

IBM Sterling Transformation Extender

Tables of Contents

Introduction

Introduction	1
The business role of IBM Sterling Transformation Extender	1
Accessibility features for IBM Sterling Transformation Extender	1
Globalization	2
To change application locale (Windows)	2
To change the application locale (Windows) for the Design Studio application	2
To change the application locale (Windows) for tools and runtime applications	3
To change the application locale (UNIX)	3
To change the Launcher Administration locale	3
To change the Management Console locale	4
To change the Resource Registry locale	4
Locale values	5
Product overview	5
Product architecture	5
Runtime services	6
Design environment	6
Projects	6
Schema design	6
Map design	7
Input and output cards	8
Transformation, routing, and business logic rules	8
Adapter configuration for input and output	8
Resource adapters	8
Connection and action design	9
Configuration variables	9
Database Interface Designer	9
Integration Flow Designer	9
Developing application interfaces	10
Modeling the data of business objects	10
Defining transformation rules	11
Defining data sources and targets	11
Defining process models	11
Formulating business process models	12
Defining resource connectivity	12
Defining event rules	12
Configuring map settings	12
Managing systems	12
Type Tree Maker	12
Server components	12
Management and monitoring tools	13
Launcher Administration	13
Simple Network Management Protocol (SNMP) support	13
Management Console	13
Launcher Monitor	13
Snapshot Viewer	14
Software Development Kit (SDK)	14
Software Development Kit Application Programming Interfaces (APIs)	14
Software Development Kit options	14
Adapter toolkit	14
B2B management (Trading Manager)	14
Partner Manager	15
Message Manager	15
Other IBM Sterling Transformation Extender solutions	15
Integration maps	15
Map behavior during execution	16
Input and output card settings	16
Map settings	16
Configuration variables	17
Reserved words and symbols	17
Quotation marks	18
Hex, decimal, and symbol values	18
File name extensions	20
Execution	20
Executing in test and production environments	21
Executing on multiple platforms	21
Command-driven execution model	21
Execution command overriding a database target example	21
Event-driven execution model	22
Launcher	22

Triggers and watches: asynchronous communication	22
Synchronous coordination	22
Launcher Architecture	22
Launcher methodology	23
Business Advantages of the Launcher	23
Audit and transaction logging	23
Application-embedded execution model	23
Examples	24
Tivoli License Manager	24
What's new	
What's new in V11.0.1.0	24
What's new in Packs V10.2.3.0	26
What's new in Packs V10.2.0.1	28
Configuration	
Configuration	28
Data Directory	29
The IBM Sterling Transformation Extender configuration file config.yaml	29
Configuration file syntax validation	29
Configuration file expansion expressions	29
Environment variable expansion	29
Master Key File (MKF) expansion	29
Customizing the Trace	30
Customizing the Trace for IBM Sterling Transformation Extender Rest Execution	30
How to verify the Config.yaml file	31
Enhancing Security, preventing Server Side Forgery Requests attacks	31
Design Server	
Installation	32
Windows installer	32
IBM Sterling Transformation Extender Server Components	32
Installation prerequisites	33
Verify that the following ports are available on your machine	33
Data folders used by IBM Sterling Transformation Extender	33
Additional data folders	34
Installation procedures	34
Installing IBM Sterling Transformation Extender Server with Install Shield	34
Manually Installing IBM Sterling Transformation Extender Server and Runtime	34
Post installation action	34
Modify an existing installation	35
Starting and Stopping IBM Sterling Transformation Extender application	35
Accessing IBM Sterling Transformation Extender	35
Customizing the installation	35
Customizing the Redis and IBM Sterling Transformation Extender Databases	35
Customizing IBM Sterling Transformation Extender URL and Selecting HTTPS protocol	35
Uninstalling IBM Sterling Transformation Extender	36
Troubleshooting the installation	36
Manually Uninstalling the IBM Sterling Transformation Extender	36
Troubleshooting IBM Sterling Transformation Extender installation process	37
Manually updating Apache Tomcat 9 for the IBM Sterling Transformation Extender application	37
Linux installation	37
IBM Sterling Transformation Extender Utility	38
CONFIGURE command	38
INSTALL, UNINSTALL, START, STOP commands	38
STATUS command	38
LOGS command	39
Native installation	39
Prerequisites	39
System Configuration	39
Temporary directory mounting options	40
Changing the mount option for /tmp	40
Changing the IBM Sterling Transformation Extender temporary directory	40
Installation procedures	40
Manually updating Apache Tomcat 9 for the IBM Sterling Transformation Extender application	41
Docker installation	41
Docker configuration	41
Installation	42
Podman installation	42
Troubleshooting	42
Using the OneDB wire listener as a MongoDB server	43
IBM Sterling Transformation Extender design data	43
Design data storage	43
Design data backup and migration	43
MongoDB database operations	43

Design databases	44
Additional accounts	44
Backing up and restoring databases	44
MongoDB migration example	44
Filesystem data backup and restore	45
Filesystem data migration example	45
Administration	45
User Management	45
Managing user accounts	46
Add a user	46
Introduction	46
Installation	46
User Administration	46
Default User Administration	46
Creating a Realm	47
Configuring Clients	47
Connecting to Design Server	47
LDAP User Authentication	48
Selecting LDAP provider in Keycloak	48
Required settings for a successful connection to your LDAP/AD provider	48
User synchronization	49
Mappers	49
Runtime REST API	49
Connecting Runtime REST API server	49
Outbound connections to Runtime Servers	49
Design Server concepts	50
Projects	50
Importing and exporting	50
Connections and actions	50
Project-level connections and actions	51
Map-level connections and actions	51
Connection testing	51
Files	51
Schemas	51
Schema design	51
About schemas	51
Subtypes	52
Schema hierarchy	52
Defining data	52
Objects, types, and classes	52
Testing part of a schema	53
Invalid input message from test data generation	53
Importers	53
COBOL Copybook Importer	53
Running the COBOL copybook importer in Design Server UI	54
Runtime options	54
COBOL copybook Specification	54
Type tree Mapping	54
Clause	55
CSV Importer	55
Running the CSV Importer in Design Server UI	55
CSV importer Properties	55
JSON Importer	56
Importing JSON Schema in Design Server UI	56
Importing JSON Template in Design Server UI	57
The representation of JSON types in schemas	57
Using native JSON schemas in a map	57
JSON cards and text encodings	57
Type properties	57
Defining type properties	58
Basic type properties	58
Name	58
Class	59
Description	59
Intent	59
Partitioned	59
Order subtypes	59
Initiator	59
Terminator	60
Release characters	60
Building release characters for output data	60
Guidelines for using release characters	60
Release character example	60

Empty	61
Empty type property example	61
Document Type	61
Where used	61
Symmetric swapping	62
Orientation	62
Shaping	62
Item properties	63
Item subclass	63
Number item subclass properties	63
Interpret as binary	64
Binary integer presentation	64
Binary float presentation	64
Binary packed presentation	64
Binary BCD presentation	64
Length (bytes)	64
Byte order	64
Interpret as character	65
Character integer presentation	65
Character decimal presentation	65
Zoned character presentation	65
Places > implied	65
Size (digits)	65
Excluded from min and max size	66
Size example	66
Separators	66
Integer separators	66
Separator > format	66
1000's syntax > value	67
1000's syntax (literal) > value	67
1000's syntax (variable) > default	67
1000's syntax (variable) > item	67
1000's syntax (variable) > find	67
Decimal separators	67
Separators > format	68
Separators > 1000's syntax	68
Separators > fraction syntax	68
Sign	68
Pad	69
Pad > value	69
Pad > Padded to	69
Padded to > length	70
Padded to > SizedAs	70
Padded to > CountsTowardMinContent	70
Padded to > Allow Excess Trailing Pads	71
Pad > justify	71
Pad > apply pad	71
Pad > fill	72
Restrictions	72
Restrictions > ignore case	72
Restrictions > rule	72
National language	72
National language > data language	72
Supported code pages	72
NONE and Zero	76
NONE > Special Value and Zero > Special Value	76
NONE > Required on input and Zero > Required on input	76
Places	76
E-Notation	76
Data parsing expectations	76
Generating a data item defined with E-Notation	77
E-Notation output	77
Text item subclass properties	77
Interpret as binary	64
Interpret as character	65
Size (content)	78
Pad	69
Restrictions	72
National language	72
NONE	79
NONE > Special Value	79
NONE > Required on input	79

Bidirectional	80
Date & Time item subclass properties	80
Date	81
Date > format	81
Time	81
Time > format	81
Format	81
Use of format elements	82
Custom date format	82
Custom Time Format	82
Time zones	83
Time zone format string for XML	83
Optional time segments of the time format string	84
Date and time format examples	84
NONE and Zero	84
NONE > Special Value and Zero > Special Value	84
NONE > Required on input and Zero > Required on input	85
Syntax item subclass properties	85
Syntax objects with variable values	85
Example of variable syntax object as an item type	85
Syntax objects as data	85
Example of syntax objects as components of a type	86
Delimiter > find	86
Group properties	86
Group subclass	86
Properties of group subclasses	87
Choice group components	87
Unordered group components	87
Sequence group formats	87
Explicit format	87
Track	88
Fixed syntax	88
Guidelines for defining a fixed group	88
Explicit delimited syntax	88
Delimiter	88
Implicit format	89
Floating component	89
Implicit whitespace syntax	89
Build as	89
Character set	89
Implicit delimited syntax	89
Delimiter	90
No syntax	90
Distinguishable components of an implicit group	90
Specifying a delimiter	90
Literal	90
National language	72
Data language	90
Variable	91
Location	91
Delimiter value appears as data	91
Allow Excess Trailing Delimiters	91
Defining exclude characters	91
Escaping an excluded character in the data content	92
XML properties in the schema	92
Support for XML constructs	92
XML schema datatypes	93
Simple types	93
Complex types	93
Elements	93
Attributes	94
Groups and substitution groups	94
Identity constraints	94
Namespaces	94
Element type declarations	94
Element and attribute wildcards	94
Type propagation for Category, Group, and Item Properties	94
To Propagate in Category/Group/Item property	95
To Propagate Restrictions in Category/Group/Item property	95
Item restrictions	95
Restrictions settings	95
Value restrictions	95

Character descriptions	96
To add character restrictions to an item	96
Range restrictions	96
Value not in range	96
Value not in range	96
To add range restrictions to an item	97
Inserting symbols	97
Ignoring restrictions	97
Components	97
Components are required for group types	97
Components must be in the same schema	97
Importance of component order	98
Component range	98
Indefinite number	98
Single occurrence	98
Defining components	98
Guidelines for defining components	99
Complete type name	99
Relative type names	99
Moving types with the same relative type name	99
Ambiguous type names	99
Specifying minimum and maximum consecutive occurrences in the component list	99
Fixed and variable ranges	100
Specifying a component range	100
Variable component names	100
Required and optional data	100
Significance of required data	100
Defining component rules	101
Examples of component rules	101
Component rule syntax	101
Entering object names in component rules	101
Shorthand notation	102
Component rules are context-sensitive	102
Special characters in component rules	102
Comments in component rules	102
Component attributes	102
Identifier attribute	102
Restart attribute	102
Sized attribute	103
Include self in size	103
Partitioning	103
Determining when to partition	103
Required partitioning	103
Partitioning for convenience	104
Benefits of partitioning	104
Partitioning types	104
Partitioning items	104
Partitioning an item type using initiators	104
Partitioning an item type using restrictions	104
Example of using restrictions	105
Partitioning an item type by format	105
Partitioning groups	105
Partitioning a group type using initiators	105
Partitioning a group type using identifiers	105
Partitioning a group type using component rules	106
Type inheritance	106
Inheritance of item properties and restrictions	106
Inheritance of category properties and components	106
Organizing types under a category	106
Using categories for inheritance	106
When not to use categories	107
Propagation of type properties	107
Propagation of type properties common to all types	107
Propagation of type properties for specific types	107
Error detection	108
How error detection works	108
Existence indicators	108
Existence versus presence of components	109
Error recovery	109
Using the Restart attribute	110
How the Restart attribute works	110
Mapping invalid data	110

Schema analyzer	110
Mapping effects	110
Internal consistency	111
Logical analysis	111
Structural analysis	111
Error and warning messages	111
Distinguishable objects	111
Objects in a data stream	111
Schema analyzer and distinguishable objects	112
Bound types	112
Bound components	112
Component of a fixed group	112
Component of an explicit delimited group	112
Component of an implicit group	113
Component of a choice group	113
Component of an unordered group	113
Group starting set	113
Group unbound set	113
Unbound set of a sequence group	113
Initiator-distinguishable types	114
Determining if a component is initiator-distinguishable from its following set	114
Determining if a partition is initiator-distinguishable from its following set	114
Determining if two types are initiator-distinguishable	114
Distinguishable objects of the same component	115
Content-distinguishable components	115
Content-distinguishable types	116
Ending-distinguishable types	118
Distinguishable data objects of an implicit group	119
Guidelines for defining an implicit delimited sequence	119
Guidelines for defining an implicit sequence that has no delimiter	119
Guidelines for defining an implicit unordered group that is delimited	119
Guidelines for defining an implicit unordered group that has no delimiter	120
Distinguishable data objects of an explicit group	120
Guidelines for defining an explicit fixed group	120
Guidelines for defining an explicit delimited group	120
Objects of a choice group	120
Objects of a partitioned type	120
Distinguishable syntax objects	120
Return codes and error messages	121
Type Tree Analyzer errors and warnings	121
Schema analysis logic error messages	121
Logic error and warning messages	127
Schema analysis structure error messages	127
Schema analysis structure warning messages	127
Maps	129
Map design	129
Introduction to the Map Designer	129
Using the Map Designer	130
Define data objects and properties	130
Create maps to specify sources and targets	130
Auto Map preferences	130
Mapping Scope	130
Rule Creation Option	131
Name Matching Options	131
Mapping Criteria	131
Match percent examples	131
Profiler preferences	132
Where Used view	132
Search options	133
Search and replace	133
Search For	133
Scope	134
Using search and replace	134
Find and replace	134
Using find and replace	135
Maps and map source files	135
Map name guidelines	135
Map source file differences	136
Troubleshooting tip	136
Input and output cards	136
Card overview	136
Card specifics	137

Compositional hierarchy	137
Native XML schema support	137
Input-card type requirements for XML documents	137
Parsing native XML schemas	138
Running the Native XML Schema Customization wizard task flow	138
Support for XSDL hints in output cards	138
Native JSON schema support	138
Static input cards	139
Static file validation and tracing	139
Automatically mapping source to target	140
Auto Map overview	140
Running the Auto Map task flow	140
Setting the Auto Map options	141
Selecting the rules to create	141
Editing rule proposals	141
Renaming the map	142
Card settings	142
Schema	142
CardName	142
CardName guidelines	142
Schema	143

BackupLocation > FileName > Action	154
BackupLocation > FileName > Value	154
Effects of modifying a schema	155
Changing a type that is used for a card	155
SyntaxCard	155
Editing a card	155
Changing a card name	155
Changing the type of an input card	156
Changing the type of an output card	156
Changing the schema of a card	156
Map events	156
Map rules	156
Map rules overview	157
Rule editor	157
Color coding of map rules	157
Configuring colors for map rules	157
Map rules as expressions	157
Map rules define how to generate data objects	158
Map rules are evaluated independently in sequential order	159
Generating no output	159
Text literals as NONE	159
Special characters in map rules	159
Syntax errors in map rules	159
Data object names in map rules	159
Card names in map rules	160
Component names in map rules	160
Index in map rules	160
Partition in map rules	160
Comments in map rules	160
Unavailable rule cells	161
Use ellipses	161
Search functionality	161
To search in a Map using Search icon	161
Formulating map rules	161
When input data is missing	161
When portions of an input series are missing	162
When an output evaluates to NONE	162
Mapping an input item to an output item	162
Automatic item conversions	163
Intermediate item conversions	163
Concatenating text strings	163
Mapping a group to a group	163
Automatic conversion of syntax items	163
Mapping to a group with a maximum range of 1	163
Outputs with maximum range greater than 1	164
Indexing an output	164
Mapping to multiple occurrences of a group	164
Indexing an Input	164
Mapping from a floating component type	164
Functional map basics	164
When to use a functional map	165
Similarities of input and output data	165
Using a functional map	165
Example scenario for using a functional map	166
Comparing executable and functional maps	166
Syntax of a functional map expression	166
Determining the arguments of a functional map	167
Input argument to a functional map evaluates to NONE	167
Entering the map rule that references the functional map	167
Input card types of a functional map	168
Input arguments as data objects	168
Output card type of a functional map	168
Entering map rules	169
Using multiple inputs in a functional map	169
Input objects are triggers	169

Rename a functional map	169
Map settings	169

Character restrictions	325
To add character restrictions to an item	326
Range restrictions	326
Value not in range	326
To add range restrictions to an item	327
Inserting symbols	327
Ignoring restrictions	327
Components	327
Components are required for group types	328
Components must be in the same type tree	328
Importance of component order	328
Component range	328
Indefinite number	329
Single occurrence	329
Group views	329
Viewing nested components	329
Defining components	329
Complete type name	330
Relative type names	330
Moving types with the same relative type name	330
Ambiguous type names	330
Manual entry of types with same relative type names	330
Always drag components	331
Viewing the component number	331
Specifying minimum and maximum consecutive occurrences in the component list	331
Fixed and variable ranges	331
Specifying a component range	331
Viewing the range column	332
Types that can be components	332
Guidelines for defining components	332
Variable component names	332
Opening a component view	333
Required and optional data	333
Significance of required data	333
Defining component rules	333
Examples of component rules	334
Component rule syntax	334
Entering object names in component rules	334
Shorthand notation	335
Component rules are context-sensitive	335

Special characters in component rules	335
Inserting functions into component rules	335
Formatting a component rule	335
Comments in component rules	335
Syntax errors	336
Managing components	336
Component attributes	336
Identifier attribute	336
Restart attribute	336
Sized attribute	336
Include self in size	337
Partitioning	337
Determining when to partition	337
Required partitioning	337
Partitioning for convenience	338
Benefits of partitioning	338
Partitioning types	338
Partitioning items	338
Partitioning an item type using initiators	338
Partitioning an item type using restrictions	339
Example of using restrictions	339
Partitioning an item type by format	339
Partitioning groups	339
Partitioning a group type using initiators	339
Partitioning a group type using identifiers	340
Partitioning a group type using component rules	340
Type inheritance	340
Inheritance of item properties and restrictions	340
Inheritance of category properties and components	341
Organizing types under a category	341
Using categories for inheritance	341
When not to use categories	341
Propagation of type properties	341
Propagation of type properties common to all types	341
Propagation of type properties for specific types	342
Propagating type properties	342
Error detection and recovery	343
Error detection	343
How error detection works	343
Existence indicators	343
Existence versus presence of components	344
Error recovery	344
Using the Restart attribute	345
How the Restart attribute works	345
Mapping invalid data	345
Type Tree Analyzer	346
Mapping effects	346
Internal consistency	346
When to Analyze Structure or Logic	346
Logical analysis	346
Structural analysis	346
To analyze a type tree	346
Error and warning messages	347
Distinguishable objects	347
Objects in a data stream	348
Type tree analyzer and distinguishable objects	348
Bound types	348
Bound components	348
Component of a fixed group	349
Component of an explicit delimited group	349
Component of an implicit group	349
Component of a choice group	349
Component of an unordered group	349
Group starting set	349
Group unbound set	350
Unbound set of a sequence group	350
Initiator-distinguishable types	350
Determining if a component is initiator-distinguishable from its following set	350
Determining if a partition is initiator-distinguishable from its following set	350
Determining if two types are initiator-distinguishable	350
Distinguishable objects of the same component	351
Content-distinguishable components	352

Content-distinguishable types	352
Ending-distinguishable types	354
Distinguishable data objects of an implicit group	355
Guidelines for defining an implicit delimited sequence	355
Guidelines for defining an implicit sequence that has no delimiter	356
Guidelines for defining an implicit unordered group that is delimited	356
Guidelines for defining an implicit unordered group that has no delimiter	356
Distinguishable data objects of an explicit group	356
Guidelines for defining an explicit fixed group	356
Guidelines for defining an explicit delimited group	356
Objects of a choice group	357
Objects of a partitioned type	357
Distinguishable syntax objects	357

Using a database as a source	501
Defining a database source in the Map Designer	501
Database GET> Source settings	502
GET> Source> Command setting	502
Using a database as a target	502
Defining a database target in the map designer	502
Database PUT > Target settings	503
PUT > Target > Command setting	503
Database connections and transactions	503
Transactional control	503
Database connection management	503
Connection factors	504
Connection rules	504
Connection example	504
Updating database tables	504
Using key and update columns	504
Defining key and update columns	505
Specifying update mode	505
Using the Map Designer or Integration Flow Designer	505
Using an adapter command at execution time	505
Update key columns	505
Example using update columns	506
Database functions	506
Accessing database information in a map rule	506
Using DBLOOKUP and DBQUERY	506
Syntax1 - using a static MDQ file	507
Syntax2 - using dynamic adapter commands	507
Syntax2 formatting issues	508
Examples	508
Example 1 - obtaining a single column value	508
Example 2 - using DBQUERY to obtain multiple columns or rows	509
Example 3 - using DBQUERY to provide map input to RUN function	509
Example 4 - using WORD to parse multi-column output from DBQUERY	509
Example 5 - using DBQUERY with adapter commands to obtain a single column value	510
Uses	510
Using bind values in database functions	510
Using stored procedures	511
Calling stored procedures	511

Database-independent syntax for calls	511
Examples using stored procedures	512
Returning the Value from a stored function	512
Using a stored procedure as an input	512
Using a query to execute a stored procedure	512
Using a stored procedure as an output	513
Stored procedures with object type parameters	513
Database triggers	514
Database triggers overview	514
Database support	514
Installation requirements	514
Column-based triggering	515
Tables created for triggering	515
Maintaining triggering tables	515
Handling unexpected shutdowns	515

Syntax summary	885
Data sources and targets	885
Using the Java Class Adapter	885
Simple Java class example	886
Type tree elements	886
Adapter action sequence	886
Complex Java class example	887
Return values	887
Return value rules	888

Java Class Importer	888
Configuring JVM options in the config.yaml file	888
Running the Java Class Importer	888
Return codes and error messages	889
Java Class Adapter messages	889
JAXB Adapter	889
System requirements	889
Java class requirements	889
JAXB adapter command overview	890
Command alias	890
Class name (-C) command	891
File location (-U) command	891
Object ID (-I) command	891
Encoding (-jaxb.encoding) command	891
Schema location (-jaxb.schemaLocation) command	891
No namespace schema location (-jaxb.noNamespaceSchemaLocation) command	892
Generate document-level events (-jaxb.fragment) command	892
Create trace file (-T) command	892
Trace adapter errors (-TE) command	892
JDBC Adapter	893
Introduction	893
JDBC adapter command overview	893
Authenticating Connections	894
Adapter properties and commands	894
Examples	899
JDBC adapter -KEY command examples	899
JDBC adapter -BIND command examples	899
JMS Adapter	900
System requirements	901
Messaging modes	901
Point-to-Point (PTP)	901
Publish and subscribe (Pub/Sub)	901
Command Alias	901
JMS Adapter commands	902
ConnectionFactoryName (-CFN)	902
CorrelationID (-CID)	903
DeliveryMode (-DM)	903
DurableSubscriber (-DS)	903
Expiration (-E)	903
GroupID (-GID)	904
Header (-HDR)	904
InitContextFactory (-ICTXF)	904
InitContextFactoryURL (-ICTXFURL)	905
JNDI Method (-JM)	905
Listen (-LSN)	905
Priority (-PRI)	905
Property (-PRP)	906
Password (-PW)	906
Queue (-QN)	906
Quantity (-QTY)	906
Reply (-R)	907
Selector (-SEL)	907
Trace (-T)	907
Text (-TT)	908
Topic (-TN)	908
UserName (-UN)	908
Syntax summary	908
Data sources	909
Example 1	909
Data targets	909
Example 2	909
Using the Adapter	910
Message content	910
Header	910
Header Fields Table	910
Properties	910
Application-specific Properties	910
JMS-specific Properties	911
Vendor-specific Properties	911
Using Message Properties	911
Body or Payload	912
Message	912
Bytes message	912
Stream message	913

MapMessage	913
TextMessage	913
ObjectMessage	913
Message Selection	913
Example Files	913
JMS Importer	913
Configuring JVM Options in the config.yaml File	913
Running the JMS Importer	914
JMS Adapter dependent jars	914
Return Codes and Error Messages	914
Messages	914
JNDI Adapter	914
System requirements	915
Command alias	915
JNDI commands	915
List of commands	915
Authentication Method (-AM)	915
InitContextFactory (-ICTXF)	915
InitContextFactoryURL (-ICTXFURL)	916
Max Hits (-MAXHITS)	916
Timeout (-TIMEOUT)	916
Trace (-T)	916
Syntax summary	917
Data sources	917
Data targets	917
Example 1	917
Example 2	917
Using the adapter	918
Theory of operation	918
Adapter capabilities	918
Adapter limitations	918
Adapter scenarios	918
Return values	919
Schemas	919
JNDI service providers	919
LDAP	920
Operations supported	920
Command line options supported	920
URL format	920
Initial Context factory	921
LDAP schema	921
COS naming	921
Operations supported	922
Command line options supported	922
URL format	922
Initial Context factory	922
Generic naming type tree (COS Naming)	922
RMI	923
Operations supported	923
Command line options supported	923
URL format	923
Initial Context factory	923
Generic naming type tree (RMI)	923
DNS	924
Operations supported	924
Command line options supported	924
URL format	924
Initial Context factory	925
DNS Type Tree	925
File system	925
Operations supported	925
Command line options supported	926
URL format	926
Initial Context factory	926
Generic naming schema (file system)	926
WebLogic	926
Operations supported	927
Command line options supported	927
URL format	927
Initial Context factory	927
Generic naming type tree (WebLogic)	927
Interoperability between JNDI adapter and other adapters	928
Binary data	928

Example files	928
Memory Link Adapter	928
MIME Adapter	929
MIME Adapter overview	929
System requirements	930
Command alias	930
MIME commands	930
List of commands	930
Decode (-DECODE)	930
Encode (-ENCODE)	931
Generate ID (-GENID)	931
Message Digest (-DIGEST)	931
Session (-SESSION)	931
Example	932
Trace (-T)	932
Transport (-TRANSPORT)	932
Syntax summary	932
Data sources	933
Data targets	933
Example	933
Using the adapter	933
MIME structure	933
MIME header fields	934
MIME version header field	934
Content-type header field	934
Content-transfer-encoding header field	934
Content-ID header field	935
Content-description header field	935
Multipart messages	935
Representing MIME data in type trees	935
Message	936
Header	936
Message Parts	937
Using the type tree example	937
MongoDB Adapter	937
Type tree requirements	938
Instance document formats	938
MongoDB adapter commands	939
MSMQ Adapter	940
Overview	940
MSMQ message content	940
System and configuration requirements	940
Command alias	940
GET > Source settings	941
GET > Source > Command setting	941
Source > Transaction > OnSuccess setting	941
Source > Transaction > OnFailure setting	941
Source > Transaction > Scope setting	941
Source > Transaction > Warnings setting	942
PUT > Target settings	942
PUT > Target > Command setting	942
Target > Transaction > OnSuccess setting	942
Target > Transaction > OnFailure setting	942
Target > Transaction > Scope setting	942
Target > Transaction > Warnings setting	943
MSMQ commands	943
MSMQ Adapter commands	943
Wildcard support	943
Correlation ID (-CID)	944

Other Healthcare Components	1597
Supply Chain EDI	1597
EDI Compliance check	1597
Setup for Design Studio V1-based map executions	1597
Setup for Design Server V2-based flow executions	1598
Compliance Check Execution	1598
Supply Chain Examples	1599
SAP Applications	1599
Install and run SAP maps	1600
Run SAP example maps using endpoint for V1 REST API	1600
Run SAP example maps using endpoint for V2 REST API	1601
Pack for Financial Payments (FINPAY)	1601

Prerequisites	1602
Configuring SWIFT MT JVC	1602
Building maps for Linux	1602
Porting artifacts to UNIX host	1603
Example map execution on ITX-RS using endpoint for V1 REST API	1603
Overrides on input, output cards due to backward slashes	1603
Example map execution on ITX-RS using endpoint for V2 REST API	1604
Not available for execution on ITX-RS	1604
Pack for Financial Payments Plus (FINPLUS)	1605
Prerequisites	1605
Configuring CBPR+ Translation	1605
Building maps for Linux	1606
Porting artifacts to UNIX host	1606
Example map execution on ITX-RS using endpoint for V1 REST API	1606
Example map execution on ITX-RS using endpoint for V2 REST API	1608
Example flow execution on ITX-RS using endpoint for V2 REST API	1610
IBM MQ Client	1614
Helm Chart	1615
ibm-itx-rs-prod Package	1615

Pack for SAP Applications

Introduction	1618
Pack for SAP Applications overview	1619
Integrating information	1619
Overview of SAP R/3 interfaces	1619
Intermediate Documents (IDocs)	1619
Application Link Enabling (ALE)	1619
ALE Message Handler (AMS)	1620
Electronic Data Interchange (EDI)	1620
DXOB/Data Migration Interface (DMI)	1620
Business Application Programming Interface (BAPI)	1620
Setting up your SAP R/3 environment	1620
System requirements and installation	1620
Pack for SAP R/3 Server	1620
SAP Gateway	1620
Configuring the SAP R/3 system	1621
1. Creating a logical system (BD54)	1621
2. Creating RFC destination for outbound data (SM59)	1621
Setting up an RFC destination	1622
Gateway options	1622
tRFC options	1622
Collective error processing	1623
3. Creating a Distribution Model (BD64)	1623
Creating message types for the Distribution Model	1623
4. Generating a Partner Profile (BD82)	1624
5. Manually creating partner profiles (WE20)	1624
Inbound parameters	1625
Creating SAP connections, actions, and schemas	1625
Overview of the Importer Wizard	1625
Running the Importer Wizard	1625
The R/3 adapters	1626
Overview of the R/3 adapters	1626
Unicode support	1626
Using R/3 adapter commands	1627
Execution command overrides	1627
Card settings	1627
R/3 data retrieval behavior for bursts	1627
OnFailure behavior with R/3 adapters	1627
Adapter commands syntax and usage	1627
RUN, GET, and PUT functions	1628
RUN example	1628
GET example	1628
PUT example	1628

From the Map Designer	1628
From the Integration Flow Manager	1629
Connection commands	1629
Required connection commands for JALE sources	1629
Required connection commands for JALE targets and for calling a BAPI	1629
Adapter commands list	1629
Program ID (-A)	1630
Audit (-AR3)	1631
Backup (-B)	1631
Load Balancing (-BAL)	1631
Bytes Per Character (-BPC)	1632
Client Number (-C)	1632
Character Set Encoding (-enc)	1632
Destination (-D)	1633
Gateway Host (-G)	1633
IDoc Field Generation (-GEN)	1634
Group (-GROUP)	1634
Host ID (-H)	1634
Logon Language (-L)	1635
Listen (-LSN)	1635
Listener Threads (-N)	1635
Password (-P)	1635
Packet Size (-PKT)	1636
Reprocess backup files (-R)	1636
System ID (-S)	1636
Timeout (-timeout)	1636
Trace (-T)	1636
Transaction ID (-TID)	1637
IDoc Type (-TY)	1637
User ID (-U)	1637
Gateway Service (-X)	1637
Syntax summaries for R/3 adapters	1638
JALE adapter commands syntax summary	1638
JBAPI adapter commands syntax summaries	1638
R/3 adapter aliases	1638
Using R/3 system commands	1639
Intermediate Documents (IDocs)	1639
Overview of IDocs	1639
IDoc structural format	1639
Generating the IDoc parser report	1640
Using the Importer Wizard for IDocs	1640
Understanding the IDoc schema	1640
Implementing an ALE interface	1640
IDoc selection and metadata download (WE63)	1641
Creating a Unicode metadata file	1641
Mapping	1641
Using the Importer Wizard for ALE	1641
Creating an outbound map	1641
Creating an input card and configuring outbound processing	1641
Creating an output card and configuring inbound processing	1642
Inbound and outbound processes	1642
Inbound ALE to SAP	1642
Outbound ALE from SAP	1643
Control records for IDoc mapping	1643
Control record example	1643
Sending EDI IDocs using ALE	1644
Data Transfer Objects (DXOB)	1644
Overview of Data Transfer Objects	1644
Generating DXOB metadata	1644
Data Transfer Workbench (SXDA)	1645
Mapping	1645
Using the SAP:DXOB Importer	1645
DXOB formats	1645
Understanding the DXOB schema	1645
Creating a map for DXOB formatted data	1646
Transferring the Mapped Data	1646
Transferring the mapped data to the application layer	1646
Creating the Batch Input Session	1646
Processing the Batch Input Session (SM35)	1647
Business Application Programming Interface (BAPI)	1647
Overview of the Interface (BAPI)	1647
Mapping	1648
Understanding the BAPI schema	1648
Calling a BAPI from a map	1648

Unicode	1649
SAP S/4 HANA Adapter	1649
Troubleshooting	1649
Troubleshooting tools	1649
MapAudit log	1649
Data Log	1650
Execution audit	1650
ExecutionLog per burst	1650
ExecutionSummary per map	1650
Map Settings	1650
Data settings	1650
R/3 adapter audit files	1650
R/3 adapter trace files	1651
R/3 adapter trace - Verbose option	1651
R/3 return codes and error messages	1651
Viewing R/3 source and target data	1652
Backup settings	1652
Remaining temporary data in TIDDATA directory	1652

Pack for Financial Payments

Overview	
Financial Services standards	1652
The IBM Transformation Extender product family	1652
International Program License Agreement	1652
Installation and uninstallation	1653
FIX component	
Overview of the FIX component	1653
What the FIX component contains	1653
Major components of the pack	1653
The utilities subdirectory	1653
The trees subdirectory	1654
The schemas subdirectory	1654
FIX component examples	1654
FIX type trees and message structure	1655
FIX message protocol	1655
Message types per FIX version number	1655
Session messages	1656

