scenario.credit_transfer.maps.isoccd01?
input=1;FILE;../data/iso_pain001_to_ccd_ct_input.xml&return=audit" -H "accept: application/json" -H "Content-Type:
application/json" -d "{}"
```

Map isoccd08 on ACH to ISO 20022 Payment Initiation Direct Debit example

```
curl -X PUT "http://localhost:8080/tx-
rest/v1/itx/maps/direct/.finpay.nacha.examples.ach_iso20022.scenario.direct_debit.maps.isoccd08?
input=1;FILE;../data/iso_pain008_to_ccd_dd_input.xml&return=audit" -H "accept: application/json" -H "Content-Type:
application/json" -d "{}"
```

Map isorjt01 on ACH Reject to ISO 20022 transformation example

```
curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/
direct/.finpay.nacha.examples.ach_iso20022.scenario.reject.maps.isorjt01?input=1;FILE;../data/
iso_pain002_to_reject_ccd_ct_input.xml&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"
```

Map isorth01 on ACH Return to ISO 20022 transformation example

```
curl -X PUT "http://localhost:8080/tx-
rest/v1/itx/maps/direct/.finpay.nacha.examples.ach_iso20022.scenario.returns.maps.isorth01?
input=1;FILE;../data/iso_camt053_to_returns_ccd_ct_input.xml&return=audit" -H "accept: application/json" -H "Content-Type:
application/json" -d "{}"
```

Map sepfr3ct_pacs_008_minos on SEPA France example

```
curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finpay.sepa.examples.france.maps.sepfr3ct_pacs_008_minos?
output=1;FILE;../data/fr_ct_sepa_pacs008_minos.out&return=audit" -H "accept: application/json" -H "Content-Type:
application/json" -d "{}"
```

Map sepde2dd_pain008_dtaus on SEPA Germany example

```
curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finpay.sepa.examples.germany.maps.sepde2dd_pain008_dtaus?
input=2;FILE;../data/BIC.txt&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"
```

Map fxfm0001_email_fix_to_fixml on FIX Email example

```
curl -X PUT "http://localhost:8080/tx-
rest/v1/itx/maps/direct/.finpay.fix.examples.fixFMLEmail.maps.fxfm0001_email_fix_to_fixml?
output=1;FILE;../data/fixxml_email_50_out.xml&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d
"{}"
```

Map fxfm0009_adv_fix_to_fixml on FIX Advertisement example

```
curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finpay.fix.examples.fixFMLadv.maps.fxfm0009_adv_fix_to_fixml?output=1;FILE;../data/fixxml_adv_50_out.xml&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"
```

Example map execution on ITX-RS using endpoint for V2 REST API

Prerequisites

1. Import the example .zip projects on <WINDOWS_pack_install_dir>/financial_payments_vn.n.n.n/UIProjectImports into Design Server. See pack release notes for complete list of Design Server projects.
 2. Create packages for each project including all maps and files.
 - OPTIONAL: Clear out the URL of run maps, leaving only main maps with URL.
- WORKAROUND: Any issues running any of the endpoints for V2 REST API listed below that is related to XML metadata, manually add native XML schemas into package by importing them under File tab with a logical folder schemas since deployment of package does not include XSDs from project.
3. Deploy package into ITX-RS server instance.
 4. Set config.yaml property rest.mode to fenced.

Below are examples of REST calls using curl commands to execute compliance maps:

SWIFT

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/validate_messages?output=2;FILE;../data/maps/finpay/swift/mt/jvc/data/results.xml&return=log&audit_file=always" -H "accept: */*"  
curl -X PUT "http://localhost:8080/tx-rest/v2/run/swiftval?input=1;FILE;../data/pacs_008_001_13_invalid.xml&output=3;FILE;../data/maps/finpay/swift/mx/data/results.xml&return=log&audit_file=always" -H "accept: */*" -H "Content-Type: application/xml"
```

SEPA

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/sepavalid?input=1;FILE;../data/pacs008c_invalid.xml&output=3;FILE;../data/maps/finpay/sepa/mapsandschemas/results.xml&return=log&audit_file=always" -H "accept: */*" -H "Content-Type: application/xml"
```

NACHA

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/achval01?output=4;FILE;../data/maps/finpay/nacha/examples/ach_validation/data/results.xml&return=log&audit_file=always" -H "accept: */*" -H "Content-Type: application/xml"
```

Map isoccd01 on ACH to ISO 20022 Payment Initiation Credit Transfer example

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/isoccd01?output=3;FILE;../data/maps/finpay/nacha/examples/ach_iso20022/scenario/credit_transfer/data/results.txt&return=log&audit_file=always" -H "accept: */*" -H "Content-Type: application/xml"
```

Map isoccd08 on ACH to ISO 20022 Payment Initiation Direct Debit example

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/isoccd08?output=3;FILE;../data/maps/finpay/nacha/examples/ach_iso20022/scenario/direct_debit/results.txt&return=log&audit_file=always" -H "accept: */*" -H "Content-Type: application/xml"
```

Map isorjt01 on ACH Reject to ISO 20022 transformation example

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/isorjt01?output=3;FILE;../data/maps/finpay/nacha/examples/ach_iso20022/scenario/reject/results.txt&return=log&audit_file=always" -H "accept: */*" -H "Content-Type: application/xml"
```

Map isortn01 on ACH Return to ISO 20022 transformation example

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/isortn01?output=3;FILE;../data/maps/finpay/nacha/examples/ach_iso20022/scenario/returns/results.txt&return=log&audit_file=always" -H "accept: */*" -H "Content-Type: application/xml"
```

Map sepfr3ct_pacs_008_minos on SEPA France example

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/sepfr3ct_pacs_008_minos?output=1;FILE;../data/maps/finpay/sepa/examples/france/data/results.xml&return=log&audit_file=always" -H "accept: */*" -H "Content-Type: application/xml"
```

Map sepde2dd_pain008_dtaus on SEPA Germany example

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/sepde2dd_pain008_dtaus?output=1;FILE;../data/maps/finpay/sepa/examples/germany/data/results.txt&return=log&audit_file=always" -H "accept: */*" -H "Content-Type: application/xml"
```

Map fxfm0001_email_fix_to_fixml on FIX Email example

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/fxfm0001_email_fix_to_fixml?output=1;FILE;../data/maps/finpay/fix/examples/fixFMLEmail/data/results.xml&return=log&audit_file=always" -H "accept: */*" -H "Content-Type: application/xml"
```

Map fxfm0009_adv_fix_to_fixml on FIX Advertisement example

```
curl -X PUT "http://localhost:8080/tx-rest/v2/run/fxfm0009_adv_fix_to_fixml?output=1;FILE;../data/maps/finpay/fix/examples/fixFMLadv/data/results.xml&return=log&audit_file=always" -H "accept: */*" -H "Content-Type: application/xml"
```

Not available for execution on ITX-RS

The following examples are not supported on ITX-RS:

SWIFT

- Sterling B2B Integrator Envelope, De-envelope examples
- SWIFT MT validation launcher example

SEPA

- z/OS examples
 - Bundle
 - unbundle
 - passthrough
 - sample_jcl

NACHA

- Sterling B2B Integrator Envelope, De-envelope examples.

Pack for Financial Payments Plus (FINPLUS)

- [Prerequisites](#)
- [Configuring CBPR+ Translation](#)
- [Building maps for Linux](#)
- [Porting artifacts to UNIX host](#)
- [Example map execution on ITX-RS using endpoint for V1 REST API](#)
- [Example map execution on ITX-RS using endpoint for V2 REST API](#)
- [Example flow execution on ITX-RS using endpoint for V2 REST API](#)

Prerequisites

Procedure

1. Extract finipayplus_n.n.n.n_v1101_4c.zip on Windows.
2. On the host mounted directory `<bind_mount_dir>`, define a finplus directory, that is, `/tmp/itx-rs/maps/finplus`.
3. Define the similar directories and subdirectories under `<bind_mount_dir>/maps/finplus` as defined under the following:

```
<WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/cbpr_plus  
<WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/chaps_enh  
<WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/chaps_l4l  
<WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/eba_e1s1  
<WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/nbor_regis  
<WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/sic_rtgs  
<WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/swift_gpi  
<WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/swift_uc  
<WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/t2_clm  
<WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/t2_coco  
<WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/t2_rtgs  
<WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/t2_sec
```

Note:

- No need to define a directory for type trees.
- `<bind_mount_dir>` refers to directory specified in volume (-v) option on the docker run command, that is,

```
docker run --name itx-rs -it -d -p 8080:8080 -v /tmp/itx-rs/data:/data -v /tmp/itx-rs/ logs:/logs ibm-itx-rs:11.0.1.0.20240927
```

Configuring CBPR+ Translation

Procedure

1. On `<WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/UIProjectImports`, extract contents of cbprJnodesConfigIBM.tar.gz.
2. Copy the following jars from `<TX_install_dir>/jars`
 - jackson-core-n.n.n.jar
 - jackson-annotations-n.n.n.jar
 - jackson-databind-n.n.n.jar

Or, download from com/fasterxml/jackson/core.

Note: It is recommended to use the latest version.

3. Copy the following JVC jars to the <bind_mount_dir>/extra directory:

- jnodesO.jar
- jackson-core-n.n.n.jar
- jackson-annotations-n.n.n.jar
- jackson-databind-n.n.n.jar

4. Restart the ITX-RS container, that is,

```
docker restart itx-rs
```

Building maps for Linux

Procedure

1. Compile all maps for the Linux platform, with a file extension that matches the property rest.map.fileExtension specified in config.yaml. Default file extension for compile maps is set to mmc.
2. Execute the scripts under <WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/tools/build_scripts. For example, build_deploy_cbpr_plus_mt2mx_translation.bat LINUX
3. When running any _framework maps and _val maps, ensure the following run maps are built for Linux but with an extension <rest.map.fileExtension>. For all other run maps, retain the extension .mmc.

Porting artifacts to UNIX host

- Port compiled maps, schemas, data files to the corresponding <bind_mound_dir>/finplus directories.
- All compiled maps must be ported as BINARY.
- All XML schemas must be ported as BINARY.
- All data files must be ported as BINARY.

Example map execution on ITX-RS using endpoint for V1 REST API

Below are examples of REST calls using curl commands to execute translation and compliance maps:

- **CBPR+ Translation**
 - **MT-MX**

```
curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.mt-mx.maps.cbpr2800_mt103_framework?input=1;FILE;../data/MT103.inp&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"

curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.mt-mx.maps.cbpr2810_mt202_framework?input=1;FILE;../data/MT202_ADV.inp&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"

curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.mt-mx.maps.cbpr2811_mt205_framework?input=1;FILE;../data/MT205_COR.inp&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"

curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.mt-mx.maps.cbpr1500_mt9n0_framework?input=1;FILE;../data/MT900.inp&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"

curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.mt-mx.maps.cbpr2820_mtn96_framework?input=1;FILE;../data/MT196.inp&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"

curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr_plus.mt-mx.maps.cbpr2820_mtn96_framework?input=1;FILE;../data/MT296.inp&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"
```

- **MX-MT**

```
curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.mx-mt.maps.cbpr2500_pacs002_framework?input=1;FILE;../data/env_pacs_002_199.xml&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"

curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.mx-mt.maps.cbpr2700_pacs008_framework?input=1;FILE;../data/env_pacs_008_103.xml&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"

curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.mx-mt.maps.cbpr2710_pacs009_mt202_framework?input=1;FILE;../data/env_pacs_009_mt202cor_valid.xml&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"

curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.mx-mt.maps.cbpr2724_pacs009_mt205_framework?input=1;FILE;../data/env_pacs_009_mt205cor_valid.xml&return=audit" -H "accept: application/json" -H "Content-Type: application/json" -d "{}"
```

```

curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.mx-mt.maps.cbpr2520_camt029_framework?
input=1;FILE;../data/env_camt_029_valid.xml&return=audit" -H "accept: application/json" -H "Content-Type:
application/json" -d "{}"

curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.mx-mt.maps.cbpr2510_camt054_framework?
input=1;FILE;../data/env_camt_054_crdt.xml&return=audit" -H "accept: application/json" -H "Content-Type:
application/json" -d "{}"

curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.mx-mt.maps.cbpr2600_camt057_framework?
input=1;FILE;../data/env_camt_057_valid.xml&return=audit" -H "accept: application/json" -H "Content-Type:
application/json" -d "{}"

• CBPR+ Validation
  ○ MX Extended

    curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.mx_extended.maps.cbpr6000_val?
input=1;FILE;../data/bah_pacs_008_001_08_valid.xml&return=audit" -H "accept: application/json" -H "Content-Type:
application/json" -d "{}"

  ○ Schema Only

    curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.cbpr.schema_only.maps.cbpr6100_val?
input=1;FILE;../data/bah_pain_001_001_09_valid.xml&return=audit" -H "accept: application/json" -H "Content-Type:
application/json" -d "{}"

• CHAPS ENH Validation
  ○ MX Extended

    curl -X PUT "http://localhost:8080/tx-rest/v1/itx/maps/direct/.finplus.chaps_enh.mx_extended.maps.chen8000_val?
input=1;FILE;../data/bah_pacs_004_001_09_valid.xml&return=audit" -H "accept: application/json" -H "Content-Type:
application/json" -d "{}"

  ○ Schema Only

    curl -X PUT "http://localhost:8080/itx-rs/v1/maps/direct/.finplus.chaps_enh.schema_only.maps.chen8200_val?
input=1;FILE;../data/bah_camt_052_001_08_valid.xml&return=audit" -H "accept: application/json" -H "Content-Type:
application/json" -d "{}"

• CHAPS L4L Validation
  ○ MX Extended

    curl -X PUT "http://localhost:8080/itx-rs/v1/maps/direct/.finplus.chaps_l4l.mx_extended.maps.chlf8000_val?
input=1;FILE;../data/bah_camt_053_001_08_valid.xml&return=audit" -H "accept: application/json" -H "Content-Type:
application/json" -d "{}"

  ○ Schema Only

```

Example map execution on ITX-RS using endpoint for V2 REST API

Prerequisites

1. Import the example .zip projects on <WINDOWS_pack_install_dir>/financial_payments_plus_vn.n.n.n/UIProjectImports into Design Server. See pack release notes for complete list of Design Server projects.
2. Create packages for each project including all maps and files.
 - OPTIONAL: Clear out the URL of run maps, leaving only main maps with URL.
3. Deploy package into ITX-RS server instance.
4. Set config.yaml property rest.mode to fenced.

Below are examples of REST calls using curl commands to execute translation and compliance maps:

```

● CBPR+ Translation
○ MT-MX

curl -X PUT "http://localhost:8080/tx-rest/v2/run/cbpr2800_mt103_framework?

## Example flow execution on ITX-RS using endpoint for V2 REST API

### Prerequisites

1. Import the example .zip projects on <WINDOWS\_pack\_install\_dir>/financial\_payments\_plus\_vn.n.n.n/UIProjectImports into Design Server. See pack release notes for complete list of Design Server projects.
2. Take note of the flow variables used for each flow since their default value can be overridden upon execution.
3. Create packages for each project including all maps and files.
  - OPTIONAL: Clear out the URL of run maps, leaving only main maps with URL.
4. Deploy package into ITX-RS server instance.
5. Set config.yaml property rest.mode to fenced.

Below are examples of REST calls using **curl** commands to execute translation and compliance flows:

- CBPR+ Translation

- MT-MX

```

curl -X GET "http://localhost:8080/tx-rest/v2/run/cbpr_mt103_pacs00n?INPUT_FILE=./cbpr_plus/translation/mt-

## IBM MQ Client

IBM MQ Client 9.3.0.6 distribution is included with Runtime Server (ibm-itx-rs) image for supporting maps that use IBM MQ (client) adapter as data source to pull messages from IBM MQ, and as a data target to push messages to IBM MQ from the container. The MQ\_OVERRIDE\_DATA\_PATH environment variable has already been set and associated to /data/mqdata folder in the container.

Three other environment variables are defined for IBM MQ purposes to facilitate SSL encrypted communication between the MQ client and MQ server as following:

- MQSSLKEYR environment variable is set to /data/config/mqkeys
  - MQCHLLIB environment variable is set to /data/config
  - MQCHLTAB environment variable is set to AMQCLCHL.TAB
- 

## Helm Chart

Helm Chart for Runtime Server (ibm-itx-rs) is included in the distribution package for deploying the services to Kubernetes platform using Helm 3 package manager. Helm Charts are a set of manifest files that declare and configure the application upon deployment onto a Kubernetes platform like Red Hat OpenShift.

Helm Charts ease defining, installing, upgrading, and managing Kubernetes applications on a Kubernetes platform like Red Hat OpenShift. Helm is a Package manager for Kubernetes (analogous to yum and apt), Charts are the Packages (analogous to debs and rpms). Runtime Server Helm Chart (ibm-itx-rs-prod) defines and installs Runtime Server onto a Kubernetes platform.

- [\*\*ibm-itx-rs-prod Package\*\*](#)

ibm-itx-rs-prod Helm Chart Package includes the Helm Chart for Runtime Server. It defines and installs Runtime Server (ibm-itx-rs) as a Kubernetes application onto a Kubernetes platform like Red Hat OpenShift. The ibm-itx-rs-prod Helm Chart package includes the configuration, deployment, persistent volume claim manifest files defining Kubernetes resources, and the customization file, values.yaml.

---

## ibm-itx-rs-prod Package

ibm-itx-rs-prod Helm Chart Package includes the Helm Chart for Runtime Server. It defines and installs Runtime Server (ibm-itx-rs) as a Kubernetes application onto a Kubernetes platform like Red Hat OpenShift. The ibm-itx-rs-prod Helm Chart package includes the configuration, deployment, persistent volume claim manifest files defining Kubernetes resources, and the customization file, values.yaml.

- [\*\*Installing ibm-itx-rs-prod Package\*\*](#)
- [\*\*Kubectl commands\*\*](#)

Use **kubectl** commands to check on the kubernetes resources deployed in the kubernetes cluster platform like Red Hat OpenShift. On Red Hat OpenShift platform, **oc** command can be used besides **kubectl** command.

---

## Installing ibm-itx-rs-prod Package

### About this task

Installing ibm-itx-rs-prod Helm Chart package onto a Kubernetes platform involves the following steps:

### Procedure

1. Extract the ibm-itx-rs-prod Helm Chart package, ibm-itx-rs-prod-3.0.0.tgz, to a directory on the local machine.
2. Open values.yaml file and customize the configuration for ibm-itx-rs application:
  - a. Some of the configuration settings have the defaults set and some others have been left blank for the user to fill based on their Kubernetes platform requirements and environment.
  - b. Adding an image pull secret information to pull image from an image registry, storage class information to provision the persistent volume claims for persistence needs to save the map, input and output files.
  - c. Setting Runtime Server application specific configuration, for example, resource registry configuration file, log configuration for Server access, service and server logs and their log levels.
3. Deploy ibm-itx-rs-prod Helm Chart to your Kubernetes platform with the following command:

```
helm install itx-rs ibm-itx-rs-prod
```

The *itx-rs* designation in the above command is an example name that helps identify the current deployment of ibm-itx-rs-prod.

4. A successful deployment of ibm-itx-rs-prod to the Kubernetes platform displays as following:  
IBM Sterling Transformation Extender for Red Hat OpenShift deployed successfully
5. After customizations have been saved in the values.yaml, the charts can be saved as a package, ibm-itx-rs-prod-3.0.0.tgz, for future deployments using the following command where the ibm-itx-rs-prod package has been extracted earlier:

```
helm package
```

You can optionally install the future ibm-itx-rs-prod package as follows:

```
helm install itx-rs ibm-itx-rs-prod-3.0.0.tgz
```

6. To uninstall ibm-itx-rs-prod deployment from the cluster, run the following command:

```
helm uninstall itx-rs
```

---

## Kubectl commands

Use **kubectl** commands to check on the kubernetes resources deployed in the kubernetes cluster platform like Red Hat OpenShift. On Red Hat OpenShift platform, **oc** command can be used besides **kubectl** command.

Some of the useful commands are as following:

- List running pods in a specific namespace under Kubernetes cluster:

```
kubectl get pod --namespace=<namespace_name>
```

```
oc get pod --namespace=<namespace_name>
```

- Describe the kubernetes resources in a running Kubernetes cluster:

```
kubectl describe <resource_type> <resource_name>
```

- Display the log file of a running pod:

```
kubectl logs <pod_name> -n <namespace_name>
```

```
oc logs <pod_name> -n <namespace_name>
```

- List of ingress resources created in the Kubernetes cluster:

```
kubectl get ingress --namespace=<namespace_name>
```

```
oc get route --namespace=<namespace_name>
```

## Bulk copy

Runtime Server Data API allows deploying a single file to the data volume. You can deploy a collection of files organized in a directory structure included in a zip file which gets extracted under data volume. Bulk copy requires a special action header, **rs-action: unpack**, be included while invoking Data API.

Examples using **curl** command to deploy a single or a collection of files to the data volume are as following:

- Deploy a single compiled map file to the data volume under maps sub-directory:

```
curl -F "data=@/mydir/mymap.mmc" http://CONTAINER_HOSTNAME:8080/tx-rest/v1/itx/data/maps
```

- Deploy a collection of files in a zip file under data volume under maps sub-directory:

```
curl -F "data=@/mydir/myfiles.zip" -H "rs-action: unpack" "http://CONTAINER_HOSTNAME:8080/tx-rest/v1/itx/data/maps"
```

If your myfiles.zip has the following directory structure:

```
hipaa
|- validate.mmc
|- compliance.mmc
|- inputs
 |- input1.txt
 |- input2.xml
|- config
 |- hipaaconfig.txt
```

All the files in the zip file are extracted under /data/maps volume retaining the same directory structure as it is in the zip file once deployed through the Data API. It is a POST operation to create a single file or multiple files on the data volume. The Data API can be used to transfer a single file or multiple files under any directory level within the data volume.

If secure transport is enabled for the Runtime Server, then `http://` should be replaced with `https://` in the request URL and the port number should be changed from 8080 to 8443. You can map the default 8080 and 8443 default ports for HTTP and HTTPS with **-p** command line option for standalone container execution or through Helm Charts deployed under a Kubernetes cluster environment.

Transferring a single file or multiple files to the data volume is required before running a map under Runtime Server container unless the volume is prepopulated with the required files. This feature of copying a single file or multiple files in a zip file to a data volume is helpful to users running maps under cluster environments.

Runtime Server Helm Charts include provisions to enable either Ingress or Route for the Runtime Server to be accessible from external HTTP clients. Port is not mentioned in the URL when using route in OpenShift.

The example **curl** command using route name with HTTP protocol is as following:

```
curl -F "data=@/mydir/myfiles.zip" -H "rs-action: unpack" "http://ROUTE_NAME/tx-rest/v1/itx/data/maps"
```

Executing the example command above results in unpacking the myfiles.zip file after it is deployed to the ITX Runtime Server. ITX Runtime Server retains the same directory structure as in the zip file under target directory, /data/maps , while unpacking the contents of the zip file.

There are other ways to copy files to data volume, for example, **oc cp** command for OpenShift allows copying the file from local using the container identifier and vice-versa. Using Data API provides a consistent and easy to use mechanism for copying single or multiple files to data volume.

## Deployment Guidelines

- [GDPR](#)
- [CIS Benchmarks](#)

## GDPR

Users of ITX Runtime Server are responsible for ensuring their own compliance with various laws and regulations, including the European Union General Data Protection Regulation (GDPR). Users are solely responsible for obtaining advice of competent legal counsel as to the identification and interpretation of any relevant laws and

regulations that may affect the user's business and any actions the user may need to take to comply with such laws and regulations.

The products, services, and other capabilities described herein are not suitable for all user situations and may have restricted availability. HCL and IBM do not provide legal, accounting, or auditing advice or represent or warrant that its services or products will ensure that users are in compliance with any law or regulation.

For more information about GDPR, see:

- [EU GDPR Information Portal](#)
- [IBM GDPR website](#)

ITX Runtime Server enables an organization to integrate industry-based customer, supplier and business partner transactions across the enterprise. It helps automate complex transformation and validation of data between a range of different formats and standards. Securing and managing the personal data passed through the ITX Runtime Server for processing is a sole responsibility of the user. Some of the security guidelines that follow may help in securing the personal data:

- Harden the master and worker nodes in the cluster based on security benchmarks like CIS Benchmarks.
- Harden the Red Hat Enterprise Linux OS based on security benchmarks like CIS Benchmarks.
- Secure the communication with ITX Runtime Server using HTTPS protocol instead of HTTP.
- Secure the credentials of external systems accessed by ITX Runtime Server using AES-256 encryption in Resource Registry.
- Use secure options provided by the data source/target adapters where applicable to securely process the data.
- Encrypt and decrypt the data, process data through ITX Runtime Server's Cipher and OpenPGP adapters.
- Secure the transport of data from/to maps run by ITX Runtime Server with HTTPS, FTPS adapters.
- Cataloged maps would allow hiding the details of the map location, override settings of the deployed maps.
- Monitor the outputs generated by the ITX Runtime Server, remove input and output files when not required.
- Look out for security bulletins from ITX and Red Hat support teams to resolve security vulnerabilities.
- Apply the security patches when released and keep the cluster nodes up to date to avoid security threats.
- Refer ITX Knowledge Center and Red Hat OpenShift documentation on the security features available in the products.
- Scan map and input files for malware/virus before uploading to the data volume through application endpoint.
- Scan driver files and user-defined exit modules for malware/virus before uploading through the application endpoint.

## CIS Benchmarks

CIS Benchmarks are best practices for the secure configuration of a target system. CIS Benchmarks are developed through a unique consensus-based process of cybersecurity professionals and subject matter experts around the world. CIS benchmark guides are developed and accepted by government, business, industry, and academia.

CIS Benchmarks for Kubernetes and Red Hat OpenShift Container platform environments are available for download from the [CIS Benchmarks](#) website. These benchmark guides provide information on hardening the master and worker nodes in the OpenShift cluster. Guidance on hardening the Red Hat Enterprise Linux OS can be found in the [Red Hat documentation](#).

ITX Runtime Server has been hardened to a level that satisfies the IBM certification requirements for Container Software. Users are responsible for hardening of the nodes in the cluster that meets their security policies and requirements.

## Auditing

IBM License Service provides license consumption reporting and audit readiness for IBM containerized software. IBM License Service is useful to any customer that wants to view and understand the license consumption of IBM Certified Container Software running on a Red Hat OpenShift cluster. For more information about deploying IBM License Service and tracking license usage of standalone IBM Certified Container software, see [license tracking](#) page.

License audit snapshot is a record of license usage in your environment over a period of time. The audit snapshot is a compressed .zip package that includes a complete set of audit documents that certify your cumulative license usage. Audit snapshot is needed for compliance and audit purposes. For core license metrics, user is obliged to use License Service and periodically generate audit snapshots to fulfill container licensing requirements. For more information about core license metrics, see [Reporter metrics](#).

You do not need to complete any manual actions to prepare the license audit snapshot; you only need to generate it. At this point, the license audit snapshot is required to be generated at least once a quarter, and stored for two years in a location from which it could be retrieved and delivered to auditors. For more information on capturing license audit snapshot for compliance and audit purposes, see [retrieving audit](#) page .

Note: The requirements might change over time. You should always make sure to follow the latest requirements that are posted on Passport Advantage.

## Scaling

ITX Runtime Server pods run independently of each other and can serve client requests that can be load balanced across them in any pattern. This includes running ITX maps asynchronously, including scenarios when one pod instance processes the REST API POST call request to run the map and another pod subsequently processes the REST API GET call request to return the status of the map execution, even if the two pods are running on different worker nodes. To access the compiled maps, the pods are accessing shared persistent volume where the compiled maps are saved, and to access statuses of the asynchronous map executions the pods are utilizing Redis queues, which is the reason Redis is required when asynchronous map calls are made.

The number of pods running at any time can be controlled through the **replicaCount** property exposed by the product. When sufficient system resources are available and have been provisioned for the newly added pods to the deployment, it will increase the ability of the deployment to handle additional workload as more pods will be available to process the incoming REST API calls simultaneously.

In addition to supporting multiple pods in a single deployment (ITX Runtime Server instance), multiple deployments can be installed in the cluster, but they need to be installed in separate projects (namespaces), one instance per project. This provides for example the ability to run separate QA and Dev ITX Runtime Server deployments in the same cluster simultaneously.

ITX Runtime Server pods can be auto scaled based on threshold target CPU or Memory utilization on the worker nodes of the cluster. Auto scaling of ITX Runtime Server pods is disabled by default in the Helm Chart for IBM Sterling Transformation Extender for Red Hat OpenShift. Enabling autoscaling option disables **replicaCount** specified in the configuration. IBM Sterling Transformation Extender for Red Hat OpenShift supports horizontal pod autoscaling. However, it does not support vertical pod autoscaling at this time.

## Uninstalling

To uninstall ITX Runtime Server, run the following command, after replacing the <target\_namespace> placeholder with the name of the namespace from which you wish to uninstall the ITX Runtime Server deployment.