X12N example	2144
Location of the X12N example files	2144
X12N schemas	2144
Using the X12N example files	2145
External Code List Utilities example	2148
Terminology for NoSQL databases.	2148
Locating	2149
Example components	2149
Configuration files	2149
Maps to load or delete code set information	2149
Maps to convert code set data	2149
Schemas	2149
Data Files	2149
Using the example	2150
Using the load or delete code set maps	2150
Using the maps to convert code set data	2150
Type 7 User Exit example	2150
Location	2150
Example components	2150
Example details	2150
Using the Type 7 user exit example	2151
ClaimToExposure tracking example	2151
Location	2151
ClaimToExposureTracking example maps	2151
Claim to exposure tracking map details	2152
X12N personal health records example	2152
Example location	2152
Example maps	2152
Performance tuning	2152
Duplicate processing	2153
Unnecessary processing	2153
Over reporting	2153
Acknowledgment errors	2153
AK304 segment level	2153
IK304 error code	2154
AK403 element level	2154
IK403 error code	2154
AK502 transaction set level	2155
AK905 functional group level	2155
TA105 interchange level	2155
TED01 - error reporting/acknowledgement process	2156
HL7 component	2156
HL7 schemas	2156
HL7 component schemas	2157

hl7_v2_x schemas	2157
hl7_v2_1 schema	2157
hl7_v2_2 schema	2157
hl7_v2_3 schema	2157
hl7_v2_4 schema	2158
hl7_v2_5 schema	2158
hl7_v2_5_1 schema	2158
hl7_v2_6 schema	2158
hl7_v2_7 schema	2158
Using the Pack for HL7 schemas	2158
Schema data definitions	2158
Message structure	2159
Logical grouping of fields	2159
HL7 validation	2159
Running the HL7 validation utility	2160
HL7 component examples	2160
NCPDP-SCRIPT / HL7 mapping example	2160
Location of HL7/NCPDP-SCRIPT mapping files	2160
HL7 / NCPDP-SCRIPT mapping schemas	2161
NCPDP-SCRIPT / HL7 example maps	2161
FHIR example	2161
Location of the FHIR example files	2161
FHIR example schemas	2161
FHIR example maps	2161
Running the example for FHIR JSON format	2162
Running the example in FHIR XML format	2162
Running the FHIR PAS bundle example map	2162
FHIR Example - PAS Bundle with JSON Schema	2162
Location of the PAS Bundle with JSON example files	2162
FHIR Validation Example	2163
Location of the FHIR Validation example files	2163
HL7 MLLP Example	2163
Location of the MLLP example files	2163
NCPDP component	2163
Objects included in the pack	2164
NCPDP schemas	2164
Sample data	2164
Maps	2164
NCPDP maps	2164
Sample Data	2164
Transaction data	2164
NCPDP sample data	2165
NCPDP component examples	2165
NCPDP SCRIPT example	2165
Location of the Script example files	2166
Release indicator	2166
XML validation	2166
Using SCRIPT examples on UNIX platforms	2167
Using SCRIPT example files in the z/OS environment	2167
NCPDP SCRIPT	2167
ncpdp_script_v10_6_to_xml.mms	2167
ncpdp_xml_to_script_v10_6.mms	2167
ncpdp_script_v10_6_passthru.mms	2167
ncpdp_xml_v10_6_passthru.mms	2168
ncpdp_script_v10_6_xml_v201707.mms	2168
NCPDP PACDR example	2168
NCPDP SCRIPT schemas	2168
SCRIPT schema structure	2168
Data element type names	2168
Structure of XML schemas	2169
SCRIPT validation	2169
NCPDP validation	2169
Running the NCPDP validation utility	2169

Pack for Supply Chain EDI

Pack for Supply Chain EDI overview	2170
About Electronic Data Interchange (EDI)	2170
Example files	2170
Installation and uninstallation	2171
What is an EDI schema?	2171
ANSI X12 data	2171
Envelopes	2171
Transaction sets	2171
Segments	2172

EDIFACT data	2172
TRADACOMS data	2172
EDI version release schemas	2172
Types in EDI schemas	2173
Modifying EDI schemas	2173
Analysis of EDI schemas	2173
Summary of errors	2173
X12 transaction sets that did not pass analysis	2174
Delete X12 transaction sets in error if not used	2174
ANSI2003 the #830 transaction set	2175
ANSI2040 the #830 transaction	2175
ANSI3010 the #830 transaction	2175
ANSI3020 the #110 transaction	2175
ANSI3020 the #838 transaction	2175
ANSI3060, ANSI3070, ANSI4010, and ANSI4020 the #304 transaction	2176
Mapping purchase orders to invoices	2176
By line item	2176
Purchase order	2176
Invoices to be received	2177
ByStore map	2177
ByPO map	2178
ByLine map	2178
Editobol map source file	2178
Mapping inbound EDI #204 transaction sets	2178
EachBOL functional map	2178
MakeNameSet functional map	2179
EachDetail functional map	2179
X12 schemas	2179
About the X12 Standard	2179
Installation	2179
X12 schema details	2179
Overview	2179
ANSI	2180
Interchange	2180
Transmission	2180
ANSI category	2180
Control subtree	2180
Segment group	2181
ISA segment	2181
Interchange acknowledgment	2181
Interchange syntax extension	2181
Control elements	2182
Variant category	2182
Delimiter types	2182
Funct'IGroup subtree	2182
Version-specific subtree	2183
Elements	2183
XComposites and MComposites	2183
Segments	2183
Sets - transactions sets, loops, and blocks	2184
Transaction sets are organized under categories	2184
Loops and blocks	2184
Interchange category	2184
Restart attribute on functional group	2185
Component rule on IEA segment	2185
Transmission category	2185
Restart attribute on an interchange	2185
Mapping ANSI data	2185
Input card - receiving ANSI data from multiple partners	2186
Output card - sending ANSI data to multiple partners	2186
X12 examples	2186
asntoedi example	2187
asntoedi example notes	2187
How to run the asntoedi example	2188
editobol example	2188
editobol example notes	2188
How to run the editobol example	2188
hlLoop example	2189
Understanding Hierarchical Loops	2189
Hierarchical Design Rules	2189
Example of Record Oriented Data	2190
Example Diagram of a Hierarchy	2190
Customizing ITX Standard for Hierarchical Loop level	2190
Mapping HL levels to the output	2191

sqd example	2191
sqd example notes	2191
How to run the sqd example	2191
xmlpo example	2192
xmlpo example notes	2192
How to run the xmlpo example	2192
EDIFACT schemas	2192
About the EDIFACT standard	2192
Installation	2193
EDIFACT schema details	2193
Overview	2193
EDIFACT category	2194
Interchange	2194
Transmission	2194
EDIFACT category details	2194
Control subtree	2194
Envelope types	2195
UNA service string	2195
EDIFACT interchange envelope UNB and UNZ	2195
Functional group envelope UNG and UNE	2195
Message envelopes - UNH and UNT	2195
Element category	2195
Delimiter category	2195
Composite category	2196
Group subtypes	2196
Msg subtype	2196
Version specific subtype	2196
Composite category	2196
Viewing the Element category's full description	2196
Segment category	2197
Set category	2197
Groups of segments	2197
Interchange category	2197
Restart attribute on functional group	2198
Component rule on UNZ segment	2198
Transmission category	2198
Restart attribute on an interchange	2198
Mapping EDIFACT data	2198
Input card - EDIFACT data from multiple trading partners	2198
Output card - sending EDIFACT data to multiple partners	2199
EDIFACT examples	2199
arrival example	2200
arrival example notes	2200
How to run the arrival example	2201
edf2xml example	2201
edf2xml example notes	2201
How to run the edf2xml example	2201
ediblockchain example	2202
Understanding the ediBlockChain example	2202
The structure of the example:	2202
What the ediblockchain folder contains	2203
Quick execution steps:	2203
Packages example	2203
What the map source of packages example contains	2204
Security example	2204
What the map source of security example contains	2204
vermas example	2204
vermas example notes	2204
How to run the vermas example	2205
EDI Compliance Checking	
Compliance check Overview	2205
Validation	2205
X12 Validation considerations	2205
Character Encoding Processing	2206
Validation overview	2206
Validation checklist	2207
Run the EDI compliance check maps	2207
Run the X12/RAIL compliance check maps	2207
To compile all the maps using Design Studio	2208
To compile all the maps using Design Server	2208
To compile select maps using Design Studio	2208
To compile select maps using Design Server	2208
Where is my output?	2208

Rest Container	2209
Run the EDIFACT/IATA compliance check maps	2210
To compile all the maps Design Studio	2210
To compile all the maps Design Server	2210
To compile select maps Design Studio	2211
To compile select maps Design Server	2211
Where is my output?	2211
Rest Container	2212
Configuration	2212
Input card details	2213
Card 1: EDI data	2213
Card 2: unique ID	2213
Card 3: configuration information	2213
Card 4: duplicate interchange flag	2214
Card 5: table data	2214
Card 6: message code list	2214
Card 7: structure detail file	2214
Card 8: system information file	2214
exitlib	2214
Card 9: trace flag	2215
System information file	2215
Configuration information details	2215
RuntimeInfo	2216
CardOutput	2216
FileOutput	2217
FileDirectory	2217
QueueOutput	2217
QueueServerClient	2217
QueueManagerName	2218
QueueNames	2218
WireOutput	2218
CreateRejectLog	2218
JsonReport	2218

Validate	2223
RecipRefInfo	2223
Deploy compliance check maps	2223
Map deployment procedure	2223
z/OS Implementation	2224
Installing the shared exit library component on z/OS	2225
Installing the shared exit library component on UNIX	2226
File naming conventions	2226
X12 and RAIL file naming conventions	2226
Valid, accepted transactions	2227
Invalid, rejected data	2227
Generated, outbound, functional acknowledgments	2227
Generated, outbound, TA1 acknowledgments	2227
Inbound, received, functional acknowledgments	2227
Inbound, received, TA1 acknowledgments	2227

EDIFACT file naming conventions	2228
Valid, accepted messages	2228
Invalid, rejected data	2228
Generated, outbound, CONTRL acknowledgments	2228
Inbound, received, CONTRL acknowledgments	2228
Performance tuning	2229
Override schema validation maps	2229
Override segment detail validation maps	2229
Debugging	2229
Compliance check logs	2230
Framework log	2230
Troubleshooting tips	2230
Pack for Supply Chain EDI samples	2231
Trading Manager	
Trading Manager Overview	2231
Installation and Configuration	2232
Overview	2232
About the Trading Manager Environment	2232
Partner Manager	2232
Message Manager	2232
Design Studio	2233
Integration Flow Designer	2233
Launcher	2233
Resource Adapters	2233
IBM WebSphere Transformation Extender Packs for EDI	2233
IBM WebSphere Transformation Extender with Launcher	2233
Installation requirements	2233
Minimum system requirements	2233
System requirements for Partner Manager	2234
UNIX platform	2234
Prerequisites	2234
Installation checklists	2234
Launcher	2234
Installing Trading Manager	2234
Determining the Trading Manager configuration	2234
Installing Trading Manager on a single workstation	2235
Installing Trading Manager on separate workstations	2235
Installing only Partner Manager	2235
Installation checklists	2235
Installing components	2235
Installing Trading Manager on Windows	2235
Installing Message Manager components of Trading Manager on UNIX	2236
Removing Trading Manager components	2236
Using Trading Manager with HIPAA	2236
Configuring Trading Manager	2236
Before you begin	2236
SQL scripts installed by Trading Manager	2237
Creating the Trading Manager Database	2237
Using an Access database	2237
Creating a Microsoft SQL Server Database	2237
Creating an Oracle Database	2238
Creating a Sybase Database	2238
Creating an IBM DB2 database	2239
IBM DB2 stored procedures	2239
Installing DB2 stored procedures	2240
Copying drop statements	2240
Determining the ODBC driver	2240
Defining an ODBC data source name	2240
Resolving ODBC difficulties	2241
Configuring Partner Manager	2241
Import structure validation	2241
Installing and using Message Manager	2242
Installing Message Manager	2242
Where to install Message Manager	2242
Client workstation installation	2242
IBM WebSphere Transformation Extender Launcher installation	2242
General configuration and setup	2242
Starting Message Manager	2243
Message Manager deployment tasks	2243
Step 1. Define the server types in the msg_mgr.msd file	2243
Step 2. Modify the msg_mgr.msd default path name settings	2244
Changing design time, run time paths	2244

Changing the .mrn path names	2244
Step 3. Deploying Message Manager on UNIX	2245
Step 4. Create a configuration file	2245
Step 5. Modify the E-mail alert settings	2245
Step 6. Configure the Launcher service startup parameters	2245
Step 7. Modify the Message Manager database/query file	2246
Step 8. Identify the Trading Manager database	2246
Identify the Trading Manager database connection	2247
Step 9. Define Partners, Post Offices and Trade Links	2247
Step 10. Run the EDI Wizard	2247
Step 11. Enable stampandsortFTP, stampandsortVAN, and stampandsortEmail maps	2247
Step 12. Modify Eemail.mtt to support proprietary data	2247
Step 13. Add application maps and link to Message Manager	2247
Adding a Message Manager application map	2248
Configuring Launcher settings	2248
Step 14. Use the deploy facility in the Integration Flow Designer	2248
Using the IFD deploy facility	2248
Step 15. Build and copy application and communication maps	2249
Generate the Launcher control file for an application system	2249
Step 16. Start the Launcher service	2249
Launcher Manager tools	2250
Using Message Manager	2250
Message Manager subsystems	2250
Archive subsystem	2250
EDIFACT subsystem	2251
EDIFACT inbound subsystem	2251
edifact_in_alert map	2251
EDIFACT outbound subsystem	2251
Send problem data alerts map	2251
StampAndSort subsystem	2251
ThreadID definition	2252
Inbound data archiving	2252
stampandsortFTP/VAN/Email maps	2252
Creating multiple stampandsortFTP maps	2253
stampandsortfile map	2253
Get file post office and put file post office	2253
stampandsortack map	2254
Resend map	2254
TRADACOMS subsystem	2254
TRADACOMS inbound subsystem	2254
TRADACOMS_in_alert_data map	2254
TRADACOMS outbound subsystem	2254
alert_data map	2254
Value Added Tax (VAT) reports	2254
Update subsystem	2255
export map	2255
dbalert map	2255
X12 subsystem	2255
X12 inbound subsystem	2256
sortx12 map	2256
X12 FA inbound map	2256
X12_In_Alert_Data map	2256
X12 outbound subsystem	2256
x12_out_alert map	2256
Support for proprietary data types	2256
Inbound data flow	2257
Adding proprietary data types	2257
Using alias files in maps	2257
Defining alias name and user defined fields	2258
Making the alias data available to application maps	2258
Choosing the alias file to use	2258
Alias files type tree (Alias.mtt)	2258
Creating user type trees	2258
Checklists	2259
Server installation checklist for Microsoft SQL Server	2259
Client installation checklist for Microsoft SQL Server	2259
Server installation checklist for Oracle database	2260
Client installation checklist for Oracle Server	2260
Server installation checklist for Sybase	2260
Client installation checklist for Sybase	2260
Server installation checklist for IBM DB2 database	2261
Client installation checklist for IBM DB2 Server	2261

Implementing custom X12 versions	2261
Overview	2261
Type trees	2262
Partner Manager	2262
Message Manager	2262
Creating structure records	2262
TPEC to Trading Manager conversion	2263
TPECAddressBook.xml file	2263
Internal partners	2263
External partners	2263
TPECPPostOffices.xml file	2263
TPECTradelinks.xml file	2264
Inbound functional groups:	2264
Outbound functional groups	2264
TPEC2CMConfig.txt file	2264
Running the TPEC to Trading Manager	2265
Setting up the TPEC2CM conversion map	2266
Running the "ConvertTPEC2CM" executable map	2266
TPEC control number conversion	2266
Running the Partner Manager XML Autoload Utility	2267
Warnings and error messages	2267
TPEC header trailer plug-in for Trading Manager	2268
TPEC plug-in requirements	2268
Planning the conversion	2268

Introduction

Congratulations on your selection of IBM® Sterling Transformation Extender as your data transformation engine.

IBM Sterling Transformation Extender is a powerful industry-leading data integration and transformation solution that enables the development of high-volume, complex data integrations without the need for hand-coding.

IBM Sterling Transformation Extender enables your organization to integrate industry-based customer, supplier and business partner transactions across the enterprise and provides industry-leading transformation capabilities supporting many types of data, with native support for JSON, XML or any proprietary data format.

IBM Sterling Transformation Extender provides an easy-to-use browser-based development environment and supports centralized team-based collaboration. The integrated design platform makes it easy for your team to create data flows of any complexity, and to deploy these to a runtime server.

Data integrations can be invoked by use of REST APIs, that run on a scheduled basis, or can be triggered upon a variety of events, such as the arrival of a message on a queue, or the creation of a file. ITX provides a large set of adapters that interface to databases, applications, APIs, messaging middleware and other technologies. A typical integration may read data from one or more sources, validate, transform and merge data, then forward the results to one or more target resources.

IBM Sterling Transformation Extender can engage data residing in the cloud – and in various hybrid cloud contexts – enabling easy access and integration of data and evolving technologies, protecting your development investments.

Additional available advanced transformation support provides metadata for mapping, compliance checking and related processing functions for specific industries – including finance, healthcare and supply chain.

- [The business role of IBM Sterling Transformation Extender](#)
- [Accessibility features for IBM Sterling Transformation Extender](#)

Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use information technology products successfully. IBM strives to provide products with usable access for everyone, regardless of age or ability.

- [Globalization](#)
- [Product overview](#)
- [Product architecture](#)
- [Runtime services](#)

With the consistent architecture and integration methodology of IBM Sterling Transformation Extender runtime services, you can create seamless, end-to-end integration solutions that support any combination of applications, interface formats, interprocess communication, and integration flow logic.

- [Design environment](#)
- [Server components](#)
- [Software Development Kit \(SDK\)](#)
- [B2B management \(Trading Manager\)](#)
- [Other IBM Sterling Transformation Extender solutions](#)
- [Integration maps](#)

Maps provide a non-programmatic approach to the development of interfaces, with prebuilt functionality for connectivity, transformation, and routing. Components can be created once and reused many times for different types of integration scenarios.

- [Execution](#)
- [Examples](#)
- [Tivoli License Manager](#)

The business role of IBM Sterling Transformation Extender

IBM® Sterling Transformation Extender provides the following:

- highly automated transformation and routing of complex data across many points of integration in real time to support high-message volumes
- enterprise-wide interoperability supported by a Services-Oriented Architecture (SOA) for seamless connectivity and interoperability across back-office systems
- support for high-performance, event-driven, transactional environments to ensure completion and validation of transactions in real time
- seamless integration across the development, data, and production layers of the enterprise, leveraging existing IT infrastructures
- out-of-the-box solutions for industry standards and regulatory compliance for operational and transactional data integration

Accessibility features for IBM Sterling Transformation Extender

Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use information technology products successfully. IBM strives to provide products with usable access for everyone, regardless of age or ability.

Accessibility features

The following list includes the major accessibility features in IBM® Sterling Transformation Extender. These features support:

- Keyboard-only operation.
- Interfaces that are commonly used by screen readers.

Keyboard navigation

The following product components use standard Microsoft Windows navigation keys:

- Design Studio applications

- Command Server
- Launcher Monitor
- Snapshot Viewer

Resource Registry, Management Console, and Launcher Administration use standard Java navigation keys.

Vendor software

IBM Sterling Transformation Extender includes certain vendor software that is not covered under the IBM license agreement. IBM makes no representation about the accessibility features of these products. Contact the vendor for the accessibility information about its products.

Related accessibility information

The following applications have some additional keyboard functionality. The key combinations are documented in the application-specific documentation.

- Database Interface Designer
- Integration Flow Designer
- Launcher Management Tools
- Map Designer
- Type Designer

IBM and accessibility

See the [IBM Accessibility Center](#) for more information about the commitment that IBM has to accessibility.

Related information

- [Unique key combinations for the Integration Flow Designer](#)

Globalization

Globalized products can be used without language or culture barriers and can be enabled for a specific locale.

Check the latest information about translated documentation in the [release notes](#).

By default, your computer's locale setting determines the language in which the IBM® Sterling Transformation Extender user interface is displayed. For example, if you purchased your computer in Germany, your computer's locale is most likely set to "German" by default. In this case, the IBM Sterling Transformation Extender interface elements and error messages display in German. Date and time formats, as well as currencies, are presented in accordance with the region that is specified.

- [To change application locale \(Windows\)](#)
IBM Sterling Transformation Extender applications are designed to display in the same language or locale to which your computer is set, provided that the applications support that language.
- [To change the application locale \(UNIX\)](#)
- [To change the Launcher Administration locale](#)
- [To change the Management Console locale](#)
- [To change the Resource Registry locale](#)
- [Locale values](#)
Locale values set the language locale of your computer.

To change application locale (Windows)

IBM® Sterling Transformation Extender applications are designed to display in the same language or locale to which your computer is set, provided that the applications support that language.

You can change the locale of IBM Sterling Transformation Extender to a language or locale other than the one to which the computer is set. For example, the application displays Spanish but you want it to display English instead.

This functionality is not available for MVS, CICS, or Batch.

- [To change the application locale \(Windows\) for the Design Studio application](#)
You can change the locale of the Design Studio application that runs on Windows operating systems.
- [To change the application locale \(Windows\) for tools and runtime applications](#)
You can change the locale of IBM Sterling Transformation Extender tools and runtime applications such as the Command Server and the Launcher that run on Windows operating systems.

To change the application locale (Windows) for the Design Studio application

You can change the locale of the Design Studio application that runs on Windows operating systems.

The Design Studio application must be closed before performing this task.

- From the product installation directory, open the DTXCommon.bat file using a text editor.
In the Locale for Eclipse Applications section, the following verbiage is present:

```
@rem set NLLOCALE=
```

- Remove the remark comment indicator (@rem) in front of `set NLLOCALE=`.
- At the end of the line, enter a valid [locale value](#).
- Save and close the DTXCommon.bat file.

The next time you open the Design Studio application, the interface elements and error messages are displayed in the selected language.

Related concepts

- [Locale values](#)

To revert back to the computer's default locale for the Design Studio application

- Open the DTXCommon.bat file using a text editor.
- Place a remark comment indicator (@rem) in front of `set NLLOCALE=`.
- Save and close the DTXCommon.bat file.

To change the application locale (Windows) for tools and runtime applications

You can change the locale of IBM® Sterling Transformation Extender tools and runtime applications such as the Command Server and the Launcher that run on Windows operating systems.

The IBM Sterling Transformation Extender tools and runtime applications must be closed before performing this task.

- From the product installation directory, open the config.yaml file using a text editor.
In the config.yaml /runtime/locale section, the following verbose is present:

```
# Possible values: de,en,es,fr,it,ja,ko,pt_BR,ru,zh_CN,zh_TW
locale: en
```
- Replace the value `en` with a valid [locale value](#).
- Save and close the config.yaml file.

The next time you open the IBM Sterling Transformation Extender tool or runtime application, the interface elements and error messages are displayed in the selected language.

To revert back to the computer's default locale for tools and runtime applications

- Open the config.yaml file using a text editor.
- Set the value of /runtime/locale: to an empty string in the config.yaml file. For example:

```
/runtime
  /locale:
```

- Save and close the config.yaml file.

To change the application locale (UNIX)

IBM® Sterling Transformation Extender applications must be closed before performing this task.

- Open common.sh in a text editor.
- Find `export USRLOCALE=` and enter a [locale value](#).
Example for Korean: `export USRLOCALE=ko`
- Save and close the file.

To revert back to the computer's default locale, remove the locale value and save changes.

Related concepts

- [Locale values](#)

To change the Launcher Administration locale

The Launcher Administration application must be closed before performing this task.

- Open `install_dir/LauncherAdmin.bat` (launcheradmin.sh) in a text editor.
- At the `REM set USRLANGUAGE=` line, remove the `REM` comment indicator. At the end of the line, enter a [locale value](#).
Example for Korean: `set
USRLANGUAGE=ko`
- At the next line, `REM set USRCOUNTRY=`, remove the `REM` comment indicator. At the end of the line, enter the corresponding country indicator if needed.
Example for Brazilian Portuguese:

```
set USRLANGUAGE=pt
set USRCOUNTRY=BR

4. At the line that begins with REM call %JRE% -DINSTALLDIR="%DTXHOME%" -Duser.language=%USRLANGUAGE% ..., remove the REM comment indicator from the beginning of the line.
5. At the next line (call %JRE% -DINSTALLDIR="%DTXHOME%" -Dsun.java2d.nodraw ...), add an REM comment indicator to the beginning of the line.
For Brazilian Portuguese, the modified text should look similar to the following:
```

```
set USRLANGUAGE=pt
set USRCOUNTRY=BR

call %JRE% -DINSTALLDIR="%DTXHOME%" -Duser.language=%USRLANGUAGE% ...
REM call %JRE% -DINSTALLDIR="%DTXHOME%" -Dsun.java2d.nodraw ...
```

6. Save and close the file.

To change the Management Console locale

The Management Console application must be closed before performing this task.

1. Open *install_dir/MgmtConsole.bat* (*mgmtconsole.sh*) in a text editor.
2. At the REM set USRLANGUAGE= line, remove the REM comment indicator. At the end of the line, enter a [locale value](#).
Example for Spanish: set
USRLANGUAGE=es
3. At the next line, REM set USRCOUNTRY=, remove the REM comment indicator. At the end of the line, enter the corresponding country indicator if needed.
Example for Simple Chinese:

```
set USRLANGUAGE=zh
set USRCOUNTRY=CN
```

4. At the line that begins with REM call %JRE% -DINSTALLDIR="%DTXHOME%" -Duser.language=%USRLANGUAGE% ..., remove the REM comment indicator from the beginning of the line.
5. At the next line (call %JRE% -DINSTALLDIR="%DTXHOME%" -Dsun.java2d.nodraw ...), add an REM comment indicator to the beginning of the line.

For Simple Chinese, the modified text should look similar to the following:

```
set USRLANGUAGE=zh
set USRCOUNTRY=CN

call %JRE% -DINSTALLDIR="%DTXHOME%" -Duser.language=%USRLANGUAGE% ...
REM call %JRE% -DINSTALLDIR="%DTXHOME%" -Dsun.java2d.nodraw ...
```

6. Save and close the file.

To change the Resource Registry locale

The Resource Registry application must be closed before performing this task.

1. Open *install_dir/ResourceRegistry.bat* (*resourceregistry.sh*) in a text editor.
2. At the REM set USRLANGUAGE= line, remove the REM comment indicator. At the end of the line, enter a [locale value](#).
Example for Japanese: set
USRLANGUAGE=ja
3. At the next line, REM set USRCOUNTRY=, remove the REM comment indicator. At the end of the line, enter the corresponding country indicator if needed.
Example for Traditional Chinese:

```
set USRLANGUAGE=zh
set USRCOUNTRY=TW
```

4. At the line that begins with REM call %JRE% -DINSTALLDIR="%DTXHOME%" -Duser.language=%USRLANGUAGE% ..., remove the REM comment indicator from the beginning of the line.
5. At the next line (call %JRE% -DINSTALLDIR="%DTXHOME%" -Dsun.java2d.nodraw ...), add an REM comment indicator to the beginning of the line.

For Traditional Chinese, the modified text should look similar to the following:

```
set USRLANGUAGE=zh
set USRCOUNTRY=TW

call %JRE% -DINSTALLDIR="%DTXHOME%" -Duser.language=%USRLANGUAGE% ...
REM call %JRE% -DINSTALLDIR="%DTXHOME%" -Dsun.java2d.nodraw ...
```

6. Save and close the file.

Product overview

IBM® Sterling Transformation Extender performs transformation and routing of data from source systems to target systems in batch and real-time environments. The sources may include files, relational databases, MOMs (message-oriented middleware), packaged applications, or other external sources. After retrieving the data from its sources, the IBM Sterling Transformation Extender product transforms it and routes it to any number of targets, providing the appropriate content and format for each target system.

The IBM Sterling Transformation Extender product delivers the following:

- connectivity to a wide range of mainframe, legacy, and enterprise applications, databases, messaging systems, and external information sources
- a comprehensive library of pre-built functions to reduce development time and simplify specification of rules for validation, transformation, and routing
- multiple execution options to support right-time, right-style transformation—whether it is batch, real-time, or embedded
- enterprise-class capabilities for development, deployment, and maintenance plus high-availability platform support.

This reduces on-going administration and implementation risks and delivers results sooner than hand-coding.

IBM Sterling Transformation Extender is a runtime environment that implements both event-driven and command-driven integration for:

- Enterprise Resource Planning (ERP) applications
- Customer Relationship Management (CRM) applications
- Supply Chain Management (SCM) applications
- other off-the-shelf applications
- customer-developed, in-house applications
- direct, business-to-business integration
- business community integration
- integration with trade networks, net markets, and business service providers

In IBM Sterling Transformation Extender terms, an integration solution consists of a system of related interfaces, implemented as rule-based maps, that consume and produce data in support of a business process. Maps define interfaces between applications, data stores, middleware, and other maps.

Product architecture

The IBM Sterling Transformation Extender product is client/server software composed of a client-based design environment, several server-based execution options, and administration and operation capabilities that can be run on the client or server.

Runtime services

With the consistent architecture and integration methodology of IBM® Sterling Transformation Extender runtime services, you can create seamless, end-to-end integration solutions that support any combination of applications, interface formats, interprocess communication, and integration flow logic.

- Launcher
The Launcher monitors and evaluates runtime events and triggers map execution according to associated rules.
- Command Server
The IBM Sterling Transformation Extender Command Server supports command-driven and scripted invocation of integration solutions.
- Engine
The IBM Sterling Transformation Extender engine executes maps in the runtime environments.
- IBM Sterling Transformation Extender resource adapters
The IBM Sterling Transformation Extender resource adapters bind logical map interfaces with applications, databases, middleware services, and other resources, hiding the details of APIs, marshalling, and low-level interaction protocols.

Design environment

With the TX design environment, you can develop event-driven application-to-application (A2A) integration, business-to-business (B2B) integration, and consumer-to-business (C2B) application integration. The design environment models and tests integration solutions.

You use the design environment to create IBM Sterling Transformation Extender data integration solutions. The design environment provides a graphical interface for managing the integration of applications and business processes.

The Design Server is the client interface into an extensive array of functionality that is available to create application integration solutions. Application integration solutions created with the Design Server run on transformation servers specific to the IBM Sterling Transformation Extender product being used. The separation of design and execution provides exceptional flexibility for implementing enterprise-wide integration solutions. A single Design Server can deploy integration solutions to multiple servers. Multiple instances of Design Server can create integration solutions for a single production environment.

With the Design Server, you can:

- Define the structure of source data and target data with the schema designer
- Import database object metadata and identify characteristics of those objects to meet mapping and execution requirements with the Database Interface Designer
- Define transformation rules with the map designer
- Design systems of maps to model data integration processes with the Integration Flow Designer
- Develop and test maps and systems with the map designer and the Integration Flow Designer
- Deploy maps and systems to the execution environment with the Integration Flow Designer

Projects

A project organizes maps and artifacts in Design Server. You can reuse project-level artifacts in multiple maps.

Schema design

Use the schema designer to:

- Create and manage schema that define properties for data structures.
- Define containment of data.
- Create data validation rules.

Using schemas

A **schema** is a graphical data dictionary that contains metadata definitions of the structure of the inputs and outputs that are the source and target data for integration solutions. It provides visual cues for understanding the structure of an object and supports point-and-click techniques enabling you to "drill down" to uncover an object's complete definition.

Each data object in the input or output data is defined as a reusable object in a schema that uses a sophisticated set of properties to describe attributes such as length, justification, possible values, delimiters, and the order of the data objects that comprise a complex data object. You can use the schema designer to define properties for text or binary data, different character sets, data structures, and semantic validation rules. The sophisticated type properties and type model of IBM Sterling Transformation Extender enable the precise definition of highly complex data, such as EDI, SWIFT, and legacy data structures.

- Schemas can be manually created using the schema designer.
- Schemas can be automatically created by a schema importer or the Database Interface Designer. These components generate schemas based on known metadata, such as database catalogs, SAP R/3 IDocs, or COBOL Copybooks.
- Schemas can be predefined and included as part of IBM Sterling Transformation Extender Packs that support particular standards, such as ASC/X12, UN/EDIFACT, SWIFT, or HIPAA.
- Schemas can be created by the Type Tree Maker: a tool that enables creation of custom importers to automate the capture of metadata definitions from other machine-readable sources.
- The IBM Sterling Transformation Extender includes native support for XSD and JSON schemas.

Importing schemas

The schema designer includes importers to automatically generate schemas (data object definitions) from known metadata, such as COBOL Copybooks.

Some importers are available in the Design Server. Additional importers for data formats are provided as part of the IBM Sterling Transformation Extender Packs.

Comparing schemas for differences

You can use the schema differences feature in the schema designer to compare two schemas. When the analysis is complete, both schemas appear. Source compare differences are distinguished by either blue or red text. When a type is present in one schema but not in the other, the text is blue. When a type is present in both schemas, but they each have different properties, components, or restrictions, the text is red. There is a "step-through" facility that cycles through each of the differences in turn. In extremely large, complex schemas, this can save a great deal of time.

Related concepts

- [Other IBM Sterling Transformation Extender solutions](#)

Map design

The IBM® Sterling Transformation Extender map designer is the modeling component used to formulate transformation and business rules. The map designer uses definitions of data objects created in the schema designer as inputs and outputs. The map designer provides functionality for specifying rules for transforming and routing data, as well as the environment for analyzing, compiling, and testing the maps that are developed.

This process is facilitated by convenient "from" and "to" windows, drag-and-drop techniques, and spreadsheet-like rules. Mapping rules are added using logical statements. The map designer provides a rich set of predefined functions for operations such as conditional testing, table lookups, mathematical functions, character string parsing, and data extraction.

Using maps

A **map** is the embodiment of complete definitions of data objects and the rules for their transformation. A map can implement a wide range of integration functions—from simple transformation to sophisticated integration solutions involving multiple, heterogeneous inputs and outputs, rule-based routing, and complex interface structures.

Maps are created using the map designer, a graphical tool that makes complex transformations easier to define and maintain. Maps are analyzed, compiled, and tested directly in the Design Server environment.

Any number of inputs or outputs can be used within a single map in an any-to-any fashion. A map contains a *card* for each input and output of the transformation.

The capability for mapping from multiple inputs to multiple outputs gives IBM Sterling Transformation Extender products unique transformation power. Each input to and output from a map is associated with a specific data object definition and a resource adapter. Data object definitions are reusable—the same definition can apply to one or more inputs; to both input and output for the same map; or to different maps. When a data object is used as input, data is validated to ensure the data conforms to the data object definition. When used as output, the data object is constructed automatically, in its entirety.