```
helm uninstall itx-rs -namespace <target_namespace>
```

## Upgrades and Rollbacks

Upgrade or Rollback activity of ITX Runtime Server instances from Helm Chart version 2.1.x or earlier has to be performed by uninstalling the current deployment and reinstalling the ITX Runtime Server Helm Chart version 3.0.0, which uses the ITX container image 11.0.1. Helm uninstall and install commands are to be used to deploy a new major version of ITX Runtime Server Helm Chart.

Whenever a Helm upgrade is made to an existing deployment with a Helm chart version of 3.x, the pods that are associated with the installation will not automatically restart - unless the change affects the actual deployment manifest. For example, an update to the image name or resource metrics will change the deployment manifest of the installation, which in turn will trigger an automatic restart of the pods. However, a basic change to a values.yaml property that is linked to the ITX config.yaml file, such as the logging level, will not trigger an automatic restart. The restart would need to take place manually, as provided by the Kubernetes scale command.

## Limitations

- ITX Runtime Server is supported on OpenShift 4.14, and on Linux 64 only. This means that any maps designed to run on other platforms, such as those using adapters supported on Windows operating systems only, will not be able run in ITX Runtime Server.
- Because of the unique characteristics of running workloads in Kubernetes environments compared to running them in on-prem environments, existing ITX maps may require adjustments before they can be run in ITX Runtime Server, especially if they rely on invoking custom tools or applications, or are making assumptions about the underlying host's operating system, network, local storage or other system-level resources.
- Any files referenced by the maps must assume /data/maps path as the map directory. If a map writes to a file without specifying its path, the file will be created in the /data/maps directory.
- Deploying multiple instances of ITX Runtime Server to the same projects (namespaces) is not supported. Deploying ITX Runtime Server to multiple projects (namespaces), with one instance per project, is supported.
- The V2 configuration API is not supported in Helm installations.

## Migration

- The migration guidelines given below are applicable for the following releases:
  - IBM Sterling Transformation Extender Runtime Server 10.0.3
  - IBM Sterling Transformation Extender for Red Hat OpenShift 10.1.1
  - IBM Sterling Transformation Extender for Red Hat OpenShift 10.1.2
- Both container and non-container variants of the Runtime REST API endpoints have been synchronized. The /itx-rs/v1 substring in the endpoints has to be replaced with /tx-rest/v1/itx when invoking V1 REST API endpoints of the Runtime Server. API synchronization allows consistent invocation of REST API endpoints across environments, thereby easing the design, development, testing, deployment, and maintenance of user applications.
- Swagger 2.0 documentation is no longer provided for REST API endpoints. Only OpenAPI 3.0 documentation is provided for REST API endpoints. By default, deployed map and flow endpoints of V2 REST API are shown to users in the Swagger web UI page if rest.defaultSwagger property is not set to v1.
- Environment variables that were supported to configure the container deployment are no longer supported. All configuration settings have to be specified through an overridden config.yaml file if the default value is not suitable for your deployed environment. It is mandatory to accept the license for running the product successfully. The environment variable, ITX\_RS\_LICENSE\_ACCEPT, is indirectly set during a Helm install based on the license parameter, which should only be set to true after reading through the license terms and conditions.
- The default map extension expected by the Runtime Server has been changed from lnx to mmc. Compiled maps with .lnx extension should be renamed to .mmc extension before deploying them to the Runtime Server. If the .lnx extension is still desired, override the rest.mapFileExtension setting from mmc to lnx.

Tip:

Design Server generates multi-platform composite maps. Users may opt to generate multi-platform composite maps in Design Studio, by selecting Windows and Linux platforms under Window > Preferences > Transformation Extender > Map > Build Options panel. Multi-platform composite maps get .mmc extension. You may also change the default extension of the compiled map for a specific platform under Window > Preferences > Transformation Extender > Map > Compiled Map Extensions panel.

## Introduction

This introduction to the Pack for SAP Applications includes the following topics:

- [Overview Pack for SAP Applications](#)

- [Integrating information](#)
  - [Overview SAP R/3 interfaces](#)
  - [Pack for SAP Applications overview](#)
  - [Integrating information](#)
  - [Overview of SAP R/3 interfaces](#)
- 

## Pack for SAP Applications overview

The Pack for SAP Applications is a unique data transformation technology for interfacing SAP R/3 software applications with third-party applications and legacy systems. Connectivity to the SAP R/3 environment is provided for both inbound and outbound data, and is supported on the major SAP platforms. Communications are similar to SAP R/3 to SAP R/3 communication, except the components used in IBM, and the Pack for SAP Applications appear as if they are another SAP R/3 system.

The Pack for SAP Applications makes use of SAP's synchronous and asynchronous (transactional) Remote Function Calls (RFCs). This approach ensures effective and secure communication between external systems and SAP R/3. Detailed knowledge of RFCs is not required to create interfaces for SAP R/3 that are reliable, efficient, and easy to maintain. Some knowledge of Remote Communication Basis is helpful but not required.

In addition, the pack can be used with several file-based interfaces, such as SAP DXOB/DMI and EDI subsystems.

The Pack for SAP Applications is used for:

- Initial data load
  - Ongoing real-time or near-real time interfaces
- 

## Integrating information

Success with SAP R/3 depends on an ability to integrate and share information with other systems. In a typical corporate setting, a single SAP R/3 system needs to integrate with a wide range of applications. These include legacy systems, applications provided by a third-party, and other SAP systems within the enterprise.

SAP R/3 data synchronization between applications is critical, requiring the transfer of transactions and master data. Events occurring in one location, such as the receipt of a customer order, may trigger actions at other locations, such as the generation of a production order or the updating of inventory. To achieve a distributed, fully integrated SAP R/3 environment, the hardware and software infrastructure must be in place to support the flow of this vital information seamlessly between systems.

---

## Overview of SAP R/3 interfaces

The Pack for SAP Applications supports the following interfaces and technologies that include the automatic generation of metadata-specific schemas:

- Intermediate Documents
    - Application Link Enabling (ALE)
    - ALE Message Handler (AMS)
    - Electronic Data Interchange (EDI)
  - DXOB/Data Migration Interface (DMI)
  - Business Application Programming Interface (BAPI)
  - For the adapter-specific commands, see the [Adapter Commands List](#).
  - [Intermediate Documents \(IDocs\)](#)
  - [DXOB/Data Migration Interface \(DMI\)](#)
  - [Business Application Programming Interface \(BAPI\)](#)
- 

## Intermediate Documents (IDocs)

The IDocs interface consists of the definition of a data structure and the processing logic for this data structure. This interface is used to exchange business data between two different systems. SAP R/3 support for the IDoc interface includes both Electronic Data Interchange (EDI) and Application Link Enabling (ALE) technologies.

- [Application Link Enabling \(ALE\)](#)
  - [ALE Message Handler \(AMS\)](#)
  - [Electronic Data Interchange \(EDI\)](#)
- 

## Application Link Enabling (ALE)

ALE links multiple SAP R/3 systems in distributed environments, and non-SAP systems to SAP R/3 without file-to-file transfers. The SAP R/3 architecture supports the transfer of data between applications using messaging as opposed to files. SAP R/3 enables the creation of a distributed, fully integrated suite of loosely coupled applications.

The SAP component supports the integration of distributed SAP R/3 systems under ALE and the flow of information among multiple SAP R/3 systems to accomplish specific business objectives. It also embraces integration among non-SAP R/3 applications, such as third-party applications or legacy systems, by providing the conversion technology required to accomplish this level of integration among diverse systems.

The ALE adapter (JALE) adds Unicode character set data support inbound to and outbound from SAP.

## ALE Message Handler (AMS)

The AMS interface provides connectivity between SAP R/3 and one or more disparate applications sending and receiving IDocs for one or more SAP R/3 instances. AMS does not provide any conversion function and delivers IDocs without changing them. Transactional RFC must be the communication method used between the SAP R/3 system and the ALE Message Handler.

## Electronic Data Interchange (EDI)

EDI enables companies with the ability of communicating business transactions and documents electronically with their partners, vendors, and clients.

## DXOB/Data Migration Interface (DMI)

DXOBs are SAP R/3 business objects that can be transferred automatically into the SAP R/3 system. Examples of business objects are organizational units or master data. The Pack for SAP Applications support for the DXOB interface includes data transfer object structures in both beta and released formats. During data transfer, data is transferred from an external system into the SAP R/3 system.

SAP applications support the data transfer of numerous SAP business objects. The data transfer program specifies the data format definition that is necessary to import the data into the SAP R/3 system. The pack provides the data transformation server to convert the external system data format to the format of the DX object.

## Business Application Programming Interface (BAPI)

The BAPI adapter (JBAPI) enables full Unicode support when installed with the latest version of ITX. The JBAPI adapter provides unified access to both Unicode and non-Unicode systems. BAPI provides a business-oriented interface for accessing SAP R/3 business processes and data from external systems. BAPIs are part of the SAP business framework, an open component-based architecture enabling software components from SAP and other providers to be integrated.

The Pack for SAP Applications supports the ability to call a synchronous BAPI in the mapping rule of an output card. Data returned from the BAPI can be mapped to other output data objects, or can be used for conditional logic. The SAP R/3 adapters support BAPI as well as any remote enabled function module (RFC).

## Setting up your SAP R/3 environment

The system requirements for installing and running SAP R/3 on Windows and UNIX platforms are detailed in the following sections.

Installation and use of the SAP Stand-Alone Gateway and RFC destination activation is discussed. There is also a description of how to set up your SAP R/3 environment to successfully send and receive data.

- [System requirements and installation](#)
- [Pack for SAP R/3 Server](#)
- [SAP Gateway](#)
- [Configuring the SAP R/3 system](#)

## System requirements and installation

For details about the minimum system requirements and instructions for installing or removing your Windows SAP R/3 product refer the [Release notes for IBM Transformation Extender Pack for SAP Applications V10.2.0.1](#).

IBM is installed on a Microsoft Windows platform and contains the product components necessary for establishing a build-time environment for the development of maps. In addition to the Design Server, there are several Pack for SAP Applications product components that are installed that facilitate the development of SAP R/3 interfaces:

- Examples for each of the SAP R/3 interfaces supported by the Pack for SAP Applications
- Type tree importers. For information, see the platform-specific documentation.

## Pack for SAP R/3 Server

The server on which the IBM and the Pack for SAP Applications is installed is referred to as the IBM Pack for SAP R/3 Server.

For supported platforms, see the system requirements on the Support Portal.

Note: SAP JCo library 3.1.10 or later is used on all platforms. For information about downloading and installing SAP JCo, see SAP Note 1672418: Downloading the SAP JCo. Refer to the Release Notes for installation information.

## SAP Gateway

The SAP Gateway is a SAP software product available for Windows and UNIX platforms to provide network connectivity. The R/3 adapters support the Registration method for RFC destination activation. To achieve the necessary RFC destination activation, the SAP Gateway, used as a stand-alone product, must be installed. The SAP Stand-Alone Gateway provides a secure method for communications between SAP and external systems. This communication method is the communication method of choice by SAP. SAP requires the use of a stand-alone gateway for all certified ALE interfaces.

For information on how to install the SAP Gateway, refer to your SAP documentation.

## Configuring the SAP R/3 system

Your SAP R/3 system must be properly configured to send and receive data. This configuration requires:

["1. Creating a Logical System \(BD54\)"](#)

["2. Creating RFC Destination for Outbound Data \(SM59\)"](#)

["3. Creating a Distribution Model \(BD64\)"](#)

["4. Generating a Partner Profile \(BD82\)"](#)

- ["1. Creating a logical system \(BD54\)"](#)
- ["2. Creating RFC destination for outbound data \(SM59\)"](#)
- ["3. Creating a Distribution Model \(BD64\)"](#)
- ["4. Generating a Partner Profile \(BD82\)"](#)
- ["5. Manually creating partner profiles \(WE20\)"](#)

### 1. Creating a logical system (BD54)

Every SAP R/3 client used for ALE/RFC must have a base logical system (LS) associated with the SAP client.

Note: This association is typically created at installation time by the SAP Applications installation team.

Every base LS becomes the sender for outbound messages and a receiver for inbound messages.

In addition to the base LS, additional logical system(s) must be created within that SAP R/3 system for every SAP R/3 and external system used for ALE interfaces. In an inbound ALE/RFC interface, this second LS represents the sender with respect to the base LS. In an outbound ALE/RFC interface, this second LS is a receiver.

A logical system may be created for each external system that communicates with SAP R/3. The design of your maps and systems dictate what is an external system. Generally, you create an external system to correspond to each distinct non-SAP system.

Transaction **BD54** creates a logical system to represent the server system for the distribution of data to and from the SAP R/3 system.

To create a logical system

1. Enter **/nBD54** in the command field and click **Enter**.
  2. Click **Enter** in the information window, which alerts you that you are in the process of maintaining a client-independent table and that any changes that you make will have an effect on all other clients in the system.  
The Change View "Logical systems": Overview window opens, listing the logical systems that are currently defined.
  3. Click **New entries** to create the logical system (LS).
- The New Entries: Overview of Added Entries window opens.
4. Enter a name for the LS and a meaningful description. (Throughout this example, the LS name will be **CUSTOMERLS**. The name of the base LS is **E47CLNT800**.)  
Note: The naming convention you follow for the LS should be informative because it will be used in naming the RFC destination and the partner profiles.
  5. Select **CTRL + F4**.  
The Change ==...> Display dialog box opens to confirm the change.
  6. Click **Yes** to save.  
The Prompt for Workbench request dialog box opens.
7. To complete the creation of the LS, you must obtain a request number. Create a request number for each new LS added. In the **Request** field, select a value from the drop-down list and click **Enter**.
  8. Return to the Display View "Logical systems": Overview window.
  9. Choose **Save** from the Table View menu and click **Enter**.  
The LS is created.

### 2. Creating RFC destination for outbound data (SM59)

The RFC destination is used during the Communication Layer of ALE processing. When Receiver Determination identifies a tRFC communication, the RFC destination defines the physical communication to the remote destination. RFC destinations are used only for communications outbound from SAP R/3.

To create RFC destination for outbound data:

- Set up a RFC destination.
- Set gateway options to reflect the values used when installing the stand-alone gateway.
- Optionally, set tRFC options to set the specifications for connection retries in the event of communication timeouts or connection errors. This is done by specifying the number of retry attempts, as well as the interval between two consecutive attempts. Alternatively, you can suppress the background job for connection retries.

SAP R/3 has a collective error-processing feature that you can enable to do error handling through a scheduled job that runs in the background.

- [Setting up an RFC destination](#)
- [Gateway options](#)
- [tRFC options](#)
- [Collective error processing](#)

## Setting up an RFC destination

The RFC destination may be created to define the physical communication to the remote destination. The following steps refer to the design of the SAP R/3 Enterprise application.

To set up a RFC destination:

1. Enter transaction /nsm59 in the command field.  
The Display and maintain RFC destinations window opens.
2. Right-click on TCP/IP connections and click Create.  
The RFC Destination window opens.
3. Enter the options as defined in the table. The RFC Destination window propagates with your information.

Table 1. Details for the RFC Destination window

| Field           | Enter                                                                            |
|-----------------|----------------------------------------------------------------------------------|
| RFC destination | Enter the name for the RFC destination. Use the same name as the Logical System. |
| Connection type | Enter T (TCP/IP) for the Connection type.                                        |
| Description     | Enter a meaningful description in the Description field.                         |

4. Click the Special Options tab. The Trace feature is located under the Special Options tab.  
You can enable Trace for testing purposes. However, do not enable Trace in a production environment.

5. Click the Technical Settings tab. Enter the following information:

Table 2. Technical Settings tab

| Field           | Enter                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Activation type | Enable Registered Server Program.                                                                                                            |
| Program ID      | Enter the Program ID. This is the program ID that is specified when using the Program ID (-A) adapter command for any R/3 source (outbound). |

6. Click the Logon/Security tab. Activate or Inactivate the Security Option. Click the Save button.

## Gateway options

Gateway options are set to correspond exactly to the values used when installing the SAP Stand-Alone Gateway.

To set gateway options:

1. Enter transaction /nsm59 in the command field.  
The Display and maintain RFC destinations window opens.
2. Expand TCP/IP connections and double-click the applicable TCP/IP connection.  
The RFC Destination window opens.
3. Click the Technical settings tab. Enter the information as defined in the table.  
Note:  
The values for Gateway host and Gateway service can be symbolic names. However, specifying the IP address and service number can improve performance and reduce errors.

Table 1. Gateway options

| Field           | Enter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Gateway host    | Enter the name of your gateway host or the IP address of your gateway host. (In this example, it is <b>192.168.1.229</b> .)<br>The value that you enter in Gateway host must match the value that you specify when using the Gateway Host (-G) adapter command for any SAP R/3 source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Gateway service | Enter the name of your gateway service. Gateway service is the service name created during the installation of the SAP Stand-Alone Gateway software. The default is sapgw00. Alternatively, you can use the port address instead of the gateway service name (In this example, the value is 3300.)<br>The value that you enter in Gateway service (-x) must match the value that you specify when using the Gateway Service adapter command for any SAP R/3 source.<br><br>When migrating to SAP JCo 3, in order to use the JALE, you must perform the following when using SAP Gateway Service:<br><br>If using SAP Gateway Service name sapgwXX, or sapmsXXX, a lookup in the etc/services is required: -x sapgw00. As an example, if you are using a Windows platform, you must modify the services file located in C:\WINDOWS\system32\drivers\etc. In this case, sapgwXX must be added to the services file, along with port number and protocol type:sapgw00 3300/tcp #sap gateway for sapserver1.company.com<br><br>Note: The use of port numbers instead of symbolic service names prevents the lookup. |

## tRFC options

Depending on your configuration, you may find it useful to specify automatic retries for outbound data. tRFC options (retry options) dictate the SAP R/3 behavior during communication errors or failures. If you are experiencing frequent communication time outs or connection errors (visible in SM58 tRFC Monitoring), implement these retry options.

Note: Setting tRFC options is a one-time step. You can maintain tRFC Options by clicking the tRFC button in the RFC Destination window. Set tRFC Options to specify automatic retries for outbound data. Also, SAP R/3 has a collective error-processing feature that can be enabled, which does error handling through a scheduled job that runs in the background.

To set the tRFC Options:

1. Enter transaction `/nsm59` in the command field.  
The Display and maintain RFC destinations window opens.
2. Expand TCP/IP connections and double-click the applicable TCP/IP connection. (For this example, double-click DATASTGTX1.)  
The RFC Destination window appears.
3. From the Destination menu, choose tRFC Options.  
The Transactional RFC: System Setting for Connection Error dialog box opens.
4. In the Suppress background job if conn.error field, enter the value `x` and click Continue.  
The RFC Destination window reappears.
5. From the Destination menu, choose Save.

---

## Collective error processing

SAP R/3 handles RFC errors by starting a background process that restarts the RFC until it is processed successfully. If the connection with the receiving system is broken, this process can run indefinitely. This scheme can result in a large number of background processes running in the sending system that will degrade overall performance. To minimize these effects in a production environment, use collective error processing. With collective error processing, the failed RFC will not be resubmitted immediately. Instead, a periodically scheduled background job will collect failed RFCS and restart them as a packet. This technique is applicable for SAP R/3 and TCP/IP connections.

---

### Setting collective error processing for RSARFCEX

Periodically schedule program **RSARFCEX** to process failed transmissions.

---

### Setting collective error processing using SM58

1. After the above settings are in place, you can manually select transaction **SM58**.
2. Select the appropriate criteria and click Execute.
3. Select a failed function module and select Execute LUW from the Edit menu.

---

## 3. Creating a Distribution Model (BD64)

A Distribution Model contains the specifications identifying which messages (Message Types) flow to which logical system. A Distribution Model designates the type of data to be exchanged.

You will be modeling the exchange of data types from both the Sender view and the External system view for your SAP R/3 system and for IBM.

- [Creating message types for the Distribution Model](#)

---

### Creating message types for the Distribution Model

Message types are used in a Distribution Model to represent the type of data being exchanged between your SAP R/3 system and the Pack for SAP Applications.

To create message types:

1. Enter `/nbd64` in the command field.  
The Display Distribution Model window appears.
2. Expand SUBSYSTEMS to view the list. (Typically, the default SUBSYSTEMS Distribution Model is used.)
3. Select your SAP R/3 system. (For example `E47CLNT800`.)
4. Click the Add message type button.  
The Add Message Type dialog box opens.
5. Enter the message type data for the communication from the SAP R3 system to an external system.
  - Sender: Enter the current SAP R3 logical system. (In this example, it is `E47CLNT800`.)
  - Receiver: Enter the name of the logical system that was created. (In this example, it is `CUSTOMERLS`.)
  - Message type: Enter the message type. (This example uses `DEBMAS`.)

Note: A communication model from the SAP R3 system to an external system (`CUSTOMERLS`) is established.
6. Click Enter.
7. Return to the Change Distribution Model window and continue with the process of adding another message type to complete the distribution model.
8. Select SUBSYSTEMS and then click Add message type.  
The Add message type dialog box opens.

9. Enter the message type data for communication from the external system to the SAP R/3 system:
  - Sender: Enter the Logical system for the external system. (In this example, it is CUSTOMERLS).
  - Receiver: Enter the name of the current SAP R3 logical system. (In this example, it is E47CLNT800).
  - Message type: Enter the message type. (This example uses DEBMAS).

Note: A communication model from an external system to the R3 system is established.
10. Click Enter to return to the Change Distribution Model window.
11. In the Model menu, choose Save and click Enter.

## 4. Generating a Partner Profile (BD82)

The port definition can be generated based on the RFC destination and the partner profile. The partner profile is generated based on the Distribution Model and the port definition.

To generate a partner profile:

1. Enter /nbd82 in the command field.  
The Generating partner profile window opens.
2. In the Model view field, select a distribution model view from the drop-down list. (In this example, it is SUBSYSTEMS.)
3. In the Partner system field, select a Logical System from the drop-down list. (In this example, it is CUSTOMERLS.)
4. Select Collect IDocs and transfer. (This is the default, which can be changed using transaction code **WE20**.)
5. Select Trigger by background processing so there is no overriding by express flags. (This parameter is the default, which can be changed using **WE20** transaction code.)
6. Click Execute.  
The Generating partner profile window opens listing the messages and confirming the generation of a port and partner profile.

## 5. Manually creating partner profiles (WE20)

The Distribution Model is only applicable to ALE interfaces. When using the Distribution Model, the BD82 transaction will automatically update/create partner profile definitions and create RFC port definitions as needed. However, these definitions must be created or modified manually in situations such as the following:

- When you are not able to use the Distribution Model, you must manually create your partner profile definitions (WE20) and port definitions (WE21). Reference the *SAP Online Library* for additional information.
- When using the EDI file-based method of IDoc creation, you will need to manually create partner profiles.
- When modifying the Partner Profile parameters prior to production or to create partner profiles manually.

There are situations where partner profiles must be created or modified manually.

- **Inbound parameters**

### To manually create partner profiles

1. Enter /nWE20 transaction in the command field.  
The Partner Profiles window opens.
2. From the Partners menu, select Create or Display Change to create a new profile or to modify an existing profile.
3. Enter Outbound parameters or Inbound parameters as appropriate.

In the Outbound Parameters window, you can add or change the information as required.

From transaction codes the various reports can be run.

- RSEOUT00: Dispatch collected IDocs in a batch job.
- RSEOIND: Check the successful completion of the transmission of a tRFC to the communication layer. If successfully completed, the status of the IDoc is changed.

#### Schedule report RSEOUT00

As SAP recommends, the program RSEOUT00 should be scheduled to send IDocs by using transactional RFCs. This sends IDoc packages in one transmission, using one logon, and may provide better performance than sending IDocs individually. Avoid sending individual IDocs because each transmission involves significant overhead such as the loading of programs, establishing the connection, and logging on.

When using RSEOUT00, note the size of the IDoc packages, which can be defined in the outbound parameters of the corresponding partner agreement. For optimization, the size of the data objects involved and the number of available processes at the transmitting and receiving ends must be considered. SAP R/3 generally recommends packing 2 to 20 IDocs per package for IDocs that have numerous segments (such as ALEUD and GLDCMT) and 20 to 2,000 IDocs per package for IDocs with a small number of segments.

The use of RSEOUT00 requires one or more dialog work processes to enable parallel transmissions of IDoc packages. For SAP R/3 versions 3.1i and higher, tRFC resource management support is available. SAP R/3 advises that to avoid timeouts, the number of sender-side dialog work processes should be less than or equal to the number of available processes on the receiver. See *OSS note 74141* in the *SAP R/3 Documentation* for details.

When sending IDoc packages in parallel using this method, the packages cannot be received in serial order. If serialization of IDoc package transmission is required, use a periodic process on the received packages. To do this, configure your partner profiles for background processing and select a processing interval sufficiently large enough to ensure all interdependent packages can be received. Based on their time stamp, the packages are then reordered before processing.

#### Schedule Report RBDMOIND

When outbound IDocs are passed to the communication layer successfully, they are assigned the status **data passed to port OK**. This does not mean that it was a successful tRFC transmission. The RBDMOIND report from **SE38** should be regularly started to check whether the communication was successfully completed. If

successfully completed, the status of the IDoc is changed.

The RBDMOIND report indicates whether the outbound IDocs were transmitted to the communication layer successfully and should be scheduled to run regularly.

## To schedule the RBDMOIND report

---

1. Define variants for the job.
  2. Schedule the job with the report and one variant in one step.
- 

## Inbound parameters

From the Partner profiles: Inbound parameters window, you can add or change the a partner profile information as required.

To change inbound parameters for the Partner Profile, choose the appropriate Message type and the corresponding Process code, which is linked to the Function Module.

Run report RBDAPP01 to process the background IDoc.

## Schedule report RBDAPP01

---

Processing of the background IDoc is done by report RBDAPP01.

Avoid single IDoc transmissions because significant overhead is involved (such as program loading, connection, and logon).

Inbound processing time is affected at the receiving end when IDoc packages are initially separated into separate IDocs and individual inbound IDocs are stored in the database. The application transmission control defined in the corresponding partner agreement determines if the IDoc should be processed immediately or scheduled for processing by program RBDAPP01. SAP recommends using RBDAPP01 to improve performance if immediate processing is not required.

The information provided is minimal and may not address all of your communication requirements such as information about global company code maintenance, change pointer activation, maintaining number ranges, and so on. Refer to the *SAP Online Library* for additional information.

Also, the default parameter values in the instance profile are not sufficient for high-volume ALE interfaces. Consult with your SAP Applications installation team and OSS notes for recommended changes to these values.

---

## Creating SAP connections, actions, and schemas

Use the Importer Wizard to import BAPI, IDoc, and DXOB files to automatically generate a schema.

For more information about the Importer Wizard, review the following:

- [Overview of the Importer Wizard](#)
  - [Running the Importer Wizard](#)
  - [Overview of the Importer Wizard](#)
  - [Running the Importer Wizard](#)
- 

## Overview of the Importer Wizard

The Importer Wizard uses SAP R/3 structure-specific metadata input to generate schemas containing the corresponding type definitions. The Importer Wizard uses a series of maps to convert metadata into a schemascript file. The Type Tree Maker then processes this schema script and generates a schema containing all the supported types defined in the metadata that is imported.

For example, the following illustration shows several RSEIDOC3 IDoc definition files being imported into the Importer Wizard, which automatically generates the corresponding schema.

Schemas generated by the Importer Wizard can be used immediately for map development. Depending on the contents of the interface-specific metadata file, it may be necessary for the generated schema to be modified using the Type Designer. See each interface-specific section for information about the generated schemas.

---

## Running the Importer Wizard

When SAP metadata input contains one of the supported structures describing the data for which you want to create an interface, you are ready to run the Importer Wizard.

To run the Importer Wizard:

1. Start the Design Studio.
2. Select **File > Import**.  
The Importer Wizard opens.
3. Expand the folder.
4. Select the SAP interface (IDOC, DXOB, BAPI) for which you want to generate a schema and click **Next**.
5. The next dialog box opens, prompting you for information about the SAP system that originated the metadata file you are importing. Enter the appropriate information and click **Next**.

- The language dialog box opens.
6. Specify the national language and data character set that describe the data for map execution then click Next.
  7. The next dialog boxes that appears depends on the interface for which you are generating a schema. The Wizard presents the applicable dialog boxes for you to specify interface-specific information. For example, when generating a schema for BAPI, the SAP Connection Settings dialog box appears to enable you to specify adapter connect parameters. See each interface-specific chapter for this particular information.
  8. After entering the interface-specific information presented by the Wizard, a dialog box opens requesting the full path and file name of the metadata for which you are generating a schema.
  - Specify the metadata object for which you want to generate a schema and provide any additional information that is required by the Importer Wizard for your specific interface. For example, when generating schema from an IDoc, you must designate whether the IDoc file represents data that is for an ALE or EDI interface. See each interface-specific section for additional information.
  9. Enter the name of the schema to be generated and any additional information required by the Wizard for your specific interface, and click Next. See the interface-specific chapter for additional information.
  10. The next Importer Wizard dialog box opens showing the status of the schema being created.  
You can scroll through the schema. The Importer Wizard dialog box also shows the number of errors and warnings that have occurred when generating the schema.

---

## The R/3 adapters

The SAP specific components for the SAP R/3 runtime environment are the R/3 adapters for Windows based and UNIX based platforms.

This section introduces the R/3 adapters and provides instructions for adapter use, adapter settings, and adapter commands, including the following:

- [Overview of the R/3 adapters](#)
- [Using R/3 adapter commands](#)
- [Connection commands](#)
- [Syntax summaries for R/3 adapters](#)
- [R/3 adapter aliases](#)
- [Using R/3 system commands](#)
  
- [Overview of the R/3 adapters](#)
- [Using R/3 adapter commands](#)
- [Connection commands](#)
- [Adapter commands list](#)
- [Syntax summaries for R/3 adapters](#)
- [R/3 adapter aliases](#)
- [Using R/3 system commands](#)

---

## Overview of the R/3 adapters

Both client and server functionality is supported within an R/3 adapter. An R/3 adapter contains the Remote Function Calls (RFCs) necessary to pass inbound and outbound data to and from SAP R/3. The adapter includes transparent integration of the RFCs so that it is not necessary to possess detailed knowledge about the RFCs. The adapters also manage transactional information such as message transaction IDs (TIDs) as needed. This feature ensures seamless integration with SAP R/3 and also provides a robust auditing mechanism.

When a map has an input card that defines an R/3 adapter as the source, the adapter's server function is invoked to perform the RFCs required to ensure successful collection of the input data from the SAP R/3 system. For example, an SAP R/3 system has data that has been defined as input for a specific map executing on a Command Server. The map contains an input card that has the R/3 adapter defined as the adapter source. The R/3 adapter (server) receives the necessary RFCs to retrieve the SAP R/3 data. The adapter then passes the data through memory buffers from SAP R/3 directly into the running map for transformation into the target format.

For an output card, after a IBM map transforms the source data, the client function of the R/3 adapter is invoked, which performs the RFCs required to ensure successful delivery of the inbound data to the target on an SAP R/3 system.

The R/3 adapters used to interface with the SAP R/3 application are:

- JALE (for Unicode and non-Unicode)
- JBAPI (for Unicode and non-Unicode)
  
- [Unicode support](#)

---

## Unicode support

The JBAPI adapter is based on JCo, the SAP Java API that enables communication with SAP systems. The JBAPI adapter is fully backward-compatible with the native BAPI adapter; however the JBAPI adapter provides full Unicode support.

The JBAPI adapter supports Unicode directly and provides unified access to both Unicode and non-Unicode systems.

The JALE adapter includes Unicode character set data support inbound to, and outbound from, SAP. To enable Unicode support maps that use the JALE adapter you must use the IDoc schemas generated by the IDoc importer with the data character set option defined as Unicode.

---

## Sending Unicode data inbound to SAP from the JALE adapter

The JALE adapter is able to communicate Unicode data to an SAP R/3 system. The Unicode data format supported by the JALE adapter is UTF-16BE, Unicode big-endian. For mapping purposes it is strongly recommended you use the schemas generated by the IDoc schema importer. Using IDoc Unicode schema guarantees that data passed

to the JALE adapter has the correct syntax, recognizable by the JALE adapter. To send Unicode data to the JALE adapter use the ALE schema for the Unicode character set. The SAP R/3 system must be Unicode compliant to be able to process the Unicode data sent to it from the JALE adapter.

## Sending Unicode data outbound from SAP to the JALE adapter

---

The JALE adapter is able to receive and process Unicode data from an SAP R/3 system. The Unicode data format supported by the adapter is UTF-16BE, Unicode big-endian. Before sending Unicode data from an SAP R/3 system to an external system, the SAP RFC destination assigned to the external system must be configured correctly.

To enable the Unicode options:

1. Enter SAP transaction /nsm59.
2. Click the Special Options tab.
3. Select the Unicode option under the Character Width in Target System section.
4. Save the changes.

After saving, you will be able to send Unicode data to the selected RFC Destination. The IDoc schema that will be used to parse the JALE data source must also support Unicode data.

Use the IDoc schema importer to generate the IDoc schema. Using the IDoc Unicode schema guarantees that data passed to the JALE adapter has the correct syntax, recognizable by the JALE adapter. To send Unicode data to the JALE adapter, use the ALE schema for Unicode character set.

---

## Using R/3 adapter commands

R/3 adapter commands are used to customize the adapter's operation and can be specified for the data source of an input map card, the data target for an output map card, or both.

For more information, see Resource Adapters in the online documentation.

- [Execution command overrides](#)
- [Card settings](#)
- [R/3 data retrieval behavior for bursts](#)
- [OnFailure behavior with R/3 adapters](#)
- [Adapter commands syntax and usage](#)
- [RUN, GET, and PUT functions](#)
- [From the Map Designer](#)
- [From the Integration Flow Manager](#)

---

## Execution command overrides

Execution commands can be used, through command lines, to override settings for an existing SAP R/3 source. You can also override existing files, application, message source, or message target.

---

## Card settings

For details on card settings, see the Map Designer information in the online documentation.

The following values can be used for the source input card and target output card to enable SAP adapters:

- JALE
- JBAPI

---

## R/3 data retrieval behavior for bursts

All SAP R/3 objects (IDoc, BAPI, and DXOB) are retrieved from the adapter prior to the first burst. The server then consumes them at the rate specified by the FetchUnit setting.

---

## OnFailure behavior with R/3 adapters

When the Transaction>OnFailure input card setting equals Commit and the map does not complete successfully, the IDoc data is lost.

---

## Adapter commands syntax and usage

The following example is a command Target setting on an output card for an ALE adapter.

```
-c 800 -u ALE-USER -p IDES -h M699 -s 00 -ar3
```

Adapter commands are used in connecting to the SAP R/3 system to which the transformed data is being targeted.

Table 1. Adapter Commands Syntax and Usage

| Adapter command/value    | Interpretation                                                                                                                                                                                           |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-c 800</code>      | Identifies the client number. Required for logging onto the SAP R/3 system.                                                                                                                              |
| <code>-u ALE-USER</code> | Identifies the user name. Required for logging onto the SAP R/3 system.                                                                                                                                  |
| <code>-p IDES</code>     | Identifies the password. Required for logging onto the SAP R/3 system.                                                                                                                                   |
| <code>-h M699</code>     | Identifies the host name or SAP route string of the SAP R/3 server to connect.                                                                                                                           |
| <code>-s 00</code>       | Identifies the system number.                                                                                                                                                                            |
| <code>-ar3</code>        | Specifies the creation of an adapter log file containing information about the transactions that occurred for this target during map execution. (In the example, <code>-ar3</code> signifies Audit R/3.) |

See the [Adapter Commands List](#) for information about the syntax and the use of each adapter command.

## RUN, GET, and PUT functions

You can use the R/3 adapter commands when using `RUN`, `GET`, and `PUT` functions when defining map rules in the Map Designer. See the *Functions and Expressions* information in the online documentation for information about the `RUN`, `GET`, and `PUT` functions.

- [RUN example](#)
- [GET example](#)
- [PUT example](#)

### RUN example

The following example shows map rules using a `RUN()` function for JALE using R/3 adapter commands to override execution commands.

```
RUN ("somemap.mmc" ,
 "-OMJALE1 ` -c remo -u " +
 userid:profile + " -p " + password:profile +
 " -h SAPh03 -s 03'")
```

In this example, a map named somemap is being executed overriding output card #1.

### GET example

A `GET()` function uses the R/3 adapter to retrieve data.

The following examples show map rules using a `GET()` function for JALE and JBAPI using R/3 adapter commands to specify the destination key for the Saprfc.ini file.

```
GET ("JALE", "-D MY_R3 -AR3")
GET ("JBAPI", "-D MY_R3 -c 800 -u IDES_USER -p initpass",
 CPACKAGE (JBAPI, "NATIVE"))
EITHER (GET ("JBAPI", "-D MY_R3-c 800 -u IDES_USER -p initpass",
 CPACKAGE (JBAPI, "NATIVE")),
 IF (0 < LASTERRORMSG(), FAIL(LASTERRORMSG())))
```

Note: The JBAPI adapter can only be used in the GET function. It cannot be used in a map input card, map output card, or PUT function.

### PUT example

A `PUT()` function sends data to the R/3 adapter.

The following example shows the `PUT()` function being used to send data to the R/3 adapter as well as enabling an adapter trace.

```
PUT ("JALE", "-c 800 -u IDES_USER -p initpass -h 127.0.0.1 -s 00 -t",
 CPACKAGE (CREMAS IDoc Input, "NATIVE"))
```

## From the Map Designer

From the Map Designer, you can use the R/3 adapter for a source or target. For example, in the output card, you can select R/3 ALE or JALE as the value for the target settings.

This example output card named **Legacy\_Data** is for a map named ALE Outbound DEBMAS.mms. The Target Command setting is composed of several R/3 adapter commands, including the required adapter commands `-c`, `-u`, `-p`, `-h`, and `-s`, which specify the necessary client, user ID, password connection information, host identifier, and system identifier. The `-ar3` adapter command specifies the creation of an adapter log file containing information about the transactions that occurred for this target during map execution.

## From the Integration Flow Manager

From the Integration Flow Manager, when you access the execution settings (either Launcher or Command Server) for a map, you can select one of the SAP R/3 adapters as a source or target.

For example, to override adapter settings of an output card or specify the SAP R/3 adapter for a target, access the execution settings for a map. Select R/3 ALE or JALE from the Target drop-down list and specify the adapter commands in the field.

This example of the Launcher settings for a map component named OrdersByDepartment shows that for **Output #1Target Command Accounting**, the R/3 adapter is specified as the target. The Target Command setting is composed of several R/3 adapter commands, including the required adapter commands for connection: **-c**, **-u**, **-p**, **-h**, **-s** that identify the client, user ID and password respectively, and **-d** which specifies the destination key for saprfc.ini that designates the additional connection information). The trace (**-t**) adapter command indicates to enable adapter trace, which creates a trace file that contains information detailing adapter activity and **-ar3**, which indicates to create the audit log.

## Connection commands

When you use an R/3 adapter, it is dependent on the SAP R/3 interface and the action that you want to specify. Many of the SAP R/3 adapter commands are required in particular situations and with specific SAP R/3 interfaces. The following topics explain situations where particular SAP R/3 adapter commands apply:

- [Required connection commands for JALE sources](#)
- [Required connection commands for JALE targets and calling a BAPI](#)
- [Optional connection commands for JALE sources and targets](#)
- [Optional connection commands for all sources and targets](#)
- [Required connection commands for JALE sources](#)
- [Required connection commands for JALE targets and for calling a BAPI](#)

## Required connection commands for JALE sources

The following adapter commands are required for a JALE source when connecting to an SAP R/3 system and the Saprfc.ini file is not used. Each adapter command is used to provide the necessary connection information required by the SAP system.

```
-U usr_id -P pwd -H host_name -S sys_num -C clnt_num
-A pgm_id -G gtwy_name -X gtwy_conn
```

The Destination adapter command is required when using the Saprfc.ini file, which contains the default connection information. The value specified with this adapter command is case sensitive.

```
-D dest_key
```

## Required connection commands for JALE targets and for calling a BAPI

The following adapter commands are required when calling a BAPI and for JALE targets for connection to a SAP system.

```
-C clnt_num -U usr_id -P pwd
```

After specifying **-c**, **-u**, and **-p** arguments, you must use one of the following three adapter command groupings, which are required to complete the connection information:

- Use these adapter commands to specify the SAP host ID and the SAP system number:  
  

```
-H host_name -S sys_num
```
- The Destination (**-d**) adapter command is required when using the Saprfc.ini file, which contains the default connection information. The value specified with this adapter command is case sensitive.  
  

```
-D dest_key
```
- This group of adapter commands is required when using the SAP R/3 load balancing principle:  
  

```
-BAL -H host_name -G grp -S sys_name
```
- The Language (**-l**) adapter command is an optional adapter command that can be used when needed for your particular connection requirements. Depending on the SAP system, this adapter command may be required for connection.  
  

```
-L lang_cd
```

## Adapter commands list

The following table lists each R/3 adapter command, the command syntax, and the interfaces for which it can be used for a source (outbound data), target (inbound data), or both.

Table 1. Adapter command list

| Name                   | Command Syntax                                     | JALE          | JBAPI  |
|------------------------|----------------------------------------------------|---------------|--------|
| Program ID             | <b>-A <i>pgm_id</i></b>                            | source        |        |
| Audit                  | <b>-AR3 [+ U] [%tid%   <i>full_path</i> ]</b>      | source/target |        |
| Backup                 | <b>-B [I] [X] [%tid%   <i>full_path</i> ]</b>      | source/target |        |
| Load Balancing         | <b>-BAL</b>                                        | target        | target |
| Bytes Per Character    | <b>-BPC</b>                                        | source/target |        |
| Client Number          | <b>-C <i>cint_num</i></b>                          | source/target | target |
| Character set encoding | <b>-enc</b>                                        | source        |        |
| Destination            | <b>-D <i>dest_key</i></b>                          | source/target | target |
| GatewayHost            | <b>-G <i>gtwy_name</i></b>                         | source        |        |
| IDoc Field Generation  | <b>-GEN [0 1] [ <i>flds</i> ]</b>                  | target        |        |
| Group                  | <b>-GROUP <i>NAME</i></b>                          | target        | target |
| Host ID                | <b>-H <i>host_name</i></b>                         | source/target | target |
| Logon Language         | <b>-L <i>lang_cd</i></b>                           | target        | target |
| Listen                 | <b>-LSN {0 1} <i>dur</i> [: <i>int</i> ]</b>       | source        |        |
| Listener Threads       | <b>-N</b>                                          | source        |        |
| Password               | <b>-P <i>pwd</i></b>                               | target        | target |
| Packet Size            | <b>-PKT <i>IDoc_qty</i></b>                        | target        |        |
| Reprocess backup files | <b>-R</b>                                          | source        |        |
| System ID              | <b>-S <i>sys_num</i></b>                           | source/target | target |
| Timeout                | <b>-timeout <i>secs</i></b>                        |               | target |
| Trace                  | <b>-T[V E N] [+ U] [%tid%   <i>full_path</i> ]</b> | source/target | target |
| Transaction ID         | <b>-TID <i>trans_ID</i></b>                        | source/target |        |
| IDoc Type              | <b>-TY OTHER\$ <i>doc_type*</i></b>                | source        |        |
| User ID                | <b>-U <i>usr_id</i></b>                            | target        | target |
| Gateway Service        | <b>V</b>                                           | source        |        |

## Program ID (-A)

Use the Program ID (-A) adapter command to specify the program ID to be used for RFC activation when using the Registration method. The program ID is a unique identifier that is used by the SAP Gateway to identify the listener (the program). SAP recommends a format of machine.program for the program identifier. This identifier must match the Registration Program ID defined in SM59. SAP R/3 uses this identifier to distinguish multiple programs registered at the same SAP Gateway. For example, the program IDs **xyz.CREMAS** and **xyz.MATMAS** could both be registered at the same SAP Gateway (**-G 186.114.3.126**) and gateway number (**-X 3300**).

**-A *pgm\_id***

### Option

#### Description

*pgm\_id*

Unique program identifier.

SAP recommended format machine.program.

Has no relationship to the logical system, although a common practice is to name the key similarly to the logical system.

## Audit (-AR3)

Use the Audit (-AR3) adapter command to create a file that records the adapter activity for each specified input and output card. The default is to produce a file named m4r3adapter.log in the directory where the map is located. Optionally, you can append the audit information to an existing file, specify to use the transaction\_id for the file name, specify your own file name, incorporate the transaction\_id into your own file name, or specify a full path for the file.

**-AR3 [+][U] [%tid%|full\_path]**

### Option

| Option           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>+</b>         | Append audit information to an existing file.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>U</b>         | For Command Server: Produce a file named <i>transaction_id.log</i> where <i>transaction_id</i> is the SAP R/3 assigned Transaction Identifier (TID) that is always in the map directory, regardless of whether u is in the input or output card of the map.<br>For Launcher: Produce a file named <i>transaction_id.log</i> where <i>transaction_id</i> is the SAP R/3 assigned Transaction Identifier (TID). If u is in the input or output card, then <i>transaction_id.log</i> is in the map directory. |
|                  | If a Transaction Identifier (TID) cannot be assigned, <i>transaction_id</i> is m4r3serial_number. When this option is used and the Backup (-B) adapter command is also specified, the name of the backup file and the audit file always match.                                                                                                                                                                                                                                                             |
| <b>%tid%</b>     | When specifying the name for the audit file, you can incorporate this literal as part of the file name and it will be replaced by the TID_number.                                                                                                                                                                                                                                                                                                                                                          |
| <b>full_path</b> | Specify the name for the audit file, which can include the directory path.                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Backup (-B)

Use the Backup (-B) adapter command to create a backup file of processed IDocs. The default is to produce a file named *transaction\_id.tid* where *transaction\_id* is the SAP R/3 assigned Transaction Identifier (TID) in the map directory.

If a Transaction Identifier (TID) cannot be assigned, *transaction\_id* is m4r3serial\_number. Optionally, you can specify that the file be input for a map, delete the file upon successful map execution, specify your own file name, incorporate the *transaction\_id* into your file name, or specify a full path for the file.

Note: When a failure occurs, a *transaction\_id.tid* backup file is created with the connection information and the IDOC (when normal usage of -B occurs only the IDOC is created).

Note: When the Audit adapter command and its U option (-AR3U) is used in conjunction with this adapter command, the name of the audit file and the backup file always match.

**Source -B[I][X] [%tid%|full\_path]  
Target -B[X] [%tid%|full\_path]**

### Option

| Option           | Description                                                                                                                                         |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>I</b>         | Create backup file in temporary directory instead of using memory buffers. This option is only applicable when the ALE adapter is used as a Source. |
| <b>X</b>         | Delete the backup file from the temporary directory upon successful completion of map execution.                                                    |
| <b>%tid%</b>     | When specifying the name for the backup file, you can incorporate this literal as part of the file name and it is replaced by the TID_number.       |
| <b>full_path</b> | Specify the name for the backup file, which can include the directory path.                                                                         |

The following are examples using the Backup (-B) adapter command:

### Command

#### Result

|                         |                                                                                                                                                                                                                                                                                                  |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-B %tid%</b>         | <i>dstx_directory\TID_number.tid</i> where <i>dstx_directory</i> is the installation directory and <i>TID_number</i> represents the TID number generated. Before using the -B adapter option with %tid%, you must first create a resource registry entry for tid and assign it a value of %tid%. |
| <b>-B d:\bak\%tid%</b>  | <i>d:\bak\TID_number.tid</i> where <i>TID_number</i> represents the TID number generated.                                                                                                                                                                                                        |
| <b>-B Archive\%tid%</b> | <i>dstx_directory\ArchiveTID_number.tid</i> where <i>dstx_directory</i> is the installation directory and <i>TID_number</i> represents the TID number that is generated.                                                                                                                         |

## Load Balancing (-BAL)

Specify the Load Balancing (-BAL) adapter command to logon with SAP R/3 load balancing. The load balancing principle allows a login to a server that will dynamically route processes based on the availability of the application servers. Using load balancing typically results in improved performance and addresses the potential for failure from connecting to one specific application server. Additional information about load balancing can be found in the SAP RFC SDK.

Note: Using the SAP R/3 load balancing principle requires the existence of a logon group in the SAP system. Consult your Basis team for assistance and information about this logon group.

**-BAL -H HOST -S R3NAME -G GRP**

**Option****Description**

|                         |                                                                              |
|-------------------------|------------------------------------------------------------------------------|
| <b>-H <i>HOST</i></b>   | Specify the server host name.                                                |
| <b>-S <i>R3NAME</i></b> | Specify the R/3 name of the system.                                          |
| <b>-G <i>GRP</i></b>    | Specify the logon group.<br>Group typically has the default value of PUBLIC. |

Note: When using **-BAL**, the values passed using **-H**, **-S**, and **-G** are always the values for **-BAL**. Therefore, never use the connection adapter commands for Host ID, System Number, or Gateway Host, which also use **-H**, **-S**, and **-G** for their values.

In addition, an entry must be added to the Services file, which is located in c:\winnt\system32\drivers\etc\services using the following syntax:

```
sapms R3NAME 36SYSNR/tcp
```

For example:

```
s apmsTSI 3600/tcp
```

The following is an example of the R/3 adapter command string for load balancing:

```
-c 800 -u JSharp -p S836GJ -bal -h MSG40 -s TSI -g PUBLIC
```

If it is necessary to connect to a gateway, you can specify **GHOST=gwhost** directly within the adapter commands.

The Saprfc.ini file also supports the use of load balancing. The following is the example distributed by SAP as a sample entry in the Saprfc.ini file.

```
/*=====
/* Type B: R/3 system - load balancing feature */
/*=====

DEST=BIN
TYPE=B
R3NAME=TSI
MSHOST=MSG40
GROUP=PUBLIC
RFC_TRACE=0
ABAP_DEBUG=0
USE_SAPGUI=0
```

The following is an example of the R/3 adapter command string to accommodate using the Saprfc.ini file with load balancing:

```
-d BIN -c 800 -u JSharp -p S836GJ
```

## Bytes Per Character (-BPC)

The following are optional client connection parameters. A command parameter, **-BPC** is used for Bytes Per Character.

The **-BPC** parameter allows the client connection to be bypassed. For example, a connection string of: "-BPC 2 -a pgm\_id -g gtwy\_name -x gtwy\_conn -t+ ar3" will use a BPC of 2 to indicate Unicode. BPC is used only if none of the parameters for Client, User, Password, System Host and Destination are present. If neither BPC, nor the other parameters are set, a default BPC value of 1 is assumed.

In the command line, where CHUPSD represents the parameters, **-C**, **-H**, **-U**, **-P**, **-S** and **-D**

- If (-BPC and any of CHUPSD): Log "BPC cannot be used with connection parameters"
- If (-BPC and none of CHUPSD): the BPC is used, no connection attempted
- If (no -BPC and any of CHUPSD): Connection is attempted to retrieve BPC
- If (no -BPC and none of CHUPSD): default BPC of 1 is used

The parameters **-C**, **-H**, **-U**, **-P**, **-S** and **-D** are now optional.

## Client Number (-C)

Use the Client Number (**-C**) adapter command to specify the client number in the SAP R/3 system to connect to. This adapter command is required for SAP connection when calling a BAPI and for all targets. Typically, this client number is specified in the SAP R/3 login window whenever you log into your R/3 system.

```
-C clnt_num
```

**Option****Description**

|                 |                           |
|-----------------|---------------------------|
| <i>clnt_num</i> | R/3 system client number. |
|-----------------|---------------------------|

## Character Set Encoding (-enc)

To receive IDoc messages from a Unicode SAP R/3 system, specify the character set encoding for SAP ALE data sources, using this command option. By default the IDoc data received from a Unicode SAP system will be encoded in UTF-16BE big-endian format. Use this command option, also to decode IDoc data into another format.