Input objects are not consumed when used in a transformation rule. This allows for a one-to-many relationship between an input and its outputs. An output can be constructed from any number of zero or more inputs. This creates a one-to-many relationship between an output and its inputs. Taken together, IBM Sterling Transformation Extender products provide many-to-many transformation support between inputs and outputs.

Data object definitions, data maps, and resource adapters are all separately managed objects. Each object is reusable in any number of integration scenarios. The result is flexibility, ease of use, and reduced maintenance as integration requirements change.

Defining server platforms for maps

The map definition is completely portable between all supported server platforms. Simply select the target platform from a list when building the map to generate a compiled map file that is optimized for the specified platform.

Exporting maps

The Design Server can export the rules and execution settings of both maps and schemas to JSON documents.

Comparing maps for differences

The map designer allows you to compare two map source files.

- [Input and output cards](#)
- [Transformation, routing, and business logic rules](#)
- [Adapter configuration for input and output](#)

Related concepts

- [Integration maps](#)

Input and output cards

Each input and output is represented in a separate map card. The data structure for each of the inputs and outputs is represented by a schema created using the schema designer.

Transformation, routing, and business logic rules

Schemas are completely interchangeable between inputs and outputs. The same schema can be reused multiple times by multiple maps. After an output card for a map is associated with a type in a schema in the map designer, a rule in the output card defines how to build the output data.

Adapter configuration for input and output

IBM® Sterling Transformation Extender connections, actions, and resource adapters retrieve data from sources and send data to targets. They do not perform transformation. (Map rules describe the nature of the transformation, and the transformation server transforms the data.)

IBM Sterling Transformation Extender includes adapters for common, enterprise-level resources. In its simplest form, specifying an adapter for an input or output card means selecting the required adapter from a list.

Adapter settings defined in a connection can be overridden with different adapter settings at map run time.

The resource adapters are loosely coupled with the transformation process. An adapter retrieves data to be processed by the map as a byte stream. This means that, to the extent that the type definitions and byte streams are compatible, schemas and adapters can be used interchangeably.

For example, you might use a file as a data source when testing, while in the production environment, the data source is a database. As long as the format of the data retrieved from the database is consistent with the format of the data in the file, you only need to change the input from using the **File** adapter to using the **Database** adapter to run the map in production.

In fact, the map source file does not need to be changed at all because the map execution settings, including the adapter configuration settings, can be overridden at run time.

Where possible, resource adapters use the native client libraries of the concerned resources to connect to those resources. It is through this mechanism that IBM Sterling Transformation Extender products can achieve "direct" connectivity to those resources. For example, the IBM Sterling Transformation Extender Oracle adapter uses the Oracle Net8 client to achieve connectivity to Oracle databases.

IBM Sterling Transformation Extender provides an open API to allow for the development of a user-defined adapter, should the need arise. This allows connectivity to unforeseen, possibly proprietary systems (such as a "home-grown" HR system), in addition to the standards-based adapters that IBM Sterling Transformation Extender provides.

Related concepts

- [Map settings](#)

Resource adapters

IBM Sterling Transformation Extender includes an extensive collection of resource adapters to connect maps to middleware, DBMSs, and utility services.

Resource adapters can indirectly integrate with enterprise applications that consume inputs or produce outputs using message queues, standard transports, file systems, and databases. In addition, resource adapters enable message-based integration with external and internal applications, including applications and services from SAP, Oracle, and others.

- Database adapters support databases such as DB2, Informix, ODBC, OLE DB, Oracle, and Sybase.
- Internet adapters support email, FTP and HTTP.
- Message-Oriented Middleware (MOMs) adapters support Microsoft MSMQ, Oracle AQ, and TIBCO Rendezvous.
- Synchronous adapters support COM+ and Sockets.
- Utility adapters support archive, batch, and directory (LDAP) services.
- File adapters support platform-specific file systems.

In addition to pre-built resource adapters and packs, the Adapter Toolkit provides a standard interface and set of services for implementing your own adapters to connect directly with other applications and services.

Related concepts

- [Runtime services](#)
-

Connection and action design

Connections define the adapter properties that are required to connect to an external resource. An action uses a connection to provide source data to a map or write target data from a map. You can define both connections and actions at the project level or at the map level.

Configuration variables

Configuration variables are aliases that resolve to actual resources at run time.

You can use variables for connection and action properties, paths in map and card settings, and map rules. You can define a variable to resolve to a different resource based on the server it's deployed to. Configuration variables make it possible to use the same map in different deployment environments.

Database Interface Designer

The Database Interface Designer is the modeling component used to import metadata about queries, tables, and stored procedures for data stored in relational databases. The Database Interface Designer identifies characteristics such as update keys and database triggers, of those objects to meet mapping and execution requirements.

Use the Database Interface Designer to:

- Specify the databases to use for a source or target, along with the user IDs and passwords required for the connection.
- Define query statements.
- Automatically generate schemas for queries, stored procedures, input and output parameters, or tables.
- Define tables for which any inserts, updates, or deletions would trigger maps using the Launcher.

If connectivity to the database server is not available from the development platform, the mtmaker utility is provided to execute on the server platform. This utility creates a script file that can be transferred to the development environment to generate the schemas.

Integration Flow Designer

The IBM® Sterling Transformation Extender Integration Flow Designer is the modeling component used to define and manage data integration processes. The Integration Flow Designer is used to define interactions among maps and systems of maps, to validate the logical consistency of workflows, and to prepare systems of maps to run.

Using systems

A system is a set of maps, or subsystems, that are combined to form a data integration process flow. Systems are defined in the Integration Flow Designer.

Systems are defined as having one of two execution modes-Launcher or Command Server, depending upon how they will be deployed. If a system is developed for the Launcher, the system will include definitions of events based upon the map execution to be triggered. As mentioned previously, these events may be time events (for example, execute every 10 minutes or every Monday at 2:43 AM), source events (for example, a message appearing on a queue, a row being updated in a database), or compound events comprised of some combination of time and/or source events.

The set of events that initiates a map within a system is called a *watch*. Each event that contributes to the initiation of a map is called a *trigger*. When the resource (file, database, or message queue) that is an input to a map changes state (that is, it is created or modified), this input event can cause the Launcher to initiate a map. Adapters that can be used to trigger maps have a listener function to detect the appropriate external resource change.

The Launcher starts maps based upon these triggers. There may be multiple triggers that must collectively exist before a map is initiated. The Launcher manages the coordination of these events to ensure that the correct set of circumstances has occurred before a map is initiated.

For more information about the Integration Flow Designer, see the *Integration Flow Designer* documentation. For more information about the Launcher, see the *Launcher* documentation.

Using links

A link is a connection that the Integration Flow Designer creates between two components in a system. Links represent the direction of data flow between the system components at execution time, thus showing the source and target dependencies between system components.

Managing systems

The Integration Flow Designer provides clarity and control to manage the more complex systems built using IBM Sterling Transformation Extender products. It also reduces the administrative burden and simplifies the non-development activities associated with interface development. Some of the key features of the Integration Flow Designer are:

- Graphical data flow design
Visual data flows are created to aid in the design of integration solutions. You can use a graphical palette to produce system definition diagrams and to easily navigate among the IBM Sterling Transformation Extender Design Studio tools. Point-and-click techniques can be used to select the map and subsystem components to place in a specific integration flow diagram.

Using the Integration Flow Designer, you can also define specific map settings that take effect at run time. Select the maps and the data flow between them is automatically determined from the inputs and outputs. The **Override** tool in the Integration Flow Designer toolbox can be used to modify the inputs and outputs to achieve the desired data flows. These modifications do not affect the source map. This allows the same map to be reused in multiple data flows.

- Analysis of integration provided for logical consistency
The Integration Flow Designer includes a System Analyzer that checks your system definitions for logical consistency to ensure they can be executed. The System Analyzer detects any inconsistencies you may have introduced in the definition while experimenting with system models.
- Capability to build and port entire systems with simple mouse-clicks
After a system has been designed, the Integration Flow Designer offers another benefit that saves time when preparing a system for operation. One mouse-click builds and deploys all of the integration objects and supporting data (such as lookup files and scripts).

Parameters for different servers representing different operating environments can be defined within the Integration Flow Designer.

After the appropriate server definitions have been created, it is then possible to produce, using the wizard, automated deployment definitions that are specific to each server.

It is possible to specify, within a script, that either all maps are built and transferred or that only a specific subset of the maps in a system are build and transferred. You can also include additional files required to support the system's operation in the transfer.

For more information about the Integration Flow Designer, see the *Integration Flow Designer* documentation.

- [Developing application interfaces](#)

Developing application interfaces

The IBM Sterling Transformation Extender development environment includes a robust set of integrated tools designed to solve varied application integration problems. Except for scenarios in which the IBM Sterling Transformation Extender Software Development Kit (SDK) is used, you can use these tools to solve integration problems without modifying your applications.

IBM Sterling Transformation Extender products are designed to fit your interface architecture, whether it is hub-based or distributed. Some companies prefer hub-models with a centrally managed integration server. Other organizations choose to distribute integration servers to reside on the same platform as the applications they service. IBM Sterling Transformation Extender products can be used in either configuration.

To design an application interface, you need to understand the content of each data source and target, as well as the middleware, transports, and data services needed to communicate with corresponding sources and targets. You also need to define rules for transforming data content from inputs to outputs.

As you develop more and more interfaces, you will want to reuse metadata and integration rules. Additionally, you will want to formulate business process models: interface systems consisting of integration components that are configured to work together. These systems also need to be reusable.

Use the IBM Sterling Transformation Extender Design Server to develop new integration components and to reuse existing components so that you can leverage your development efforts across integration projects.

- [Modeling the data of business objects](#)
- [Defining transformation rules](#)
- [Defining data sources and targets](#)
- [Defining process models](#)

Modeling the data of business objects

Although you can use the IBM® Sterling Transformation Extender Design Studio to represent the properties of individual fields, elements, and records, its strength lies in defining complete *business objects*. In the IBM Sterling Transformation Extender Design Studio, business objects are the substance of business transactions such as the following: health claims, invoices, bank transfers, airline reservations, ship notices, or telephone bills.

Business objects that include interface syntax, semantics, and structure are implemented in the IBM Sterling Transformation Extender products as *schemas*, which may be pre-defined (in the case of standards supported out-of-the-box by IBM Sterling Transformation Extender), imported from metadata, or defined using the IBM Sterling Transformation Extender schema designer. Once defined, they can be re-used to describe interface content for multiple sources and targets.

- Use the Type Designer to define properties for text or binary data, different character sets, data structures, and semantic validation rules. The resulting type definition is enforced automatically and transparently, when the IBM Sterling Transformation Extender system executes.

- When external metadata exists, you can reduce the effort of defining business objects by using application importers. For example, you can use the COBOL Copybook Importer to generate schemas from COBOL record structures, or the Database Interface Designer to generate type trees from database catalog entries. You can use the DTD Importer to generate type trees from XML Document Type Definitions (DTDs). SAP R/3 users can generate type trees from application-maintained metadata, using IBM Sterling Transformation Extender-supplied importers.
- IBM Sterling Transformation Extender products provide a repository of predefined type trees for popular e-commerce, healthcare, insurance, and financial standards, including ASC X12, EDIFACT, HIPAA, HL7, SWIFT, ISO 15022, and others.
- Using the Type Tree Maker, which is also part of the IBM Sterling Transformation Extender Design Studio, you can build your own importer to automate the capture of metadata definitions from machine-readable sources.

Regardless of method used, the result is a set of reusable business object definitions encapsulated in a schema.

Defining transformation rules

Complete definitions of data objects and the rules for their transformation are embodied in an IBM® Sterling Transformation Extender *map*. Map objects are created using the Map Designer, a graphical tool that makes complex transformations easier to define and maintain. Maps are analyzed, compiled, and tested directly in the IBM Sterling Transformation Extender Design Studio environment.

A map object can implement a wide range of interface functions, from simple transformation to sophisticated integration solutions involving multiple, heterogeneous inputs and outputs, rule-based routing, and complex interface structures.

The IBM Sterling Transformation Extender Design Studio transformation server processes interface data without pre-formatting or preprocessing. You can compare, move, and transform data using any combination of sources and targets, without regard for underlying interface formats. The graphical environment of the Design Studio also delivers complete integration solutions that require no programming to complete the job. Complex interface problems that involve multiple input sources and multiple output targets can be handled in a single map. There is no need to break up a unit of work into multiple steps unless the business problem requires it.

The Design Studio's comprehensive set of integration rules enables you to go beyond transformation to construct and route entirely new business objects. You can apply rules to route business objects to appropriate targets based on data content, runtime conditions, or any other criteria you choose. You can apply rules to filter, scrub, calculate, validate, parse, substitute, expand, change character set or otherwise convert data from multiple inputs to multiple outputs. All of these capabilities supplement simple, drag-and-drop mapping where needed.

With the Design Studio, data sent to an output does not have to come from an input. You can compute data, look up something in a database, sort, extract, merge, or use any of dozens of IBM Sterling Transformation Extender functions to create output, where appropriate.

You can also map outputs to each other. For example, you can transform data that was generated at the top of an output to the bottom of the same output so that you can summarize, tally, or validate what has been created. You can also map an output that was generated in one output to another output. For example, you can generate a message as one output and archive all or part of it as another output.

Multiple input and output types can be used within a single map for any number of sources (adapters) in an any-to-any fashion. IBM Sterling Transformation Extender is also designed for one-to-many, many-to-one and many-to-many processing. This flexibility provides unconstrained support for common integration needs, such as creating a sales distribution document and an invoice from the same purchase order and updating the inventory database at the same time.

Defining data sources and targets

A data source is defined in an IBM® Sterling Transformation Extender system by specifying a resource adapter for an input. A data target is defined by specifying a resource adapter for an output. IBM Sterling Transformation Extender includes resource adapters for files, memory, databases, messaging middleware products, HTTPS, FTP, e-mail, and more. Application adapters are also available for interfacing with popular commercial applications. Furthermore, you can develop your own adapters to integrate directly to new types of sources and targets by using the IBM Sterling Transformation Extender open adapter interface.

The way in which business objects are defined and the way in which map rules are specified is generally independent of the actual data source or data target due to the abstraction afforded by the schema implementation. Business objects deal with the *format* and *content* of the data, serving to answer questions such as "What should the data look like?" and "What should the value of the data be?" Maps deal with the transformation logic required to create new business objects from existing ones. By contrast, resource adapters answer such questions as "Where should the data come from or go to?" and "How does the application or resource expect the map to send or receive the data?"

During interface design, you specify a resource adapter for each input and for each output. This determines the default adapters to be used during execution. You can always change the source or target by using the process modeling component, the Integration Flow Designer, or at execution time. IBM Sterling Transformation Extender transformation solutions are resource-independent.

You can also use resource adapters in map rules. For example, you can use database adapters in a map rule to look up cross-reference data stored in a database. When the resource adapter you want to use varies, depending upon the data content, you can dynamically allocate the resource from within a map rule. The transformation solutions from IBM Sterling Transformation Extender software can be reconfigured.

Defining process models

The Integration Flow Designer is the graphical process modeling component of the IBM® Sterling Transformation Extender Design Studio. Use the Integration Flow Designer during development to model a set of logically related maps called a *system*. Systems can be used as a focal point for interfacing to other development components and for preparing maps for execution.

- [Formulating business process models](#)
- [Defining resource connectivity](#)
- [Defining event rules](#)
- [Configuring map settings](#)
- [Managing systems](#)

Formulating business process models

Using the Integration Flow Designer, you formulate a business process model as a system. System components can be maps or other systems. A transformation component and its inputs and outputs are represented in graphical form. Data flow links are automatically diagrammed from information about the resource adapters assigned to inputs and outputs. During development, you can navigate to an underlying map where integration rules are defined and to the underlying definitions of input and output business objects.

Defining resource connectivity

When you use the Integration Flow Designer to specify resource adapters for map components, links are automatically established when the target of one component is used as the source of another. You can see the flow of information among system components as you design.

Defining event rules

The Integration Flow Designer can be used to configure the event rules that determine the conditions under which a map will run.

A map component can be initiated based on one or more time, file, database application, or message events. For example, you can specify the insertion of data into a database table to be a map trigger. Alternatively, you can also specify the synchronous coordination of multiple events, such as "Trigger this map every day at 4:00 P.M. if there is a message on my queue." Event management can also include wildcard matching for events across inputs and outputs. For transaction-based transformations, there are also rollback, delete, and retry options.

Configuring map settings

The Integration Flow Designer includes many options for configuring each map such as: priority, event expiration settings, audit logging, paging, multi-threading options, and more. This allows you to configure your production systems for optimal performance.

Managing systems

To prepare a system for deployment, you will want to build, analyze, and possibly port, all the map components in that system. Use the Integration Flow Designer to do this.

Consistent control information can be generated from the graphical diagram of system components. For example, you can generate map command files for a Command Server or control files for an Launcher. This information can be used to distribute transformation components and subsystems across different servers to execute systems as an integrated whole.

Type Tree Maker

The Type Tree Maker is a scripting tool that automates the capture of metadata from machine-processable sources to create graphical metadata in the form of type trees.

For more information about the Type Tree Maker, see the *Type Tree Maker* documentation.

Server components

Several mechanisms, including a Java API that enables Java-based interfaces to maps, are available for integration components. All of the methods share a common core engine and adapters. The main methods of execution are:

- Command-driven
The Command Server provides command-driven execution and is used primarily for batch processing.
- Event-driven
The Launcher provides event-driven execution, in which systems of maps can be coordinated to provide a scalable, distributed, multithreaded, execution environment.
- Application-embedded model
The Software Development Kit maps to be embedded in third-party applications.
- [Management and monitoring tools](#)

Related concepts

- [Execution](#)

Management and monitoring tools

The management and monitoring tools are a set of graphical applications that provide a way to manage and view processes running in the Launcher. These graphical tools are available on Windows- and UNIX-based platforms and can be used with IBM Sterling Transformation Extender Launchers that are either local or remote.

- [Launcher Administration](#)
- [Simple Network Management Protocol \(SNMP\) support](#)
- [Management Console](#)
- [Launcher Monitor](#)
- [Snapshot Viewer](#)

Launcher Administration

The Launcher Administration is the administrative interface to the Launcher, from which the user specifies deployment directories, configures users and user access rights, specifies listening ports, and defines properties for Java Remote Method Invocation (RMI).

Configurations can be defined for:

- automatic system startup when the Launcher service is started
- connection ports for the Management Console
- resource resolution directives as defined in the Resource Registry

Simple Network Management Protocol (SNMP) support

Using the SNMP Agent, you can monitor and manage the status of the Launcher and associated map events. The SNMP Agent can be used to configure thresholds, monitor Launcher performance, and assist in identifying failure situations.

SNMP support is provided with the Launcher on all Windows and UNIX platforms. It supports the following traps:

Trap

Warnings and Errors Generated

Map failure

It signals when a map fails.

State and listener change

It signals a change in the state of the Launcher or listeners.

Launcher/resource connection failure

It notifies the SNMP management software that the connection to the Launcher and the resource could not be established.

Thresholds

It signals when a map or connection pending state threshold has been met.

Additionally, an SNMP adapter allows for custom-defined traps to be issued from within the business logic of a map.

For more information about the SNMP Agent, see the *SNMP Agent* documentation.

Management Console

The IBM Sterling Transformation Extender Management Console is the management and monitoring interface for the Launcher, from which the user can start, stop, pause, and resume the system, as well as view information about the status of the Launcher and maps that are currently running. The Management Console also permits centralized, remote management of all Launcher installations.

Separate connections are defined for each Launcher installation. Each Launcher then appears in the main window of the Management Console, and each can be managed from the single, remote interface.

From the Management Console, it is possible to remotely stop, start, and pause systems. Launcher debugging can also be enabled to assist in operational troubleshooting of Launcher operations.

The Management Console provides a variety of statistics about the Launcher, including the length of time it has been running and the number of maps that have been processed.

- Summary: provides a general view of performance and status information.
- Status: contains active and pending system status information.
- History: contains a rollup of the total number of maps that have been run, the number of successes and failures, and so on.
- Configuration: contains the configuration parameters for the Launcher.

For more information about the Management Console, see the *Launcher* documentation.

Launcher Monitor

The IBM Sterling Transformation Extender Launcher Monitor is a GUI that provides a dynamic, detailed view of watches (single map instances) as they run. It also provides the capability to create snapshots of detailed watch activity.

For more information about the Launcher Monitor, see the *Launcher* documentation.

Snapshot Viewer

The Snapshot Viewer is a GUI that displays snapshots taken in the Launcher Monitor. These snapshots show details about the activity of the Launcher at a specific moment in time.

For more information about the Snapshot Viewer, see the *Launcher* documentation.

Software Development Kit (SDK)

The IBM Sterling Transformation Extender Software Development Kit (SDK), which is included in the Design Studio product installation, and related options, provide the means to include transformational capabilities within a custom application or environment and to extend IBM Sterling Transformation Extender product capabilities using an adapter toolkit. When used with an application server or web server, the components in the SDK can be used to facilitate web-based integration scenarios.

The following components comprise the Software Development Kit:

- Software Development Kit Application Programming Interfaces (APIs)
- Software Development Kit Options
- Adapter Toolkit
- [Software Development Kit Application Programming Interfaces \(APIs\)](#)
- [Software Development Kit options](#)
- [Adapter toolkit](#)

Software Development Kit Application Programming Interfaces (APIs)

At the center of the IBM® Sterling Transformation Extender Software Development Kit (SDK) are object-oriented application programming interfaces (APIs) that are available for environments such as C, Java, RMI, and COM. These APIs provide common functionality that is represented in language-specific methods and objects. All APIs within the SDK contain the same underlying objects and methods. The APIs support multithreading to ensure high performance by allowing multiple instances of maps that can be run in parallel.

Map and card settings and parameters that can be changed in the Design Server or Integration Flow Designer can also be passed to the map at runtime through these APIs, thus allowing runtime control of specific instances of the map. For example, an application variable can be used to control audit settings for a particular map or to pass in a filename to be accessed.

Related concepts

- [Application-embedded execution model](#)

Software Development Kit options

Software Development Kit options integrate IBM® Sterling Transformation Extender maps with other application integration and business process management products.

Adapter toolkit

The Software Development Kit includes a toolkit for developing robust custom adapters that can:

- tightly integrate with IBM® Sterling Transformation Extender products using the XML registration file
- participate in connection pooling
- provide an event listener

B2B management (Trading Manager)

The IBM Sterling Transformation Extender Trading Manager is an optional B2B management component. It is a client/server product for managing and processing electronic commerce data that provides the capabilities for managing and controlling the Business-to-Business (B2B) integration of partner relationships and message flow. Trading Manager users can audit, control, monitor, and view the entire B2B integration environment across the extended enterprise with secure data exchange fully integrated with back-end systems. The Trading Manager consists of the following components:

- Partner Manager
Partner Manager is a graphical administration environment used to trade partner profiles and relationships. Partner Manager also provides runtime monitoring, auditing, and reporting functions.
- Message Manager

Message Manager is a runtime subsystem that uses trading profiles maintained by the Partner Manager to automate document exchange among e-commerce partners.

For more information about Trading Manager and its components, see the Trading Manager documentation.

- [Partner Manager](#)
 - [Message Manager](#)
-

Partner Manager

The IBM Sterling Transformation Extender Partner Manager is a GUI application used to create a comprehensive database of an organization's electronic commerce information and to manage its e-commerce activity. Partner Manager is used to:

- define the trading relationships with Electronic Data Integration (EDI) partners, including details such as the version of each document, control numbering schemes, tracking, error handling, status, and post office used.
- maintain the information for each trading partner, including details regarding addresses, contacts, and the individual departments or other groups within trading partner organizations.
- provide audit and control information collected in the Commerce Manager database that is used to monitor ongoing inbound and outbound e-commerce transaction activity.
- provide alerts when error conditions occur in e-commerce inbound or outbound processing.

For more information about the Partner Manager, see the Partner Manager documentation.

Message Manager

The IBM Sterling Transformation Extender Message Manager is a predefined system of maps specifically designed to process electronic commerce data. The maps are used to validate and route data. The Message Manager is the runtime component of the Trading Manager.

Electronic commerce data flows from external sources to internal destinations, from internal sources to external destinations, and possibly to other internal organizations. The Trading Manager manages this flow and the tracking of e-commerce data.

The Message Manager supports two distinct data flows: inbound and outbound. The inbound data flow typically represents the receipt of data in EDI or proprietary format from an external trading partner. The outbound data flow typically represents the retrieval of data from an internal application system in its native format for subsequent conversion and routing to an external trading partner.

The information from the Partner Manager is shared with the Message Manager for the validation, tracking, and routing of e-commerce data. Information about this e-commerce activity is then incorporated into the Partner Manager database for monitoring and reporting.

Trading Manager can be used for internal/external, external/internal, and internal/internal trading scenarios.

For more information about the Message Manager, see the Trading Manager documentation.

Other IBM Sterling Transformation Extender solutions

A range of products extend the out-of-the-box integration services provided by IBM® Sterling Transformation Extender and the Software Development Kit, which is included in the Design Studio product installation. There are Industry Solutions and Enterprise Application packages contain predefined interface definitions (schemas), adapters, importers, and other components designed to facilitate integration with various enterprise applications and business-to-business interfaces.

Integration maps

Maps provide a non-programmatic approach to the development of interfaces, with prebuilt functionality for connectivity, transformation, and routing. Components can be created once and reused many times for different types of integration scenarios.

Maps support integration scenarios such as:

- Asynchronous, event-driven architecture
- Component or Enterprise JavaBean (EJB) architecture
- Synchronous, web-based architecture
- Application-embedded architecture
- Batch interface architecture

A map is made up of:

- Input and output map cards that represent the sources and targets.
- Map rules that define how the output data is built based upon business rules.
- Specifications of the resource adapter used to retrieve and send data.
- [Map behavior during execution](#)

- [Input and output card settings](#)
- [Map settings](#)
- [Configuration variables](#)

Configuration variables are aliases that resolve to specific resources within the enterprise. The variables resolve automatically to actual resources such as directory paths, database names, message queue names, and server names. Configuration variables make it possible to use the same map and system definitions in different deployment environments.

Map behavior during execution

The execution characteristics of a map are determined by the execution parameters that are configured at design time. However, these map execution characteristics or map settings can also be overridden at run time.

The behavior of a single map invocation is as follows:

1. The adapters that are configured for their respective input cards retrieve some of the input data.

The input data is validated against the schema definition of the respective input card(s). This ensures that only valid data is passed to the output building process. It is for this reason that *any* piece of *any* of the input data can be used to build *any* of the output data. All of the input data is validated and stored in the map's workspace before any output data is built. Because the entire workspace is available to the map at the time it has to build the output, any portion of the input data can be used, counted, or manipulated to generate any part of the output data.
2. After the input data has been validated, output objects can be used as inputs for a subsequent output.

You can create temporary outputs to signify map logic in certain situations. The Sink adapter can be employed to ensure that the data is not retained.

By default, the rollback behavior applies to the entire map thread level. Therefore, nothing will be committed to output nor deleted from input until all inputs have been successfully validated *and* all outputs have been successfully written. Many commit and rollback options are available within the configuration settings of each input and output card. By manipulating these settings, you can significantly change the default commit and rollback behavior of a map.

Input and output card settings

Card settings define the data object that the card represents and how the data is retrieved or routed and compiled into the map. The behavior of input and output cards configured in the compiled map can be overridden.

- Schemas represent the data source for an input card and the output data structure for an output card.
- SourceRule settings in the input card specify the data to be retrieved and how to do it, where to get it, how much of it to get, and what to do when an error occurs.
- TargetRule settings in the output card specify the data that is output, how the output data is routed, and what to do when an error occurs.

Map settings

Map settings dictate the behavior of the entire map—across *all* input and output cards.

The following map settings provide the ability to control aspects of the map's execution such as:

- [MapAudit](#)

This setting specifies options to create an audit of the map's execution, data, and execution settings, in addition to the level of detail of the audit.
- [MapTrace](#)

For troubleshooting purposes during development, this setting specifies options to create a trace and the level of detail of the trace.
- [WorkSpace](#)

This setting specifies the location (in a file or in memory) of the workspace and the amount of memory to allocate for the execution of the map.
- [Retry](#)

If compiled map files, work files, audit log files, or trace files that are needed during map execution cannot be opened, this setting specifies whether to attempt to run the map again and the interval of time between each attempt.

Almost all of the source, target, and map setting parameters can be overridden with different values at run time. This capability is available for all modes of map execution.

This allows you to change map execution parameters for different deployment environments, sources, and destinations (such as development, user acceptance testing (UAT), and production environments) without having to modify and recompile the maps.

Related concepts

- [Adapter configuration for input and output](#)

Configuration variables

Configuration variables are aliases that resolve to specific resources within the enterprise. The variables resolve automatically to actual resources such as directory paths, database names, message queue names, and server names. Configuration variables make it possible to use the same map and system definitions in different deployment environments.

Reserved words and symbols

Reserved words and symbols have a special meaning and can be used only in the manner described in this documentation. The following is the list of reserved words and symbols, and their intended use.

Reserved Word or Symbol

Intended Use

\$ Shorthand representation of the object name in a component rule or a map rule.

: Used to separate components.

:: Shorthand representation of a unique component or partition path.
For example, **A::B** refers to the unique path from the type **A** to the type **B**.

<> Separates a partition from its partitioned type

, Used to separate arguments of functions and maps

"" Used to enclose literal text strings.

() Used for a component range, to enclose function or map arguments, and to block sub-expressions in a rule

@ Separates a comment from a component.

[] Denotes an indexed member of a series.

{} Used to enclose a list of literals.

Names of Functions

Names of functions are reserved words. Names of functions can be used as type names, but cannot be used as map names.
For a complete list of functions, see the Functions and Expressions documentation.

Operators

Operators are reserved.

For a complete list of operators, see the Functions and Expressions documentation.

ANY

Represents one or more types in a component name.
ANY cannot be used in component rules or map rules.

COMPONENT

Refers to any component preceding the current one in the same component list. Used in the Type Designer to refer to preceding components of the same component list.

This reserved word can only follow the reserved word IN. For example:

COUNT (Record IN COMPONENT)

FALSE

Represents the logical false.

IN

Separates a component from an object that contains it. For example, **LineItem IN File** refers to all occurrences of the type **LineItem** in the type **File**.

LAST

Special index value that refers to the previous data object of a particular series.

NONE

Stands for the null value or non-existence of data content. Can be used in a component rule to test the presence of data. Can be used in a map rule to generate no occurrences of an output.

<space>

Separates type names. (This is an actual space.)

The names of individual types in component names are separated by spaces. Component names themselves are separated by colons. For example,

C:A B is the **C** component of the **A** subtype of **B**;

C:A B:X is the **C** component of the **A B** component of type **X**; and so forth.

<symbol>

Symbol abbreviations for entering non-printable characters. For example, <CR>.

TRUE

Represents the logical true.

WHERE

Can be used in the LOOKUP or EXTRACT function in place of the comma (,) between arguments.

Quotation marks

Although there are platform-specific limitations regarding the usage of double and single quotation marks, when adding a text string into any map rule, component rule, or command line, use the following characters for quotation marks.

Symbol	ASCII Character	Text Reference in Documentation
'	039	Single quotation mark
"	034	Double quotation mark
"	039 and 039	Two single quotation marks (for some non-Windows environments)

Using any other characters can produce unexpected results.

Hex, decimal, and symbol values

In this list, some characters in the character name are capitalized to indicate the common abbreviation for the character. For example, the <STX> abbreviation represents the Start of TeXt character.

The hexadecimval values are provided as a reference. For any literal value specified in the Type Designer Properties window, hexadecimval values must be enclosed in double angle brackets. For example, <<0A>> represents the hexadecimval value for a line feed character.

The decimal values are provided as a reference. Decimal values can be used with the SYMBOL function. For any literal value specified in the Type Designer Properties window, decimal values must be enclosed in single angle brackets. For example, <10> represents the decimal value for a line feed character.

Symbols can be inserted into map rules and component rules. You can insert them from the Symbols dialog box or by typing the hexadecimval or decimal value.

Execution

The main methods for map execution are as follows:

Execution Method

Description

command-driven

This is primarily geared towards batch processing using the IBM® Sterling Transformation Extender Command Server.

event-driven

This is a method in which systems of maps can be coordinated together by the IBM Sterling Transformation Extender Launcher to provide a scalable, distributed, multi-threaded, execution environment.

application-embedded

This is a method in which maps can be embedded in third-party C, Java, and COM applications. When used with an application server or web server, the components in the Software Development Kit can facilitate web-based integration scenarios.

- [Executing in test and production environments](#)
- [Executing on multiple platforms](#)
- [Command-driven execution model](#)
- [Event-driven execution model](#)
- [Application-embedded execution model](#)

Related concepts

- [Server components](#)

Related information

- [Deploying what you develop](#)

Executing in test and production environments

During the development process, test execution takes place in the same IBM® Sterling Transformation Extender Design Server environment in which you develop your integration solution. Testing can be performed offline, using the Design Server, even when the planned execution platform, deployment mode, or adapter assignments differ from those used in the test environment.

You can configure your environment with multiple servers at multiple sites, and on multiple platforms. Alternatively, you can select a single server as your deployment environment. For example, you can develop a system that includes all the information about how to process payments. You can then provide this map to multiple locations in your company, for execution on different server platforms. The distributed sites do not need to know anything about your development environment.

Executing on multiple platforms

A single IBM® Sterling Transformation Extender map can execute on any of the platforms that the IBM Sterling Transformation Extender products support.

Command-driven execution model

The IBM® Sterling Transformation Extender Command Server provides a command-driven capability for the execution of integration maps. This model is normally associated with batch-driven, on-demand integration processes. The methods for executing maps in command mode include the following:

- Executing a single map from a command prompt
- Executing multiple maps in sequence using a command parameter file
- Executing from the Windows-based Command Server, which provides a graphical user interface (GUI) for loading and running maps, as well as for overriding map settings
- Executing as part of a batch file or shell script
- Executing as part of a mainframe job as specified in the Job Control Language (JCL)
- Executing using commands specified in a scheduling program

By default, the execution settings of a map (such as `MapAudit` and `WorkSpace`) are compiled into the runtime object. In all modes of execution, it is possible to override almost all settings at run time. For Command Server invocation, the overrides are supplied as parameters on the command line.

- [Execution command overriding a database target example](#)

Related concepts

- [Runtime services](#)

Execution command overriding a database target example

Suppose you want to run the map `multitran.hp`, overriding some of the settings for the fourth output card, which is a database target.