```
-enc ch_set_command
```

| <b>Option</b>               | <b>Description</b>                                                                                                                                                                                                                                                                                     |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ch_set_command</code> | Possible values for the character set command option are listed in the IANA Charset Registry (available from iana.org). Not all character sets listed are supported.<br>Valid character sets are those that are supported by the J2SE Java Runtime Environment (JRE).<br>Value must be a string value. |

## Destination (-D)

The Destination (-D) adapter command is required in order to specify the destination key when using the Saprfc.ini file for connection to an SAP R/3 system. SAP support of the Saprfc.ini file, which replaces the previous SIDEINFO technology, allows for RFC specific parameters to be contained in the .ini file.

`-D dest_key`

Note: The destination key has no relationship to the logical system, although a common practice is to name the key similarly to the logical system.  
The SAP provided example Saprfc.ini file contains the documentation explaining the file format.

By default, the RFC libraries look for the Saprfc.ini file in the directory specified by the RFC\_INI system environment variable. Therefore, make sure to set the environment variable RFC\_INI to specify the path and file name where the Saprfc.ini file is located. For example, if the file is located in the C:\IBM directory (RFC\_INI=c:\IBM\saprfc.ini), perform the following steps to set the system environment variable:

1. From the Start menu, select Settings > Control Panel > System.
2. Select the Environment tab.
3. Select any variable in the System Variable section. (Add your new system variable in the System Variable section, not in the User Variable section.)
4. Add RFC\_INI in the Variable field at the bottom of the window and add the location of your saprfc.ini file in the Value field.
5. Click Set > Apply > OK.

Note: Saprfc.ini entries take precedence over values that are entered in any adapter command string. ASHOST is the equivalent of the Host ID (-H) connection adapter command. SYSNR is the equivalent of the System Number (-S) connection adapter command. The value of the DEST= (-D adapter command) is case-sensitive.

6. Reboot your system.

## Example inbound -D R/3 adapter command string

The following example shows an inbound -D R/3 adapter command string with the Saprfc.ini file.

`-d R3EXAMPLE -c 800 -u userid -p pswd`

The following example is the entry in the Saprfc.ini file:

```
/*=====
/* Type A: R/3 system - specific application server */
/*=====*/
DEST=R3EXAMPLE
TYPE=A
ASHOST=sp2
SYSNR=00
RFC_TRACE=0
ABAP_DEBUG=0
USE_SAPGUI=0
```

Note: Entries are case-sensitive. The string must match the entry in the Saprfc.ini file.

Saprfc.ini entries take precedence over anything entered in any adapter command string. ASHOST is the equivalent of the Host ID (-H) connection adapter command. SYSNR is the equivalent of the System Number (-S) connection adapter command.

## Example outbound -D R/3 adapter command string

The following example shows the outbound -D R/3 adapter command string for use with the Saprfc.ini file.

`-d R3EXAMPLE -t`

The following example shows the entry in the Saprfc.ini file:

```
/*=====
/* Type R: Register a RFC server program at a SAP Gateway */
/* or connect to an already registered RFC server program */
/*=====*/
DEST=R3EXAMPLE
TYPE=R
PROGID=4handler
GWHOST=192.168.1.127
GWSERV=3300
RFC_TRACE=1
```

Note: Entries are case-sensitive. The string must match the entry in the Saprfc.ini file.

Saprfc.ini entries take precedence over anything entered in any adapter command string. PROGID is the equivalent of the name of the program registered. GWHOST is the equivalent of (-G) and GWSERV is the equivalent of (-X) in the adapter commands.

## Gateway Host (-G)

Specify the host name or SAP route string of the gateway host using the Gateway Host (-G) adapter command. When not using the Saprfc.ini file, this adapter command is required for connection purposes for ALE sources (outbound from SAP R/3).

**-G *gtwy\_name***

**Option**

**Description**  
**gtwy\_name**

Gateway host name or gateway host SAP route string.

---

## IDoc Field Generation (-GEN)

Specify automatic field generation using the IDoc Field Generation

(-GEN) adapter command. Use this adapter command to control the way IDoc fields are generated. The adapter automatically generates certain fields for an ALE client call. These fields will not be mapped because the adapter overrides them (except as noted in the options table). Separate fields in the list with a comma and omit the field list to change the behavior of all fields.

**-GEN [0|!] [*field1*[,*field2*...]]**

| Option | Option                             | Description                                                                |
|--------|------------------------------------|----------------------------------------------------------------------------|
| 0      |                                    | Specify IDoc fields to generate if blank.                                  |
| !      |                                    | Specify to suppress IDoc generation.                                       |
|        | [ <i>fld1</i> [, <i>fld2</i> ...]] | Specify the following IDoc fields as desired:                              |
|        | <b>MANDT</b>                       | as specified by -c                                                         |
|        | <b>DOCNUM</b>                      | sequentially assigned for each IDoc                                        |
|        | <b>DIRECT</b>                      | '2'                                                                        |
|        | <b>RCVPOR</b>                      | 'SAP' + remote system id                                                   |
|        | <b>RCVPRT</b>                      | 'LS'                                                                       |
|        | <b>RCVPRN</b>                      | copied from RCVPOR (possibly also generated) if not mapped by the user     |
|        | <b>SNDPOR</b>                      | 'CUSTOMERLS' if not mapped by the user                                     |
|        | <b>SNDPRT</b>                      | 'LS'                                                                       |
|        | <b>SNDPRN</b>                      | copied from SNDPOR (possibly also generated) if not mapped by the user     |
|        | <b>CREDAT</b>                      | system date                                                                |
|        | <b>CRETIM</b>                      | system time                                                                |
|        | <b>SEGNUM</b>                      | sequentially assigned for each segment                                     |
|        | <b>PSGNUM</b>                      | copied from the SEGNUM assigned to the first IDoc in the preceding HLEVEL. |
|        | <b>HLEVEL</b>                      | copied from the most recently assigned HLEVEL if not mapped by the user    |

All fields except RCVPOR and RCVPRN will be recorded in the backup file if a backup file is used. RCVPOR and RCVPRN are determined after an RFC connection is established. The control records are updated at that time.

PSGNUM generation requires that HLEVEL be specified. PSGNUM is generated by applying control-break logic to the HLEVEL field. The HLEVEL need only be entered for the first segment at each level, subsequent segments at that level can be left blank (for PSGNUM generation purposes, it is assumed to be the same). The SEGNUM for the first segment at an HLEVEL is used as the PSGNUM for segments at the next higher HLEVEL. PSGNUM for HLEVEL 01 is 000000.

The following are examples of using the IDoc field generation adapter command.

**Example**

**Description**  
**-GEN**

Automatic generation of all IDoc fields listed in the IDoc Field Generation (-GEN) topic.  
This is the default. User does not have to specify this adapter command.

Adapter automatically generates all IDoc fields regardless of the value of the fields in the input.

**-GEN0 *fld1*, *fld2***

Adapter generates IDoc fields for input field1, if it is blank and input field2, if it is blank.

**-GEN! *fld1*, *fld5***

Adapter suppresses automatic generation of those IDoc fields listed next to -GEN!

---

## Group (-GROUP)

The Group (-GROUP) adapter command is required to specify a group name to associate with the Batch Input Session. This adapter command is used for BDC targets only to pass the value directly to a Batch Input Session.

**-GROUP *NAME***

**Option**

**Description**  
**NAME**

Group name.  
Value must be specified in uppercase.

---

## Host ID (-H)

Specify the host name or SAP route string of the SAP R/3 server to which to connect using the Host ID (-H) adapter command. This adapter command may be required for connection. Use SAPLogon or the SAPGUI parameter.

**-H host\_name**

**Option**

**Description**

**host\_name**

R/3 server host name or R/3 server SAP route string.

The SAP router serves as a proxy in a secure network connection between SAP R/3 systems and external RFC systems. It is a useful extension to an existing firewall system because it allows connections through the firewall. When a SAP router is in use, a valid route string is used as the host name value. For example:

**-H /H/saprouter1/S/3300/H/saprouter2/S/3300/H/SAPappServer/S/SAPservice**

For more information about the SAP router, refer to SAP Online Library BC- Basis Components > BC-SAP Router.

---

## Logon Language (-L)

Specify the code for the logon language using the Logon Language (-L) adapter command.

**-L lang\_cd**

**Option**

**Description**

**lang\_cd**

Logon language.

---

## Listen (-LSN)

The Listen (-LSN) adapter command can be used for ALE sources. Use this adapter command to specify how long (in seconds) to wait for a message. If duration is omitted, then listen indefinitely. In addition, duration can optionally be specified as *count:interval*. For the Launcher only, when the **Listen** command is not specified, the ALE adapter will assume the **Listen** option values are set to 15:5. To implement registration method with a Command Server, the 0 option is required.

**-LSN {0 | dur[:int]}**

Table 1. Listen (-LSN) adapter command

| Option     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dur</b> | Specifies how long in seconds to listen for data. If the LSN command is omitted, the values default to 15:5. To listen for an indefinite period, specify 0 as the duration. Required value for registration method with a Command Server.<br>To fine-tune the listener, because the listener does not respond to service control requests while listening, specify an interval for the duration in seconds. A colon is used to separate the duration from the interval.<br><br><b>Example:</b><br>-LSN 0<br>-LSN 30:10 |

---

## Listener Threads (-N)

The Listener Threads (-N) adapter command can be used for ALE sources only when using the Launcher. Use this adapter command to specify to the listener to register multiple times at the gateway and to listen for incoming IDocs. To process large IDocs sent from the SAP ALE adapter, use this command. This adapter command may increase performance at the gateway by allocating more work processes (worker threads) to service requests. The recommended count for listener threads is a number equal to the total work processes of the SAP Application Server.

**-N cnt**

**Option**

**Description**

**cnt**

Listener thread counts.

---

## Password (-P)

Specify the password assigned to the user name for authorization for the SAP R/3 system using the Password (-P) adapter command. This adapter command is required for SAP connection for BAPI sources and all targets.

**-P pwd|@full\_path**

**Option**

**Description**

**pwd**

Password associated with the user name.

**@full\_path**

Accesses a security file, which is used to store passwords, with the specified name in the specified directory. (By default, the directory is where the map is located.)

Note: If password expiration is used in the SAP R/3 system, the maps must be updated or overridden, as appropriate, to accommodate the valid password.

## Packet Size (-PKT)

Use the Packet Size (-PKT) for output (inbound to SAP R/3) only. Specify the number of IDocs to include in a packet. A separate call is made for each packet. This option is useful for tuning the performance of the ALE interface and helps to reduce communication errors. This also eliminates the need for pre-adapters that use the **RUN()** function to break an IDoc transmission into smaller chunks.

**-PKT *IDoc\_qty***

**Option**

**Description**

*IDoc\_qty*

Number of IDocs to be included in a packet.

## Reprocess backup files (-R)

Use the Reprocess backup files (-R) command to process backup files left from the previous Launcher session. This command option is valid for data sources, and can be used only in combination with the (-BIX) command option. When this command option is specified on Launcher startup, the ALE listener will look for all backup files created in the previous Launcher session that were not processed. For each backup file, the ALE listener triggers one map execution to process the backup file IDoc data.

**-R**

## System ID (-S)

Specify the system number of the SAP R/3 system to which to connect using the System ID (-S) adapter command. This adapter command may be required for connection. Use the value as indicated for system number in SAPLogon or SAPGUI (for example, 00).

**-S *sys\_num***

**Option**

**Description**

*sys\_num*

SAP R/3 system number specified in SAPLogon or SAPGUI.

## Timeout (-timeout)

Specify the time in seconds for the adapter to wait for a response from the SAP server. If there is no response from the SAP server in the given time, a timeout error will be returned.

If no value is defined, the default value is 30 seconds (-timeout 30).

**-timeout *secs***

**Option**

**Description**

*secs*

Number in seconds that the adapter waits for a response from the SAP server.

## Trace (-T)

Use the Trace (-T) adapter command to enable the R/3 adapter trace file. By default, m4r3adapter.mtr is located in the same directory as the map, where adapter is the adapter type such as JALE or JBAPI. Optionally, you can specify to record detail information about all adapter activity or only errors. Also, you can append the trace information to an existing file or specify a name or the full path for the file.

**-T[V|E|N] [+ ] [full\_path]**

The **N** suffix disables creation of the RFC trace files.

If **N** is not set (as -T), both, the adapter and the RFC trace file are created.

If it is set (as -TN), only the adapter trace file will be created, while the RFC trace file will not.

**Option**

**Description**

**V**

Designates verbose. Detailed trace information is recorded.

**E**

Produces a trace file that contains only the errors that occurred during the map execution. If there are no errors, the trace file will not be created. When the **-TE** command is used with SAP and the map fails, the resulting trace file has an extension of .mtr unless a specific file name is designated.

- N** Disables creation of the RFC trace files.
- +** Append trace information to an existing file.

**full\_path** Creates a trace file with the specified name in the specified directory. (By default, the directory is where the map is located and the file name is *m4r3adapter.mtr*.)

---

## Transaction ID (-TID)

Use the Transaction ID (**-TID**) adapter command for ALE sources or targets. When used for a target, specify the Transaction ID (TID) for which a previously failed transmission is being resubmitted. When resubmitting a transaction, this adapter command is required so that SAP R/3 can recover properly from the previous failed attempt and avoid duplicate IDoc processing in the R/3 system.

**-TID trans\_ID**

### Option

#### Description

**trans\_ID**

Transaction ID of the previously failed transmission that is being resubmitted.

Transaction ID is a Globally Unique Identifier (GUID) that is calculated by the SAP R/3 system. It is a unique value that does not contain values to mask. The following is an example of a transaction ID:

**COA8012A004A38AC3BC60585**

Use this adapter command for a source to enable Matching Source Names to Target Names using the SAP R/3 TID number as the source wildcard value. This is useful when using the Launcher for map execution. If a source has a wildcard, any target that contains an asterisk is assigned the source wildcard value. For example, you might use **-TID \*** on the source, and a file target of **\myData\IDoc.\*** to name the destination files.

Note: For additional information, refer to the Launcher information in the online documentation.

---

## IDoc Type (-TY)

The IDoc Type (**-TY**) adapter command can be used for ALE sources and to designate the document types that can be received.

Note: When using this adapter command to designate document types, there is a potential for misconfiguration if SAP R/3 sends an IDoc type for which there is no map. If no handler exists for the IDoc, the R/3 adapter raises an RFC exception, causing the offending transaction to be held in the tRFC queue (SM58).

When using the Integration Flow Designer, a map component of a ITX system that is executed using the Launcher can use the special document-type **OTHER\$** to catch the IDocs that do not match the types designated by another map component contained in the same system definition file (.msl). In this scenario, if IDocs other than the type specified in a map component are received, rather than causing an RFC exception, a second map component with **-TY OTHER\$** defined is automatically triggered and handles the unmatched IDocs as specified.

**-TY OTHER\$ | doc\_type\***

### Option

#### Description

**OTHER\$**

When using the Launcher, use this option in a map component to handle all of the types not matched by any other trigger. When unmatched IDocs are detected, they become triggers for the OTHER\$ type instead of causing an RFC exception.

**doc\_type\***

You specify the document type that can be received. If SAP R/3 sends an IDoc that does not match what is specified, the adapter will raise an RFC exception.

Document types are case-sensitive.

Example:

**-TY DEBMAS\***

---

## User ID (-U)

Specify the SAP R/3 user name for login to the SAP R/3 system using the User ID (**-U**) adapter command. This adapter command is required for SAP R/3 system connection when calling a BAPI, and for ALE targets. The user is typically a CPIC user, but must be enabled for ALE/EDI permissions. See your Basis team, or SAP User Authorizations documentation for additional information.

**-U usr\_id|@full\_path**

### Option

#### Description

**usr\_id**

SAP R/3 user name.

**@full\_path**

Accesses a security file, which is used to store user IDs, with the specified name in the specified directory. (By default, the directory is where the map is located.)

---

## Gateway Service (-X)

Specify the service name or port number of the gateway process at the gateway host using the Gateway Service (-x) adapter command. When not using the Saprfc.ini file, this is a required adapter command for SAP connection for ALE sources (outbound from R/3).

-x *gateway\_conn*

**Option**

**Description**  
*gtwy\_conn*

Gateway process service name or port number.

---

## Syntax summaries for R/3 adapters

Syntax summaries provide a detailed list of required and optional adapter commands as they are used with the R/3 adapters. Syntax summaries use the command syntax notation.

Syntax summaries for the R/3 adapters are organized by ALE and BAPI.

- [JALE adapter commands syntax summary](#)
  - [JBAPI adapter commands syntax summaries](#)
- 

## JALE adapter commands syntax summary

The syntax of the JALE adapter commands used with data sources is as follows:

```
-A pgm_id -G gtwy_name -x gtwy_conn
 -C clnt_num -U usr_id -P pwd
 [-H host_name -S sys_num]
-D dest_key
[-AR3[+][U] [%tid%|full_path] [-B[I][X] [%tid%|full_path] [-R]]
[-TID trans_ID]
[-LSN {0|dur[:int]} [-TY OTHER$|doc_type*]]
[-T[V|E][+] [full_path]]
[-N num_of_threads] [-enc encoding]
```

The syntax of the JALE adapter commands used with data targets is as follows:

```
-C clnt_num -U usr_id -P pwd
 {-H host_name -S sys_num} -D dest_key
 -BAL -H HOST -S R3NAME -GROUP GRP [-AR3[+][U] [%tid%|full_path]
-B[I][X] [%tid%|full_path] trans_ID
[-GEN[0|1]] [fld1[,,fld2...]] [-PRT IDoc_qty]
[-L lang_cd]
[-T[V|E][+] [full_path]]
```

---

## JBAPI adapter commands syntax summaries

The syntax of the JBAPI adapter commands used with data sources is as follows:

```
-C clnt_num -U usr_id -P pwd {-H host_name -S sys_num} -D dest_key
-BAL -H HOST -S R3NAME -GROUP GRP
[-L lang_cd] [-T[V|E][+] [full_path]]
```

---

## R/3 adapter aliases

You can specify the adapter commands using an execution command string on the command line or you can create a command file that contains adapter commands that dictate the desired execution settings.

Use the execution commands **-IM** and **-OM** with the appropriate adapter alias that is specific for the utility adapter as follows:

| Adapter | Alias | As input        | As output       |
|---------|-------|-----------------|-----------------|
| JALE    | JALE  | -IMJALEcard_num | -OMJALEcard_num |
| JBAPI   | JBAPI | N/A             | N/A             |

When using an adapter alias in conjunction with the execution command, the adapter commands can be issued on the command line or in a command file. You can use the adapter commands to specify adapter functions such as specifying a particular message identifier, allowing output data to be broken up into multiple messages, or to retrieve a logical message from a source queue with a correlation identifier.

For example, to override the adapter commands defined in output card 1, the command string for the R/3 adapter might be

```
dstx testclnt -AE -WD -R0 -B -OMALE1 '-c 800 -u userid -p password -h sp2 -s 00 -t -ar3'
```

For example, an existing data source that is a file can be overridden and specified to be the R/3 adapter using the Input Source Override (-IM) execution command and the **JALE** alias. Alternatively, you can override an existing target with a different target using the Output Source Override (-OM) execution command with the correct R/3 adapter alias. For information about the options that you can use within these commands, see *Execution Commands* in the online documentation.

## Using R/3 system commands

The R/3 adapter passes any other SAP supported commands and connection parameters to the SAP R/3 system as defined in the RFC DK. These are defined in [RfcOpenEx](#). See your SAP documentation for details.

An example of using an SAP R/3 system command as an optional R/3 adapter command is specifying SAPLOGON\_ID=SAP\_logon\_key to read connect parameters from Saplogon.ini if SAPLogon is installed. After specifying the required connection R/3 adapter commands (for example, -c, -u, -p), you can use SAPLOGON\_ID= to specify the SAP\_logon\_key, which is the name defined in SAPLogon (the one that appears in the menu). Enclose the entire argument in single or double quotes so that the adapter correctly interprets it for your platform (especially if the name contains spaces).

Using this feature, the commands needed to open a connection to a SAP system such as DEST, GHOST, GSERV, ASHOST, SYSNR, MSHOST, R3NAME, GROUP, and SNC are not necessary because the RFC library obtains this information from the SAPLOGON data files. This feature provides a potential maintenance benefit for SAPLogon users and is recommended because the connection information exists in only one location (saplogon.ini), as opposed to two (saplogon.ini and Saprfc.ini).

## Intermediate Documents (IDocs)

IDocs are SAP standard data containers or formats that provide the basis for both ALE and EDI interfaces to SAP R/3. The topics below discuss using IDocs with SAP R/3 and provides the specific information required for ALE and EDI interfaces:

- [Overview of IDocs](#)
- [Generating the IDoc Parser report](#)
- [Using the Importer Wizard for IDocs](#)
- [Implementing an ALE interface](#)
- [Mapping](#)
- [Inbound and outbound processes](#)
- [Control records for IDoc mapping](#)
- [Sending EDI IDocs using ALE](#)
  
- [Overview of IDocs](#)
- [Generating the IDoc parser report](#)
- [Using the Importer Wizard for IDocs](#)
- [Implementing an ALE interface](#)
- [Mapping](#)
- [Inbound and outbound processes](#)
- [Control records for IDoc mapping](#)
- [Sending EDI IDocs using ALE](#)

The following are 3.x and 4.x control record examples to assist you in mapping to and from an IDoc.

## Overview of IDocs

Several hundred IDocs are shipped with each SAP R/3 system version 3.0. ALE and EDI interfaces use functionally equivalent IDocs; however, they differ in the manner in which the IDocs are communicated to or from SAP R/3.

- ALE IDocs are communicated through memory buffers, without intermediate files, directly to or from an RFC port using transactional remote function calls (RFCs).
- EDI IDocs are passed using an intermediate file.

These interfaces (ALE and EDI) that use the IDoc structure represent SAP's strategic approach to interfacing SAP R/3 with legacy and third-party applications where loose coupling is appropriate. Therefore, the SAP R/3 IDoc approach should be considered the first choice for developing interfaces where asynchronous, near-real time, or batch links are required. This pack supports SAP-supplied IDocs as well as user-defined IDocs.

One or more IDocs are held in a container called a packet. A packet is the largest data container in an IDoc schema. The restart attribute is automatically added to reject invalid IDocs contained within a packet.

Note: When using the Importer Wizard to create a schema in the structure of your IDocs, you have the option of selecting whether you want to include restrictions. You select with a flag that lets your map know at runtime to create restriction lists.

- [IDoc structural format](#)

## IDoc structural format

The IDoc format consists of hierarchically structured segments with multiple levels of nesting. IDocs exist for master data such as customers and materials, for transactional data such as sales orders, and for control data such as company codes. In ALE terms, these are called IDoc types, which are described as follows:

### Control record

There is one control record, and its format is identical for all IDoc types. It consists of the IDoc ID, Sender ID, Receiver ID, IDoc type, and EDI attribute.

### Data records

There can be one or more data records. A data record consists of a fixed administration section (IDoc ID, Sequence/Hierarchy) and a data part (Segment). A

Segment is the formal definition for header data and item data. The number and format of the segments can be different for each IDoc type.

### Status records

The status records describe the processing stages through which an IDoc can pass, and contain the IDoc ID and status information. There will be several status records.

The IDoc types are assigned to release-independent message types, which themselves are assigned to object types in the Business Object Repository (BOR). Customer enhancements are generally subject to naming conventions. IDoc data segments are a maximum of 1000 bytes in length and generally only contain CHAR fields. The data segments of an IDoc type are described by release-independent segment types and have release-specific segment definitions that are stored as internal structures in the Dictionary. This means IDocs can be sent with different data contents to different recipients because the recipient's release is defined in the sending system.

## Generating the IDoc parser report

The SAP:IDoc Importer is a facility for automatically generating schemas that describe the format of IDocs used in your SAP R/3 system. The Importer Wizard uses the definition of an IDoc contained in an IDoc parser report (RSEIDOC3) to automatically generate schemas from IDocs for use in mapping external data to SAP R/3 data. See [Running the Importer Wizard](#) for additional information.

After you have identified the IDoc type you want to use, use transaction WE63 or the program RSEIDOC3 to generate the IDoc parser report. RSEIDOC3 reports can be produced from a SAP R/3 system for SAP-supplied IDocs, modified SAP-supplied IDocs, or customized IDocs. The Importer Wizard works with any of these IDocs. It also works with IDocs produced from any version of a SAP R/3 system.

The IDoc definition that is input to the Importer Wizard must be in the format produced by running the RSEIDOC3 report from your R/3 system. When you run the RSEIDOC3 program, you may want to save the report to a file with the extension .ido because that is the default for IDocs when using the Importer Wizard.

Note: The definition file produced by the RSEIDOC3 report can contain definitions for one or more IDocs. If the definition file contains more than one IDoc, all of the valid IDoc definitions are created in a single schema.

Note: You must also enable the Control record (in RSEIDOC3) and Data record check boxes.

After you have produced the appropriate RSEIDOC3 report(s) from SAP R/3, download it to your PC on which the Importer Wizard is installed using the Download File option. Be sure to select Unconverted.

Note: SAP supplied IDocs may change from one SAP R/3 version to another. When you update from one version to another or when you have reduced or modified a SAP-provided IDoc, use the Importer Wizard to regenerate your schema.

## Using the Importer Wizard for IDocs

After you have produced an RSEIDOC3 report from SAP R/3 that describes the format of the IDoc or IDocs and you have moved that file to your local PC, you are ready to run the Importer Wizard. See [Running the Importer Wizard](#).

An IDoc report file produced in SAP R/3 is used to test how the Importer Wizard creates a type tree for an IDoc structure.

To run the SAP:IDoc Importer:

1. In the Type Designer, select Import from the Tree menu.
2. After the Importer Wizard starts, select SAP:IDOC as the structure for which you want to generate a type tree. Click Next.
3. Click Next until the File Name field appears in the window. In the **File Name** field, enter the file you want to import, specify the RSEIDOC3 report for which you want to generate a type tree, and select either ALE or EDI to specify the interface for which you want to generate the type tree.
  - [Understanding the IDoc schema](#)

## Understanding the IDoc schema

The RSEIDOC3 report is composed of a packet container that can hold one or more IDocs. Therefore, the schema generated represents the contents. Each IDoc contains a control record, many data records, and some status records. Each IDoc consists of, and its sequence and structure are dictated by, the sequence and structure of segments in a particular kind of IDoc.

The IDoc structure is either ALE or EDI and schemas are generated for each format appropriately.

- The ALE format is designed specifically for use with SAP's Application Linking and Enabling architecture. Each schema generated is compatible with ALE/RFC communications. It requires that each data segment in an IDoc be of the same length with no terminators and the control segment be of fixed length. Each segment is padded to a fixed length.
- The EDI format is loosely modeled after Electronic Data Interchange standards. Each schema generated is compatible with EDI/FILE-based communications. Each segment is variable-length and line-character-terminated.

The attributes of a schema correlate directly to the IDoc metadata report. The IDoc fields correspond to items in a type. For example, the field name generates the item name and the text generates the item description. IDoc data is character-based and only the text or item description is language-dependent.

The schemas generated for either ALE or EDI contain types that are identically defined named Packet, IDoc, Group\_number, Field, and Control Record. However, there are differences in how the segments are defined for the two different formats. A schema generated for ALE does not contain a Status Record type.

## Implementing an ALE interface

The SAP Application Link Enabling (ALE) technology enables data communication between two or more SAP R/3 systems and/or SAP R/3 and external (for example, legacy) systems. The SAP R/3 system must be configured to send and receive IDocs.

To implement an ALE Interface:

1. Enter transaction code /nWE63 in the SAP application to select IDoc(s) and download the metadata.
2. Use the Importer Wizard to generate the schema.

3. Use the Map Designer to create the map.

4. Configure the SAP R/3 system for inbound or outbound processing. See [Configuring the SAP R/3 system](#) in and [Setting up an RFC destination](#).

- [IDoc selection and metadata download \(WE63\)](#)
  - [Creating a Unicode metadata file](#)
- 

## IDoc selection and metadata download (WE63)

The IDoc type indicates the SAP format that is to be used to interpret the data of a business transaction.

To select a Basic IDoc:

1. Enter **/nwe63** in the command field and click **Enter**.  
The **Documentation** window opens.
  2. Enable Basic type and select from the drop-down list the IDoc type. (For this example, choose **DEBMAS03**.)
  3. Click **Parser** to execute.  
The Documentation for Basic type window opens.
  4. In the System menu, choose **List Save > Local File**.  
The Save list in file dialog box opens.
  5. Select unconverted as the format and click **Enter**.  
The Save As dialog box opens.
  6. Specify the full path in which to save the file, then click **Save** to transmit the list and save the file.
- 

## Creating a Unicode metadata file

The IDoc importer is able to generate Unicode metadata (schema with Unicode Type Names). SAP currently does not support Unicode characters for metadata names, but it does support Unicode characters for metadata descriptions. To generate schemas that can contain Unicode Type Names, generate the IDoc metadata file and save it as a Unicode file:

Note: SAP currently does not support Unicode character for metadata names, but it does support Unicode characters for metadata descriptions. To generate schemas that can contain Unicode Type Names, generate the IDoc metadata file and save it as a Unicode file:

1. Log onto the SAP R3 system using the SAP Front end/SAP logon.
  2. Go to transaction **/nwe63** and type in the name of the Basic Type (or enhancement/extension), select Control Record, Data Record and Status Record. Set the Segment release. Then click Parser (F9)
  3. Select **System > List > Save > Local File**
  4. Select Unconverted.
  5. Select Encoding as **UTF8 (4110)** and click Generate.
- 

## Mapping

After you have configured the RFC destination and created and transferred the metadata file, use the Map Designer to create the map.

- [Using the Importer Wizard for ALE](#)
  - [Creating an outbound map](#)
- 

## Using the Importer Wizard for ALE

In the Type Designer, select Import from the Tree menu to start the Importer Wizard. The Importer Wizard guides you through schema generation process. Enter the appropriate information, which includes:

- Specifying the ALE format
  - Generating the schema from the transferred metadata file
- 

## Creating an outbound map

Use the Map Designer to create a map to send the source data from SAP R/3 to the target external system.

- [Creating an input card and configuring outbound processing](#)
  - [Creating an output card and configuring inbound processing](#)
- 

## Creating an input card and configuring outbound processing

Create an input card that specifies JALE for the Source setting.

When the R/3 adapter is specified as the input card source, it performs the RFCS required to ensure successful communication of server IDoc outbound data from the R/3 system. The data is retrieved and passed through memory buffers into the executing map for transformation into the destination target format.

Note: The R/3 system configuration must have already been completed.

## To obtain an IDoc (DEBMAS) from the SAP system and pass it to the map

---

1. Enter /nbd12 in the command field and click Enter.  
The Send Customers window opens.
2. Enter Customer information in the appropriate field, then click Execute.
3. An Information window opens indicating that the master data sent was read from the database and formatted into an IDoc format. This IDoc is called a master IDoc. The master IDoc is stored in a memory buffer until the communication IDoc is generated.  
Click Enter.
4. An Information message opens indicating that the ALE service layer generated a separate IDoc from the master IDoc for each recipient who is interested in the data. These recipient-specific IDocs are called communication IDocs and are stored in the database. The recipients are determined from the Distribution Model.  
Click Enter.

## To obtain the information on the status and the data of the IDoc

---

1. Enter /nwe02 in the command field and click Enter.  
The IDoc Lists window opens.
2. Execute by clicking Enter.
3. The SAP window opens, displaying status information about the data passed to the port.  
Select an IDoc by double-clicking it.
4. In this window, you can view the Customer Master Data sent by the SAP system.  
To read the Status Records, click the individual status message.

If the partner profile is configured for Dispatch immediate, a map immediately executes for each transmitted IDoc. For example, if five IDocs are generated, five maps will execute. However, if the partner profile is configured for Collect IDocs, it is necessary to dispatch the IDocs. Do this by using transaction BD88 or by scheduling the job RSEOUT00. Maps will execute after this job completes. The number of map instances depends on the number of IDocs collected in a packet as defined in the partner profile. If the defined number of IDocs per packet is 20 and five IDocs are generated, one map will execute.

During a map execution, the status information displays: map name, status, elapsed time, input, output, and number of objects.

## Creating an output card and configuring inbound processing

---

Create a map using Map Designer to transform data from an external system to IDoc format providing inbound data to SAP R/3.

- In the output card of the map, select R/3 JALE for the Target setting and specify the adapter settings, including entering the adapter commands in the Target Command setting.
- Build and run the executable map.  
During the map execution, status information displays: map name, status, elapsed time, input, output, and number of objects.

To obtain the information on the status of the IDoc you sent into SAP:

1. Enter /nwe02 in the command field and click Enter.  
The IDoc list window opens.
2. Execute by clicking Enter.
3. Select the desired IDoc by double-clicking it.  
When inbound IDocs have been successfully posted through the communication layer, they are assigned the status **IDoc added**. When inbound IDocs have been successfully posted through the application layer, they are assigned the status **Application document posted**. If the IDoc did not go through the application layer, an error message displays.

## Inbound and outbound processes

---

This section provides a summary of possible inbound and outbound ALE scenarios describing a high-level technical overview of the communications processes between SAP R/3 and an external non-SAP R/3 system using the Pack for SAP Applications.

- [Inbound ALE to SAP](#)
- [Outbound ALE from SAP](#)

## Inbound ALE to SAP

---

The R/3 adapter can retrieve input from many different non-R/3 systems (including files, databases, MCM, web, or ERP applications) as defined by the maps executing on either the Launcher or the Command Server.

To retrieve input from a non-SAP R/3 system into an SAP R/3 system:

- As the transformation server continues to execute the map(s) as defined, output is produced and passed to the R/3 adapter.
- The R/3 adapter connects to the R/3 system using the provided connection information and user ID. SAP R/3 confirms the authorizations of the user.
- If a connection failure occurs, the adapter returns a failure code to the transformation server.
- The R/3 adapter makes the RFC calls to load the output data into the Internal Table used by the RFC libraries.
- If automatic field generation or automatic EDI to ALE conversion is enabled, the adapter produces these conversions as data is loaded into the Internal Table.
- If OnFailure setting is set to Rollback, the R/3 adapter waits for final acknowledgement from the transformation server that all output resources are ready to commit. Use of this option requires the adapter to use memory equal to two times the IDoc data size.
- Data is passed (committed) to the SAP R/3 system by packet. One packet at a time is assigned a unique TID number and processed by SAP R/3. If a communication failure occurs at this time, only packets that are not committed are in the rollback file.
- If communication failure occurs at this point, the R/3 adapter returns a failure code to the transformation server.

## Outbound ALE from SAP

The R/3 adapter can retrieve output from many different SAP R/3 systems as defined by the maps executing on either the Launcher or the Command Server.

To retrieve output from an SAP R/3 system into a non-SAP R/3 system

- One of the application modules of SAP generates a request for IDoc data. This request can be on demand by using ALE, or based on events such as those defined with Output Determination. This generates the IDoc Data.
- This request is directed to the partner profile. The configuration of the partner profile determines the port designation.
- The defined port determines whether this is a file-based communication or an ALE memory-based communication. For memory-based communications, the port designates the RFC Destination.
- The RFC Destination determines that the communication method is Registration (or Start) and also the physical parameters of the external system.
- The IDoc data is passed to the gateway. Inquiry into the IDoc logs will indicate a message Passed to Port OK.
- The communication layer connects to the external system as configured in the RFC Destination. If the communication is successful, the outbound communications start. If the communication fails, the RFC Transaction monitor (SM58) will indicate a communication error.
- For successful connections, the communication layer will connect to the SAP R/3 server functionality of the R/3 adapter. The communication layer makes the RFC calls to establish the communication, perform the TID management functions, and pass the IDoc data.
- The IDoc data is passed to the R/3 adapter by means of memory. This implies that the external system and user have adequate memory resources on the external platform. The RFC layer requires up to twice the IDoc data size so that there is sufficient memory to decompress the IDoc data. (The data is transmitted on the network in compressed form to increase network performance.) In addition, it is required to have memory equal to the data size to hold the data in memory. The data is held from the time it is received until it can be processed by the appropriate map(s). This requires careful planning if using the Launcher, especially if the maps have low throughput (or are single-threaded) because maps in the init pending state are consuming memory for staged IDocs.
- When the R/3 adapter has received the IDoc data, a backup file of IDoc data is created if the **-B** adapter option is used. The transformation server begins the validation of all input files, building temporary work files as necessary.
- The transformation server builds all output data and connects to any non-file systems via resource adapters.
- If the map completes successfully, the R/3 adapter closes the connection from SAP. If the map does not complete successfully, a rollback file of the IDoc data is created if the **OnFailure** setting is set to **Rollback** for the ALE input.

## Control records for IDoc mapping

The following are 3.x and 4.x control record examples to assist you in mapping to and from an IDoc.

- [Control record example](#)

## Control record example

| Pos | Field   | Description                                  | Value      |
|-----|---------|----------------------------------------------|------------|
| 1   | TABNAM  | Name of table structure                      | "EDI_DC40" |
| 2   | MANDT   | Client                                       |            |
| 3   | DOCNUM  | IDoc number                                  |            |
| 4   | DOCREL  | SAP Release for IDoc                         |            |
| 5   | STATUS  | Status of IDoc                               |            |
| 6   | DIRECT  | Direction                                    |            |
| 7   | OUTMOD  | Output mode                                  |            |
| 8   | EXPRSS  | Overriding in inbound processing             |            |
| 9   | TEST    | Test flag                                    |            |
| 10  | IDocTYP | Name of basic type                           | "CREMAS01" |
| 11  | CIMTYP  | Name of extension type                       |            |
| 12  | MESTYP  | Logical message type                         | "CREMAS"   |
| 13  | MESCOD  | Logical message code                         |            |
| 14  | MESFCT  | Logical message function                     |            |
| 15  | STD     | EDI standard, flag                           |            |
| 16  | STDVRS  | EDI standard, version and release            |            |
| 17  | STDMES  | EDI message type                             |            |
| 18  | SNDPOR  | Sender port (SAP system, external subsystem) |            |
| 19  | SNDPRT  | Partner type of sender                       |            |
| 20  | SNDPFC  | Partner function of sender                   |            |

| <b>Pos</b> | <b>Field</b> | <b>Description</b>                             | <b>Value</b>    |
|------------|--------------|------------------------------------------------|-----------------|
| 21         | SNDPRN       | Partner number of sender                       | BD64<br>"LSEXT" |
| 22         | SNDSAD       | Sender address (SADR)                          |                 |
| 23         | SNDLAD       | Logical address of sender                      |                 |
| 24         | RCVPOR       | Receiver port (SAP system, external subsystem) |                 |
| 25         | RCVPRT       | Partner type of recipient                      |                 |
| 26         | RCVPFC       | Partner function of recipient                  |                 |
| 27         | RCVPRN       | Partner number of recipient                    | "T90CLNT090"    |
| 28         | RCVSAD       | Recipient address (SADR)                       |                 |
| 29         | RCVLAD       | Logical address of recipient                   |                 |
| 30         | CREDAT       | Created on                                     |                 |
| 31         | CRETIM       | Time created                                   |                 |
| 32         | REFINT       | Reference to transfer (EDI interchange)        |                 |
| 33         | REFGRP       | Reference to message group (EDI message group) |                 |