Use the following command:

```
/install_dir/bin/dtx /install_dir/maps/multitran.hp -G  
-OD4R5:3B '-TRACE ERROR'
```

Option	Description
<code>multitran.hp</code>	This specifies the name of the map to be executed.
<code>-G</code>	All item properties (including size, presentation, and restrictions) are fully validated.

Option	Description							
<p>-OD4R5:3B `...'</p> <p>Value</p> <table> <thead> <tr> <th style="text-align: center;">Description</th> </tr> </thead> <tbody> <tr> <td>R5:3</td> </tr> <tr> <td>If the database resource is unavailable, attempt to make the connection five more times at three-second intervals.</td> </tr> <tr> <td>B</td> </tr> <tr> <td>If the map does not complete successfully, roll back any changes made to the database table.</td> </tr> <tr> <td>'-TRACE ERROR'</td> </tr> <tr> <td>Generates an adapter trace file containing error information only.</td> </tr> </tbody> </table>	Description	R5:3	If the database resource is unavailable, attempt to make the connection five more times at three-second intervals.	B	If the map does not complete successfully, roll back any changes made to the database table.	'-TRACE ERROR'	Generates an adapter trace file containing error information only.	This overrides the default settings compiled into the map using the database target for the data of output card #4 (-OD4) as follows:
Description								
R5:3								
If the database resource is unavailable, attempt to make the connection five more times at three-second intervals.								
B								
If the map does not complete successfully, roll back any changes made to the database table.								
'-TRACE ERROR'								
Generates an adapter trace file containing error information only.								

For more information about execution commands, see the *Execution Commands* documentation.

Event-driven execution model

The event-driven execution model relies upon the Launcher to coordinate the triggering of map threads based upon either input event or time event triggers. With its ability to define complex event-triggering criteria, combined with a robust set of adapters that provide listener interfaces to detect these events, the Launcher is the cornerstone for providing real-time, event-driven integration.

- [Launcher](#)
- [Launcher Architecture](#)
- [Audit and transaction logging](#)

Launcher

The IBM Sterling Transformation Extender Launcher provides a real-time, event-driven model for executing maps and systems of maps defined in the Integration Flow Designer. The Launcher runs on a server platform and manages one or more systems concurrently. Systems are asynchronous, multi-threaded processes, whose atomic units are transactional maps. Systems can execute in a distributed environment in which a Launcher resides on each server. When events occur, the Launcher is notified and starts maps based upon that notification. Distributed data is received or routed during map execution.

- [Triggers and watches: asynchronous communication](#)
- [Synchronous coordination](#)

Related concepts

- [Runtime services](#)

Triggers and watches: asynchronous communication

The set of events that initiate a map within a system is called a *watch*. Each event that contributed to the initiation of a map is called a *trigger*. Triggers are asynchronous events resulting from time or source state changes (for example, the creation of a file in a directory or a message appearing on a queue). The Launcher starts maps based upon triggers defined in the Integration Flow Designer. In some cases, there may be multiple triggers that must collectively exist before a map is initiated. The Launcher manages the coordination of these events to ensure that the correct set of circumstances has occurred before a map is initiated. Although each instance of a map is considered a separate watch, the Launcher must also manage the resource interfaces used by other maps and other instances of the same map to properly synchronize these asynchronous events.

Data sources using database adapters can serve as input event triggers that are defined in the Database Interface Designer, enabled in the Integration Flow Designer, and executed by a Launcher.

The listener interface, supported by various adapters, handles triggering through database updates and messages arriving on queues.

Synchronous coordination

Synchronous interaction between steps within the data integration process may sometimes be required. For example, it might be important to complete a transaction only when an acknowledgment of an action is received. Synchronous interaction can be accomplished in different ways:

- Communicate with other maps from a map rule during the data transformation process. Using a map rule in this way, the Launcher manages coordination among maps to avoid deadlocked situations and to ensure that shared resources are reliably accessed or deleted.
- Synchronize coordination to interact with other applications using a resource adapter for a data source or target. For example, when a file is sent to a server using the FTP target adapter, the FTP server response is received before the mapping process completes.

Launcher Architecture

The Launcher architecture is an event-driven software model executing maps. Systems contain maps supporting a system data flow that is specified by using the Integration Flow Designer.

An Launcher runs on a server platform and can concurrently manage one or more systems. Launcher functionality is based upon the following premises:

- The event manager sub-component of the Launcher controls the initiation of maps based upon the sources to which a map subscribes.
 - The resource manager sub-component of the Launcher synchronizes shared data and timing interfaces among heterogeneous sources and targets.
 - Maps publish data that result from the content transformation of source data.
 - Maps are transactional processes, with each map having its own error detection and recovery procedures.
 - The Launcher runs as a single process with multiple threads. An associated process monitors input source resource changes.
 - [Launcher methodology](#)
 - [Business Advantages of the Launcher](#)
-

Launcher methodology

Whenever the Launcher detects a new event trigger, the watches associated with that trigger are either:

- initiated, thereby causing the map to execute
- placed in an initiation pending state, awaiting the completion of all specified triggers
- maintained in an initiation-pending state until operating system resources (such as threads) are available

The Launcher initiates an individual map thread for each successful combination of specified triggers. Multiple instances of the same map component can be invoked and executed simultaneously if the Launcher is configured to take advantage of concurrent multi-threading of map execution for performance. Alternatively, if strictly sequential execution architecture is required (FIFO); configuring the Launcher accordingly can accommodate this. This concurrent-versus-sequential capability can be configured at the individual map component level. As a result, maps contained in a system could be concurrent, while others could be set to execute sequentially.

Business Advantages of the Launcher

Some of the main business advantages to using the Launcher are:

- automatic system execution
 - multi-threaded environment for multiple transactions, which allows linear scaling across multiple CPUs
 - process prioritization
-

Audit and transaction logging

The totally flexible architecture of IBM® Sterling Transformation Extender products allows the design and development of sophisticated transaction and audit logging using standard functionality. This is supported by the complete range of resource adapters and the many tools available in the complete line of IBM Sterling Transformation Extender products.

Maps are transactional processes and each map can be configured to have its own error detection and recovery procedures, as well as auditing capability. The resulting audit logs themselves can be mapped, as input data, to dedicated execution logging, error logging, and exception handling routines.

Typically, audit and transaction logging processing is achieved by designing reusable map systems to process audit logs resulting from map execution.

Application-embedded execution model

The mechanism that is used for this model is basically the same as the one providing runtime instructions for a map's execution from the command prompt. Overrides are submitted to control the map's execution. The difference is that these overrides are programmatically supplied, in memory, rather than on the command line. However, even under IBM® Sterling Transformation Extender Command Server execution, the overrides specified on the command line are passed by the Command Server, in memory, to the core execution code, which is embodied in the various APIs. Note that, regardless of the execution model employed, the same underlying IBM Sterling Transformation Extender technology prevails.

The benefit of embedding a map within an application is that all of the power of the standardized transformation and connectivity capabilities of the IBM Sterling Transformation Extender products can be fully leveraged. Rather than needing to write Java, C, or C# code to perform complex transformation, connectivity, and routing, maps can be fully leveraged to perform these tasks. Again, as with other execution models, the same inherent IBM Sterling Transformation Extender technology components are used: maps. This means that a more unified skill set is applicable across all integration models, thereby reducing the overhead of writing the code to perform transformation, routing, and connectivity to a minimum. This allows more time to concentrate efforts upon developing the business logic in the application layer code, resulting in a much quicker implementation. In addition, because the source components, such as schemas and map source files, are not procedural code listings, but rather visual, object-based components, the ongoing maintenance of these components is more straightforward, using the extensive capabilities provided by the Design Server.

APIs are provided for the following applications:

- [Applications](#)
- [Java applications](#)
- [COM applications](#)
- [C# applications](#)
- [J2EE applications](#)

C applications

IBM Sterling Transformation Extender includes two APIs available to C programmers: the TX Programming Interface and the z/OS Platform API. Customers creating new applications should use the TX Programming Interface, C API. The z/OS Platform API continues to be supported for legacy applications. However, any new features or functionality will be available only in the TX Programming Interface, C API.

Java applications

There are several ways in which a Java application can run a map:

- By using the TX Programming Interface Java API
- By using the TX Programming Interface RMI API

With the RMI API, a map (and the underlying native core code) can be executed out of process. Also, with RMI, IBM Sterling Transformation Extender can run on any platform that supports the Java RMI API. (And this is not necessarily the same platform as the ones upon which Java Application Servers run.) This enables maps to be executed by an Enterprise JavaBean containing business logic and subsequently to be deployed to an application server. Examples of this are provided.

Java-based applications that invoke a map through the API can also take advantage of using the Java Class Adapter to access additional Java objects. For EJB functionality, access to serializable objects is supported. From the user's Java Application or EJB, objects are serialized using Java Serialization and passed (using a STREAM adapter override) to input cards of a map. Within the map, the Java Class adapter can be used to deserialize an object (and store it in the Object Pool). Access to fields and methods on Objects stored in the Object Pool is permitted using the Java Class adapter. (Objects are also accessible using the JNDI and JMS adapters.) To pass objects back to the user's application from a map, objects are serialized using the Java Class adapter. The resulting byte[] is passed back to the calling EJB using a STREAM adapter override. The Java application or EJB re-constructs the Object using Java Serialization.

COM applications

For customers using Microsoft's Component Object Model (COM) technology, the IBM Sterling Transformation Extender Programming Interface (TXPI) for COM provides the functionality to run an IBM Sterling Transformation Extender map from scripting languages such as VBScript and Jscript. This also allows IBM Sterling Transformation Extender maps to be executed from Active Server Pages.

C# applications

Using the TX Programming Interface, COM API, and the interoperability library provided in the Software Development Kit (SDK) examples, a C# application running on .NET can also run an IBM Sterling Transformation Extender map for transformation.

J2EE applications

Java 2 Platform, Enterprise Edition (J2EE) defines the standard for developing component-based, multi-tier, enterprise applications. Applications built using J2EE can use the various Java-based APIs described.

Examples

Another source for learning about IBM® Sterling Transformation Extender products is by running the examples that are provided with the product. The examples illustrate how to use IBM Sterling Transformation Extender product components to accomplish specific tasks and can prompt ideas for achieving your goals. The examples are located at *install_dir/examples*.

Tivoli License Manager

IBM Tivoli License Manager (ITLM) enables you to monitor the usage of IBM (and other) software products. ITLM provides you with the following software auditing functionality:

- Monitor the licenses used across different machines.
- Help keep unnecessary licenses to a minimal.
- Guard against software license compliance problems.

IBM® Sterling Transformation Extender supports ITLM. To find out more about using ITLM to monitor usage of your IBM software, see the [IBM License Metric Tool](#) knowledge center.

What's new in V11.0.1.0

This is what's new in this version of IBM Sterling Transformation Extender:

Installation

IBM Sterling Transformation Extender can be installed on Linux platforms in three modes: Native, Docker, and Podman. Podman is the new installation mode supported on Linux platform in this version of product.

On the Red Hat Linux distribution, the IBM Sterling Transformation Extender installation supports Podman installation types, while on other Linux distributions (like Ubuntu, SuSE), IBM Sterling Transformation Extender supports both Docker and Podman container engines.

Nodes

New nodes

Format Converter node

The Format Converter node can be used to quickly convert data from one format to another.

The Format Converter node supports these formats:

- CSV
- Delimited
- JSON
- YAML
- XML

Adapters

New adapter

Redis adapter: The Redis adapter provides access to Redis databases for storing and retrieving the keys and their values as part of data transformation. The Redis adapter is used in maps and flows to set and get key-value pairs in the Redis databases. Redis adapter is supported with all runtime map and flow execution environments.

Updates to existing adapter

- Oracle adapter: Oracle adapter is updated with multi-row table insert support. A new command line option **-INSERTALL/-IA** enables multiple rows of data to get inserted into an Oracle table at once instead of one row at a time. Throughput can be increased several-fold with multi-row insert support under heavy load transaction scenarios.
- Apache ActiveMQ adapter: Apache ActiveMQ adapter has added support for standard JMS headers and user-defined custom properties in the messages produced to the ActiveMQ broker, and while messages consumed from the ActiveMQ broker.
- RabbitMQ adapter: RabbitMQ adapter is now supported in Design Studio and Integration Flow Designer. RabbitMQ adapter can be invoked from maps running under Launcher systems during runtime.

Maps

Map Audit enhancement

Input validation errors are included in the Map Audit log when SummaryAudit setting is turned ON in the map settings. In environments where map trace is not allowed to capture the validation errors, a map audit log having detailed error information would be the only way to identify and resolve data errors.

Map Audit enhancement is not available in z/OS Batch and CICS environments, but z/OS USS environment generates data validation errors in the map audit log when SummaryAudit is turned ON.

Launcher

Cooperative Listener directory permissions

Cooperative listener directories' permissions have been adjusted to allow multiple launchers running under cooperative mode to be able to use the same directories. Instead of bailing out with errors due to insufficient permissions while writing onto them by launchers running under different accounts within the same group on Unix platforms.

ini2yaml migration utility

A new migration tool, ini2yaml, has been added for this release which facilitates the configuration information in dtx.ini file to config.yaml file. Customer environments that use several configuration files, ini2yaml tool eases the migration effort and reduces errors during migration.

Design Studio

Design Studio has been enhanced to run on the newer Eclipse 4.31 platform. This newer Eclipse platform brings in a newer look and feel, advanced features of the platform for users. Eclipse based applications integrated with Design Studio can take advantage of the newer Eclipse 4.31 platform and Java 17 support provided in this version of the product.

Design Server

Transport Layer Security (TLS) support

Transport Layer Security (TLS) client settings can be configured for outbound connections from the Design Server to Runtime Servers. See the mapping server.outbound.ssl in config.yaml. Use of these settings is not required if the previous behavior for outbound connections is sufficient. These settings are intended to allow secure connections to runtime installations including those that use a customized TLS configuration. Mutual TLS (mTLS) is supported when values are provided for config.yaml keys server.outbound.ssl.certFile and server.outbound.ssl.keyFile. These values are optional when mTLS is not used.

Java

Java 17 support

IBM Sterling Transformation Extender distributes IBM Semeru Java 17 Certified Edition Runtime Environment with all supported platforms of the product. All Java based components and tools in the product support Java 17. Removed packages from Java 8 are substituted with Jakarta API packages in the components for this product release. Applications that use IBM Sterling Transformation Extender Java API or Java RMI API are recommended to recompile their applications with Java 17.

This is what's new in this version of packs:

What's new in Packs V10.2.3.0

This is what's new in this version of packs:

What's new in Pack for Financial Payment v10.2.3.0

SWIFT component:

- Support is provided for 2024 SRG Standards
- Corresponding updates are as follows:
 - SWIFT type trees
 - LMF maps and trees
 - Java Validation Component
 - MX schemas, type trees, and validation framework
- For TX version 11.0.1, and later
 - IFD deployment script will need saved .msl to TX_INSTALL_DIR/system folder.
 - Prop file will no longer have sub-directories references under TX install directory.
 - As a pre-requisite, users will need to edit the property file to replace generic PACK_INSTALL_DIR with the actual location where the ZIP distro was unzipped.
 - Utility jvcsetup.sh in swiftJVCconfigIBM.targz is for Docker, and Podman based installations.
- For Design Server installation:
 - Copy the jvalccyy.jar and jvcwrap.jar into the directory set in the config.yaml server.persistence.libs, by default, this is set to /opt/tlxlibs. Then restart the tx-server, for example ./ITX, stop and then start ./ITX
- Configuring JVC on Design Server:
 - After importing the swiftMTCompliance.zip project, the jvalccyy.prop file must be copied into the workdir directory under directory set in the config.yaml server.persistence.files, default settings is /opt/tlxfiles/workdir.
 - On the project, update the map rule on the validate_message map, on output card #1 item JvalPropPath. Change the map rule from =NONE to the location of the jvalccyy.prop.
 - For example:
 - On UNIX: ="DS_DATA_DIR/workdir"
 - On WINDOWS: ="DS_DATA_DIR\workdir"Where DS_DATA_DIR refers to the Design Server data directory, set in the config.yaml server.persistence.files previously TX_FILE_DIR.
- Post EAP updates:
 - Enforce field level validation related to error code T78 on tag 81J, 91J, and 96J on SWIFT MT common messages MTn92, MTn95, and MTn96
 - Support the new SWIFT MX Funds messages
 - reda.004.001.07 - will replace reda.004.001.06
 - setr.006.001.05 - will replace setr.006.001.04
 - setr.012.001.05 - will replace setr.012.001.04

NACHA component:

Support 2024 NACHA Operating Rules - Supplement #1-2024.

FIX component:

Support FIX 5.0 SP2 Extension Packs (FIX Latest) up to EP291.

Miscellaneous:

- For ITX 11.0.1, build JVC jars using IBM Semeru JAVA 17.
- ZIP distros are digitally signed.

Deprecated components:

- SWIFT MT-MX translation example maps.
- SWIFT Sterling B2B Integration examples.

What's new in Pack for Financial Payment Plus v10.2.3.0

CBPR+ Translation:

- For Design Server installation:
 - Copy the following jars into the directory pointed to the config.yaml server.persistence.libs by default, this is set to /opt/tlxlibs, then restart the running application ./ITX stop and then ./ITX start.
 - jnodes0.jar
 - jackson-core-n.n.n.jar
 - jackson-annotations-n.n.n.jar
 - jackson-databind-n.n.n.jar
- Updated translation frameworks to support CBPR+ Translation guide version 1.5.2 bug fixes.

- Additional CBPR+ Translation scenarios:
 - MT103 RETN <=> pacs.004.001.09
 - MT202 RETN <=> pacs.004.001.09
 - MT205 RETN <=> pacs.004.001.09

CBPR+ Validation:

- Support version SR2023, SR2024 schemas based on MyStandards Readiness CBPR+ Readiness Portal, date of publication 24 April 2023 and 12 December 2023.
- New 2024 CBPR+ messages:
 - camt.105.001.02
 - camt.105.001.02 mlp (multiple charges)
 - camt.106.001.02
 - camt.106.001.02 mlp (multiple charges)
 - camt.109.001.01 (already included in version 10.2.2.0)

EBA E1S1 Validation:

- Support version EBACL_E1S1_UG2024 (MR2019) based on SWIFT MyStandards Readiness EBA Portal, date of publication 01 August 2024.

NBOR ReGIS Validation:

- New version v1.1 based on SWIFT MyStandards Readiness NBOR ReGIS Portal, date of publication 20 August 2024.

T2 CLM Validation:

- New version UDFS T2 R2024.JUN schemas based on SWIFT MyStandards Readiness TARGET2 CLM Portal, date of publication 11 June 2024.

T2 RTGS Validation:

- New version UDFS T2 R2024.JUN schemas based on SWIFT MyStandards Readiness TARGET2 RTGS Portal, date of publication 11 June 2024.

T2 CoCo Validation:

- New version UDFS CRDM T2 R2024.JUN schemas based on SWIFT MyStandards Readiness TARGET2 CoCo Portal, date of publication 11 June 2024.

T2S Validation:

- New validation frameworks (schema only) based on SWIFT MyStandards TARGET2 T2S Portal version UDFS T2S R2024.JUN date of publication 9 June 2024.

SWIFT GPI/SWIFT Go Validation:

- New version schemas based on SWIFT MyStandards Readiness Swift GPI Portal, date of publication as below:
 - trck.001.001.03, trck.002.001.02
 - gCCT/gCOV/gFit - date of publication 15 March 2024
 - swiftGo - date of publication 15 January 2024
 - trck.003.001.02 - date of publication 05 March 2024
 - trck.004.001.02 - date of publication 14 December 2023
 - trck.005.001.02 - date of publication 12 January 2024

SIC RTGS Validation:

- New validation frameworks (schema only) based on SIX Interbank Clearing (SIC) Ltd Platform Releases 4.11 (RTGS services SIC and euroSIC) and 5.1 (SIC IP service).

Miscellaneous:

- Validation frameworks enhanced reporting to handle messages with unsupported versions.
- Support for XML messages with diacritic characters.
- New utility map for parsing the validation reports (under tools folder).
- Design Server flow redesign to standardize and streamline examples.
- For ITX 11.0.1, built CBPR+ Translation jar using IBM Semeru JAVA 17.
- ZIP distros are digitally signed.

Deprecated components:

- CHAPS L4L validation

What's new in Pack for Healthcare v10.2.3.0

HIPAA

- Support for 277DRA compliance checking (5010X364).
- Support for 6020X313 and 6020X315 transactions to support CMS-0053-P for claims attachments.
- New parameter added for 277CA/277DR acknowledgements to control whether the STC segment at all 277CA and 277DR loop levels reflects an error at that level or lower and includes a valid entity code instead of the generic Ack/Receipt code.
- Support in Type 7 checking to allow return of invalid element and sub element values.
- Ability to include ISA Sender and Receiver IDs, ISA Control number, GS Sender and Receiver Codes and GS Control number in the transaction data passed to the Type 7 user exit.
- Code List updates.

NCPDP

- The Annual Code lists updates.
- Additional validation in NCPDP PACDR trees versions 51-53.
- Support for Java 17 in validation exit jar file.

HL7

- FHIR Mapping examples updated to use JSON schema, and to also create a JSON response bundle based on X217 278 Response.

What's new in Pack for Supply Chain EDI v10.2.3.0

New configuration settings:

- **Edicc.ini file:**

This file contains configuration for the edisvu exit location and z/os processing flag. A new configuration for z/os processing has been added to suppress the run map log. This setting could show a performance enhancement for large file processing with reduced I/O.

- **XML and JSON configuration files:**

- SKIPTVALIDATION configuration:

There are three main processes performed during the compliance checking as follows:

- Standard Type Tree validation
 - Structure checking
 - Segment checking

The Standard Type Tree validation uses the full standard to determine if the input file contains errors. If there are no errors, no further validation is needed. If there are errors, the second and third processes are executed. This first process can take a considerable amount of time depending on the standard and the message type. The SKIPTVALIDATION setting will skip the first process and always execute the structure checking and segment checking and eliminate the amount of data parsing and restarts. It also eliminates the ttval run map execution.

Tooling:

With the extensive list of EDI standard versions supported and the compliance checking process to validate the structure of the messages/transactions, the structure validation file has become large. New utilities in the EDIFACT and X12 components can be used to reduce the size of the structure validation file by selecting standard versions and message/transaction type being used to eliminate unused records.

In addition, a new referenced structure file can be found in the mapsandschemas folder to be used with input card #7. This file contains a reference record for each message/transaction that identifies each standard version a particular structure record can be used with. This avoids duplication or records when the message/transaction structure does not change from release to release.

X12 and X12U component:

- Contains the X12 Standard currency updates with version 8050.

EDIFACT component:

- Contains the EDIFACT Standard currency updates with D23A version.
- Configuration setting to allow validation for inbound EDIFACT CONTRL messages.

Pack installation:

ITX has configured CISO Code signing infrastructure to verify the ITX software (including the Industry Packs) and images in the HCL lab based on the guidelines provided by IBM. IBM Code Signing service holds the certificate used to sign the ITX software and images.

What's new in Packs V10.2.0.1

This is what's new in this version of packs:

What's new in the Pack for SAP V10.2.0.1

Support for the latest versions of IBM Sterling Transformation Extender:

The Pack for SAP Applications v10.2.0.1 includes installation packages for all currently supported releases of TX at the time of the release, which includes ITX versions 10.1.0, 10.1.1, 10.1.2, 11.0.0, and 11.0.1.

SAP S/4 HANA Adapter option to use API key authentication:

In this version, the SAP S/4 HANA Adapter includes an option to use API key authentication. Before, the API key needed to be added to the Base Headers. Now, there is a separate option and field for API key authentication, simplifying the process of defining a connection.

Configuration

This section describes the configuration before or during the installation.

- [Data Directory](#)

The Data Directory is where you maintain a list of directories that can be used by the data loading and optionally, receive and store files transmitted Download.

- [The IBM Sterling Transformation Extender configuration file config.yaml](#)

- [Customizing the Trace](#)

This section describes how effectively you can configure custom trace settings for IBM Sterling Transformation Extender Rest execution. This will allow you to make the level of logging and information displayed according to your needs, enhancing the troubleshooting and analysis process.

- [How to verify the Config.yaml file](#)

This section describes how to verify the validity of your config.yaml file after making changes in it.

- [Enhancing Security, preventing Server Side Forgery Requests attacks](#)

Data Directory

The Data Directory is where you maintain a list of directories that can be used by the data loading and optionally, receive and store files transmitted Download.

Data Directory is the location for IBM Sterling Transformation Extender writable files after the installation.

During the Windows installation, you can use the current behavior by making the Data Directory same as an installation directory.

On non-Windows platforms, the Data Directory will be the same as the installation directory.

Directories and files under the Data Directory

- **Config**

Contains config.yaml, .bin and .property files for legacy java tools, MRC and MRN files default location for resource registry, MKF (Master Key File) for encryption.

- **Examples**

User who chose a read-only installation folder can run the examples that are shipped.

- **Logs**

Contains log files that include redis and tomcat logs.

- **Snapshots**

It is a new directory for the Legacy Launcher Monitor and to create the snapshot (MSS) files. Prior to this release, files were written to the root of the installation directory.

- **Systems**

Default location for Launcher System (MSL) files.

The IBM Sterling Transformation Extender configuration file config.yaml

For the IBM Sterling Transformation Extender installation, configuration information is provided in config.yaml. This file contains several YAML mappings. The value of a key of such a mapping may itself be a YAML mapping. In this documentation, JSON Pointer strings are used to refer to the value of a key value of a YAML mapping. For example, /mongo/auth/password refers to the value of the MongoDB password which should be used to access the MongoDB database which IBM Sterling Transformation Extender uses for design data. Alternatively, dot notation may be used for the same purpose, for example mongo.auth.password.

- [Configuration file syntax validation](#)

- [Configuration file expansion expressions](#)

Two kinds of expansion expressions allow values to be provided in the config.yaml configuration file from another source. An expansion expression is allowed as the value of a key-value pair of a YAML mapping.

Configuration file syntax validation

For each execution, the flow command server attempts to read the installation configuration file. This behavior allows the flow command server version reporting option -v to be used to validate a configuration file for syntax errors. If present, a YAML syntax error will be reported when the following command is executed. See the "Flow Command Server" section in the "Runtimes" section for more information about using the flow command server. The following command demonstrates use of the -v option.

```
flowcmdserver -v
```

Configuration file expansion expressions

Two kinds of expansion expressions allow values to be provided in the config.yaml configuration file from another source. An expansion expression is allowed as the value of a key-value pair of a YAML mapping.

- [Environment variable expansion](#)

- [Master Key File \(MKF\) expansion](#)

Environment variable expansion

Environment variable substitution is performed at run-time only. An expansion expression of the following form is replaced with the value of the named environment variable: \${env:<environment variable name>}

For example, the value \${env:DTXHOME} would be replaced with the value of the environment variable DTXHOME.

If the environment variable is not defined, then the expansion expression is replaced with the empty string.

Master Key File (MKF) expansion

To allow the inclusion of sensitive data, a Master Key File (MKF) encryption expansion expression is replaced at run-time and install-time with its decrypted value. The MKF encryption expansion expression should have been produced using a tool which is provided for this purpose. See the following description of the available tools given below.

MKF encryption expansion expressions have the following form:

```
 ${enc_mkf: mk_id=<master key ID>, check_id=<encryption check data>, iv=<encryption initialization vector>, data=<encrypted data>}
```

The master key which is used for encryption determines the encryption algorithm which is used to encrypt the data.

A default MKF file is provided with an IBM Sterling Transformation Extender installation. A new MKF file can be created and used instead of the default file. See the sections on MKF files in the “Variables” documentation for information about creating a master key file.

A configuration property value can be encrypted in both Windows and Linux installations of IBM Sterling Transformation Extender. Encryption can be performed in place. This means that the value is read from the config.yaml file and replaced with an MKF encryption expansion expression. Alternatively, a value to be encrypted can be provided in a command line. The encryption tools use a JSON Pointer string to refer to the configuration property value to be encrypted.

For a Windows installation:

1. Open an administrator shell, and change the working directory to <installation root>/DesignServer
2. Execute the following script using either the -inplace option or not.
 - a. **encryptproperty.bat -inplace <JSON Pointer config.yaml path>**
 - b. **encryptproperty.bat <JSON Pointer config.yaml path> <string to encrypt>**

For a Linux installation:

1. Under an appropriate user, open a shell.
2. Execute command IBM Sterling Transformation Extender encrypt with the appropriate arguments. For example, from the installation root directory, execute one of:
 - a. **./IBM Sterling Transformation Extender encryptproperty -inplace <JSON Pointer config.yaml path>**
 - b. **./IBM Sterling Transformation Extender encryptproperty <JSON Pointer config.yaml path> <string to encrypt>**

Customizing the Trace

This section describes how effectively you can configure custom trace settings for IBM Sterling Transformation Extender Rest execution. This will allow you to make the level of logging and information displayed according to your needs, enhancing the troubleshooting and analysis process.

- [Customizing the Trace for IBM Sterling Transformation Extender Rest Execution](#)

Customizing the Trace for IBM Sterling Transformation Extender Rest Execution

About this task

To customizing the trace for IBM Sterling Transformation Extender Rest execution, complete the following steps:

Procedure

1. Locate the config/config.yaml file in the data directory of the product. The data directory is configurable on Windows during the installation. On Unix, it is defined with **DTX_DATA_DIR** environment variable.
2. Open the config.yaml file using a yaml editor.
3. Find the /rest/logging path in the config.yaml file. This is where you can configure the trace settings for the REST API execution.
4. To enable verbose logging, set the trace level to "ALL" or "TRACE" by updating the value associated with the trace level setting. For example:

```
/rest/logging:  
  trace_level: ALL
```

For informational messages, set the trace level to "INFO":

```
/rest/logging:  
  trace_level: INFO
```

To trace errors only, set the trace level to "ERROR":

```
/rest/logging:  
  trace_level: ERROR
```

Note: Trace level specifies the verbosity level of execution logs. The options range from least verbose to most verbose: ALL, TRACE, INFO, ERROR, and NONE. Also, to include a header that explains each row in the trace file, set the Header value as true.

5. Customize the information displayed in the log file by selecting desired columns. Use the /rest/logging/columns path to include or exclude specific trace file columns. For example, if you want to include specific columns:

```
/rest/logging/columns: (This section specifies which columns of information to show in the log entries. Each column has  
its own sub-settings, if any values set to false, so that column would not be shown.)  
  - time (Displays the time of the log entry in UTC with milliseconds)  
  - uuid (Displays the UUID of each instance.)  
  - rc (Displays the return code associated with the log entry.)  
  - rcText (Displays a text description of the error code.)  
  - msgID (Displays the ID of a trace message.)  
  - flowName (Displays the flow, node, or adapter name that generated the message.)  
  - msg (Displays the actual trace message.)
```

```
-funcName (Displays the function name)
- sourceInfo (Displays source file and line information).
```

6. Save the changes to the config.yaml file.
7. The trace file will be saved in the product logs directory (<DATA_DIR>/logs) with a naming format such as flowexecredis_<PID>_<DATE>.log.
Note: Make sure that any modifications you make to the config.yaml file is valid. To verify the config.yaml file, see [How to verify the config.yaml file](#) for detailed instructions.

How to verify the Config.yaml file

This section describes how to verify the validity of your config.yaml file after making changes in it.

When editing the config.yaml file, it is crucial to ensure that the modifications you make are valid. To verify the validity of your config.yaml file after making changes, follow these steps:

1. Open a command prompt or terminal window.
2. Run the following command:

```
flowcmdserver -v
```

This command will check the configuration file for any errors and provide feedback on its validity.

3. If the config.yaml file is valid, you should see an output similar to the following:

```
flowcmdserver.exe -v
IBM Sterling Transformation Extender
11.0.0.0(16)
(c) Copyright IBM Corporation 2006, 2023 All rights reserved.
Configuration loaded from <Program Data Folder>\config\config.yaml
```

This indicates that your configuration file is valid and successfully loaded.

4. If there are any issues with the config.yaml file, you will receive an error message similar to the following:

```
flowcmdserver.exe -v
IBM Sterling Transformation Extender
11.0.0.0(16)
(c) Copyright IBM Corporation 2006, 2023 All rights reserved.
Failed to load yaml file. illegal map value line=53 column=6
Configuration file is C:\IBM\TransformationExtender_11.0.0\config\config.yaml
```

This error message will provide details about the specific problem in the configuration file.

Note: Make sure to carefully review any error messages and correct the issues in your config.yaml file accordingly. This step is essential to ensure the proper functioning of your system after making changes.

Enhancing Security, preventing Server Side Forgery Requests attacks

Server Side Forgery Requests (SSFR) are attacks that involve port and network scanning, as well as probing at the backend of a web application, using the application's built-in capabilities. ITX Design Server has two capabilities that can be misused to perform SSFR attacks:

1. When an end user defines the ITX Design Server REST API connection parameters while designing REST API service endpoints (services are designed using the ITX Design Server's services functionality), SSFR can be performed by manipulating the external endpoint connection parameters. This can be done by pointing the REST URL connections to intranet addresses or by pointing to external URL internet addresses.
2. When an end user defines runtime server connections (runtime server connections are designed using the ITX Design Server's servers functionality, and the created servers are used to deploy flows, maps, and endpoints), SSFR can be performed by manipulating the server URL. This can be done by pointing the URL to intranet addresses or by pointing to external URL internet addresses.

To mitigate SSFR attacks, ITX Design server offers protection through fine tuning of config.yaml settings:

```
"""
...
server:

# Defines minimum timeout for the runtime server connection test
# This feature prevents port scans using SSF
testConnectionMinimumTimeout: 6

runtime:
  #Deployment is allowed only to this list of runtime servers
  servers:
    - localhost:8443
    - localhost:9443
    - localhost:8080
    - tx-rest:8443
    - tx-rest:8080

  services:
    endpoints:
      # List any addresses that should be blocked in service endpoint URLs
      # Block local and private network requests to prevent SSF attacks
      blacklist:
        - "0.0.0.0-255.255.255"
        - "127.0.0.0-127.255.255.255"
        - "169.254.0.0-169.254.255.255"
        - "100.64.0.0-100.127.255.255"
```

```

    - "10.0.0.0-10.255.255.255"
    - "192.168.0.0-192.168.255.255"
    - "172.16.0.0-172.31.255.255"
    - "localhost"
#If set to true, allow only connections to endpoints that are whitelisted
enable_whitelist: false
whitelist:
    - "127.0.0.1"
    - "localhost"
    - "myserver3:port"
...
...

```

Installation

Everything you need to know to install IBM Sterling Transformation Extender.

- [Windows installer](#)

This documentation describes how to install the IBM Sterling Transformation Extender using the Windows Installer.

- [Linux installation](#)

You have the choice of three installation types: Native, Docker, and Podman.

- [Using the OneDB wire listener as a MongoDB server](#)

The OneDB wire listener may be used in place of a MongoDB server when it is suitably configured.

- [IBM Sterling Transformation Extender design data](#)

The documentation provided here describes data backup, data restoration, and data migration of IBM Sterling Transformation Extender design data.

Windows installer

This documentation describes how to install the IBM Sterling Transformation Extender using the Windows Installer.

- [IBM Sterling Transformation Extender Server Components](#)

The IBM Sterling Transformation Extender windows installation has the following components:

- [Installation prerequisites](#)

If you have a previous version of IBM Sterling Transformation Extender installed, you must uninstall it completely. IBM Sterling Transformation Extender windows installation does not support multiple IBM Sterling Transformation Extender installations on a single computer.

- [Installation procedures](#)

- [Starting and Stopping IBM Sterling Transformation Extender application](#)

After Installing, to start and stop IBM Sterling Transformation Extender , follow the steps:

- [Accessing IBM Sterling Transformation Extender](#)

Instructions for accessing the IBM Sterling Transformation Extender.

- [Customizing the installation](#)

IBM Sterling Transformation Extender customization instructions.

- [Customizing the Redis and IBM Sterling Transformation Extender Databases](#)

IBM Sterling Transformation Extender installation includes Redis server. If you want to use a preinstalled Redis server, you must customize your IBM Sterling Transformation Extender installation.

- [Customizing IBM Sterling Transformation Extender URL and Selecting HTTPS protocol](#)

- [Uninstalling IBM Sterling Transformation Extender](#)

Instructions for uninstalling IBM Sterling Transformation Extender.

- [Troubleshooting the installation](#)

In the case of IBM Sterling Transformation Extender Install/Start/Stop errors, review the log files from this folder:

- [Troubleshooting IBM Sterling Transformation Extender installation process](#)

If IBM Sterling Transformation Extender installation fails, verify that ports listed in the table are available on your machine.

- [Manually updating Apache Tomcat 9 for the IBM Sterling Transformation Extender application](#)

This procedure defines the steps to manually update the installed Apache Tomcat 9 software for the IBM Sterling Transformation Extender application. If the currently installed version of Apache Tomcat 9 has a security issue that is resolved in a later version, you can follow these steps to update it.

IBM Sterling Transformation Extender Server Components

The IBM Sterling Transformation Extender windows installation has the following components:

- An IBM Sterling Transformation Extender design time, used to design Schemas, Maps and Flows. The IBM Sterling Transformation Extender design time is a Web based application, runs on a Node.js Application Server and on a Tomcat Application Server. IBM Sterling Transformation Extender design time is also referred by the Windows IBM Sterling Transformation Extender installer as IBM Sterling Transformation Extender Server.
- An IBM Sterling Transformation Extender runtime (REST API), used to run Maps and Flows, runs on a Tomcat Application Server.
- An IBM Sterling Transformation Extender design time MongoDB Database that stores User accounts and IBM Sterling Transformation Extender Map and Flow designs. The database requires the MongoDB server to be available before installation is started. Optionally OneDB can be used instead of MongoDB.
- An IBM Sterling Transformation Extender design time execution engine, the runtime that runs designed Maps and Flows directly from the IBM Sterling Transformation Extender UI.
- A Redis server, is used by the IBM Sterling Transformation Extender runtime and design-time for communication purposes. The IBM Sterling Transformation Extender windows installer installs Redis server as default option. IBM Sterling Transformation Extender can be configured to use preinstalled Redis server.

A Windows IBM Sterling Transformation Extender installation typically installs runtime and design time, you can customize the installation and select to install IBM Sterling Transformation Extender runtime or design time.

Installation prerequisites

If you have a previous version of IBM Sterling Transformation Extender installed, you must uninstall it completely. IBM Sterling Transformation Extender windows installation does not support multiple IBM Sterling Transformation Extender installations on a single computer.

Before you install IBM Sterling Transformation Extender design time on a Windows computer, verify that MongoDB Server is available on the network (Instead of MongoDB, OneDB with MongoDB json listener can be used to store the IBM Sterling Transformation Extender database). The IBM Sterling Transformation Extender windows Installer will present you the MongoDB connection configuration dialog, and test the MongoDB connection with the specified parameters, the installation will not continue if MongoDB connection test fails.

Note: Refer to the Recommendations for configuring the OneDB wire listener documentation, if a OneDB wire listener will be used instead of a MongoDB server.

- [**Verify that the following ports are available on your machine**](#)

Required ports and related IBM Sterling Transformation Extender configuration properties:

- [**Data folders used by IBM Sterling Transformation Extender**](#)

Required data folders and related IBM Sterling Transformation Extender configuration properties:

- [**Additional data folders**](#)

This version of IBM Sterling Transformation Extender Windows installation introduces additional data folders that are used to store the IBM Sterling Transformation Extender configuration files, logs, examples and temporary files, Table below lists new data folders and its default location and description.

Verify that the following ports are available on your machine

Required ports and related IBM Sterling Transformation Extender configuration properties:

Default Port	Used by IBM Sterling Transformation Extender features	Configuration file location (relative to the IBM Sterling Transformation Extender installation folder)	Configuration property name
4443	IBM Sterling Transformation Extender Server	config\config.yaml	/client/inbound/port
80	IBM Sterling Transformation Extender Server	config\config.yaml	/client/inbound/protocol (To activate https protocol client.inbound.protocol must be set to https)
8080	Runtime and IBM Sterling Transformation Extender Server	config\config.yaml	TomcatPingURL TomcatPortHttp AppDocsURL_tx-rest Note: These properties are controlled by config.yaml properties tomcat.inbound.* Note: Do not change these properties manually as these properties are updated automatically by the ITX installer and ITX start stop commands.
8443	Runtime and IBM Sterling Transformation Extender Server	config\config.yaml	authentication.server (used only If the authentication of the runtime is enabled, authentication.basic.auth.enabled property must be set to true) TX_SERVER_HOST Note: These properties are controlled by config.yaml properties tomcat.inbound.* Note: Do not change these properties manually as these properties are updated automatically by the ITX installer and ITX start stop commands.
8005	Runtime and IBM Sterling Transformation Extender Server	config\config.yaml	client.outbound settings

The IBM Sterling Transformation Extender windows installation will present you with a dialog that allows you to configure the IBM Sterling Transformation Extender design time (IBM Sterling Transformation Extender UI) ports, typically 4443 and 80. The installation verifies that the port is available on the machine. The installation will not continue if the port is not available.

Also, the IBM Sterling Transformation Extender Windows installer opens a dialog that allows you to configure IBM Sterling Transformation Extender application server ports (typically ports 8080, 8443 and 8005). The Installation verifies that the selected ports are available on the machine. The installation will not continue if those ports are not available. The Event Reporter, port 15901 from the table, must be manually verified to ensure that the port is available

Data folders used by IBM Sterling Transformation Extender

Required data folders and related IBM Sterling Transformation Extender configuration properties:

This table lists data folders used by the IBM Sterling Transformation Extender application. Verify that the free disk space is large enough to contain the IBM Sterling Transformation Extender data, 50GB of free disk space should be enough in most cases.

Default folder location	Used by IBM Sterling Transformation Extender feature	Configuration property name
C:\IBM\txfiles	IBM Sterling Transformation Extender Server	/server/persistence/files
C:\IBM\txmodules	IBM Sterling Transformation Extender Server	/server/persistence/modules
C:\IBM\txlibs	IBM Sterling Transformation Extender Server	/server/persistence/libs
C:\data	IBM Sterling Transformation Extender Server	/rest/persistence/files
C:\data\maps	Runtime	/rest/persistence/maps
C:\data\config	Runtime	/rest/persistence/config
C:\data\tmp	Runtime	/rest/persistence/work
C:\data\log	Runtime	/rest/persistence/log

Additional data folders

This version of IBM Sterling Transformation Extender Windows installation introduces additional data folders that are used to store the IBM Sterling Transformation Extender configuration files, logs, examples and temporary files, Table below lists new data folders and its default location and description.

Default location	Used by IBM Sterling Transformation Extender feature	Description
C:\ProgramData\IBM\TransformationExtender_<version>	All components	Base data folder location, this location is selected during the ITX Windows InstallShield procedure at the beginning of the installation process.
C:\ProgramData\IBM\TransformationExtender_<version>\logs	All components	Stores Tomcat service, Flow execution runtime service, and NodeJS design time log files.
C:\ProgramData\IBM\TransformationExtender_<version>\examples	All components	Stores the example files.
C:\ProgramData\IBM\TransformationExtender_<version>\config	All components	Stores the config.yaml configuration file. Encryption key file used to encrypt/decrypt config.yaml property values and resource registry values
C:\ProgramData\IBM\TransformationExtender_<version>\tmp	All components	Used to store temporary files by runtime and design time services.

Installation procedures

- [**Installing IBM Sterling Transformation Extender Server with Install Shield**](#)

To install IBM Sterling Transformation Extender, complete the following steps:

- [**Manually Installing IBM Sterling Transformation Extender Server and Runtime**](#)

The IBM Sterling Transformation Extender Install Shield typically installs all the features. If you do not select IBM Sterling Transformation Extender Server and Runtime at IBM Sterling Transformation Extender Install Shield Installation time, you can install them later.

- [**Post installation action**](#)

Modify Windows user access to IBM Sterling Transformation Extender application.

- [**Modify an existing installation**](#)

If you modify any of the settings in <installation root>\config\config.yaml, then you must restart the IBM Sterling Transformation Extender application.

Installing IBM Sterling Transformation Extender Server with Install Shield

To install IBM Sterling Transformation Extender, complete the following steps:

1. Copy the .exe file that you downloaded at the time of purchase into a directory called IBM on your computer.
2. Double click on the .exe file.
3. Install Shield opens to guide you through the installation process.

Manually Installing IBM Sterling Transformation Extender Server and Runtime

The IBM Sterling Transformation Extender Install Shield typically installs all the features. If you do not select IBM Sterling Transformation Extender Server and Runtime at IBM Sterling Transformation Extender Install Shield Installation time, you can install them later.

Use these steps to manually install IBM Sterling Transformation Extender Server and runtime:

1. Configure your IBM Sterling Transformation Extender Server and runtime installation by making any required changes to C:\ProgramData\IBM\TransformationExtender_<version>\config\config.yaml.
2. Open a Windows terminal window, and select Run as administrator.
3. Go to the installation directory of the IBM Sterling Transformation Extender base product.
4. Run the command: clean.bat
5. Run the command: install.bat

Post installation action

Modify Windows user access to IBM Sterling Transformation Extender application.

By default, all Windows users that are logged in can modify files and folders used by IBM Sterling Transformation Extender application. To limit access to IBM Sterling Transformation Extender to a specific Windows user, assign the IBM Sterling Transformation Extender services “Log On” credentials and the IBM Sterling Transformation Extender files access privileges to a specific Windows user account.

1. Open the Windows services management console.
2. Decide Windows user to run the IBM Sterling Transformation Extender services.
3. Modify the following IBM Sterling Transformation Extender Windows services “Log On” credentials by selecting this account option and providing Windows credentials for the selected user from step 2:
 - a. “Apache Tomcat 9.0 IBM Sterling Transformation Extender”
 - b. “redis server for IBM Sterling Transformation Extender”
 - c. “IBM Sterling Transformation Extender WEB UI”
4. Give write access to all IBM Sterling Transformation Extender folders to the user which was selected in step 2. For the list of folders used by IBM Sterling Transformation Extender, refer to the “Data folders by IBM Sterling Transformation Extender” table in the “Installation prerequisites” section.

Modify an existing installation

If you modify any of the settings in <installation root>\config\config.yaml, then you must restart the IBM Sterling Transformation Extender application.

In addition, if you change any variable in the config.yaml file, you must restart the application following the steps:

1. Open a Windows terminal window and select Run as administrator.
2. Run the command: <install_dir>\stop.bat
3. Run the command: <install_dir>\install.bat

Starting and Stopping IBM Sterling Transformation Extender application

After Installing, to start and stop IBM Sterling Transformation Extender , follow the steps:

1. You can open a shell with the appropriate privileges, and change the current folder to c:\IBM\IBM Sterling Transformation Extender_<version>\DesignServer
2. To start the server run, the start.bat command. The server start time might take several minutes depending on the performance of your computer.
3. To stop the server, run the stop.bat command. The server should stop in several seconds.

Accessing IBM Sterling Transformation Extender

Instructions for accessing the IBM Sterling Transformation Extender.

You can access the IBM Sterling Transformation Extender web UI by pointing the web browser to the local URL: <https://localhost:4443/login>. To login for the first time, use username “admin” and the initial administrator password which is stored in c:\IBM\txfiles\adminpassword.txt. After you log in, change the initial password of the administrator account.

After changing the administrator account password, the password file can be deleted.

Customizing the installation

IBM Sterling Transformation Extender customization instructions.

IBM Sterling Transformation Extender customization can be performed by editing settings in the file: c:\IBM\IBM Sterling Transformation Extender_<version>\config\config.yaml

Review the file content for detailed description of all customization options.

Customizing the Redis and IBM Sterling Transformation Extender Databases

IBM Sterling Transformation Extender installation includes Redis server. If you want to use a preinstalled Redis server, you must customize your IBM Sterling Transformation Extender installation.

Redis customization instructions are written in the config.yaml file. Locate the “redis:” section, ND modify Redis host and port settings to match your environment and then restart the IBM Sterling Transformation Extender application.

Customizing IBM Sterling Transformation Extender URL and Selecting HTTPS protocol

The IBM Sterling Transformation Extender default URL
<https://localhost:4443/login>
uses HTTPS protocol on port 4443.

If you want to use a non-default port and HTTPS, then you must update the client inbound settings in the configuration file <install_dir>/config/config.yaml section:

- server.inbound.port
- server.inbound.protocol
- server.inbound.host

For detailed instruction see the config.yaml file.

Uninstalling IBM Sterling Transformation Extender

Instructions for uninstalling IBM Sterling Transformation Extender.

Follow this procedure to uninstall IBM Sterling Transformation Extender:

1. Start Windows system settings console by typing "Add or remove programs" in the windows search dialog.
2. Select "IBM Sterling Transformation Extender <version number> runtime" from the list of programs.
3. Click on the "Uninstall" button.

Troubleshooting the installation

In the case of IBM Sterling Transformation Extender Install/Start/Stop errors, review the log files from this folder:

c:\IBM\IBM Sterling Transformation Extender_<version number>\DesignServer

The install.log/start.log/stop.log logs contain information about the issues and steps you will need to resolve these issues.

- [Manually Uninstalling the IBM Sterling Transformation Extender](#)

Follow these Instructions on how to uninstall the IBM Sterling Transformation Extender manually.

Manually Uninstalling the IBM Sterling Transformation Extender

Follow these Instructions on how to uninstall the IBM Sterling Transformation Extender manually.

If the IBM Sterling Transformation Extender installation gets corrupted and the uninstall procedure does not work, follow these steps to uninstall the application manually.

1. Open the Windows terminal with administrative privileges.
2. Uninstall IBM Sterling Transformation Extender services:

a. To uninstall the IBM Sterling Transformation Extender WEB UI, run the following commands:

```
sc stop ibmsterlingtransformationextenderwebui.exe  
sc delete ibmsterlingtransformationextenderwebui.exe
```

b. To uninstall the IBM Sterling Transformation Extender Application Server Service, run the following commands:

```
sc stop "IBM-Sterling-Transformation-Extender"  
sc delete "IBM-Sterling-Transformation-Extender"
```

c. To uninstall the IBM Sterling Transformation Extender Redis Service, run the following commands:

```
sc stop "redis server for ibm transformation extender"  
sc delete "redis server for ibm transformation extender"
```

3. Cleanup registry (ensure you create a backup of the registry keys before modifying the keys).

- a. Run command regedit.
- b. Navigate to the registry key Computer\HKEY_LOCAL_MACHINE\SOFTWARE\IBM\Transformation Extender
- c. Delete the registry key.
- d. Navigate to the registry key Computer\HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Apache Software Foundation\Procrun 2.0\IBM.
- e. Delete the registry key.
- f. Search for the string 'IBM Sterling Transformation Extender' Under Computer\HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\Windows\CurrentVersion\Uninstall.
- g. Delete the registry Key containing the String 'Transformation Extender'.

4. Restart the computer.

5. Delete the IBM Sterling Transformation Extender installation folder, for example, C:\IBM\IBM Sterling Transformation Extender_<version>.

Troubleshooting IBM Sterling Transformation Extender installation process

If IBM Sterling Transformation Extender installation fails, verify that ports listed in the table are available on your machine.

To verify the required port availability, follow this procedure:

1. Open the windows terminal with administrative privileges.
2. Run the command for each of the listed ports

```
powershell -command  
" (Get-NetTCPConnection -LocalPort <port  
number>) .OwningProcess"
```

Note: If any of the ports are occupied, command will return the owning process id.

If any of the ports are already used by some other applications, either uninstall the port owning application, or change the default port values. You can change the related port configuration parameters:

1. During IBM Sterling Transformation Extender InstallShield installation.
2. Post installation, you will need to reinstall IBM Sterling Transformation Extender as described in the table below.

Refer Installation prerequisites section for "Ports used by IBM Sterling Transformation Extender application" table.

Manually updating Apache Tomcat 9 for the IBM Sterling Transformation Extender application

This procedure defines the steps to manually update the installed Apache Tomcat 9 software for the IBM Sterling Transformation Extender application. If the currently installed version of Apache Tomcat 9 has a security issue that is resolved in a later version, you can follow these steps to update it.

Before you begin

Important: Ensure that you back up the <IBM Sterling Transformation Extender installation folder>/restapi/ folder.

About this task

To manually update Apache Tomcat 9 for IBM Sterling Transformation Extender application on windows platform, complete the following steps:

Procedure

1. Download the latest 64-bit Windows binaries of Apache Tomcat 9 in ZIP format from the official [Apache Tomcat website](#).
2. Copy the downloaded ZIP archive into the <IBM Sterling Transformation Extender installation folder>/restapi/tomcat folder.
3. Complete the following steps:
 - a. Type **WINDOWS+R**.
 - b. Right-click the Command Prompt window and select Run as Administrator.
 - c. In the Command Prompt window, change the current directory to <IBM Sterling Transformation Extender installation folder>\DesignServer.
4. Run the following command to clean any existing Apache Tomcat installation:

```
clean.bat
```
5. Use a Text Editor to modify the dtxtomcat.ini configuration file located at the <IBM Sterling Transformation Extender installation folder>\restapi\tomcat\ location. Update the string TomcatVersion=9.0.XX to match the version of the downloaded Apache Tomcat 9 from Step 1. Save the changes.
6. From the same command prompt window folder, as mentioned in Step 3, run the following command to install Apache Tomcat:

```
install.bat
```

Linux installation

You have the choice of three installation types: Native, Docker, and Podman.

There is a consistent command line interface for the installation and management of either type. The IBM Sterling Transformation Extender script is the entry point for the CLI.

- **[IBM Sterling Transformation Extender Utility](#)**

After you extract the IBM Sterling Transformation Extender package, you can interact with the IBM Sterling Transformation Extender script to begin installation.

- **[Native installation](#)**

Procedures for installing IBM Sterling Transformation Extender using the Native installation.

- **[Docker installation](#)**

Procedures for installing IBM Sterling Transformation Extender using the Docker installation.

- **[Podman installation](#)**

Procedures for installing IBM Sterling Transformation Extender using the Podman installation.

- **[Troubleshooting](#)**

Documentation to describe how to troubleshoot an installation.

IBM Sterling Transformation Extender Utility

After you extract the IBM Sterling Transformation Extender package, you can interact with the IBM Sterling Transformation Extender script to begin installation.

See the steps provided in the Native, Docker, and Podman Installation sections of this documentation.

The IBM Sterling Transformation Extender script supports these commands:

- ITX configure: Configure the installation. Required prior to running other commands.
- ITX install: Install IBM Sterling Transformation Extender according to your configuration.
- ITX uninstall: Uninstall IBM Sterling Transformation Extender according to your configuration.
- ITX start: Start IBM Sterling Transformation Extender according to your configuration.
- ITX stop: Stop IBM Sterling Transformation Extender according to your configuration.
- ITX status: Retrieve the status of all IBM Sterling Transformation Extender components.
- ITX createuser: Create an IBM Sterling Transformation Extender user with administrative privileges.
- ITX encryptproperty: Encrypts the specified property in the configuration /home/docker_install_itx/config.yaml file.
- ITX logs: Prints the primary log of chosen component.
- ITX help: To read about a specific command.

You can view details about these commands by using the 'ITX <command> --help' option when interacting with the utility.

- **CONFIGURE command**

The CONFIGURE command is required before using any other command. This command is used to specify the installation type, the license file location, and the user/group that the installation is associated with upon completion.

- **INSTALL, UNINSTALL, START, STOP commands**

The behavior of the INSTALL, UNINSTALL, START and STOP commands is similar so we can group them for simplicity.

- **STATUS command**

The STATUS command retrieves the status of each IBM Sterling Transformation Extender component. Though the usage is similar between the native, docker, and podman installation types, the possible states are different.

- **LOGS command**

The LOGS command prints the primary log of the chosen component.

CONFIGURE command

The CONFIGURE command is required before using any other command. This command is used to specify the installation type, the license file location, and the user/group that the installation is associated with upon completion.

You can rely on the default values, but it is recommended that you specify **--type**

CONFIGURE command options

--type <native/docker/podm an>	Specify the installation type. Default: native
--integration	This option is intended for customer use only. Do not use if you purchased IBM Sterling Transformation Extender as a standalone product.
--user	The user to install IBM Sterling Transformation Extender as. This determines which user has ownership of the processes and directories. This must be an existing user. Default: current user.
--group	The group to install IBM Sterling Transformation Extender as. This provides you with the flexibility to share IBM Sterling Transformation Extender directories with a group of administrators. Default: current group

Note: You cannot change the integration type after you run install. If you notice an error after installation, you must extract the IBM Sterling Transformation Extender package into a new directory and begin again.

INSTALL, UNINSTALL, START, STOP commands

The behavior of the INSTALL, UNINSTALL, START and STOP commands is similar so we can group them for simplicity.

All commands will act upon the default components if none are specified as options. You can finetune the scope of each action by listing individual components.

INSTALL, UNINSTALL, START, STOP options

-r, --runtime	Installs the Runtime REST API used for running maps and flows.
-d, --server	Installs the Server and Client used to design, manage, and deploy maps and flows.

STATUS command

The STATUS command retrieves the status of each IBM Sterling Transformation Extender component. Though the usage is similar between the native, docker, and podman installation types, the possible states are different.

STATUS command options

-r, --runtime	Installs the Runtime REST API used for running maps and flows.
-d, --server	Installs the Server and Client used to design, manage, and deploy maps and flows.

Possible states - Native

- Not installed
- Stopped
- Running
- Unknown

Possible states - Docker

- Not installed
- Created
- Dead
- Exited
- Paused
- Running
- Restarted

Possible states - Podman

- Not installed
- Created
- Dead
- Exited
- Paused
- Running
- Restarted

LOGS command

The LOGS command prints the primary log of the chosen component.

Log files can grow to a large size. For that reason, you should pipe the output of this command into a tool like less, to facilitate better navigation.

LOG command options

-r, --runtime-app	Prints the log of the Runtime REST API Web App.
-d, --server-app	Prints the log of the Server Web App.
-c, --client	Prints the log of the Client.

Native installation

Procedures for installing IBM Sterling Transformation Extender using the Native installation.

- [**Prerequisites**](#)

Prerequisites for the Native installation.

- [**System Configuration**](#)

The documentation provided here describes how to configure the IBM Sterling Transformation Extender Native installation.

- [**Installation procedures**](#)

These instructions describe how to perform a Native installation.

- [**Manually updating Apache Tomcat 9 for the IBM Sterling Transformation Extender application**](#)

This procedure defines the steps to manually update the installed Apache Tomcat 9 software for the IBM Sterling Transformation Extender application. If the currently installed version of Apache Tomcat 9 has a security issue that is resolved in a later version, you can follow these steps to update it.

Prerequisites

Prerequisites for the Native installation.

System dependencies:

- bash (Bourne Again Shell)
- ksh (KornShell)
- libnsl
- GNU sed

Runtime dependencies:

- MongoDB Server or the OneDB wire listener.

Note: Refer to section “Using the OneDB wire listener as a MongoDB server” if a OneDB wire listener will be used instead of a MongoDB server.

System Configuration

The documentation provided here describes how to configure the IBM Sterling Transformation Extender Native installation.

To configure most properties of IBM Sterling Transformation Extender, use this file:

config.yaml

Review the **config.yaml** file before you perform the installation to confirm that the default options are as expected.

To reconfigure after the installation, update those files, and restart IBM Sterling Transformation Extender.

You will notice several directories specified in the configuration files. If you, or your group, do not have Read / Write access to these directories, contact a system administrator to create the directories and transfer ownership to you.

If you are performing the installation as a non-root user, use ports above 1024 to avoid permission issues. The default ports are:

Tomcat (REST API + Server): HTTPS 8443, HTTP 8080

UI Client: HTTPS 4443

- [Temporary directory mounting options](#)

Temporary directory mounting options are provided here.

Temporary directory mounting options

Temporary directory mounting options are provided here.

The system must not mount /tmp using the noexec option. If the system does mount /tmp using the noexec option, follow one of the two options listed here.

- [Changing the mount option for /tmp](#)

Check to see if the /tmp directory is mounted with noexec by running the following command from a command window.

```
mount | grep /tmp
```

```
tmpfs on /tmp type tmpfs (rw,nosuid,nodev,noexec,relatime)
```

Changing the mount option for /tmp

Check to see if the /tmp directory is mounted with noexec by running the following command from a command window.

```
mount | grep /tmp
```

If /tmp is mounted with noexec, follow this procedure to change the mount option for /tmp:

1. Edit **/etc/fstab** as root and remove **noexec** from the mount options of **/tmp**.
2. Reboot the system, or run the following command from a command window:

```
mount -o remount /tmp
```

Changing the IBM Sterling Transformation Extender temporary directory

To change the IBM Sterling Transformation Extender temporary directory, complete the following steps:

1. Create a new directory. Ensure that the location is not mounted with the **noexec** option. Check the output of the mount. For example, you can run the following from a command window:

```
mkdir /opt/hiptmp  
chmod 777 /opt/hiptmp
```

2. Add a new line to **tomcat-context/install/restapi/tomcat/setenv.sh** to specify the new directory. For example:

```
export JAVA_OPTS="$JAVA_OPTS -Djava.io.tmpdir=/opt/hiptmp"
```

3. Modify the existing lines in **config.yaml** for the long and short workers as shown here:

```
longTaskProcessJvmOptions="-Xmx2g -Djava.io.tmpdir=/opt/hiptmp"  
shortTaskProcessJvmOptions="-Djava.io.tmpdir=/opt/hiptmp"
```

4. Restart the IBM Sterling Transformation Extender.

Installation procedures

These instructions describe how to perform a Native installation.

Read the IBM Sterling Transformation Extender Utility documentation before following these installation instructions. You may need to adjust commands according to your use-case.

The commands shown here demonstrate a quick-start scenario:

```
./ITX configure --type native
```

```
./ITX install
```

Either start all components or continue to the troubleshooting section for any errors.

```
./ITX start
```

Manually updating Apache Tomcat 9 for the IBM Sterling Transformation Extender application

This procedure defines the steps to manually update the installed Apache Tomcat 9 software for the IBM Sterling Transformation Extender application. If the currently installed version of Apache Tomcat 9 has a security issue that is resolved in a later version, you can follow these steps to update it.

Before you begin

Important: Ensure that you back up the <IBM Sterling Transformation Extender installation folder>/tomcat-context/install/restapi/ folder.

About this task

To manually update Apache Tomcat 9 for IBM Sterling Transformation Extender application on Linux native platform, complete the following steps:

Procedure

1. Download the latest Linux binaries of Apache Tomcat 9 in **.tar.gz** format from the official [Apache Tomcat website](#).
2. Open a Linux terminal window and change the current directory to the IBM Sterling Transformation Extender installation directory <IBM Sterling Transformation Extender installation folder>.

Important: Ensure that you are logged in as the same user who initially installed the IBM Sterling Transformation Extender application.

3. Execute the following commands to stop and uninstall the current IBM Sterling Transformation Extender installation:

```
./ITX stop  
./ITX uninstall
```

4. Change the current directory to the installation directory <IBM Sterling Transformation Extender installation folder>/tomcat-context, run the following command:

```
cd <IBM Sterling Transformation Extender installation folder>/tomcat-context
```

5. Create a temporary folder and extract the contents of IBM Sterling Transformation Extender hip-core.tar.gz to it, run the following command:

```
mkdir tmp  
tar -xf hip-core.tar.gz -C tmp
```

6. Copy the downloaded **.tar.gz** binaries into <IBM Sterling Transformation Extender installation folder>/tomcat-context/tmp/restapi/tomcat folder.

7. Open the dtxtomcat.ini configuration file located at <IBM Sterling Transformation Extender installation folder>/tomcat-context/tmp/restapi/tomcat/ location using a Text Editor. Update the string TomcatVersion=9.0.XX to match the version of the downloaded Apache Tomcat 9 from Step 1. Save the changes.

8. Update the IBM Sterling Transformation Extender hip-core.tar.gz file by running the following command from the <IBM Sterling Transformation Extender installation folder>/tomcat-context/tmp folder:

```
tar -czf .. /hip-core.tar.gz .
```

9. Change the current directory to the IBM Sterling Transformation Extender installation directory <IBM Sterling Transformation Extender installation folder>, by running the following command:

```
cd <IBM Sterling Transformation Extender installation folder>
```

10. Execute the following commands to install and start IBM Sterling Transformation Extender:

```
./ITX install  
./ITX start
```

Docker installation

Procedures for installing IBM Sterling Transformation Extender using the Docker installation.

Note: Before you continue with any of the procedures in this section, make sure certain Docker is installed.

Note: IBM Sterling Transformation Extender does not offer Docker installation compatibility on Red Hat platforms version 8 and beyond.

- [Docker configuration](#)
Description of how to configure your Docker installation.
- [Installation](#)
Procedures in this documentation describe how to perform a Docker installation.

Docker configuration

Description of how to configure your Docker installation.

To configure most properties of IBM Sterling Transformation Extender, use this file:

`config.yaml`

Review the **config.yaml** file before you perform the installation to confirm that the default options are what you expect.

To reconfigure after installation, update those files, and restart IBM Sterling Transformation Extender.

You will notice several directories specified in the configuration files. If you, or your group, do not have Read / Write access to these directories, you will need a system administrator to create the directories and transfer ownership to you.

If you are installing as a non-root user, use ports above 1024 to avoid permission issues. The default ports are:

REST API: HTTPS 9443, HTTP 8080

Server: HTTPS 8443

UI Client: HTTPS 4443

Installation

Procedures in this documentation describe how to perform a Docker installation.

Read the IBM Sterling Transformation Extender Utility documentation before following the installation steps. You may need to adjust commands according to your use-case.

The commands shown here demonstrate a quick-start scenario.

`./ITX configure --type docker`

`./ITX install`

Either start all components or continue to the troubleshooting section for any errors.

`./ITX start`

Podman installation

Procedures for installing IBM Sterling Transformation Extender using the Podman installation.

On the RedHat Linux distribution, IBM ITX application installation supports Podman installation types. On other Linux distributions (For example: Ubuntu), IBM ITX supports both Docker and Podman container engines. Select Podman method for ITX installation.

Prerequisites

Before installing ITX in Podman mode, ensure that the ITX installation folder and data folders are not located on a network file system. The ITX application and its data must be on the local computer's file system. Additionally, do not inherit data folders from previous ITX installations of different types.

The **config.yaml** file specifies the ITX data folders. Make sure these folders and their subfolders are located on the local computer's file system:

- `/opt/data`
- `/opt/itx`
- `/opt/txfiles`
- `/opt/txmodules`
- `/opt/txlibs`
- `/opt/tx-rest`
- `/tmp`

Podman Configuration

To configure the ITX installation to Podman mode, run the following command:

`./ITX configure -type podman`

Installation Procedures

After configuring the ITX installation to install in Podman mode, run the following command:

`./ITX install`

Troubleshooting

Documentation to describe how to troubleshoot an installation.

Most installation issues include an error message printed either to your terminal, or written to `<command>.log`

For any errors relating to start up of a component, check the log for the component. Use the `logs` command to view the log.

Common errors

Error:

IBM Sterling Transformation Extender client logs show *ENOSPC: System limit for number of file watchers reached*

Solution:

Increase the inotify max_user_watches property.

```
echo fs.inotify.max_user_watches=524288 | sudo tee -a /etc/sysctl.conf
```

```
sudo sysctl -p
```

Using the OneDB wire listener as a MongoDB server

The OneDB wire listener may be used in place of a MongoDB server when it is suitably configured.

OneDB wire listener configuration recommendations:

- Choose a MongoDB API version for the value of the mongo.api.version configuration property that is compatible with the installed version of IBM Sterling Transformation Extender.
 - Error messages may occur in the IBM Sterling Transformation Extender User Interface, if the wire listener uses a short idle connection timeout value for the value of the listener.idle.timeout configuration property. A suitable large value, for example a timeout of 12 hours (listener.idle.timeout=43200000), should be used. If appropriate, idle connection closure may be disabled (listener.idle.timeout=0).
-

IBM Sterling Transformation Extender design data

The documentation provided here describes data backup, data restoration, and data migration of IBM Sterling Transformation Extender design data.

- [Design data storage](#)
This documentation describes data stores used by IBM Sterling Transformation Extender for design activities, and data storage configuration.
 - [Design data backup and migration](#)
Overview of backing up and restoring, or migrating data used by IBM Sterling Transformation Extender for design activities.
-

Design data storage

This documentation describes data stores used by IBM Sterling Transformation Extender for design activities, and data storage configuration.

For design activities, an IBM Sterling Transformation Extender installation uses these data stores:

- Databases which are managed by a MongoDB server
- Directories in a file system.