| 34         | REFMES       | Reference to message (EDI message)             |                 |
| 35         | ARCKEY       | Key for (external) message archive             |                 |
| 36         | SERIAL       | Serialization field                            |                 |

## Sending EDI IDocs using ALE

To maximize performance during development and testing, always use ALE format IDocs when sending data using a JALE target. The SAP R/3 adapter will translate EDI format IDocs to ALE when necessary. This simplifies the development effort when converting file-based interfaces such as EDI to ALE.

Note: This automatic conversion feature should be used only for development and testing. It should not be used in a production environment because it severely degrades performance (by a factor of about 1,000).

## Data Transfer Objects (DXOB)

Data transfer objects (DXOB) are SAP R/3 business objects that can be transferred into an SAP R/3 system. To use SAP R/3 to create DXOB interfaces including the creation of initial data transfer files (DXOB reports) and using the Importer Wizard to generate the corresponding schemas read the sections below:

- [Overview of Data Transfer Objects](#)
- [Generating DXOB metadata](#)
- [Mapping](#)
- [Transferring the mapped data](#)
  
- [Overview of Data Transfer Objects](#)
- [Generating DXOB metadata](#)
- [Mapping](#)
- [Transferring the Mapped Data](#)

## Overview of Data Transfer Objects

DXOB (Data Transfer Object) reports are produced from SAP-supplied DXOBs or modified SAP-supplied DXOBs.

The Importer Wizard works with either of these DXOB types.

Note: SAP supplied DXOBs may change from one SAP R/3 version to another. When you upgrade SAP R/3 versions, use the Importer Wizard to regenerate your schemas accordingly.

The DXOB definition that serves as metadata input to the Importer Wizard must be in the format produced by running the DXOB report from your SAP R/3 system. When you run the DXOB program, you may save the report to a file with the extension .dx, which is the default for the Importer Wizard.

After you have produced the appropriate DXOB report(s) from SAP R/3, transfer the report file to the PC on which the Type Designer is installed.

Note: The metadata file produced by the DXOB report will contain definitions for a single DXOB.

To process DXOB interfaces, follow the steps in these topics:

1. [Generating DXOB metadata \(SXDA\)](#).
2. [Using the SAP-DXOB Importer](#) to generate the schema.
3. [Creating a map for DXOB formatted data](#)
4. [Transferring the mapped data to the application layer](#).
5. [Processing the Batch Input Session \(SM35\)](#)

## Generating DXOB metadata

SAP R/3 provides a Data Transfer Workbench (transaction code SXDA) to facilitate initial data loads into SAP R/3. The Data Transfer Workbench provides a central point of control for creating DXOB reports and starting the DX programs.

- [Data Transfer Workbench \(SXDA\)](#)

## Data Transfer Workbench (SXDA)

To generate DXOB metadata:

1. Enter /nsxda in the command field and click Enter.  
The Data Transfer Workbench window opens.
2. From the Goto menu, select DX Tools.  
The Data Transfer - Tools window opens.
3. In the Object Type field, select the DXOB from the drop-down list for which you want to generate a report. (For example, use DX object KNA1 for Customer.)
4. In the Program type field, select a program type from the drop-down list. (For example, BINP.)
5. In the Program field, select a method from the drop-down list. (For example, RFBIDE00.)
6. In the Extras menu, select Display Import Structure.  
The Documentation Dataset Record Types for Initial Data Transfer (Parser) window opens. This example shows the interface structure for Customer master data required of the DX object **0050**.
7. In the List menu, select Download to transfer this structure to a path that exists on the PC on which the Design Studio is installed.  
The Save list in file dialog opens.
8. Select unconverted and click **Enter**.  
The Save As dialog opens.
9. Specify the full path for the file that you are downloading and click Save. (In this example, the file is DXOB0050.dx.)  
The file transfer is complete.

## Mapping

After you have finished creating the DXOB report and transferred this metadata file, use Map Designer to create the map.

- [Using the SAP:DXOB Importer](#)
- [Creating a map for DXOB formatted data](#)

## Using the SAP:DXOB Importer

After you have produced a DXOB report describing the format of the desired DXOB(s) and you have transferred that file to your Design Studio PC, you are ready to run the Importer Wizard. The SAP:DXOB (Initial Data Transfer [DX]) Importer for SAP R/3 is a facility for automatically generating schemas that describe the format of Data Transfer Objects (DXOBs) used in your SAP R/3 system.

An example of the DXOB report is in the examples\packs\sap\_r3\r3\ERP\DXOB directories included in the Pack for SAP Applications installation. This DXOB report file contains the definitions for the Human Resources data transfer object. You can use this file as metadata input to run the SAP:DXOB Importer.

To run the SAP:DXOB Importer:

1. In the Type Designer, select Import from the Tree menu.
  2. Choose SAP:DXOB as the structure for which you want to generate a schema. Click Next.
  3. Continue clicking Next until the File Name field appears in the window. In the File Name field, enter the metadata file you want to import (in this example, it is DXOB0050.dx) to generate a schema.
- [DXOB formats](#)
  - [Understanding the DXOB schema](#)

## DXOB formats

The SAP Data Transfer Object (DXOB) structure is available in two different formats:

Released format

This is the standard format in version 4.0 and above. The second line of the Released format begins with **BEGIN\_DXOB 00200000** and will typically contain **IDENTVALUE** fields at the beginning of each segment.

## Understanding the DXOB schema

The DXOB metadata file produced by the DXOB report contains the definition for a single DXOB. The schema generated by the Importer Wizard will correspond accordingly. Types generated in the schema represent the following:

- Single Session
- 0 is the identifier for the record containing a Session prefix

- 1 is the identifier for the record containing Header data
  - 2 is the identifier for the record containing Document segment data
- Note: A slash (/) character indicates no data.
- 

## Creating a map for DXOB formatted data

Using the Map Designer, create a map that contains the logic required to transform input data into DXOB-formatted data.

To create a map to transform data into DXOB-formatted data:

1. Create the input card (for outbound data) that specifies the source of the input data for the map. Select File for the value of the **Source** setting and specify the card settings.
  2. Create an output card (for inbound data) that specifies the target for the output data of the map. Select File for the value of the Target setting and specify the card settings.
  3. After defining the input and output cards, enter the mapping rules to provide values for each of the fields and screens that you want to create for this transaction. Enter =NONE as the map rule for unused fields and screens.
  4. Continue with the mapping process (build, analyze, and run) until the map is producing the correct output data.
- 

## Transferring the Mapped Data

Executing the map has created the output data. The data needs to be transferred from the PC to the application layer.

- [Transferring the mapped data to the application layer](#)
  - [Creating the Batch Input Session](#)
  - [Processing the Batch Input Session \(SM35\)](#)
- 

## Transferring the mapped data to the application layer

Use the Data Transfer Workbench window to transfer the output data resulting from the map execution from the PC to the application layer.

The steps are based on the 4.7 Enterprise Application design. To transfer the mapped data from the PC to the application layer:

1. Enter /nsxda in the command field and click Enter.  
The Data Transfer Workbench window appears.
  2. From the Goto menu select DX Tools.  
The Data Transfer - Tools window opens.
  3. Click Copy.  
The Copy File window opens.
  4. Select Presentation Server and specify the name of the map output file to transfer. It is the output of the map that contains the required data for the Customer master in the format for the SAP DX object.
  5. Select Application Server and select a data type for the target from the drop-down list in the File type field.
  6. In the File Name field, enter the file name for the target on the R/3 application server in the default location.
  7. Click Enter. The file is copied to the application layer.  
The Data Transfer - Tools window opens.
  8. In the File type field, select a data type for the input file from the drop-down list.
  9. In the File Name field, enter the location of the input file on the R/3 application server.
  10. Click Display.
  11. The File & Transactions window appears which contains the names of the various segments and the data fields associated with those segments. The slash character (/) is used to transfer empty fields into SAP.
  12. Click Save.
- 

## Creating the Batch Input Session

The data created by the map has been transferred from the PC to the application layer. Now, a batch input session will be created for the .txt file now residing on the application server.

The steps above are based on the 4.7 Enterprise Application design. To create the Batch Input Session:

1. Enter /nsxda in the command field and click Enter.  
The Data Transfer Workbench window appears.
2. Click Convert data.
3. Click LSM Workbench.  
The Legacy System Migration Workbench window opens.
4. Click Execute.  
The LSM Workbench window opens.

5. In the LSM Workbench window, click User Menu.  
The User Menu dialog displays.
6. Select Create Batch Input Session and click Enter.  
The Create Batch Input Session option is now added to the LSM Workbench window.
7. Select Create Batch Input Session and click Execute.  
The Batch Input Interface for Customers window opens. The file path name defaults to customer.txt.
8. Enable Check file only.
9. In the Program menu, select Execute to check for any terminations in the batch input session.  
Note: This program can also be executed in the background by selecting Execute in Background.
10. Click Enter.
11. After the .txt file has been validated, execute the batch input interface program for the data transfer.
12. Disable the Check file only check box.
13. Execute the program by selecting Execute from the Program menu.  
The Information dialog box displays, providing status information about the batch input session. The following example shows the batch input session being created.
14. Click Enter.

---

## Processing the Batch Input Session (SM35)

The data created by the map has been transferred from the PC to the application layer. Also, a batch input session has been created for the .txt file now residing on the application server. Now you can access the Batch Input Session and process the data in the .txt file.

To process the Batch Input Sessions:

1. Enter transaction code /nsm35 to access the batch input sessions.
2. In the Session list, select the session you want to process.
3. In the Session menu, select Process session.  
The Process Session dialog box opens.
4. Select one of the options for the Run mode:
  - Process/foreground: Runs the session in the foreground, displaying every screen and field. If you change a screen in this option, the process halts.
  - Display errors only: Runs the session in the foreground, displaying only errors.
  - Background: Runs the session in the background.
5. Select Additional functions as desired. (In this example, TESTDXOB will be processed in Display errors only run mode with Dynpro standard size.)
6. Click Process.  
Note: A session can be terminated at any time by selecting System > Services > Batch Input > Delete Transaction.
7. Click Yes to save the data for the customer master data.  
The batch input session is processed and the Information dialog box opens with the process status.
8. Click Exit.  
The processing is complete. (In this example, one batch input session for each customer master data has been created.)
9. Highlight the BDC session you just processed and click Log to access the results.  
The Batch Input: Log Overview window opens.
10. Select the log and click Display to view the results.  
The Batch Input Log for Session session\_name window opens.

---

## Business Application Programming Interface (BAPI)

SAP R/3 automates implementing interface solutions for Business Application Programming Interface (BAPI) objects. This section discusses the support provided by SAP R/3 for developing BAPI interfaces. The topics discussed include the following:

- [Overview of the interface \(BAPI\)](#)
- [Mapping](#)

Note: The JB API Adapter can only be used in the GET function. It cannot be used in a map input card, map output card, or PUT function.

- [Overview of the Interface \(BAPI\)](#)
- [Mapping](#)

---

## Overview of the Interface (BAPI)

SAP Business Objects reside in the Business Framework and provide the interoperability of software components. Collectively, Business Objects are contained within the Business Object Repository (BOR). They cover a wide range of SAP R/3 business data and processes. BAPIs allow external non-SAP R/3 systems, such as products in the Pack for SAP Applications, to access the methods on a SAP Business Object. SAP Business Objects and their BAPIs provide an object-oriented view of SAP R/3 functionality.

BAPIs are used in mapping rules. They are typically used within other interface methods, which need access to the information provided by the Business Object. A developer can call a synchronous BAPI in the mapping rule of an output card as provided by the R/3 BAPI adapter support for BAPIs. The data returned from the BAPI can be mapped to other output data objects or it can be used for conditional logic. The R/3 adapter has the functionality to call a BAPI on an R/3 system. The R/3 adapter supports BAPI as well as any remote enabled function module (RFC).

BAPIs are accessed in SAP R/3 using the transaction code BAPI.

Vendor is a Business Object in the Financial Accounting area of Business Framework. Expanding the Vendor Business Object exposes the available methods.

ChangePassword is a method (BAPI) on the Vendor Business Object. This method provides the capability to change a vendor's password, which is selected by the key field VendorNo. The BAPI name of this method is found by clicking the Detail tab. The BAPI name is BAPI\_VENDOR\_CHANGE\_PASSWORD, the name you specify in the Importer Wizard.

The dialog box also provides documentation on the parameters and attributes of the BAPI. All BAPIs are composed of a combination of Importing, Exporting, and/or Table parameters. Importing parameters are input, Exporting are output, and Tables are in/out. A BAPI may have any combination of these parameter types. Documentation for the parameters, structures, and scalars of a BAPI can be found in the BAPI Browser, the SAP Assistant, and the Function Module.

## Mapping

The SAP:BAPI (Business Application Programming Interfaces) Importer is a facility for automatically generating schemas that describe the format of data used in BAPI programs in your SAP R/3 system. After you have identified a BAPI to be used as the metadata input for the Importer Wizard, generate the schema, and create the map.

To run the SAP:BAPI Importer:

1. From the Type Designer, select Import a type tree. Click OK.
  2. Choose SAP:BAPI as the structure for which you want to generate a type tree and click Next.
  3. Continue to click Next until the Adapter Command Line field appears in the window. Enter the adapter connect parameters in the Adapter Command Line field. Or, click the Configure button to display the R/3 Connection Settings dialog box in which you can enter the connection values. Click the Diagnostics tab to enable Trace for the adapter, specifying a detailed trace and a trace file name. When finished, click OK.
  4. Click Next.
  5. In the Function Module Name field, enter the name of a valid function module in SAP; or select the appropriate module by clicking the Configure button to display the BAPI Explorer. From the BAPI Explorer, expand a Business Object, select a method, and click OK. The method appears in the Function Module Name field.
  6. Click Next.
  7. The File Name window opens. Enter the name of the type tree you wish to create or select a file name. BAPI is the default for the pull-down menu list.
  8. When naming the type tree, there is an option for creating a metadata file. Enable this option to save the metadata file. Click Next. The Importer Wizard connects to the SAP R/3 system and reads the function module importing and exporting parameters. While the Importer Wizard is connecting with the SAP R/3 System, a message appears and the type tree is generated.
- [Understanding the BAPI schema](#)
  - [Calling a BAPI from a map](#)
  - [Unicode](#)

## Understanding the BAPI schema

The following shows the example schema named bapi\_creditor\_getdetail and provides an overview of the correlation between the structure of the BAPI and the schema generated by the Importer Wizard

You can use these directories to test the Importer Wizard.

- The Group type named BAPI has one component, which is Method BAPI\_CREDITOR\_GETDETAIL.
- Contained in the Method BAPI\_CREDITOR\_GETDETAIL component are the Importing Parameters, Exporting Parameters, and Tables Parameters.
- The Importing Parameters are the importing attributes CREDITORID and COMPANYCODE.
- The Exporting Parameters are the structures CREDITOR\_GENERAL\_DETAIL, CREDITOR\_COMPANY\_DETAIL, and RETURN.
- The Tables Parameter is composed of the structure CREDITOR\_BANK\_DETAIL.

## Calling a BAPI from a map

After the type tree is generated, create a map that calls the BAPI.

To call a BAPI from a map:

1. Using the Map Designer, create an output card that uses the type tree generated by the Importer Wizard, including map rules to provide values for the BAPI importing parameters.  
The object for this card is the group object BAPI of the BOR root.
2. Create a second output card that will use the **GET()** function and a **RUN()** function.  
The **GET()** function is used to call the BAPI adapter passing the importing parameters as echoed data and receiving, in return, a text blob containing the populated BAPI structure.

The card object is the xBAPI group object from the BAPI type tree.

The **RUN()** function is used to pass the exporting parameters as the data for an input card of another map.

See *Functions and Expressions* in the online documentation for more information about using the **GET()** and **RUN()** functions.

Important: If the data passed to the run map does not match the expected definition, your mapping process will not complete successfully. The input data trace file helps you to troubleshoot. To produce an input trace, add `-TI` to the options for your `RUN()` function. `-TI` should only be used for debugging purposes.

Note: BAPI examples are in the `examples\packs\sap_r3\r3\ERP\BAPI` directory included in the Pack for SAP Applications installation.

The BAPI example, `bapi_example.mms`, demonstrates the method to implement a BAPI scenario with a SAP R/3 environment. The BAPI adapter call is made from a map rule on the output card using the `GET()` function. The data returned by the BAPI call can then be used to map to any desired output. This is achieved by using the `RUN()` function to pass the data to the second map.

## Unicode

The JB API adapter is based on JCo, the SAP Java API, and is fully compatible with the previous BAPI adapter. The JB API adapter supports all the functionality of the previous BAPI adapter and provides full Unicode support.

## SAP S/4 HANA Adapter

The SAP S/4 HANA adapter provides support for executing SAP S/4 HANA Cloud APIs using OData V2 or OData V4 interfaces.

The SAP S/4 HANA adapter provides support for connecting to a compliant SAP S/4 HANA Cloud service, discovering entity sets exposed by the services and importing entity definitions in form of native JSON schemas. The adapter further supports fetching entities in managed mode, where the entity data complies with the imported schemas, as well as in raw mode where the SAP S/4 HANA Cloud service is accessed directly and the exchanged data is not constrained and validated by the adapter-provided schema.

The SAP S/4 HANA adapter extends the OData adapter. For implementation details including adapter properties and commands, please refer to: [OData Adapter - IBM Documentation](#), noting that the adapter alias used in GET and PUT rules is "SAPHANA".

## Troubleshooting

The following sections explain troubleshooting tools that are available when you encounter problems using SAP R/3 objects as data sources or targets for a map. Methods for viewing data extracted from a SAP R/3 system or loaded into an SAP R/3 system are also presented.

- [Troubleshooting tools](#)
  - [MapAudit log](#)
  - [R/3 adapter audit files](#)
  - [R/3 adapter trace files](#)
  - [R/3 return codes and error messages](#)
  - [Viewing R/3 source and target data](#)
  - [Remaining temporary data in TIDDATA Directory](#)
- 
- [Troubleshooting tools](#)
  - [MapAudit log](#)
  - [R/3 adapter audit files](#)
  - [R/3 adapter trace files](#)
  - [R/3 return codes and error messages](#)
  - [Viewing R/3 source and target data](#)
  - [Remaining temporary data in TIDDATA directory](#)

## Troubleshooting tools

If you receive an error while generating a type tree in the Importer Wizard, or run a map that uses sources and/or targets and receive a runtime error or do not get the expected output, use the following troubleshooting tools:

- Map Audit Log (`map_name.log`)
- Map Execution Trace file (`map_name.mtr`)
- Map Source and Target Data
- R3 Adapter Audit File (`m4r3adapter.log`)
- R3 Adapter Trace File (`m4r3adapter.mtr`)

## MapAudit log

If the problem encountered was the result of executing a map with sources or targets, you can produce the Execution section of the Audit Log. The MapAudit logs can be enabled from the MapSettings dialog box in the Map Designer, or Windows-based transformation server or the command line.

See Map Designer, or Command Server, in the online documentation for information about how to enable the execution log from the MapSettings dialog box. See the *Execution Command*, in the Map Designer documentation, for information about using an execution command.

The default name for the audit log is the full name of the map with a .log extension. By default, it is located in the same directory as the compiled map file.

The MapAudit can contain four different sections: BurstAudit, SummaryAudit, SettingsAudit, and AuditLocation. The sections produced depend on the Log settings for MapAudit.

- [Data Log](#)
  - [Execution audit](#)
  - [Map Settings](#)
  - [Data settings](#)
- 

## Data Log

The information in the Data Log section of the MapAudit can be configured by using the Data Audit Settings tab in the Organizer. See Map Designer in the online documentation for information about configuring these options and interpreting the information in the Data Log.

---

## Execution audit

When the Execution Log setting is set to ON, the MapAudit log contains an ExecutionLog entry for each burst within the map. The ExecutionSummary section provides a summary of the return codes, sources, targets, and work areas for the map.

- [ExecutionLog per burst](#)
  - [ExecutionSummary per map](#)
- 

## ExecutionLog per burst

When the Data Log or Execution Log setting is set to ON, the MapAudit log contains a section for each burst within the map. If all inputs have a CardMode of Integral, there is a single Burst section.

The ExecutionLog section identifies the return code and elapsed time for the burst, as well as the status of each input or output, including both an adapter return code and a content return code.

---

## ExecutionSummary per map

The ExecutionSummary provides information at the map level.

The execution log provides high-level debugging information, including the following:

### Map return code and message

The map return code and message indicate how the mapping operation completed and whether there were any problems. For example, a map return code of 0 and message of Map completed successfully indicate that no execution errors were encountered. This information helps in analyzing the source information in this log.

### SourceReport and TargetReport

For each source or target, the ExecutionSummary includes information indicating the adapter, the size of the data for the source or target, the adapter return code and message, and so on.

### WorkArea

For each input or output for which a WorkArea is created, the ExecutionSummary includes information such as the location and size.

The Execution log is a good place to start when diagnosing map execution problems because you can quickly determine the sources or targets that are in error. Then, using the information in the log, you can produce more detailed troubleshooting information for only those sources or targets that experienced problems.

---

## Map Settings

mapsThe map settings in the Map Designer contains a list of all MapSettings, including the settings for MapAudit, MapTrace, WorkSpace, Century, Validation, Retry, and Warnings.