When you install IBM Sterling Transformation Extender, configuration information for each of these data stores is provided. This information resides in a configuration file. Depending upon the operating system, the path to the configuration file is as follows:

- Windows: <Data directory>\config\config.yaml, for more details see [Additional data folders](#).
 - Linux (native and docker installations): <installation directory>/config.yaml
-

Design data backup and migration

Overview of backing up and restoring, or migrating data used by IBM Sterling Transformation Extender for design activities.

Note: Due to the variability in MongoDB installations and file system configuration, the exact steps for backing up and restoring design data will vary between individual IBM Sterling Transformation Extender installations.

- [MongoDB database operations](#)
 - [Filesystem data backup and restore](#)
-

MongoDB database operations

This documentation includes a description of how to back up the design databases and how to restore the databases.

The documentation also includes an example of commands that can be executed in order to migrate from a local MongoDB server instance to a remote MongoDB server instance.

- [Design databases](#)
IBM Sterling Transformation Extender uses a master database and a resource database to store some of its design data.

- [**Additional accounts**](#)

Additional accounts may be associated with a MongoDB server instance. Each account is associated with its own account ID and resource database. The account ID is stored in the accounts collection in the manner described above. Additional accounts are not present in default IBM Sterling Transformation Extender installations.

- [**Backing up and restoring databases**](#)

Backing up the design databases consists of backing up the master database and each resource database. Similarly, restoring the design databases, whether to a previously used, or to a new MongoDB server instance, consists of restoring the master database and each backed up resource database.

- [**MongoDB migration example**](#)

This documentation describes example commands for MongoDB server instance migration with a native Linux IBM Sterling Transformation Extender installation.

Design databases

IBM Sterling Transformation Extender uses a master database and a resource database to store some of its design data.

The name of the master database was provided during IBM Sterling Transformation Extender installation by the value of /mongo/masterDb in config.yaml. During a Windows installation, the value of this property is usually provided through the installation wizard. The default value for this configuration property in a stand-alone IBM Sterling Transformation Extender installation is mdb. Other names may be used in different contexts.

An IBM Sterling Transformation Extender installation is associated with a default account. The default account is named Default. This name is present as the value of the name property of an account object in the accounts collection of the master database. The default account is associated with an account ID. This account ID is the value of the _id property of the account object in the collection.

A single resource database is created during default installation. The resource database is named using the pattern rdb_<account ID>. The master database and the resource database which is associated with the default account store IBM Sterling Transformation Extender project information and related resources.

An example MongoDB shell session is given below, which shows how the default account ID can be determined. The name of the master database is assumed to be "mdb"

- use mdb
- db.accounts.find({“name”: “Default”})
 - A query result such as the following should be returned
 - [{ _id: ‘61532e49396b627364f9953e’, name: ‘Default’ }]
 - 61532e49396b627364f9953e is the ID of the default account in this example.
 - A resource database named rdb_61532e49396b627364f9953e would be present in this example

Additional accounts

Additional accounts may be associated with a MongoDB server instance. Each account is associated with its own account ID and resource database. The account ID is stored in the accounts collection in the manner described above. Additional accounts are not present in default IBM Sterling Transformation Extender installations.

Backing up and restoring databases

Backing up the design databases consists of backing up the master database and each resource database. Similarly, restoring the design databases, whether to a previously used, or to a new MongoDB server instance, consists of restoring the master database and each backed up resource database.

For Linux Docker installations: For IBM Sterling Transformation Extender installations on a Linux system using Docker, the MongoDB container configuration must be known to perform MongoDB database backups. For default Docker installations, the container name is hip-server-mongo. For example, a backup could be performed by starting an interactive terminal session in the running container and dumping the master and resource databases to a directory within the container. The dumped data could then be copied out of the container.

If MongoDB databases are being migrated to a new MongoDB server instance, you must remember to update the MongoDB connection properties in the appropriate IBM Sterling Transformation Extender configuration file.

In general, it must be considered if IBM Sterling Transformation Extender downtime is necessary when migrating between MongoDB server instances. In the simplest case, IBM Sterling Transformation Extender would be stopped, the design databases would be backed up, and the restore operation in the new MongoDB server instance would be performed. The IBM Sterling Transformation Extender installation configuration update operation would then be updated, and IBM Sterling Transformation Extender could be started with the new configuration.

MongoDB migration example

This documentation describes example commands for MongoDB server instance migration with a native Linux IBM Sterling Transformation Extender installation.

This example shows commands which could be executed to migrate from a local MongoDB server instance to a remote MongoDB server instance. This example assumes that default configuration properties were used when IBM Sterling Transformation Extender was installed natively on the Linux host.

Note: The utilities mongodump and mongorestore might not be appropriate for use with a particular MongoDB server instance. Also, use of these utilities is subject to constraints. These constraints are described in MongoDB database tools documentation.

This example assumes that the target MongoDB server instance has been configured and is accessible using the standard MongoDB port from host <MongoDB host>. It is also assumed that the MongoDB database tools have been installed, so that mongodump and mongorestore are available.

Refer to the following Bash session:

1. Stops IBM Sterling Transformation Extender using the IBM Sterling Transformation Extender utility shell script.

- a. cd <IBM Sterling Transformation Extender installation directory>
 - b. ./ITX stop
 2. Creates a backup of the master database and the resource database. A directory named dump is created in the IBM Sterling Transformation Extender installation directory by mongodump. This directory holds the backups. Standard output and standard errors are appended to file itx_mongodump.log.
 - a. mongodump --db=mdb &>> itx_mongodump.log
 - b. mongodump --db=rdb_<account ID> &>> itx_mongodump.log
 3. Restores the dumped databases into the target MongoDB server instance. Standard output and standard error are appended to file itx_mongorestore.log.
 - a. mongorestore --host=<MongoDB host> &>> itx_mongorestore.log
 4. The configuration file config.yaml in <IBM Sterling Transformation Extender installation directory> must be edited to reflect the change in the location of the MongoDB server. Assuming that the default MongoDB port and a remote host are used, the value of the "host" key of the object value of the top-level "mongo" key (mongo.host) must be set to the remote host.
 5. Starts IBM Sterling Transformation Extender after updating the MongoDB server configuration. The updated values are read.
 - a. ./ITX start
 6. After confirming that IBM Sterling Transformation Extender operates with the new MongoDB server instance as expected, the dump directory should be removed:
 - a. rm -r dump
-

Filesystem data backup and restore

IBM Sterling Transformation Extender uses several file system directories to store design data. They are shown below using JSON Pointer strings to refer to a mapping value in the IBM Sterling Transformation Extender config.yaml file:

- server.persistence.files
- server.persistence.modules
- server.persistence.libs
- rest.persistence.files

Backing up filesystem design data consists of creating a backup of these directories. The backup process varies depending upon the configuration of the filesystems used to store these directories and their contents.

Restoring filesystem design data consists of populating these directories with their backed-up contents. A change in the location of one or more of these directories during a restore operation might be desired. As for a change in the IBM Sterling Transformation Extender configuration for accessing a MongoDB server instance, such a change in location is allowed, and is handled by the general IBM Sterling Transformation Extender installation configuration update operation.

- [Filesystem data migration example](#)
-

Filesystem data migration example

As an example, suppose an IBM Sterling Transformation Extender installation initially used directories on a local filesystem for the values of /server/persistence/files, /server/persistence/modules, /server/persistence/libs and /rest/persistence/files in config.yaml. If a change in the locations of these directories is desired, then the following steps could be used for file system design data migration:

1. Start an administrator command prompt session. Execute the following commands.
 2. Stops the IBM Sterling Transformation Extender installation:
 - a. cd <IBM Sterling Transformation Extender installation directory>\DesignServer
 - b. .\stop.bat
 3. Back up the directories.
 4. Create new directories in their new locations and populate them with the appropriate backed-up data.
 5. Update, as necessary, the values of server/persistence/files, /server/persistence/modules, /server/persistence/libs and /rest/persistence/files in <Link installation directory>\config\config.yaml.
 6. Starts IBM Sterling Transformation Extender after the configuration update.
 - a. .\start.bat
-

Administration

This documentation describes those administration tasks required for Design Server.

User Management

Design Server provides inbuilt support for managing users who may create, deploy and run integrations.

Users are assigned one of these roles:

- Administrator – Full access to all features of Design Server.
- Designers – They can create and modify projects and any artifacts within a project. A designer cannot access user management, cannot deploy projects, cannot import projects and cannot delete projects.

To administer users and user groups, you must have user Administrator privileges. When you first install Design Server an initial administrator user is created named admin with password admin. After installation, the password of this user should be changed.

- [Managing user accounts](#)

You can access the user management interface by performing the following steps:

- [Add a user](#)

These procedures describe how to use Design Server to add a new user.

Managing user accounts

You can access the user management interface by performing the following steps:

1. Login to the Design Server as an administrator.
2. Click the Username at the top of the screen to access the menu.
3. From the drop-down menu select Administration.

From the **Administration** window, an administrator can perform these tasks:

- Create new users
- Edit users details
- Change user's passwords
- Release locks for artifacts locked by a user

Add a user

These procedures describe how to use Design Server to add a new user.

To add a new user, login to Design Server as an Administrator, and then follow these steps on the Welcome page:

1. Click the drop-down arrow next to the Administrator tab in the upper right corner of the Welcome page.
2. Select the Administration option from the menu. The Users window opens.
3. Click the plus sign icon located to the right of the Search box at the top of the page to open Add User.
4. Complete all of the fields in Add User area with the new user's information. Be aware of the following when completing the fields:
 - The password that you assign must be at least eight characters in length and contain at least one number and one character that is neither a number or a letter.
 - In most cases the Role field will remain in its default condition and will display the Designer option.
5. Click the Add button at the bottom of the page. You are returned to the Users page. The user that you added appears in the list of users.

Introduction

Keycloak is an open-source identity and Access Management solution. It is a single sign-on security application for web applications and RESTful web services. Design Server and Runtime REST API supports Keycloak solution of user administration for authentication and authorization.

Existing user databases hold user credentials. Keycloak federates these existing external user databases through the concept of storage providers. By default, Keycloak supports an LDAP and Active Directory storage provider.

When an user tries to access the Design Server Web-console, the browser is redirected to Keycloak authentication system to authenticate user credentials. User gets a reference token from the Keycloak to connect to the server.

Installation

See [Getting Started](#) guide for installation of Keycloak.

User Administration

After you install Keycloak, you must consider how the software manages users and authentication.

You can review the default user management provided by the Keycloak server and decide what additional controls you might want to add. If you manage users and authentication through an existing LDAP/AD server, you can review how to use that server to manage users.

- [Default User Administration](#)

Keycloak uses the concept of a realm to manage and authenticate users. When you install the Keycloak server, a realm called testserver is created for you in Keycloak. All server users belong to this realm and when they log in to the server, they log into that realm.

- [LDAP User Authentication](#)

You are using a Lightweight Directory Access Protocol and Active Directory HTTP server to manage users and authentication. You want to know the best practices to use that LDAP/AD server to manage user access to Design Server.

Default User Administration

Keycloak uses the concept of a realm to manage and authenticate users. When you install the Keycloak server, a realm called testserver is created for you in Keycloak. All server users belong to this realm and when they log in to the server, they log into that realm.

As an administrator, it is important to consider the following points about the Keycloak server administration:

- By default, there is no admin user for Design server. Such an admin user is required for accessing additional Design server functions, which includes claiming ownership of Design server projects and unarchiving them. But you can assign administrative privileges to any user. You must do this by adding the admin role to the user in Keycloak. See [Getting Started](#) guide for more information
- If Keycloak authentication is enabled in Design Server, you need to create the admin user or you can synchronize users from ldap and assign administrative privileges to any user
- Keycloak does not come with a default admin user. You need to create an admin user before using the Design server application. To do this open <http://localhost:8080/auth>, fill the form with your preferred username and password
After you log in to the Keycloak Admin Console, from the Users page, you can search and select the user that you want to make an administrator. From the Groups tab, you can join the user to the Admin group.

For more information about assigning user roles, see [Groups](#) in the Keycloak documentation.

Now that you are the Keycloak server administrator, it is important to consider the following points about the default user management and authentication:

- Minimum password length defaults to 8 characters
- Email verification of new users is turned off
- The Forgot Password feature is turned on by default, but no instructions are sent to the user to reset their password
- Forgotten user passwords are changed by you, if you do not enable Keycloak to send instructions to reset a password

You can review the following sections about changing the default authentication controls.

Email settings

By default, the testserver realm sets the Forgot Password switch on. However, as an administrator, you must enable Keycloak to send an email to the user with instructions to reset their password. If you want to verify an email, you must also enable Keycloak to send an email to the user to verify their email address.

You must provide SMTP server settings for Keycloak to send an email. After you log in to the Keycloak Admin Console, see [Email Settings](#) in the Keycloak documentation.

To set up the email verification, see [Forgot Password](#) in the Keycloak documentation.

User password

Organization can give user access to the account console located at:

<https://<keycloak-url>/auth/realms/<realm>/account>

There is a form to update password (and other useful information about the account). See [User Credentials](#) in the Keycloak documentation.

User deletion

When a user is inactive or no longer access the Design server application, you can delete that user.

See [Deleting Users](#) in the Keycloak documentation.

- [Creating a Realm](#)
- [Configuring Clients](#)
- [Connecting to Design Server](#)

This topic documents how to set up connection between Keycloak and Design server.

Creating a Realm

1. Log in to the Keycloak Admin Console.
2. Click on the Select realm drop-down and click on Add realm button. The Add realm page opens.
3. Import the realm-export.json file from the installation directory. When you import the realm-export.json, it will automatically configure all the settings of realm. You can edit the configuration settings as required.
4. Specify the name of realm in the Name field.
5. Click on Create button to create a realm.
The realm is created with its realm.

Configuring Clients

1. Log in to the Keycloak Admin Console.
2. Click on Clients option from the Configure property. The Clients page opens. User can see the list of application available in the Keycloak.
3. Click on the design-server-rest client from the list. The Design-server-rest page opens. When you select the design-server-rest, it will automatically configure all the properties available in the Settings tab.
4. Go to Credentials tab, click on Regenerate Secret button to create client secret for user.
5. Go to Roles tab to edit the attributes of respective role, if required.

Connecting to Design Server

This topic documents how to set up connection between Keycloak and Design server.

1. Install the Design Server to connect to Keycloak.
2. In Keycloak, make sure that Keycloak Auth Enabled is set to true.
3. In text editor, open config.yaml to confirm the connectivity information. You can see the below information and update as appropriate to your environment:

```
# Flag indicating if keycloak is used for identity & access management
TX_KEYCLOAK_AUTH_ENABLED=true
# Keycloak server url
TX_KEYCLOAK_SERVER_URL=http://localhost:XXXX/auth
# Keycloak realm id
TX_KEYCLOAK_REALM_ID=itx
# Keycloak client id for making rest calls
TX_KEYCLOAK_CLIENT_ID=design-server-rest
# Associated client secret for above client id
TX_KEYCLOAK_CLIENT_SECRET=94a30704-7694-476c-b9c2-5fb78d151892
```

4. Log in to Design Server using Keycloak or LDAP user credentials as configured. To unlock the maps if they are locked, go to Administration in Design Server and delete locks held by a user.

LDAP User Authentication

You are using a Lightweight Directory Access Protocol and Active Directory HTTP server to manage users and authentication. You want to know the best practices to use that LDAP/AD server to manage user access to Design Server.

Design Server supports Keycloak (<https://www.keycloak.org/>) to manage and authenticate users.

Existing user databases hold user credentials. Keycloak federates these existing external user databases through the concept of storage providers. By default, Keycloak supports an LDAP and Active Directory storage provider. By adding a storage provider, you can map LDAP user attributes into Keycloak. You can also configure more mappings.

Before you configure Keycloak to use an existing LDAP/AD provider, you must consider the following best practices:

- Set up your LDAP/AD provider as a read-only repository so that Keycloak Server cannot change it
- Add and remove users in LDAP/AD and not the Keycloak local user database
- Import and synchronize your LDAP/AD users to your Keycloak local database
 - An import for an LDAP/AD user can fail, if the LDAP/AD field chosen for the username mapping in Keycloak is not filled in for that user in LDAP/AD
 - Filter LDAP/AD users by using the Custom User LDAP Filter, so you can import a subset of all your LDAP users. For example, you can set up a Server user group in LDAP and only import those users to Keycloak
- Map a login style name, for example, user1@server.com, by using the UserPrincipalName attribute in LDAP/AD to a username in Keycloak. If you want the full name of the user as your login style, use the cn attribute in LDAP/AD.

Note: The LDAP/AD user name attribute must match the LDAP/AD provider user name attribute (**Username LDAP attribute**) in Keycloak for the LDAP/AD provider to connect with Keycloak.

The following sections use these best practices to guide you to set up Keycloak to connect to your LDAP/AD HTTP server.

- **Selecting LDAP provider in Keycloak**
You can use the Keycloak Admin Console to add an LDAP/AD provider.
- **Required settings for a successful connection to your LDAP/AD provider**
The form includes many fields and several fields include default values.
- **User synchronization**
You must import all users from your LDAP/AD user database by using the option to Synchronize all users. Users are imported based on your saved settings when you set up your LDAP/AD provider.
- **Mappers**
Keycloak uses mappers to map the user attributes defined in the Keycloak user model such as username and email to the corresponding user attributes in the LDAP/AD user database. By default, when you saved your settings and created your LDAP/AD provider, the following mappers were created.

Selecting LDAP provider in Keycloak

You can use the Keycloak Admin Console to add an LDAP/AD provider.

1. Log in to the Keycloak Admin Console.
2. Go to the User Federation page to add your provider.
3. Select the provider named ldap from the list from the Add Provider drop-down list. The ldap provider is created.

Required settings for a successful connection to your LDAP/AD provider

The form includes many fields and several fields include default values.

1. Click on the ldap provider to open the settings to configure.
2. In the Settings tab, select Active Directory from the drop-down list of Vendor. Many fields complete with default values based on this selection.
3. Enter your LDAP/AD URL to connect to your LDAP/AD user database, for example: ldap://<hostname>.<domain>
4. Click on Test connection button to test the connection and confirm that the connection is successful.
5. Provide the directory where the LDAP users are listed, for example: cn=Users,dc=MYCOMPANY,dc=COM.
6. From the Bind Type drop-down list, select Simple option.

7. Provide the LDAP/AD user database administrator user ID for BIND DN and password for the BIND Credential. These credentials are used by Keycloak to access the LDAP/AD user database.
 8. Click on Test Authentication button to test the authentication and confirm that the authentication is successful.
 9. Click on Save button to save the configuration.
-

User synchronization

You must import all users from your LDAP/AD user database by using the option to Synchronize all users. Users are imported based on your saved settings when you set up your LDAP/AD provider.

A successful import is followed by a success message with the number of users imported. A failed import typically results when there is a mismatch between user attributes in the Keycloak user database and the LDAP/AD user database.

You can view all the LDAP/AD database users that were imported and authenticated from the Users page in the Keycloak Admin Console.

Users are listed with ID, Username, Email, Last Name, and First Name. The ID is generated by Keycloak. The value of the other attributes is fetched from the LDAP/AD user database by using mappers.

Mappers

Keycloak uses mappers to map the user attributes defined in the Keycloak user model such as username and email to the corresponding user attributes in the LDAP/AD user database. By default, when you saved your settings and created your LDAP/AD provider, the following mappers were created.

The username attribute that you specified in the Username LDAP attribute must match the username attribute defined in the Keycloak mapper for the LDAP/AD user database to connect with Keycloak.

If you change the Username LDAP attribute from the default value **cn** to **userPrincipalName**, Keycloak would make the same change in the mapper called username to match.

Runtime REST API

Runtime REST API supports Keycloak authentication of user credentials for running maps and flows. Like Design Server, Runtime REST API can be configured to authenticate users with Keycloak.

- [Connecting Runtime REST API server](#)
This topic documents how to set up connection between Keycloak and Runtime REST API server.
-

Connecting Runtime REST API server

This topic documents how to set up connection between Keycloak and Runtime REST API server.

1. Install Design Studio or Runtime & Monitoring.
 2. In Keycloak, make sure that Keycloak Auth Enabled is set to true.
 3. In text editor, open config.yaml to confirm the connectivity information. You can see the below information and update as appropriate to your environment:

```
keycloak.enabled=true
#Keycloak specific properties
keycloak.serverUrl=http://localhost:8080/auth
keycloak.realmId=itz
server.inbound.authentication.keycloak.clientId=itz-runtime-rest
server.inbound.keycloak.clientSecret=9465403f-0ae6-4cf8-ecdf8c4485ed
```
 4. Run Runtime REST API server to service REST client calls.
 5. REST clients invoking the Runtime REST API should include the user credentials that can be authenticated with Keycloak to run the maps or flows, or to fetch any runtime information.
-

Outbound connections to Runtime Servers

Transport Layer Security (TLS) client settings can be configured for outbound connections from Design Server to Runtime Servers.

These settings are intended to allow secure connections to runtime installations. Connecting to a customized runtime installation which uses mutual authentication (mTLS) is supported.

Use of these settings is not required if the previous behavior for outbound connections to runtime installations is sufficient. The default settings provide backwards-compatible behavior.

Connections to a Runtime Server are only allowed if the server is on the Design Server allowlist. See `server.runtime.servers` in config.yaml.

The client TLS settings are configured with the mapping `server.outbound.ssl` in config.yaml. These settings apply to all connections from Design Server to runtime installations.

If TLS is used for connections to Runtime Servers, a trust store must be provided as a PEM file which contains one or more CA certificates. The absolute path of the file should be provided as the value of server.outbound.ssl.caFile.

If a Runtime Server uses mTLS, a client certificate and client private key must be provided as PEM files. Absolute paths to these files should be provided as the values of server.outbound.ssl.certFile and server.outbound.ssl.keyFile, respectively.

The setting server.outbound.ssl.acceptCertificatesStrategy controls certificate verification. If the value **signed** is provided, then only those certificates for which a valid trust chain can be constructed are accepted. This is the recommended setting for production servers when TLS is used. If the value **all** is provided, then all server certificates are accepted. This setting should not be used for production servers. When a value is not provided, self-signed certificates are accepted in addition to valid CA-signed certificates.

If the boolean-valued setting server.outbound.ssl.verifyHostName is set to **true**, hostname verification is performed for the server certificate in addition to the verification indicated by server.outbound.ssl.acceptCertificatesStrategy.

Below is an example of the default values in config.yaml.

```
server:
  outbound:
    ssl:
      certFile: ""
      keyFile: ""
      caFile: ""
      acceptCertificatesStrategy: ""
      verifyHostName: false
```

Design Server concepts

This documentation describes basic Design Server concepts

Projects

This documentation describes Design Server projects.

- **Importing and exporting**

A project organizes related artifacts (connections and actions, schemas, maps, and files) in the Design Server repository. The import and export functions move projects or individual artifacts between the repository and the local file system. By using the import and export functions, you can reuse artifacts in multiple projects or move a project between multiple instances of Design Server.

- **Connections and actions**

A connection defines the properties that are required to connect to an external resource. An action uses a connection to provide source data to a map, or to write data from a map to a target.

- **Files**

You add a file to a project to use it as input to maps in the project. You can upload a file from your local file system to a project with the File designer. Alternatively, you can upload it when you define an action.

Importing and exporting

A project organizes related artifacts (connections and actions, schemas, maps, and files) in the Design Server repository. The import and export functions move projects or individual artifacts between the repository and the local file system. By using the import and export functions, you can reuse artifacts in multiple projects or move a project between multiple instances of Design Server.

For example, you can export a project from the Design Server instance running on a shared server at your office to import it to the Design Server instance running on your local laptop.

Exporting a project creates a .zip archive file and manifest of the project and downloads it to the local file system. Importing a project moves the project from the local file system into the Design Server repository. You can import both Design Server projects and legacy projects into Design Server. Compress legacy artifacts into a .zip archive file before you import them.

You also can select individual artifacts (connections and actions, schemas, maps, and files) to export and import. For example, you might want to export a map to send it to Support to diagnose a problem, or you might want to copy a schema from one project to another.

When you export individual artifacts, you can choose to include dependent artifacts automatically.

- Maps depend on schemas, files, connections, and actions.
- Actions depend on schemas, files, and connections.

Connections and actions

A connection defines the properties that are required to connect to an external resource. An action uses a connection to provide source data to a map, or to write data from a map to a target.

Multiple actions can use the same connection. You can define both connections and actions at either the project level, or at the map level.

- [**Project-level connections and actions**](#)

You can reuse project-level artifacts in multiple maps. You can use the Connections designer in Design Server to define a new project-level connection and its actions, or to select an existing project-level connection and its actions.

- [**Map-level connections and actions**](#)

Map-level artifacts are unique to a particular map. A map-level action can use an existing, project-level connection, or the action can define a new map-level connection.

- [**Connection testing**](#)

You can test both project-level and map-level connections.

Project-level connections and actions

You can reuse project-level artifacts in multiple maps. You can use the Connections designer in Design Server to define a new project-level connection and its actions, or to select an existing project-level connection and its actions.

For example, you can define a project-level connection to a database that is used as a data source, or target of multiple maps. A project-level action might be an SQL inquiry and schema that multiple maps use to look up the same database.

Map-level connections and actions

Map-level artifacts are unique to a particular map. A map-level action can use an existing, project-level connection, or the action can define a new map-level connection.

To define a map-level action.

Alternatively, you can specify the properties of an action directly in the input or output card. It is not necessary to create a map-level action.

Connection testing

You can test both project-level and map-level connections.

When the Design Server has access to an external resource, testing validates the properties of the resource connection. If the Design Server can not access the external resource, the connection test fails, even if the connection properties are correct.

Files

You add a file to a project to use it as input to maps in the project. You can upload a file from your local file system to a project with the File designer. Alternatively, you can upload it when you define an action.

You also can download a file from a project to your local file system. From your local file system, you can upload the file to a different project or to a different instance of Design Server.

Schemas

Schema design

Use the product and documentation to define, modify, and view schemas. A schema describes the syntax, structure, and semantics of your data. The syntax of data refers to its format including tags, delimiters, terminators, and other characters that separate or identify sections of data. The structure of data refers to its composition including repeating substructures and nested groupings. The semantics of data refer to the meaning of the data including rules for data values, relationships among parts of a large data object, and error detection and recovery.

- [**About schemas**](#)
- [**Subtypes**](#)
- [**Schema hierarchy**](#)
- [**Defining data**](#)
- [**Objects, types, and classes**](#)
- [**Testing part of a schema**](#)

You can test a schema by generating test data for an item or a group. The Type Designer creates source and compiled maps that generate and validate the test data. The test-data-generation map automatically runs and produces a text file with the sample data. After that, the test-data-validation map automatically runs on the sample data file.

About schemas

A schema defines the contents of at least one input that you intend to map or one output you intend to map. A schema is the mechanism for defining each element of your data. Similar to a data dictionary, a schema contains a collection of type definitions.

Because data definitions are defined in a schema, you should be familiar with the specifications that define your data before attempting to create one.

A data file is a simple example. The file is made up of records and each record is made up of fields. In this case, there are three kinds of data objects: a file, a record, and a field.

In a file of records, think of the data in terms of the three data objects. For example, one type defines the entire file; another type defines the entire record contained in that file. Other types in the same schema define the data fields of the record.

A schema has three datatype classifications: group, category, and item. The **root** type is the base type from which all other types stem, representing the data objects of all types in the schema. "Root" is the default name, however, you can modify any type name.

Types within a schema are listed in alphabetical order by default. To change the order for new types, modify the root type properties.

IBM Transformation Extender supports large metadata. It supports more than 65,536 types and 65,536 components in a single schema. To reduce the number of types that maps that use large schemas must process, trim these schemas so that they contain only the required types.

Subtypes

Subtypes are created for a number of reasons like identifying distinct data object. Another reason is that specific types of an object may have different properties such as different date formats.

Think of subtypes as different "flavors". Ice cream flavors can be chocolate, strawberry, or vanilla. To create a schema to represent ice cream as data, the different flavors of ice cream could be subtypes of the type **IceCream**.

The type **IceCream** is generic and describes any kind of ice cream. The type **Chocolate**, a subtype of **IceCream**, represents a certain kind of ice cream: chocolate.

A file of purchase order data may have two different kinds of records: header and detail. The schema representing this data might have a **Record** type with **Detail** and **Header** as subtypes of **Record**.

Schema hierarchy

The types in a schema are arranged in a hierarchy. If a type is subordinate to another type, it is called a *subtype*. The type on the branch stemming above a specific type is called its *supertype*.

Subtypes have more specific properties. For example, two different kinds of fields, **Name** and **Date**, may be defined as subtypes of **Field**.

The item type **Field** describes any field. The item types **Date** and **Name** are more specific kinds of fields. In a classification hierarchy such as this, the deeper the subtype is in the type tree, the more specific the data characteristics.

Example scenario

Imagine that a schema represents your house. There is a type for the entire house (**House**). A type for each room (**Bathroom**, **Bedroom**, and so on), and types for the different furnishings in these rooms (**Bed**, **Chair**, and so on). Each type represents a complete object. A house is made up of rooms. Inside these rooms are beds, chairs, couches, and so on. You know this, but you cannot see it by looking at the classification hierarchy view of the schema. You must open one of the types in the group view to see its components.

Defining data

For optimum data transformation, the entire contents of your data must be defined. Using the Type Designer, you can define input data so that each data object of the source data is identified. You can define the output data according to your output specifications.

How specifically you define the data is up to you. For example, if there is a large section of data that you want to process quickly, define it loosely as a chunk of text.

The Type Designer does not define data content as source data or target data. The purpose of the Type Designer is to define your data. Use the Map Designer to define input and output definitions for the data.

Objects, types, and classes

Schemas consist of objects, types, and classes.

Objects

A data object is a complete unit that exists in your input or is built on output. A data object can be simple (such as a date) or complex (such as a purchase order).

A data object is some portion of data in a data stream that can be recognized as belonging to a specific type. When you create types, identify all of the objects that make up the data: input objects and output objects.

Types

A type defines a set of data objects that have the same characteristics. For example, the type "Date" can be defined as representing data objects in the form MM-DD-YY. The type "CustomerRecord" can be defined as representing data objects, each of which consists of a **Company**, **Address**, and **Phone** data object.

Classes

A type is classified according to whether or not it consists of other objects. Each type in a schema must be defined in one of three classes: item, group, or category.

- **Item type**

An item type represents a simple data object that does not consist of other objects.

- **Group type**

A group type represents a complex data object that consists of other objects. For example, "FullName" is a group type that contains the components: FirstName, MiddleInitial, and LastName.

- **Category type**

A category type is used for inheritance and for organizing other types in a schema. For example, you might have a category named "OrderField" to organize the different kinds of order fields in your schema.

Testing part of a schema

You can test a schema by generating test data for an item or a group. The Type Designer creates source and compiled maps that generate and validate the test data. The test-data-generation map automatically runs and produces a text file with the sample data. After that, the test-data-validation map automatically runs on the sample data file.

For choices and partitions, the Type Designer fills the first choice and first partition with data in the generation map. For sequences, the Type Designer generates one index. The Type Designer uses implied default-value and item-value restrictions if they are available; otherwise, it generates sample values for different data types.

- **[Invalid input message from test data generation](#)**

The message One or more inputs was invalid displays when test data generates successfully but the validation map flags some data as not valid. This message can occur when there are data type constraints, component rules, or restrictions that the sample data does not account for. Trace the validation map and inspect the generation map rules to find the data types that are not generating correctly.

Invalid input message from test data generation

The message One or more inputs was invalid displays when test data generates successfully but the validation map flags some data as not valid. This message can occur when there are data type constraints, component rules, or restrictions that the sample data does not account for. Trace the validation map and inspect the generation map rules to find the data types that are not generating correctly.

Importers

There are three types of importers:

- COBOL copybook
- CSV
- XSD or JSON

- **[COBOL Copybook Importer](#)**

The COBOL Copybook Importer imports the definition of one or more COBOL copybooks in a file and generates a type tree that contains the corresponding type definitions. The copybook file might contain more than one COBOL copybook definition.

- **[CSV Importer](#)**

The CSV Importer imports the content from the CSV file to the Design Server UI.

- **[JSON Importer](#)**

COBOL Copybook Importer

The COBOL Copybook Importer imports the definition of one or more COBOL copybooks in a file and generates a type tree that contains the corresponding type definitions. The copybook file might contain more than one COBOL copybook definition.

If your file contains multiple COBOL Copybook definitions, you can import the definitions into a single type tree in the following ways:

- Import a selected subset of the definitions.
- Import all the definitions.
- Import definitions from different COBOL Copybook files.

- **[Running the COBOL copybook importer in Design Server UI](#)**

Use the COBOL copybook importer to automatically generate COBOL copybook type trees.

- **[Runtime options](#)**

Runtime options are Character set and Byte order.

- **[COBOL copybook Specification](#)**

The COBOL copybook importer uses as input a copybook file (.cpy) containing data description entries, as defined by the ANSI X3.23 specification with the following exception and additions:

- **[Type tree Mapping](#)**

The COBOL copybook import operation maps data names to type tree names.

- **Clause**

The COBOL copybook importer supports below clauses in the Design Server UI:

Running the COBOL copybook importer in Design Server UI

Use the COBOL copybook importer to automatically generate COBOL copybook type trees.

The metadata for the type trees is in the form of COBOL copybooks.

The following procedure describes how to use the COBOL copybook importer to generate a type tree from COBOL copybooks.

There is an example of a COBOL copybook file in the *install_dir\examples\general\copybook* folder.

To run the COBOL Copybook Importer in Design Server UI:

1. Create a new project using Design Server UI. See the "Create a project topic" in Knowledge Center for more instructions.
2. Open the project in Design Server UI.
3. Select Schemas > Import and click on Import.
The Import Type window opens.
4. From the Type drop-down list, select COBOL copybook option and click Next.
The Import Properties window opens.
5. Select the COBOL copybook metadata source file that you want to import from the drop-down list of Copybook File Path property.
6. Select runtime options Character set and Byte Order from the selection list.
The Identification window opens.
7. Enter the name of COBOL copybook metadata source file in the Name field and click Import.
The COBOL copybook schema is imported successfully.

Runtime options

Runtime options are Character set and Byte order.

The runtime options, Character set and Byte order, describe the runtime data. The character set code represents a standard collection of letters, numbers, and symbols. The byte order set code represents a convention a machine processor uses to position its lowest byte within a word. The processor positions the lowest byte beginning either from the leftmost or the rightmost position. The default setting for these properties is Native.

COBOL copybook Specification

The COBOL copybook importer uses as input a copybook file (.cpy) containing data description entries, as defined by the ANSI X3.23 specification with the following exception and additions:

- Each entry must have either a data-name or the reserved FILLER clause. (This is an exception to the ANSI X3.23 specification).
- The COBOL copybook importer also supports these USAGE clauses:
 - COMPUTATIONAL-3
 - COMPUTATIONAL-4
 - COMPUTATIONAL-5
 - COMPUTATIONAL-X
 - COMP-3
 - COMP-4
 - COMP-5
 - COMP-X

Trees that are generated by the COBOL copybook importer can be used immediately for map development. However, depending on the contents of the copybook file, it might be necessary for the generated type tree to be modified using the Schema Designer.

Type tree Mapping

The COBOL copybook import operation maps data names to type tree names.

The COBOL copybook data names are converted to type tree names according to the following rules:

Characters that are not valid in type tree element names are replaced with the underscore (_) character. For example, the invalid \$ character in **monthly\$total** is replaced with the underscore (_) character. Therefore, **monthly\$total** becomes **monthly_total**.

Duplicate names are made unique by appending one or more numeric digits to the names. For example, there are two instances of **year**. You can make one of the instances **year1** and leave the other instance as **year**.

The import operation maps FILLER items by appending a number incrementally to the end of the name. Examples are FILLER1, FILLER2, FILLER3, and so on.

Clause

The COBOL copybook importer supports below clauses in the Design Server UI:

- VALUES clause
- USAGE clause
- PICTURE clause
- ORDER clause
- ORDER DEPENDING ON clause

The COBOL copybook importer does not support **REDEFINES** clause in the Design Server UI.

CSV Importer

The CSV Importer imports the content from the CSV file to the Design Server UI.

- [Running the CSV Importer in Design Server UI](#)
Use the CSV Importer to automatically generate CSV type trees.
- [CSV Importer Properties](#)
This topic lists the properties of CSV importer.

Running the CSV Importer in Design Server UI

Use the CSV Importer to automatically generate CSV type trees.

To run the CSV Importer in Design Server UI:

1. Create a new project using Design Server UI. See the Create a project topic in Knowledge Center for more instruction.
2. Open the project in Design Server UI.
3. Select Schemas > Import and click on Import.
The Import Type window opens.
4. From the Type drop-down list, select CSV option and click Next.
The Import Properties window opens.
5. Select the following properties to import the CSV:
 - Sample File Path
 - Sample Row Limit
 - Has Header
 - Logging
 - Format
 - Line Break
 - Delimiter
 - Quote
 - Escape
6. Click Next.
The Identification window opens.
7. Enter the name of CSV source file as you want in the Name field and click Import.
The CSV schema is imported successfully.

CSV importer Properties

This topic lists the properties of CSV importer.

Sample File Path

Specifies the path to the file to use for detecting and evaluating the schema structure.

Sample Row Limit

Specifies the number of rows to process in the specified sample file when detecting and evaluating the schema settings.

Has Header

Indicates the first line in the data is header line when it is set to true.

Logging

Specifies the level of logging to use. The default is Off. The value Informational means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

Format

Specifies the data format. Default is Strict CSV. The other data format is Custom.

Line Break

Specifies the line break (end of the line). Default is CR LF (Carriage Return Line Feed). Other options are as follows:

- LF: Line Feed
- CR: Carriage Return
- Newline: Platform Specific

Delimiter

Specifies the field delimiter. Default is Comma. Other options are as follows:

- Pipe
- Colon
- Semicolon
- Exclamation Mark
- Equals Sign
- Tilde
- Space
- Tab
- Null
- Custom

Quote

Specifies the enclosing character. Default is Double Quote. Other options are Single Quote and None.

Escape

Specifies the escape release character. Default is Double Quote. Other options are as follows:

- Backslash
- Exclamation
- Single Quote
- Null
- None
- Custom

JSON Importer

Using a JSON document to define a schema is termed as importing the JSON document. A schema defined through this process is referred to as a native JSON schema. Two types of JSON documents can be utilized for defining a native JSON schema:

- An imported JSON document can include example data, which is employed to establish the schema. Schemas resulting from these documents are termed JSON template schemas.
- Alternatively, the imported JSON document can adhere to the JSON Schema format. In such instances, the resultant schema embodies the specifications outlined in the JSON Schema document. These schemas are referred to as JSON Schema schemas.
- [**Importing JSON Schema in Design Server UI**](#)
Import the JSON schema in Design Server UI:
- [**Importing JSON Template in Design Server UI**](#)
Import the JSON template in Design Server UI:
- [**The representation of JSON types in schemas**](#)
- [**Using native JSON schemas in a map**](#)

Importing JSON Schema in Design Server UI

Import the JSON schema in Design Server UI:

1. Open the project in Design Server UI.
2. Go to Schema and click on XSD/JSON.
XSD/JSON where you can upload the XML schemas, JSON templates and JSON schema.
- The Import XSD or JSON window opens.
3. In the Import XSD or JSON window do as follows:

- In the File field, browse a JSON schema from your local machine to Design Server UI.
 - In the Name field, enter the name of the JSON schema.
 - In the Folder field, enter the folder path where you want to import the JSON schema.
 - In the Description field, add description of the JSON schema, if required.
4. Click OK to import the JSON schema.

The JSON schema is imported in Design Server UI. You can see it in the Schema list.

Note: The JSON schema is not editable. To edit the JSON schema, you have to edit it in a local machine and re-upload it into design server.

Importing JSON Template in Design Server UI

Import the JSON template in Design Server UI:

1. Open the project in Design Server UI.
2. Go to Schema and click on XSD/JSON.
XSD/JSON where you can upload the XML schemas, JSON templates and JSON schema.
3. The Import XSD or JSON window opens.
4. In the Import XSD or JSON window do as follows:
 - In the File field, browse a JSON template from your local machine to Design Server UI.
 - In the Name field, enter the name of the JSON template.
 - In the Folder field, enter the folder path where you want to import the JSON template.
 - In the Description field, add description of the JSON template, if required.
5. Click OK to import the JSON template.

The JSON template is imported in Design Server UI. You can see it in the Schema list.

5. Edit the JSON template if you want.
Note: You can edit the JSON template unlike the XSD schema and JSON schema.

The representation of JSON types in schemas

In a native JSON schema, a JSON object is portrayed as a group type. The group type comprises components that directly correspond to the properties found within the JSON object. Each component's name, reflecting the type of the component, aligns with the respective property name in the JSON object.

Meanwhile, a JSON array is depicted as a component having an unbounded number of repetitions. For instance, when a component possesses an unlimited repetition count and represents a number item type, it effectively signifies a JSON array consisting of numeric values.

When it comes to JSON numbers, they are symbolized using number item types within the schema. Likewise, JSON strings and Boolean values are both depicted using text item types.

Using native JSON schemas in a map

You can use a native JSON schema in either an input card or an output card.

Differing from standard schemas, you cannot manually choose a specific type from a native JSON schema for a card. Instead, the system automatically selects the group type located under the root type for the card.

- [JSON cards and text encodings](#)

JSON cards and text encodings

When utilizing a native JSON schema in an input card, the automatic determination of text encoding for input data takes place during map execution.

When an output card uses a native JSON schema, the text encoding of card output is determined during map definition. The allowed text encodings for output data are UTF-8, UTF-16LE, UTF-16BE, UTF-32LE, and UTF-32BE.

Previously, the text encoding for the output of a native JSON output card was designated through a rule specified on a text item component termed "encoding." The component's path was denoted as encoding:<card name>. For instance, the rule might be '=NONE' resulting in the use of UTF-8. Alternatively, the rule could be '='UTF-16LE'" signifying the utilization of UTF-16LE.

The encoding item component has been eliminated from native JSON schemas. Currently, the text encoding for an output card is determined by selecting a UTF encoding for the Data Language card property. This property exclusively pertains to output cards employing a native JSON schema that lacks the encoding item type. In the absence of a selection, UTF-8 is defaulted for the output card. Existing maps and schemas utilizing the encoding item type remain valid.

Type properties

The properties of a type define the characteristics of the data objects of that type.

For *item* types, properties define whether that item is text, a number, a date and time, or a syntax value. Properties include such characteristics as size, pad characters, and justification.

For *group* types, the properties are related to the format of that group. The format of a group may be explicit or implicit. In addition, type properties include syntax objects that appear at the beginning or end of the object, as well as release characters.

- [Defining type properties](#)
 - [Basic type properties](#)
 - [Item properties](#)
 - [Group properties](#)
 - [XML properties in the schema](#)
-

Defining type properties

You can define specific properties for each type. Type properties generally consist of the following:

- Definition of a type's **Class**, **Group** or **Item** properties
 - Type **Initiator**, **Terminator**, and **Release** character
 - A list of where a type is used in the definitions of other types
-

Basic type properties

The following type properties are common to categories, groups, and items:

- [Name](#)
- [Class](#)
- [Description](#)
- [Intent](#)
- [Partitioned](#)
- [Order Subtypes](#)
- [Initiator](#)
- [Terminator](#)
- [Release Characters](#)
- [Empty](#)
- [National Language](#)
- [Document Type](#)
- [Where Used](#)

Item-specific properties are discussed in more detail in ["Item Properties"](#). Group-specific properties are discussed in more detail in ["Group Properties"](#).

- [Name](#)
 - [Class](#)
 - [Description](#)
 - [Intent](#)
 - [Partitioned](#)
 - [Order subtypes](#)
 - [Initiator](#)
 - [Terminator](#)
 - [Release characters](#)
 - [Empty](#)
 - [Document Type](#)
 - [Where used](#)
 - [Symmetric swapping](#)
 - [Orientation](#)
 - [Shaping](#)
-

Name

The name of the type should be as descriptive as possible and reflect the information that the type represents.

A type name must conform to the following guidelines:

- A type name cannot be more than 256 characters long.
- A type name cannot be a reserved word or contain a reserved symbol. For a list of reserved words, refer to Design Studio Introduction.
- A type name cannot contain only digits and/or periods.
- A type name may contain numbers and special characters.
- A type name cannot contain spaces. Use an underscore instead.
- A type name can contain the following:
 - Letters
 - Digits
 - ASCII characters 128-255
 - Special characters: #, ~, %, _, ? or \
 - Double-byte characters (Japan edition only)
- A type name cannot have the same name as another type on the same level in the same schema.

Class

The class of a type describes whether the type represents a simple data object (item), a complex data object (group), or whether it is used to organize types (category). Define the class of the selected type by selecting the class from the drop-down list in the **Value** column.

Category

Categories organize types that have common properties. Each category has a set of item properties and a set of group properties. Subtypes of the category inherit these properties.

A category does not define data objects in detail and it does not represent data to be used in a map. You never map a category type, so a category type does not have components. A category type may be a component of a partitioned group, after a component with the identifier attribute. A category cannot be a component of a non-partitioned group.

Item

The item type represents a simple data object that does not consist of any objects. An item does not have components.

Group

The group type represents a complex data object that consists of components.

To change a type's class, select the type and choose the desired class for the **Class** property in the Properties window.

If you change a type to an item, all the types in its subtree become items. If you change a type to a group, all the types in its subtree become groups. This is because the schema has a classification hierarchy and all the nested subtypes of an item must be items. Similarly, all the nested subtypes of a group must be groups.

Description

Use this property to record a brief description of the type. The description entered is for informational purposes only. It is not used for identifying data objects at runtime.

It is good practice to add a meaningful description of the type when you are defining it.

Intent

Indicates whether the type is a general type or an XML type.

The type can only be an XML type if the type tree was created using the XML DTD Importer or the XML Schema Importer.

Refer to ["XML Properties in the Type Tree"](#) for more information about type properties created from XML.

Partitioned

If the data of this type can be divided into mutually exclusive subtypes, it can be partitioned. For information about partitioning, see ["Partitioning"](#).

Yes

Partitioning is enabled for this type.

No

Partitioning is not enabled for this type.

Order subtypes

Choose the method in which the subtypes of this type will be added or viewed in the schema.

Ascending

Add and view subtypes of this type in alphabetic or numeric order.

Descending

Add and view subtypes of this type in reverse alphabetic or numeric order.

Add First

Add subtypes of this type to the top of the type list.

Add Last

Add subtypes to the bottom of the type list.

To manually reorder the subtypes in a schema, the **Order Subtypes** property must be either **Add First** or **Add Last**.

Initiator

An initiator is a syntax object that appears at the beginning of a data object. Defining an initiator for a type specifies that when data of that type appears, the initiator appears at the beginning of the data object. The initiator becomes part of the data type definition.

None

There is no initiator.

Literal

The initiator is literal. Expand the **Initiator** property to enter the literal initiator value and data language of the initiator value.

Variable

Allow for possible values. Expand the **Initiator** property to define the variable terminator **Default**, **Item**, and **Find** properties.

If each record begins with an asterisk *, define the * as a literal initiator of the record type.

The following data represents the classes in a college English department. An asterisk * is displayed at the beginning of each **ClassRecord**.

For information about other symbols used in the Value field of the Initiator property, see the Type Tree Importers documentation .

Terminator

A terminator is a syntax object that appears at the end of a data object. The terminator becomes part of the data type definition.

None

There are no terminators.

Literal

A constant value. Expand the **Terminator** property to define the literal terminator **Value**.

Variable

Allow for possible values. Expand the **Terminator** property to define the variable terminator **Default**, **Item**, and **Find** properties.

For example, a carriage return/linefeed (CR/LF) at the end of a record is the record's terminator.

Generally, if the data ends with a given syntax object, you should define a literal terminator. For example, it is very common to define a CR/LF as a terminator of a record when you know that the record always ends with a CR/LF, regardless of where the record appears.

Release characters

A release character is a one-byte character in your data indicating that the character(s) following it should be interpreted as data, not as a syntax object. The release character is not treated as data, but the data that follows it is treated as actual data.

- [Building release characters for output data](#)
 - [Guidelines for using release characters](#)
 - [Release character example](#)
-

Building release characters for output data

If a release character is defined for a type, a release character is inserted for each occurrence of a syntax object in the data of any item contained in that type.

Guidelines for using release characters

Guidelines for using release characters include the following:

- Release characters apply to character data only, *not* binary data.
 - Characters defined as pad characters are not released.
 - The maximum size of an item does *not* include the release characters.
-

Release character example

The group type **Record** type has a literal delimiter of , and a release character of ?. The group type **Record** has three item components. Data for the record looks like the following:

Miller?, MD,Harkin Hospital,1996

The ? releases the comma after Miller.

In the first field, the actual data value is **Miller, MD**. Because the comma appears as part of the data, it is necessary to have the release character ?, which indicates that the , following it is data, *not* a delimiter. This data would be interpreted as the following:

Data for component #1: **Miller, MD**

Data for component #2: **Harkin Hospital**

Data for component #3: **1996**

A release character can apply to a delimiter, a terminator, or even the release character itself.

If a release character appears in the data and it is not followed by a syntax item, the release character is ignored.

Empty

The **Empty** property provides alternative type syntax for groups or items when they have no data content.

When the **Empty** property is specified for a type and there is no data content, the **Empty** syntax is displayed. For example, this can be used for XML data that contains either start and end tags or an empty tag.

You can use the **Empty** type property instead of syntax object items to potentially improve the schema runtime processing time (during data validation).

The following options are available for the **Empty** property.

None

Default setting. Select None if you do not have an initiator, terminator, or release character.

Literal

A constant value. When **Literal** is selected, the **Value**, **Ignore Case**, **Required**, and **National language** sub-fields become available. You can use only one literal to indicate a zero-length data item.

- [Empty type property example](#)

Empty type property example

Consider an XML element called **Comment**. Presuming that this element has a simple content of an arbitrary length, it can be represented in a schema as a text item, with the initiator value `<Comment>` and the terminator value `</Comment>`.

This item can then be used to validate the following data:

```
<Comment>Some comment...</Comment>
```

The resulting value for the item will be:

```
Some comment...
```

As another example, the following data is also successfully validated:

```
<Comment></Comment>
```

The resulting value for the item will be a zero-length string.

The problem occurs with the following data: `<Comment/>`

From the XML perspective, this data is equivalent to the `<Comment></Comment>` data shown above, as it represents the **Empty** element **Comment**. However, from the schema perspective, this data is invalid because it does not start with `<Comment>` and does not end with `</Comment>` as required by the initiator and terminator item property values.

This is where the **Empty** property is useful. By defining the **Empty** property for the item to have a value of `<Comment/>`, it will be possible to validate the data `<Comment/>`.

Even if the data does not match the syntax described by the initiator and terminator properties, it will be validated because it will match the **Empty** property value. It will be treated as an *empty item*, that is, the resulting value for the item will be a zero-length string, similar to the example shown previously.

Document Type

The **Document Type** setting is a component of Document Verification. A requirement of using Document Verification is to set the **Document Type** properties of the associated schema object.

To use the Document Verification option for XML documents, you must do the following:

- Set the **Document Type** property to **XML**.
- Set the Document Type Metadata value to **Schema** or **DTD**.
- Specify the **Location** of the DTD or Schema file.

Default

This is the default value, which indicates a non-XML document type.

XML

Indicates an XML document type. When this value is set to **XML** and the appropriate **DocumentVerification** map settings are in place, the XML document will be validated by an external program in addition to the standard data validation process.

See the Map Designer documentation for information about using the Document Verification option.

Where used

Where Used shows how and where the type is used within other types in the tree.

Symmetric swapping

When the input and output objects have different symmetric swapping characteristics, the Symmetric Swapping property is considered "on" for the related mapping rule.

Examples

Original text	Resulting text
abcF (E) Dghi Input Object No swapping Output Object Swapping	abcF (E) Dghi
abcF (E) Dghi Input Object Swapping Output Object No swapping	abcF (E) Dghi
abcF (E) Dghi Input Object No swapping Output Object No swapping	abcF) E (Dghi
abcF (E) Dghi Input Object Swapping Output Object Swapping	abcF) E (Dghi

Orientation

Orientation is to change characters from one direction to a different direction.

Example

A simple orientation example is to define English characters "abc" as a bidirectional object with left-to-right (LTR) orientation. If you moved the object to a right-to-left (RTL) object, the output should be "cba". The following example demonstrates a string of characters that change in orientation.

Original text	Resulting text
ABC DEF Ā Ā Ā Input left-to-right (LTR)	Ā Ā Ā FED CBA
Output right-to-left (RTL)	

Shaping

Text shaping is the concept of combining or separating characters where possible. The Arabic usage is with ligatures (such as the LAM, ALEF, and LAM-ALEF characters). For example, in a non-shaped word, both LAM and ALEF characters would appear separately. In a shaped word, the two characters would be replaced with a single LAM-ALEF character.

Numeric shaping is the idea that normal regular numerals (0–9) can be shaped to be Arabic-Indic

Examples

- **Ù, = LAM**
- **í° = ALEF**
- **Ûm'i»» = LAM ALEF**

Original text	Resulting text
---------------	----------------

Original text	Resulting text
abc>>>def	abcÜ,,i°def
Input	
Shaped	
Output	
Unshaped	
Original text	Resulting text
abcÜ,,i°def	abc>>>def
Input	
Unshaped	
Output	
Shaped	

Item properties

Item types define data for a selected type. Item types are divided into the following subclasses: **Number**, **Text**, **Date & Time**, and **Syntax**. Each item subclass has a specific set of properties.

- [Item subclass](#)
- [Number item subclass properties](#)
- [Text item subclass properties](#)
- [Date & Time item subclass properties](#)
- [Syntax item subclass properties](#)

Item subclass

The subclass of an item represents the characteristics of the data. Both category and item types have the **Item Subclass** property.

To define the subclass of an item type:

1. Access the **Properties** for the selected category or item type.
2. For the **Item Subclass** property, select a value that defines the data for the type:

Number

Any number excluding active syntax objects. The interpretation can be either character or binary. See "[Number Item Subclass properties](#)".

Text

Any character excluding active syntax objects. The interpretation can be either character or binary. See "[Text Item Subclass properties](#)".

Date & Time

A valid date and time format based on the data. The interpretation can be either character or binary. See "[Date & Time Item Subclass properties](#)".

Syntax

Syntax objects are used as separators between portions of data. A restricted set of values used to define a dynamic delimiter, initiator, terminator, or release character. The interpretation is character. A syntax object cannot be longer than 120 bytes. Syntax objects, used as syntax, cannot be mapped. See "[Syntax Item Subclass properties](#)".

For text and syntax objects, character size constraints can be in bytes or characters. Numbers are considered in digits and date-time formats are sized by the format, such as CCYYMMDD.

Number item subclass properties

Number item subclass properties can be of **Character** or **Binary** value. When you choose **Number** as the **Item Subclass** value, you must choose an **Interpret as** value: **Binary** or **Character**.

The **Interpret as** value defines how the data should be interpreted. Items with a subclass of **Number**, **Text**, and **Date & Time** can be interpreted as either character or binary. Items with a subclass of **Syntax** can be interpreted as character only.

- [Interpret as binary](#)
- [Length \(bytes\)](#)
- [Byte order](#)
- [Interpret as character](#)
- [Size \(digits\)](#)
- [Separators](#)
- [Pad](#)
- [Restrictions](#)
- [National language](#)
- [NONE and Zero](#)
- [Places](#)
- [E-Notation](#)

E-Notation gives you the ability to process and build decimal numbers expressed as E-Notation.

Interpret as binary

Binary text items have content size and pad properties. Binary data is required to be sized or of a fixed size.

Binary number items interpret the data as a binary number or as a byte stream.

Items with an item subclass of **Text** can be interpreted as character or binary.

When **Interpret as** is set to **Binary**, the binary presentation options are Integer, Float, Packed, or BCD.

- [Binary integer presentation](#)
- [Binary float presentation](#)
- [Binary packed presentation](#)
- [Binary BCD presentation](#)

Binary integer presentation

The **Integer** value is a whole number.

Length(bytes)

Can have a length of **1**, **2**, **4**, or **8** bytes

Byte order

See "[Byte order](#)".

Sign

See "[Sign](#)".

Binary float presentation

The **Float** value is a number with decimals in a location as needed.

Length(bytes)

Can have a length of **4**, **8**, or **10** bytes

Binary packed presentation

The **Packed** value is a number that has size, decimal places, and sign properties.

The binary packed properties include Length, Implied places, and Sign.

Length

Can have a length of **1 - 16** bytes

Implied places

Can be from **0 - 31**

Sign

Can be **Trailing-** or **Trailing+**

For **Packed** numbers, the **Implied places** cannot exceed the **Length**.

Binary BCD presentation

The **BCD** value is a binary coded decimal number that has size.

Length (bytes)

Use the **Length (bytes)** property to select the number of bytes that equals the length of the item.

The **Length(bytes)** property is an option when the **Number** item subclass property is interpreted with a **Binary** value.

Byte order

Use the **Byte order** property to define the way that bytes in the data are ordered by selecting one of the following values from the Byte order drop-down list.

Value	Description
BigEndian	The most significant byte has the lowest address. (Usually systems such as IBM, HP, and Solaris.)

Value	Description
Little Endian	The least significant byte has the lowest address. (Usually systems such as Intel and VAX.)
Native	The order is dictated by the platform.

Byte order is an option when the **Number** item subclass is interpreted with a **Binary** value.

Interpret as character

Character number items interpret the data as symbolic data. Symbolic data has the same meaning on different computers. For example, a comma is symbolic because it has the same meaning, regardless of the computer type.

Character text items can have content size and pad properties.

When the **Interpret as** value is defined as **Character**, the **Release** property is specific to the **Character** value and is *not* available as an option for a **Binary** value. For more information, see "[Release characters](#)".

When **Interpret as** is set to **Character**, integer, decimal, and zoned presentation options are available.

- [Character integer presentation](#)
- [Character decimal presentation](#)
- [Zoned character presentation](#)
- [Places > implied](#)

Character integer presentation

The **Integer** value is a whole number.

Further information on the **Integer** value is found in "[Integer Separators](#)".

Character decimal presentation

The **Decimal** value is a number that contains decimals.

More information about the **Decimal** value is found in section "[Decimal Separators](#)".

Zoned character presentation

The **Zoned** value is a number that has a size, decimal place, pad, and sign properties.

Use the "Size (digits)" property to specify the size of the zoned number. The size of a zoned number can also be specified in terms of minimum and maximum. The minimum size must be less than or equal to the maximum size.

When the content size of a character-zoned number is used, the last digit and the sign are combined into the same digit but the content size does *not* include the initiator, terminator, release characters, or pad characters.

When the content size of a character-zoned number is important (for example, when the **SIZE** function is used on the character zoned number), the content size includes the sign but does not include the initiator, terminator, release characters, or pad characters.

Use the "[Sign](#)" property to define whether the zoned number will be signed. The default value is **No**.

The size of a zoned number is specified in terms of the minimum and maximum number of digits. If the size is specified with the **Min** and **Max** properties, the sign is *not* included.

Example

Zoned Number Not Signed	Signed Zoned Number
1230	123{
1231	123A
(Length = 4 digits)	(Length = 4 digits)

Places > implied

Numbers have implied decimal places. The number of decimal places cannot exceed the length specification. The list of available decimal places varies with the length selected. In the **Value** column, enter a total number of decimal places (not to exceed 31).

Size (digits)

Use the **Size (digits)** property to specify the minimum and maximum size of a number item.

Min

The minimum number of digits of the data object.
The default value is 0.

Max

The maximum number of digits of the data object.

If there is no maximum size, a **Max** value is not required.

- [Excluded from min and max size](#)
- [Size example](#)

Excluded from min and max size

For character number items, there are certain objects excluded from the **Min** or **Max** count. For each **Presentation** option, the following table lists what is excluded from the minimum or maximum **Size (content)** count.

Presentation:	Integer	Decimal	Zoned
	initiators	initiators	initiators
	pad characters	pad characters	pad characters
	release characters	release characters	release characters
	separators	separators	terminators
	symbols	symbols	
	terminators	terminators	

Size example

In the following ASCII number there are a total of 12 characters:

+1234567.999

However, because the initiator (+) and separator (.) are not counted, the number would validate for a maximum size of 10 (**Max=10**).

Separators

Integer and decimal number items can have a separator for thousands and fractional places. If you opt to have a separator, choose **Yes** and sub-options will appear that enable you to choose the format and syntax.

The **Zoned** value of the **Presentation** property does not have separators.

- [Integer separators](#)
- [Separator > format](#)
- [1000's syntax > value](#)
- [1000's syntax \(literal\) > value](#)
- [1000's syntax \(variable\) > default](#)
- [1000's syntax \(variable\) > item](#)
- [1000's syntax \(variable\) > find](#)
- [Decimal separators](#)
- [Separators > format](#)
- [Separators > 1000's syntax](#)
- [Separators > fraction syntax](#)
- [Sign](#)

Integer separators

For integer numbers, the separator is the thousands separator.

Integer character numbers have separator properties of:

- Format
- 1000's Syntax
- Value

These properties specify the placement and value of the thousands separator.

Separator > format

Use the Separators Format property to specify the placement and value of the thousands separator.

To define the separator format, select one of the separator formats from the drop-down list in the **Value** column.

#[.]###

The thousands separator is not required on input, but if present, it must be in the proper location. The separator is not built on output.

#.###

The thousands separator is required on input in the proper location. The separator is built on output.

1000's syntax > value

Define the thousands separator as either literal or variable. Select one of the following from the drop-down list in the **Value** column:

Literal

The thousands syntax is a constant literal specified in the **1000's Syntax > Value** column.

Variable

The thousands syntax allows for variable values. Use the **1000's Syntax > Default**, **Item**, and **Find** properties to define the variable fraction separator.

1000's syntax (literal) > value

For the literal thousands separator, define the literal separator by typing the literal separator character in the **Value** column or by clicking the browse button to display the Symbols dialog box from which you can insert any non-printable value.

A separator can be from one to 120 bytes in length. A separator cannot start or end with a digit and cannot be the? character. The ? character is a reserved character that can be used as a wildcard to represent any single valid character.

1000's syntax (variable) > default

Use the **1000's Syntax > Default** property to define the default variable separator value for the thousands place. The default literal separator value for thousands syntax is a comma.

Enter the default variable separator character or click the browse button to display the Symbols dialog box in which you can insert any non-printable value.

1000's syntax (variable) > item

For integer numbers with a variable thousands separator, the **Separator** property is **Yes**, and the **1000's Syntax** is **Variable**, you can specify an item type for the variable thousands separator.

You can select the desired syntax item from the drop-down list. Or, with the focus on the **Item** property (in the **Value** column), press **Alt** and drag the default separator type item from the schema editor into the **Value** column.

An item type with a class of **Syntax** must exist in the schema to be a valid **1000's Syntax Item**.

1000's syntax (variable) > find

For integer numbers with a variable thousands separator, the **Separator** property is **Yes** and the **1000's Syntax** is **Variable**. The value of the separator can be the current value or the value of the separator can be determined each time an occurrence of that type is found.

Yes

Determine the value of the separator each time an occurrence of that type is found. After the value of that separator is found, that particular value is used until it is reset either by another Find or by the occurrence of that separator as a component.

No

The system uses the value to which the separator item is currently set or, if not set, it uses the default value.

Decimal separators

For decimal numbers, the separator is the thousands separator and the fractional separator.

Decimal character numbers have separator properties of:

- Format
- 1000's Syntax
- Fraction syntax
- Value

These properties specify the placement and value of the fractional separator.

The item is assumed to have an implicit number of decimal places. To specify the number of implied decimal places, use the Item Subclass Places property to specify the number of implied decimal places.

Sepators > format

Use the Separators Format property to specify the placement and value of the fraction separator.

To define the separator format, select one of the separator formats from the drop-down list in the **Value** column.

#####[.##]

The fractional separator is present if there are fractional digits. There is no thousands separator.

####,##

The fractional separator is always present, even if there are no fractional digits. There is no thousands separator.

#[,###][.##]

The fractional separator is present if there are fractional digits. There is an optional thousands separator.

#[,##][.##]

The fractional separator is always present. There is an optional thousands separator.

#,###[.##]

The fractional separator is always present. There is always a thousands separator if there are more than three whole number digits.

Sepators > 1000's syntax

Use the Separators 1000's Syntax to define the thousands syntax. Select one of the following from the drop-down list in the **Value** column:

Literal

The thousands syntax is a constant literal specified in the **1000's Syntax > Value** column.

Variable

The thousands syntax allows for variable values. Use the **1000's Syntax > Default**, **Item**, and **Find** properties to define the variable fraction separator.

See the following topics for additional information:

- ["1000's Syntax \(Literal\) > Value"](#)
- ["1000's Syntax \(Variable\) > Default"](#)
- ["1000's Syntax \(Variable\) > Item"](#)
- ["1000's Syntax \(Variable\) > Find"](#)

Sepators > fraction syntax

Use the **Fraction syntax** property to define the fraction syntax as either a constant literal value or a variable value.

You can define the **Fraction syntax** as literal or variable.

Literal

A constant value.

Use the Fraction syntax...Value property to select a literal fraction separator from the **Symbols** dialog box.

Variable

Allow for variable fraction separator values. The following options are available to define the variable fraction separator:

- **Default** - Use this property to define the default variable separator value for fractions. The default literal separator value for fractions is a period. Enter the default variable separator character or click the browse button to display the Symbols dialog box in which you can insert any non-printable value.
- **Item** - For decimal numbers with a variable fractional separator, the **Separator** property is **Yes** and the **Fraction syntax** is **Variable**, you can specify an item type for the variable fraction separator.
Note: An item type with a class of **Syntax** must exist in the schema to be a valid **Fraction syntax Item**.
- **Find** - For decimal numbers with a variable fraction syntax, the **Separator** property is **Yes** and the **Fraction Syntax** is **Variable**, the value of the separator can be either the current value or the value of the separator can be determined each time an occurrence of that type is found. Select an option:
 - Yes - Determines the value of the separator each time an occurrence of that type is found. After the value of that separator is found, that particular value is used until it is reset by another find or by the occurrence of that separator as a component.
 - No - The system uses either the value that the separator item is set to currently, or, if it is not set, uses the default value.

Sign

Use the Item Subclass Sign property to define whether the number is signed for either the **Integer** or **Decimal** value. A sign is a symbol that identifies a number as being either positive or negative. A positive sign is plus (+); a negative sign is negative (-).

Yes

The number is signed. Expand the **Sign** property to define the sign values. If the **Sign** property is **Yes**, a minimum of at least one sign value (**If number is +**, **If number is -**, or **If number is 0**) must be specified and at least one value must be required on input.

No

The number is not signed. This is the default setting.

When you select Yes, you can further define the sign values. The following sub-options are available:

Leading-

The sign precedes the number when it is negative only. For input, a sign is required for negative data, but is optional for positive data.

Trailing-

The sign follows the number when it is negative only. For input, a sign is required for negative data, but is optional for positive data.

Leading+

The sign always precedes the number. A sign is required for input and output data.

Trailing+

The sign always follows the number. A sign is required for input and output data.

Custom

Defaults to **Leading-** but can be changed.

Sign values may be specified for the following:

- **If Number is +** (positive numbers)
- **If Number is -** (negative numbers)
- **If Number is 0** (value of zero)

For each value (**If number is +**, **If number is -**, or **If number is 0**), specify the following:

Leading sign

Enter the symbol to be placed before a number.

Trailing sign

Enter the symbol to be placed after a number.

Required on input

If the number has a sign, at least one value (**If number is +**, **If number is -**, or **If number is 0**) must be required on input. Select an option from the drop-down list:

Yes

The sign is mandatory on input.

No

The sign is optional on input.

Pad

Pad implementation determines how the pad value is sized during validation and how the pad value is sized when written as output.

When the data value to be mapped to the target item is smaller than the minimum length of that item, pad characters can be used to pad the data to that minimum length. Input data can contain both content and pad characters. Output data is built according to the pad definitions of the types. Bytes are the default measurement for sizing, however, both byte and character sizing options are available.

Yes

Enables the **Pad** option. Allows the item to contain both content and pad characters.

No

All data is assumed to be content on input; no pad characters are built on output.

- [Pad > value](#)
- [Pad > Padded to](#)
- [Padded to > length](#)
- [Padded to > SizedAs](#)
- [Padded to > CountsTowardMinContent](#)
- [Padded to > Allow Excess Trailing Pads](#)
- [Pad > justify](#)
- [Pad > apply.pad](#)
- [Pad > fill](#)

Pad > value

Use the Pad Value property to define a 1-character pad character. The default pad value is 0.