This information can be useful during debugging to determine why execution occurred in a certain way.

---

## Data settings

The data settings for input and output cards in the map source file in the Map Designer contains a list of all InputData and OutputData settings, including the FetchAs, WorkArea, Backup, PUT > Target > Command, GET > Source > Command, OnSuccess, OnFailure, Retry, Scope, FetchUnit, and so on.

This information can be useful during debugging to identify whether data should be copied to a backup file, whether the changes to a target should be committed if the map fails, and so on.

---

## R/3 adapter audit files

Additional troubleshooting and diagnostic information is available in the R/3 adapter audit file. Specify the **-AR3** adapter command to create a file that records the adapter activity for each specified SAP R/3 object activity. This command can be used for a source or target, or in a GET or PUT function. This adapter command can be specified for individual input and output cards on a card-by-card basis.

The default is to produce a file named `m4r3adapter.log` in the directory in which the map is located, where `adapter` is the adapter type. Optionally, you can append the audit information to an existing file or specify a name or the full path for the file.

## R/3 adapter trace files

Using the information contained in R/3 adapter trace files (`m4r3adapter.mtr`) is one of the primary tools you can use to assist in troubleshooting. These files contain detailed information generated during map execution. The trace file produced at map execution time records detailed information about the R/3 adapter activity, such as objects retrieved, data source and target activity, and so on.

To produce trace information for specific R/3 data sources or targets, use the Trace (**-T**) adapter command.

For example, to produce an adapter trace, include the **-T** adapter command in the Source Command or Target > Command setting, or use it with the appropriate execution command on the command line.

With this adapter command, trace information is generated in the `.mtr` file.

- [R/3 adapter trace - Verbose option](#)

## R/3 adapter trace - Verbose option

When the Trace command is specified, there are several options you can use including the Verbose (**v**) option, which records detailed trace information.

## R/3 return codes and error messages

The following is a listing of all the codes and messages that can be returned as a result of using the R/3 adapter for sources or targets.

Note: Adapter return codes with positive numbers are warning codes that indicate a successful operation. Adapter return codes with negative numbers are error codes that indicate a failed operation.

Table 1. R/3 adapter return codes and error messages

| Return code | Message                                                                            |
|-------------|------------------------------------------------------------------------------------|
| 0           | OK                                                                                 |
| 1           | No data provided. Create on content specified: no connection attempted.            |
| 2           | Map execution failed, data not sent                                                |
| -1          | Error in data prep                                                                 |
| -1          | Error: cannot get function definition                                              |
| -1          | RFC Open failed                                                                    |
| -1          | Put Data failed                                                                    |
| -1          | Unknown_Error                                                                      |
| -1          | Error in setup                                                                     |
| -1          | TID sent twice so not processed                                                    |
| -1          | R/3 may try again later                                                            |
| -1          | Couldn't init adapter. New_semaphore() failed.                                     |
| -1          | Couldn't init adapter. Watch count exceeded.                                       |
| -1          | Couldn't init watchpoint. New_thread() failed.                                     |
| -1          | Error in data prep (invalid Idocs).                                                |
| -1          | Error in data prep (invalid BAPI data or Idoc missing EDI_DC)                      |
| -1          | Connection Test failed                                                             |
| -1          | Connection Test not possible, handle is invalid                                    |
| -1          | RFC Accept Failed                                                                  |
| -1          | Install Function Failed                                                            |
| -1          | InitRfcConn Failed                                                                 |
| -1          | XXXXX = FAILURE(0)<br>For APIs that return nonzero on success.                     |
| -?          | XXXXX = FAILURE(?)<br>For APIs that return nonzero on success.                     |
| -1          | XXXXX = RFC_FAILURE: Error occurred.                                               |
| -2          | XXXXX = RFC_EXCEPTION: Exception raised.                                           |
| -3          | XXXXX = RFC_SYS_EXCEPTION: System exception raised, connection closed.;            |
| -3          | User data properties not set. IDoc may be corrupted.                               |
| -4          | XXXXX = RFC_CALL: Call received.                                                   |
| -5          | XXXXX = RFC_INTERNAL_COM: Internal communication, repeat<br>For internal use only. |
| -6          | XXXXX = RFC_CLOSED: Connection closed by the other side.                           |
| -7          | XXXXX = RFC_RETRY: No data yet (RfcListen or RfcWaitForRequest only).              |
| -8          | XXXXX = RFC_NO_TID: No Transaction ID available.                                   |
| -9          | XXXXX = RFC_EXECUTED: Function already executed.                                   |

| Return code | Message                                                                    |
|-------------|----------------------------------------------------------------------------|
| -10         | XXXXX = RFC_SYNCHRONIZE: Synchronous Call in Progress (only for Windows).; |
| -10         | Invalid connection, RFCPING failed, see trace file for details.            |
| -11         | XXXXX = RFC_MEMORY_INSUFFICIENT: Memory insufficient.                      |
| -12         | XXXXX = RFC_VERSION_MISMATCH: Version mismatch.                            |
| -13         | XXXXX = RFC_NOT_FOUND: Function not found.<br>For internal use only.       |
| -14         | XXXXX = RFC_CALL_NOT_SUPPORTED: This call is not supported on WINDOWS.     |
| -15         | XXXXX = RFC_NOT_OWNER: Caller does not own the specified handle.           |
| -16         | XXXXX = RFC_NOT_INITIALIZED: RFC not yet initialized.                      |
| -?          | XXXXX = RFC_UNKNOWN: Unknown result code ?.                                |
| -?          | Is an API-specific error code, made negative if >0                         |
| XXXXX       | is a SAP API or TID Mgmt Function                                          |
| -464        | Initialization failure. (sanity check failed)                              |
| -600        | Internal Error: Resource Manager Error                                     |
| -1000       | Initialization failure. (program arguments)                                |
| -2000       | Initialization failure. (backup/log init)                                  |

## Viewing R/3 source and target data

When debugging a map that uses SAP R/3 sources or targets, you cannot view the source or target data in the Map Designer by selecting the Run Results from the View menu. However, you can capture the data that was retrieved from or written to an SAP R/3 object for debugging purposes by using Backup settings.

- [Backup settings](#)

## Backup settings

Backup settings are used to determine when, where, and how the data for a specific card should be copied to a specified backup file. These settings are configured in the Input and Output Card Settings in the Map Designer and the Launcher or Command Settings in the Integration Flow Manager.

Note: Refer to the Map Designer in the online documentation for more information on Backup settings.

## Remaining temporary data in TIDDATA directory

The adapter uses the tiddata directory internally to place intermediate files. This directory is placed in the DTX\_TMP\_DIR/tiddata for Linux® and UNIX platforms.

## Financial Services standards

The IBM Transformation Extender Pack for Financial Payments, uses the strength of the data definitions and transformation capabilities from various key financial services standards.

The following industry standards are supported:

- Financial Information eXchange (FIX) which provide both tag value encoding and FIXML support
- NACHA, which provides support for clients that need to validate, create, or transform ACH messages
- Single Euro Payments Area (SEPA) - based on ISO 20022
- Society for Worldwide Interbank Financial Telecommunication (SWIFT). The SWIFT standards include the following standards:
  - SWIFT MT - based on ISO 7775 and ISO 15022
  - SWIFT MX - based on ISO 20022
- Generic ISO 20022-based XML not covered under the SWIFT or SEPA standards. This supports a tool that can standardize messages across all payment types

## The IBM Transformation Extender product family

The IBM Transformation Extender product family provides a universal transformation engine that can describe and transform any data, work directly in any architecture, and reuse the transformations across the enterprise.

IBM Transformation Extender supports specific industry segments, such as financial services, with industry packs. Together, they provide the capabilities to perform the following:

- Transform, validate, and enrich any document, message or complex data
- Deliver trustworthy information for critical business initiatives
- Meet regulatory compliance requirements
- Support codeless development; universal reuse and deployment

## International Program License Agreement

The *International Program License Agreement* installs with the pack.

The *International Program License Agreement* is provided in English (United States) as well as in various other languages. The license agreement installs in the directory:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/license

where <install\_dir> is the installation location of the Pack for Financial Payments, and n.n.n.n indicates the current version of the Pack for Financial Payments.

---

## Installation and uninstallation

Installation and uninstallation procedures are described in the release notes on the Support website.

Installation and installation procedures are described in the release notes.

## Overview of the FIX component

The Financial Information eXchange (FIX) protocol is a message standard that was developed to facilitate the electronic exchange of information that is related to securities transactions. It is used between trading partners that want to automate communications.

Many business functions are supported by the message protocol. Initially, FIX was intended to support US domestic trading with message traffic being exchanged between principals. As the FIX protocol evolved, a number of fields were added to enable cross-border trading, derivatives, fixed income and other products. This functionality is expected to continue as subsequent releases of FIX become available.

The Pack for Financial Payments, FIX component consists of a set of IBM Transformation Extender type trees and maps that form the basis for a messaging library for larger solutions that require simple FIX message creation, parsing and validation.

It is important to note that FIX is not a software application. It is instead a specification, around which developers can create commercial, or open-source software as needed to address specific business needs. Today, as the leading trade communication protocol, FIX is integral to an array of other management and trading systems, users of which often benefit from the systems without knowing the language itself.

- [\*\*What the FIX component contains\*\*](#)

FIX type trees, FIXML type trees, and example conversion maps are installed when you install this pack.

---

## What the FIX component contains

FIX type trees, FIXML type trees, and example conversion maps are installed when you install this pack.

Specifically, the following objects are installed when you install the Pack for Financial Payments, FIX component:

- FIX type trees - These type trees support all FIX versions: 4.0, 4.1, 4.2, 4.3, 4.4, 5.0, 5.0 SP1, 5.0 SP2, and 5.0 SP2 Extension Packs (up to EP291). The FIX type trees provide consistency in format and content across the various services engagements that are related to FIX solutions.
- FIXML type trees - These type trees represent XML equivalents of FIX versions: 4.1, 4.2, 4.3, 4.4, 5.0, 5.0 SP1, and 5.0 SP2 (Latest). The type trees are based on DTDs and the schemas that are provided by FIX.
- FIXML schemas - These schemas are copies of the latest published FIXML schemas that support the following FIXML versions: 4.4, 5.0, 5.0 SP1, 5.0 SP2, and 5.0 SP2 Extension Packs (based from EP291).
- FIXT 1.1 type tree - This type tree supports the FIX Session Protocol messages.
- [\*\*Major components of the pack\*\*](#)

---

## Major components of the pack

When you install the Pack for Financial Payments, FIX component, the following subdirectories are created: utilities, examples, schemas, and trees. These directories are created in the following location:

<install\_dir>/packs/financial\_payments\_vn.n.n.n/fx

- [\*\*The utilities subdirectory\*\*](#)  
The utilities subdirectory contains the data, maps and trees subdirectories.
- [\*\*The trees subdirectory\*\*](#)  
The trees subdirectory contains type trees that support various FIX standards. It also contains FIXML type trees that are generated from DTDs, or schemas.
- [\*\*The schemas subdirectory\*\*](#)
- [\*\*FIX component examples\*\*](#)  
The Pack for Financial Payments, FIX component contains examples to assist you in using the pack.

---

## The utilities subdirectory

The utilities subdirectory contains the data, maps and trees subdirectories.

These subdirectories are described as follows:

- data subdirectory - The data subdirectory contains the following sample input data files and map results are also stored in this location:
  - fix\_40.inp - This file is used with the FIX checksum utility maps.
  - fix\_40\_MVS.inp - This version of fix\_40.inp is converted to EBCDIC characters, to be used as input when executing an example on z/OS.
- maps subdirectory - The maps subdirectory contains a map source called fix\_checksum.mms. It consists of the utility example maps described as follows:
  - fxchksm1\_utility - The fxchksm1\_utility map is used to compute the FIX checksum by summing every byte value equivalent of every character that is contained in a FIX message and applying a MODULUS 256. This map requires the FIX message to be formatted in hexadecimal text stream representation.
  - fxchksm2\_validate - The fxchksm2\_validate utility map is used to verify the computed FIX checksum value against the actual FIX message field tag 10 value. The computed FIX checksum is returned by invoking the fxchksm1\_utility map. The map returns a value of PASS if the value on field tag 10 matches the computed FIX checksum. If the value on field tag 10 does not match the computed FIX checksum, a value of FAIL is returned. The map requires the FIX message to have tag 10 to be populated as the last field in the message. The fxchksm1\_utility map must be compiled before execution of this map and the compiled map must be the same location where the fxchksm2\_validate map is being executed. This map can be used for inbound mapping where the field tag 10 value must be verified.
  - fxchksm3\_compute - The fxchksm3\_compute utility map retrieves the computed FIX checksum by calling fxchksm1\_utility map. The map requires a FIX message as input. Any field tag 10 is removed before it is passed to the fxchksm1\_utility map. The first output card contains the computed FIX checksum that results from calling the fxchksm1\_utility map. The second output card contains the computed FIX body length. The body length is the number of characters from body length tag 9 up to and including the delimiter immediately preceding the checksum tag 10. The second output card is optional and provided as a convenience. It is configured with a SINK adapter, which can be overridden when needed. The fxchksm1\_utility map must be compiled before execution of this map and the compiled map must be in the same location where fxchksm3\_compute map is being executed. This map can be used for outbound mapping where the field tag 10 value must be populated.
- trees subdirectory - The trees subdirectory contains fix\_checksum.mtt, a general-purpose type tree, which is used in both the input and output cards of the FIX checksum utility maps.

## The trees subdirectory

The trees subdirectory contains type trees that support various FIX standards. It also contains FIXML type trees that are generated from DTDs, or schemas.

The type trees that are installed in the trees subdirectory are described in the following table:

| Type tree           | FIX version | Comments                                                       |
|---------------------|-------------|----------------------------------------------------------------|
| fix_40.mtt          | 4.0         | Type tree supports FIX 4.0 version messages                    |
| fix_41.mtt          | 4.1         | Type tree supports FIX 4.1 version messages                    |
| fix_42.mtt          | 4.2         | Type tree supports FIX 4.2 version messages                    |
| fix_43.mtt          | 4.3         | Type tree supports FIX 4.3 version messages                    |
| fix_44.mtt          | 4.4         | Type tree supports FIX 4.4 version messages                    |
| fix_50.mtt          | 5.0         | Type tree supports FIX 5.0 version messages                    |
| fix_50_sp1.mtt      | 5.0 SP1     | Type tree supports FIX 5.0 SP1 version messages                |
| fix_50_sp2.mtt      | 5.0 SP2     | Type tree supports FIX 5.0 SP2 version messages                |
| fix_50_sp2_ep.mtt   | 5.0 SP2 EP  | Type tree supports FIX LATEST (up to EP 291) version messages. |
| fixt_11.mtt         | 1.1         | Type tree supports FIXT 1.1 version messages                   |
| fixml_41.mtt        | 4.1         | Type tree which is generated from a FIXML DTD                  |
| fixml_42.mtt        | 4.2         | Type tree which is generated from a FIXML DTD                  |
| fixml_43.mtt        | 4.3         | Type tree which is generated from a FIXML schema               |
| fixml_44.mtt        | 4.4         | Type tree which is generated from a FIXML schema               |
| fixml_50.mtt        | 5.0         | Type tree which is generated from a FIXML schema               |
| fixml_50_sp1.mtt    | 5.0 SP1     | Type tree which is generated from a FIXML schema               |
| fix-main-latest.mtt | FIX LATEST  | Type tree which is generated from a FIXML schema               |

## The schemas subdirectory

The schemas subdirectory contains FIXML schemas in the following subdirectories:

- fixml\_44 - This directory contains the FIXML 4.4 schema: Schema version 20040109 with Revision 1, 2006-10-06
- fixml\_50 - This directory contains the FIXML 5.0 schema: Schema version 20070103
- fixml\_50\_sp1 - This directory contains the FIXML 5.0 SP1 schema: Schema version 20080314
- fixml\_50\_sp2 - This directory contains several folders corresponding to publication dates of the following FIXML 5.0 SP2 schemas:
  - 20131209 – FIXML 5.0 SP2 errata version
  - 20240704 – FIX LATEST (up to EP291)

## FIX component examples

The Pack for Financial Payments, FIX component contains examples to assist you in using the pack.

The list of FIX component examples is as follows:

- Advertisement messages
- Allocation Instruction message
- Allocation Instruction Ack message
- Don't Know Trade (DK) message

- Email message
- Execution Report message
- Indication of interest message
- List Cancel Request message
- List Execute message
- List Status message
- List Status Request message
- New Order List message
- News message
- Order Cancel Reject message
- New Order message
- Order Status Request message
- Quote message
- Quote Request message

See [FIX component examples](#).

## FIX type trees and message structure

The FIX type trees are listed in [The trees subdirectory](#). The documentation provided here describes FIX message protocol and defines message types by FIX version number.

- [FIX message protocol](#)  
The FIX protocol is defined at two levels, session and application.
- [Message types per FIX version number](#)  
This documentation shows the message types that are supported in the Pack for Financial Payments, FIX component. Messages are listed by FIX version.
- [Type tree features](#)  
The type trees contained in the Pack for Financial Payments, FIX component serve to enforce FIX message structure, message syntax, as well as to enforce additional data validation rules.
- [Example message structure](#)  
The documentation provided here shows the FIX message structure by showing an example header, body and trailer.

## FIX message protocol

The FIX protocol is defined at two levels, session and application.

The session level consists of:

- Heartbeat
- Logon
- Logout
- Reject
- Resend Request
- Sequence Reset
- Test Request
- XMLnonFIX

The application level consists of:

- Pre-trade
- Trade
- Post-trade
- Infrastructure

## Message types per FIX version number

This documentation shows the message types that are supported in the Pack for Financial Payments, FIX component. Messages are listed by FIX version.

- [Session messages](#)  
The table shows a summary of the messages under the Session category. The messages are listed by FIX version number.
- [EventCommunication messages](#)  
The table shows a summary of the messages under the EventCommunication category. The messages are listed by FIX version number.
- [Indication messages](#)  
The table shows a summary of the messages under the Indication category. The messages are listed by FIX version number.
- [MarketData messages](#)  
The table shows a summary of the messages under the MarketData category. The messages are listed by FIX version number.
- [QuotationNegotiation messages](#)  
The table shows a summary of the messages under the QuotationNegotiation category. The messages are listed by FIX version number.
- [SecuritiesReferenceData messages](#)  
The table shows a summary of the messages under the SecuritiesReferenceData category. The messages are listed by FIX version number.
- [MarketStructureReferenceData message types](#)  
The table shows the MarketStructureReferenceData message types by FIX version number.

- [\*\*PartiesAction messages\*\*](#)  
The table shows a summary of the messages under the PartiesAction category. The messages are listed by FIX version number.
- [\*\*PartiesReferenceData messages\*\*](#)  
The table shows a summary of the messages under the PartiesReferenceData category. The messages are listed by FIX version.
- [\*\*SingleGeneralOrderHandling messages\*\*](#)  
The table shows a summary of the messages under the SingleGeneralOrderHandling category. The messages are listed by FIX version number.
- [\*\*ProgramTrading messages\*\*](#)  
The table shows a summary of the messages under the ProgramTrading category. The messages are listed by FIX version number.
- [\*\*OrderMassHandling messages\*\*](#)  
The table shows a summary of the messages under the OrderMassHandling category. The messages are listed by FIX version number.
- [\*\*CrossOrders messages\*\*](#)  
The table shows a summary of the messages under the CrossOrders category. The messages are listed by FIX version number.
- [\*\*MultilegOrders messages\*\*](#)  
The table shows a summary of the messages under the MultilegOrders category. The messages are listed by FIX version.
- [\*\*Allocation messages\*\*](#)  
The table shows a summary of the messages under the Allocation category. The messages are listed by FIX version number.
- [\*\*SettlementInstruction messages\*\*](#)  
The table shows a summary of the messages under the SettlementInstruction category. The messages are listed by FIX version number.
- [\*\*SettlementStatusManagement messages\*\*](#)  
The table shows a summary of the messages under the SettlementStatusManagement category. The messages are listed by FIX version number.
- [\*\*RegistrationInstructions messages\*\*](#)  
The table shows a summary of the messages under the RegistrationInstructions category. The messages are listed by FIX version number.
- [\*\*TradeCapture messages\*\*](#)  
The table shows a summary of the messages under the TradeCapture category. The messages are listed by FIX version number.