Type the pad character symbol between angled brackets <> in the **Value** field or click the browse button to display the Symbols dialog box to insert any non-printable value.

For example, to enter a **FormFeed** value for the pad character, in the **Value** field enter <FF> or click the browse button to select the **FF (FormFeed)** symbol from the Symbols dialog box.

Pad > Padded to

Use the Pad > Padded to property to define whether the data item is padded to a fixed size or to the minimum content size defined for the data object.

Fixed size

The data object is padded to a fixed size (in bytes or characters) that you specify in the Length field.

For any item padded to a fixed size, the item must have a value specified for the Size (content)>Max property and the Padded to>Length value must be greater than or equal to the Size (content)>Max value.

Min Content

The data is padded to the value specified as the minimum size (in the Size (content)>Min field).

You can further specify whether to count pad characters toward the length using the **CountsTowardMinContent** subproperty.

Padded to > length

To pad to a fixed size, you must specify the length.

Input data can contain both content and pad characters but when an item is built for output, the item is padded to the number of bytes or characters specified in this field.

The Padded to > Length value must be greater than or equal to the Size > Max value.

You can specify the method of measurement (bytes or characters) using the **SizedAs** subproperty.

Padded to > SizedAs

Use the Padded to > **SizedAs** property to specify that padding is measured in either bytes or characters. The default setting is Bytes.

Trace file and audit log lengths are always reported in bytes.

Table 1. Pad implementation example (bytes compared to characters)

Scenario for empty field:	Result:
Data language is UTF-8 Pad > Value = Å (hexadecimal representation = 0xC3 0x80) Pad > Padded to = Fixed Size Padded to > Length = 5 Padded to > SizedAs = Bytes	Two Å pad characters using 4 bytes.
Data language is UTF-8 Pad > Value = Å (hexadecimal representation = 0xC3 0x80) Pad > Padded to = Fixed Size Padded to > Length = 5 Padded to > SizedAs = Characters	Five Å pad characters totaling 10 UTF-8 bytes.

Padded to > CountsTowardMinContent

When you select Padded to > Min Content, the **CountsTowardMinContent** field is displayed. Use this setting to specify if pad characters should count toward the length of an object when determining if it meets its minimum content length.

Yes

Pad characters are included in the count for the length of an object.

No

Pad characters are not counted toward the length of an object.

You can use the **Propagate** function here to propagate the present **CountsTowardMinContent** value to the subtypes of the present type, if present.

If you are using the trace option, there might be cases where in the trace file the content length appears to be different than the input length. A trace file lists the input length (the length used to validate an object), which includes the input length of each object plus the pad characters. In the case of numbers, signs and separators are also counted in the length.

CountsTowardMinContent > AcceptAllPads

The **AcceptAllPads** property is applicable to data objects that contain only pad characters. Use this property when you need an object that contains only pad characters (no content) to either pass or fail validation depending on whether it is a mandatory or an optional type, regardless of the minimum size requirement.

Yes

When an object contains only pad characters, the minimum size requirement is ignored and the object passes size validation. The object then passes or fails type validation depending on whether it is a mandatory or an optional type.

No

(Default setting) Pad characters do not count toward the minimum size requirement, therefore an object that contains only pad characters and that does not meet the minimum size (content) requirement fails size validation.

Example

The results of the following examples are based on these values:

Size (content)

5

Pad

Yes
Pad > Padded to
 Min Content
Padded to > CountsTowardMinContent
 No

Default Behavior: When **AcceptAllPads** is set to **No**, the following results occur:

Input Data (X = pad character)
Valid?

ABCDE
 Yes
ABC
 No
ABCXX
 No
XXXXX
 No

When **AcceptAllPads** is set to **Yes**, the following results occur:

Input Data (X = pad character)
Valid?

ABCDE
 Yes
ABC
 No
ABCXX
 No
XXXXX
 Yes (when type is optional)
No (when type is mandatory)
X
 Yes (when type is optional)
No (when type is mandatory)

Padded to > Allow Excess Trailing Pads

When you select Padded to \geq Min Content, the Allow Excess Trailing Pads property is displayed. Use this setting to flag an element as not valid when the following conditions apply:

- The element is padded to a minimum size.
- The number of pad characters exceeds the number that is required to achieve the minimum size.

Pad > justify

Use the **Justify** property to specify whether the data is padded to the left or right.

Left

The data will be on the left and will be padded (if necessary) on the right.

Right

The data will be on the right and will be padded (if necessary) on the left.

Use the **TRIMLEFT** and **TRIMRIGHT** functions to exclude pad characters from the justified side.

In the following example, xxxxxxxxxxx represent 10 spaces:

For an input of 1234567891xxxxxxxx with a right justified pad, the rule =SIZE(input) returns 20. For the same input, the rule =SIZE(TRIMRIGHT(input)) would return 10 (removing the padding on the right).

Pad > apply pad

Use the **Apply pad** property to specify when to apply the pad character. Choose a value from the drop-down list.

Fixed Group

Apply the pad characters only when the item appears in a fixed group.

Any context

Apply the pad characters when the item appears in any context.

Each item in a fixed group must be padded to a fixed size or have the same value for the minimum and maximum content size.

For example, suppose the item **Name** has a space pad character with this value:

Mary<sp><sp>

If the **Apply pad** property is **Fixed Group**, the two spaces at the end are treated as pad characters only when the item appears in a fixed group. If the **Apply pad** property is **Any context**, then the spaces are always treated as pad characters.

Each item in a fixed group must be padded to a fixed size or have the same value for the minimum and maximum content size.

Pad > fill

For padded signed numbers, this option determines placement of pad characters. Choose a value from the drop-down list.

After sign

Pad characters are placed after the sign.

Before sign

Pad characters are placed before the sign.

Restrictions

Restrictions of an item are the valid values of that item. When the **Interpret as** value is defined as **Character**, the **Restrictions** property is specific to the **Character** value and is not available as an option for a **Binary** value.

Depending on other **Item Subclass** settings, the **Restrictions** property can be set to **Value**, **Character**, or **Range**.

- [Restrictions > ignore case](#)
- [Restrictions > rule](#)

Restrictions > ignore case

By default, restrictions are case-sensitive. To enable or disable the **Ignore case** property of the **Restriction**, choose from one of the following options:

Yes

Ignore case of restrictions in item type properties.

No

Do not ignore case-sensitive restrictions.

For example, if **Ignore Case = Yes** and the restriction **Value** is **ft**, the data values **ft**, **fT**, **Ft**, and **FT** are all valid.

Restrictions > rule

This setting indicates whether you are going to include or exclude the criteria (as "valid" or "invalid") specified for the restrictions.

Include

Includes the restriction values as valid data.

Exclude

Excludes the restriction values as invalid data.

National language

The National language default value is Western. For initiator, terminator, and release character **Literal** values, you can optionally specify a ["Data language"](#).

When the **Interpret as** value is defined as **Character**, the **National language** property is specific to the **Character** value and is not available as an option for a **Binary** value.

- [National language > data language](#)
- [Supported code pages](#)

National language > data language

Use the National language > Data language property to define the data language or character set of this character text item.

Supported code pages

NONE and Zero

When the Item Subclass has a Number value and the Interpret as property has a Character value, the NONE and Zero properties are available. Expand the NONE or Zero property to specify an override data value to define the Special Value and Required on input properties.

- [**NONE > Special Value and Zero > Special Value**](#)
Enter a value in the Special Value property if the item is NONE or Zero.
 - [**NONE > Required on input and Zero > Required on input**](#)
Select a value from the Required on input property list.
-

NONE > Special Value and Zero > Special Value

Enter a value in the Special Value property if the item is NONE or Zero.

For example, if you specify * in the Special Value property for NONE, and a number object has the value *, it is interpreted as NONE.

If you enter a value in the Special Value property for NONE or Zero, enter the exact characters to be validated in the input data and built in the output data.

The maximum element length that is allowed for the Special Value property is 3000 bytes.

NONE > Required on input and Zero > Required on input

Select a value from the Required on input property list.

Yes

If the data object is NONE or Zero, the map uses the value in the Special Value property when it validates the item in the input.

No

Do not use the value in the Special Value property. No special values or input requirements are defined when data is NONE or Zero.

When the map builds the item in the output, the item might be either the value in the Special Value property or the default value for NONE or Zero. For example, if an item contains all pad characters and no actual data, the default value for NONE is used when that item is built in the output.

Places

The **Places** property allows you to specify the number of implied decimal places.

For item types defined with an **Item Subclass of Number**, a **Decimal** presentation, and a **Separator**, the **Places** property allows you to specify the minimum and maximum number of decimal places and whole number places. The minimum number of places must be less than or equal to the maximum number of places.

If the decimal number has no separator, use the **Places** property to specify the number of implied decimal places.

E-Notation

E-Notation gives you the ability to process and build decimal numbers expressed as E-Notation.

This is the common way to represent data that looks like the following:

"1.314E1" (value is 13.14)

or like this:

"-7.001e -2" (value is -.07001).

In E-Notation, a literal "E" is used to separate the coefficient from the exponent (coefficient E exponent).

Note: The data described in this documentation is "E-Notation data", and should not be confused with Scientific, or exponential notation.

- [**Data parsing expectations**](#)
 - [**Generating a data item defined with E-Notation**](#)
The following are expectations when generating a data item defined with E-Notation
 - [**E-Notation output**](#)
-

Data parsing expectations

- Data can be expressed as either "e" or "E", for example, "7.1e20" and "7.1E20 are both accepted.

- Positive exponents can have or omit the "+" sign, for example "1.314E+1" and "1.314E1" are both accepted.

To accept E-Notation from the input, toggle the E-Notation toggle on the Input Schema.

The following table shows examples of the input and the output:

Table 1.

Input	Output
1.234567890E9	1234567890
1.2E1	12
1.2E1	12
1.2E1	12
1.201E1	12.01
1.21E1	12.1
1.22345678991E10	12234567899.1
1.234E1	12.34
1.234E2	123.4
1.234E3	1234
1.2340E4	12340
1.23400E5	123400
-1.234E1	-12.34
-1.234E0	-1.234
-1.234E-1	-1.234
-1.234E-2	-0.1234
-1.234E-3	-0.01234
5.2E-4	.00052
0000.000054	.000054
0.052	.052
1.23	1.23
2222.356	2222.356

Generating a data item defined with E-Notation

The following are expectations when generating a data item defined with E-Notation

- Data is generated with the exponent as a capital "E" "1.314E1"
- Data is generated without spaces surrounding the capital "E" exponent indicator- "1.314E-4"
- Data is generated without signing the positive exponent values ("1.8E8" not "1.8E+8")

E-Notation output

On the Output Schema, toggle E-Notation to the active position.

An example of output data is shown in the table below:

Table 1.

Input	Output
12	1.2E1
12.00	1.2E1
12.000000	1.2E1
12.01	1.201E1
12.10	1.21E1
12234567899.10	1.22345678991E10
12.34	1.234E1
-12.00	-1.2E1
-12.34	-1.234E1
12	1.2E1
12.00	1.2E1
12.34E	1.234E1
-12.00	-1.2E1
-12.34	-1.234E1
12E	1.2E1

Text item subclass properties

Text item subclass properties can be interpreted with a **Character** or **Binary** value. Depending on the value, character or binary, the following are text item subclass properties:

- ["Interpret as Binary"](#) or ["Interpret as Character"](#)
- ["Size \(content\)"](#)
- ["Pad"](#)
- ["Restrictions"](#)
- ["National language"](#)

- [Interpret as binary](#)
- [Interpret as character](#)
- [Size \(content\)](#)
- [Pad](#)
- [Restrictions](#)
- [National language](#)
- [NONE](#)
- [Bidirectional](#)

Interpret as binary

Binary text items have content size and pad properties. Binary data is required to be sized or of a fixed size.

Binary number items interpret the data as a binary number or as a byte stream.

Items with an item subclass of **Text** can be interpreted as character or binary.

When **Interpret as** is set to **Binary**, the binary presentation options are Integer, Float, Packed, or BCD.

- [Binary integer presentation](#)
- [Binary float presentation](#)
- [Binary packed presentation](#)
- [Binary BCD presentation](#)

Interpret as character

Character number items interpret the data as symbolic data. Symbolic data has the same meaning on different computers. For example, a comma is symbolic because it has the same meaning, regardless of the computer type.

Character text items can have content size and pad properties.

When the **Interpret as** value is defined as **Character**, the **Release** property is specific to the **Character** value and is *not* available as an option for a **Binary** value. For more information, see ["Release characters"](#).

When **Interpret as** is set to **Character**, integer, decimal, and zoned presentation options are available.

- [Character integer presentation](#)
- [Character decimal presentation](#)
- [Zoned character presentation](#)
- [Places > implied](#)

Size (content)

Each text or syntax object can be defined with the minimum and maximum sizes in bytes and/or characters. The product determines size for text or syntax objects according to the following rules.

- When the size of an object is in bytes only, size and validation are calculated according to the size limitations set for bytes.
- When the size of an object is in characters only, size and validation are calculated according to the size limitations set for characters.
- When an object has size values defined for both bytes and characters, the object size is determined by characters (based on any character size limitations). Bytes are used to verify that the size of the data did not exceed any byte constraints that were set.

When the content size of a text or syntax item is specified in bytes, initiators, terminators, release characters, and pad characters are excluded from the count.

Min

The minimum size of the data object. You can enter values for bytes and/or characters.
The default value is 0. The largest value allowed is 65535.

Max

The maximum size of the data object. You can enter values for bytes and/or characters.
The default value is 0. The largest value allowed is 65535.
When there is no maximum content size limitation, this value is not required.

During schema analysis, checks are performed on byte and/or character Min and Max values according to the following methods:

- When values are present for both MinBytes and MinCharacters, the MinBytes value must be greater than or equal to MinCharacters.
- When values are present for both MaxBytes and MaxCharacters, MaxBytes must be greater than or equal to MaxCharacters.
- When no size limitations are present, no verification takes place.

Remember:

- Some character sets use two or more bytes per character.
- The trace file and audit log lengths are reported in bytes.

Pad

Pad implementation determines how the pad value is sized during validation and how the pad value is sized when written as output.

When the data value to be mapped to the target item is smaller than the minimum length of that item, pad characters can be used to pad the data to that minimum length. Input data can contain both content and pad characters. Output data is built according to the pad definitions of the types. Bytes are the default measurement for sizing, however, both byte and character sizing options are available.

Yes

Enables the **Pad** option. Allows the item to contain both content and pad characters.

No

All data is assumed to be content on input; no pad characters are built on output.

- [Pad > value](#)
- [Pad > Padded to](#)
- [Padded to > length](#)
- [Padded to > SizedAs](#)
- [Padded to > CountsTowardMinContent](#)
- [Padded to > Allow Excess Trailing Pads](#)
- [Pad > justify](#)
- [Pad > apply.pad](#)
- [Pad > fill](#)

Restrictions

Restrictions of an item are the valid values of that item. When the **Interpret as** value is defined as **Character**, the **Restrictions** property is specific to the **Character** value and is not available as an option for a **Binary** value.

Depending on other **Item Subclass** settings, the **Restrictions** property can be set to **Value**, **Character**, or **Range**.

- [Restrictions > ignore case](#)
- [Restrictions > rule](#)

National language

The National language default value is Western. For initiator, terminator, and release character **Literal** values, you can optionally specify a ["Data language"](#).

When the **Interpret as** value is defined as **Character**, the **National language** property is specific to the **Character** value and is not available as an option for a **Binary** value.

- [National language > data language](#)
- [Supported code pages](#)

NONE

When the Item Subclass has a Text value and the Interpret as property has a Character or Binary value, the NONE property is available. Expand the NONE property to specify an override data value to define the Special Value and Required on input properties.

- [NONE > Special Value](#)
Enter a value in the Special Value property if the item is NONE.
- [NONE > Required on input](#)
Select a value from the Required on input property list.

NONE > Special Value

Enter a value in the Special Value property if the item is NONE.

For example, if you specify * in the Special Value property for NONE, and a text object has the value *, it is interpreted as NONE.

If you enter a value in the Special Value property for NONE, enter the exact characters to be validated in the input data and built in the output data.

The maximum element length that is allowed for the Special Value property is 3000 bytes.

NONE > Required on input

Select a value from the Required on input property list.

Yes

If the data object is NONE, the map uses the value in the Special Value property when it validates the item in the input.

No

Do not use the value in the Special Value property. No special values or input requirements are defined when data is NONE.

When the map builds the item in the output, the item might be either the value in the Special Value property, or the default value for NONE. For example, if an item contains all pad characters and no actual data, the default value for NONE is used when that item is built in the output.

Bidirectional

Use the Item subclass > Bidirectional property to define the data as bidirectional.

Certain languages that are read from right-to-left often contain numeric or other phrases that are read from left-to-right. This type of data is called "bidirectional" because it changes direction in the middle of a line.

The default setting is **No**.

To enable this setting, select **Yes**. When you enable this setting, additional options are available to further define the bidirectional data.

Text items

The Bidirectional subproperties for text item types provide options for symmetric swapping, ordering, orientation, and shaping.

Symmetric Swapping

Use this property to maintain the orientation of directional pairs of characters (such as parentheses, greater than/less than symbols, brackets, braces).

Ordering Scheme

This property pertains to the order of the data as stored in memory.

Logical, the default setting, indicates that the data is stored in memory from left-to-right, regardless of the orientation of the text. Using the **Visual** ordering scheme, the data is read and stored with the start character in the right-most position both visually and in memory.

Orientation

Orientation pertains to the direction of the text as read visually. The default direction is left-to-right (LTR), meaning the text object is read starting from the left. The direction can be right-to-left (RTL), meaning the object is read starting from the right. When you select RTL, the behavior of some text functions (such as LEFT, RIGHT, MID) can change.

Use the Contextual LTR and Contextual RTL settings when the orientation should be taken from the context of the data because the data contains "strong" characters that are either orientation left or orientation right. When no strong characters are present in the data, the orientation will be based on this setting.

For example, when you set the orientation to Contextual LTR and no strong characters are encountered (meaning the data is orientation-neutral), the data orientation will be considered left-to-right.

Text Shaping

Use this property to produce output in a different glyph (shape or bit pattern). The default setting is off, or **Unshaped**.

To enable text shaping, select **Shaped**. The output will be shaped according to the code page of the target object.

Character number items

For character number item types, you can additionally define a numeric shaping characteristic.

Numeric Shaping

Use this property to indicate whether the output of numeric values will have the shapes that are used in English (Arabic digits 0123456789) or the national numerical shapes.

The default setting is **Regular**, which means Arabic digits (0123456789). Otherwise, select **Arabic-Indic** (۹۸۷۶۵۴۳۲۱۰).

The Bidirectional property is not applicable to binary numbers.

Date & Time item subclass properties

The Date & Time properties provide the flexibility to define multiple combinations of date-time formats.

Date & Time items can be interpreted as either binary or character. (See sections "[Interpret as Binary](#)" and "[Interpret as Character](#)".)

For binary **Date & Time** items, the **Presentation** property has two different values: **Packed** and **BCD**.

Packed

The **Packed** value is a number that has size, decimal places, and sign properties.

BCD

The **BCD** value is a binary coded decimal number that has size.

Other **Item Subclass** properties for **Date & Time** are displayed depending on the **Interpret as** setting (**Binary** or **Character**).

- [Date](#)
- [Time](#)
- [Format](#)
- [Time zones](#)
- [Time zone format string for XML](#)

- [Optional time segments of the time format string](#)
 - [Date and time format examples](#)
 - [NONE and Zero](#)
-

Date

For binary **Date & Time** items, use the **Date** property to define whether the date format is enabled.

Yes

Date format is enabled for this type. Expand the **Format** property to select the date format.

No

Date is not defined for this type.

- [Date > format](#)
-

Date > format

Select the date format that the data interpretation will be based on. For binary **Date & Time** items, the Date->Format property has four values.

CCYYDDD and **YYDDD** Julian date formats are supported.

- CCYYMMDD
 - YYMMDD
 - CCYYDDD
 - YYDDD
-

Time

For binary **Date & Time** items, use the **Time** property to define whether the time format is enabled. Select one of the following options:

Yes

Time format is enabled for this type. Expand the **Format** property to select the time format.

No

Time is not defined for this type.

- [Time > format](#)
-

Time > format

Select the time format that the data interpretation will be based on. For binary **Date & Time** items, the Time->Format property has several values. The following choices are available from the drop-down list:

- HH24MMSS
 - HH24MM
 - HH24:MM:SS
 - HH24:MM
 - Custom
-

Format

You can define a date-time format from within the type properties, except for native schema XML.

The output format for the native schema XML date/time field is always:

{CCYY-MM-DD}T{HH24:MM:SS.3-3+/-ZZ:ZZ}

To specify a different output format, use Xerces XML instead.

To define the Date & Time format:

1. Open the type properties.
 2. In the Item Subclass->Format property, click the browse button.
The Date Time dialog box is displayed.
 3. Make your format selections and click OK.
You can use alphabetical characters as separators. In the example,
2001-04-02T10:32:59-0500, T is the separator.
- Separators are limited to 60 characters.

Supported date formats:

- CCYYMMDD
- YYMMDD
- MMDDCCYY
- MMDDYY
- CCYYDDD
- YYDDD
- DDMMCCYY
- DDMMYY

Note: The DDMMCCYY and DDMMYY formats did not exist prior to version 6.5 of the Design Studio. If you had defined either one of these formats prior to 6.5 as a custom format, it will be recognized in 6.5 as the respective new format, instead of the previously defined custom format.

- [Use of format elements](#)
- [Custom date format](#)
- [Custom Time Format](#)

Use of format elements

If you select the same format element more than once for the same item, that item may not be validated separately. If you specify **MON** twice, the day of the month is not validated separately for both months. For example, if the date format element **MON** is used twice for a single item, with the following format string:

MON D-MON D

Suppose the data is this:

Feb 28-Mar 31

28 is not validated for the month of February.

Some combinations of reserved words are invalid. A separator must follow reserved words representing a variable number of digits (**D** and **M** for date) if data follows.

For example:

- D/M/CCYY is valid.
- CCYYM/D is invalid.
- DMCCYY is invalid.

See the Design Studio Introduction for a list of reserve words and symbols.

Custom date format

After choosing **Custom** from the date format drop-down list, click browse. The Date Format dialog box is displayed.

You can only use non-alphanumeric characters (excluding the {, } and [,] non-alphanumeric characters) as separators in the custom Date Format dialog box.

The following table provides examples of date formats.

Date Format	Description	Example
CCYY	4-digit Century + Year	1999
YY	2-digit Year (00-99)	99
MM	2-digit Month (01-12)	12
M	1- or 2-digit Month (1-12)	8
MON	3-character Month (Jan to Dec)	JAN
MONTH	Full name of Month	January
DDD	3-digit Day of year (001-366)	32
DD	2-digit Day of Month (01-31)	31
D	1- or 2-digit Day of Month (1-31)	7
DY	3-character Day of Week (Sun-Sat)	Fri
DAY	Full Name of Day of Week (Sunday-Saturday)	Friday
WW	1- or 2-digit Week of Year	13
Qn	Quarter of Year (Q1-Q4)	Q2
Custom	User defined custom date format	

After you define and save a custom format, the custom format string is displayed in the Properties window. For example, the custom date format **CCYYMMDD**, and the custom time format **HH24MMSS** display as:

{CCYYMMDD}{HH24MMSS}

Custom Time Format

After selecting **Custom** from the time format list, click browse. The Time Format window is displayed.

You can only use non-alphanumeric characters as separators, excluding the {, } and [,] non-alphanumeric characters, in the Time Format window.

The following table provides time format examples.

Time Format	Description	Example
HH24	2-digit hour in 24 hour format (00-23)	23
H24	1- or 2-digit hour in 24 hour format (0-23)	11
HH12	2-digit hour in 12 hour format (00-12)	08
H12	1- or 2-digit hour in 12 hour format (0-12)	8
MM	2-digit minute (00-59)	09
M	1- or 2-digit minute (0-59)	9
SS	2-digit second (00-59)	05
S	1- or 2-digit second (0-59)	5
AM/PM	Meridian (AM/PM)	AM
ZZZ	A time zone abbreviation. See " Time Zones " for a list of supported time zones.	EST
+/-ZZZZ	Hours and minutes before or after the Greenwich Mean Time (GMT). GMT is now referred to as Coordinated Universal Time (UTC).	+0500
+/-ZZ:ZZ	4-digit time where the format is a 2-digit hour and 2-digit minute, separated by a colon.	+05:00
+/-ZZ[;ZZ]	4-digit time where the format is a 2-digit hour and an optional 2-digit minute, separated by colon.	+05:00
+/-ZZ[ZZ]	4-digit time where the format is a 2-digit hour and an optional 2-digit minute.	+0500
TZD	4-digit time where the format is a 2-digit hour and 2-digit minute, separated by a colon. Z on output, if value is +/-00:00.	+05:00

After you define and save a custom format, the custom format string is displayed in the Properties window. For example, the custom date format CCYYMMDD, and the custom time format HH24MMSS display as:

{CCYYMMDD}{HH24MMSS}

Time zones

The following table lists the supported time zones.

Time Zone	Abbreviation	Hours before Greenwich Mean Time	Hours ahead of Greenwich Mean Time
Greenwich Mean Time (Zulu)	GMT	0	0
West African Time	WAT	-1	+23
Azores Time	AT	-2	+22
No name; Brasilia Time	###	-3	+21
Atlantic Standard Time	AST	-4	+20
Eastern Standard Time	EST	-5	+19
Central Standard Time	CST	-6	+18
Mountain Pacific Time	MST	-7	+17
Pacific Standard Time	PST	-8	+16
Yukon Standard Time	YST	-9	+15
Hawaii Standard Time	HST	-10	+14
Nome Time	NT	-11	+13
New Zealand Time	NZT	-12	+12
No name; no location	###	-13	+11
Guam Standard Time	GST	-14	+10
Japan Standard Time	JST	-15	+9
China Coast Time	CCT	-16	+8
West Australia Time	WAT	-17	+7
Zulu + 6 (Russia zone 6)	ZP6	-18	+6
Zulu + 5 (Russia zone 5)	ZP5	-19	+5
Zulu + 4 (Russia zone 4)	ZP4	-20	+4
Baghdad Time	BT	-21	+3
Eastern European Time	EET	-22	+2
Central European Time	CET	-23	+1

Time zone format string for XML

Note: The output format for the native schema XML date/time field is always:

{CCYY-MM-DD}T{HH24:MM:SS.3-3+/-ZZ:ZZ}

To specify a different output format, use Xerces XML.

The following time zone strings support the specification of a single character Z to indicate Coordinated Universal Time (UTC), as described by the World Wide Web Consortium (www.w3.org) and the ISO 8601 standard:

- +/-ZZZZ
- +/-ZZ:ZZ
- TZD

When the +/-ZZ:ZZ or +/-ZZZZ format string is specified, the data validation process works in the following manner:

- Valid data that corresponds to this format string will contain either a character literal Z (representing UTC) or a zone in the appropriate format: +/-ZZ:ZZ or +/-ZZZZ, as specified.

- If a character literal Z is present, it shall be interpreted, and treated at mapping time, as UTC, which is equivalent to +00:00 or +0000.

When the TZD format string is specified, the data validation and output generation processes work in the following manner:

- Valid data that corresponds to this format string will contain either a character literal Z, representing UTC, or a zone, in the +/-ZZ:ZZ format.
- If a character literal Z is present, it shall be interpreted, and treated at mapping time, as UTC, which is equivalent to +00:00.
- If the value is +/-00:00, it generates Z in the output. Otherwise, it generates the output in +/-ZZ:ZZ format.

The following time zone strings support the omission of the minute portion of the difference from UTC:

- +/-ZZ[:ZZ]
- +/-ZZ[ZZ]

Optional time segments of the time format string

This section discusses how you can specify a portion of a time-format string to be optional. For example, you can specify that either the *time zone* portion or the *hours, minutes, seconds, fractional seconds, Meridian* portion is optional.

This flexibility is also applicable to time-format strings used in functions or in schema scripts imported by the Type Tree Maker.

Only the time portion **or** the zone portion can be optional—not both.

To specify a portion of the time-format string as optional:

1. The following procedure assumes that the **Item Subclass** property of your schema is **Date & Time**.
2. From within the schema properties, navigate to Item Subclass.>.Format.
3. Click the browse button to open the Date Time dialog.
4. From a Format field that is set to **Time**, go to the field directly below it and choose Custom from the drop-down menu.
5. Next to the Format field with **Custom** selected, click the browse button. The Time Format dialog is displayed.
6. Choose from the following tasks:
 - To specify the *hours, minutes, seconds, fractional seconds, and Meridian*-portion of the time format string as optional, enable the check box on the far left side of the dialog.
 - To specify the *time zone* portion of the time format string as optional, enable the check box.
 Only one segment of the time format string can be specified as optional.

Date and time format examples

The following list includes examples of popular standard date and time formats:

Format	Description
X12 EDI	Fractional seconds format: HH24MM[SS[0-2]] .

SWIFT

Time Zone Designator or UTC Designator format: **HH24MSS[TZD]**.

TimeStamp format: **CCYY-MM-DDTHH:MM[SS[.0-6]][TZD]**, which is a combination of date and time.

HL7

Time format: **HH24MM[SS[.0-6]][+/-ZZZZ]**.

TimeStamp format: **CCYYMMDDHHMM[SS[.0-6]][+/-ZZZZ]**, which is a combination of date and time.

SAP

Time format: **HHMMSS**.

ODBC

Time format: **HH:MM:SS[.0-9]**, which is the form most commonly used in **ODBC** mapping. The fractional part is optional and not often used.

NONE and Zero

When the Item Subclass has a Date & Time value and the Interpret as property has a Character value, the NONE and Zero properties are available. Expand the NONE or Zero property to specify an override data value to define the Special Value and Required on input properties.

- [NONE > Special Value and Zero > Special Value](#)
Enter a value in the Special Value property if the item is NONE or Zero.
- [NONE > Required on input and Zero > Required on input](#)
Select a value from the Required on input property list.

NONE > Special Value and Zero > Special Value

Enter a value in the Special Value property if the item is NONE or Zero.

For example, if you specify * in the Special Value property for NONE, and a data and time object has the value *, it is interpreted as NONE.

If you enter a value in the Special Value property for NONE or Zero, enter the exact characters to be validated in the input data and built in the output data.

The maximum element length that is allowed for the Special Value property is 3000 bytes.

NONE > Required on input and Zero > Required on input

Select a value from the Required on input property list.

Yes

If the data object is NONE or Zero, the map uses the value in the Special Value property when it validates the item in the input.

No

Do not use the value in the Special Value property. No special values or input requirements are defined when data is NONE or Zero.

When the map builds the item in the output, the item might be either the value in the Special Value property or the default value for NONE or Zero. For example, if an item contains all pad characters and no actual data, the default value for NONE is used when that item is built in the output.

Syntax item subclass properties

Syntax objects are characters that precede, separate, or follow a particular data object. Item types with an **Item Subclass** of **Syntax** are defined and used to specify delimiters, initiators, terminators, and release characters. Syntax objects with variable values are defined as the syntax object's **Variable** property. Syntax objects appearing as actual data to be mapped as output data are defined as components of a type.

- [Syntax objects with variable values](#)
- [Example of variable syntax object as an item type](#)
- [Syntax objects as data](#)
- [Example of syntax objects as components of a type](#)
- [Delimiter > find](#)

Syntax objects with variable values

Using a syntax item to specify delimiters, initiators, terminators, and release characters is required when the value of syntax objects (delimiters, initiators, terminators, and release characters) may vary.

The restrictions of syntax items define the variable literal values.

To define a variable syntax object:

1. Create an item type with an **Item Subclass** of **Syntax** to represent the syntax object.
2. Define the restrictions for the syntax item type.
3. For the item or group type with the variable syntax object, for the **Variable** delimiter, initiator, terminator, and release character, select the item from the **Item** drop-down list in the Properties view.
4. For the **Find** property, select Yes.

Only item types defined with an **Item Subclass** of **Syntax** appear in the drop-down list.

Example of variable syntax object as an item type

In this example, the group type **Header** has variable delimiter values of: , * + ~

1. Create an item type with the **Item Subclass** of **Syntax** and the name **Delimiter**. (The name can be any valid type name, but naming this item **Delimiter** is useful).
2. To define the item restrictions, double-click the **Delimiter** type. The item view is displayed.
3. Define the restrictions in the **Include** column.
4. In the Properties window, select Syntax for the **Item Subclass** property.
5. Open the properties for the delimited group type **Header**.
6. For the **Syntax** property, choose **Delimited**.
7. For the **Delimiter** property, choose **Variable**.
8. Expand the **Delimiter** property.
9. Define the Delimiter:
Default literal value.
10. For the variable Delimiter Item property, choose the item type **Delimiter** from the drop-down list.
11. Indicate that the variable delimiter should be determined for each occurrence of the object by selecting Yes for the Delimiter:
Find property.

Syntax objects as data

The value of a syntax object (delimiters, initiators, terminators, and release characters) may appear as actual data that can be mapped. Syntax objects that appear as actual data are defined as components of a type.

Example of syntax objects as components of a type

The following is an example of defining a syntax object as a component of a group type. The following data represents a message received from multiple departments.

Each message is made up of segments. Each department uses different segment delimiters and terminators. The message format specifies that the delimiter and terminator are the first two bytes of the message, followed by the actual data.

To define syntax objects for the delimiter and terminator:

1. Define two separate syntax objects with an **Item Subclass** of **Syntax**, one for the message delimiter and one for the message terminator. Appropriate type names might be **SegmentDelimiter** and **SegmentTerminator**.
2. Define the possible message delimiter values as restrictions of the **SegmentDelimiter** item type. Define the possible message terminator values as restrictions of the **SegmentTerminator** item type.
3. Define these item types as the first two components of the group type **Message**.
4. Expand the **Delimiter** property.
5. For the variable **Delimiter.>Item** property, select SegmentDelimiter from the drop-down list.
6. For the variable **Terminator.>Item** property, select SegmentTerminator from the drop-down list.

During the data validation process, the component **SegmentDelimiter** appears in the data with a value of *. The group type **Segment** has a variable delimiter specified as the item type **SegmentDelimiter**, with the value *. Therefore, it is understood that the segment has * as the delimiter.

When the value of a syntax object appears as actual data, it can be mapped as data. For example, source data may use different delimiters from several different sources. Acknowledgments of this data must be sent back to the source using the delimiter used in the original data. This data can be mapped from the input to the output if these syntax objects are defined as components within the data.

Delimiter > find

When syntax objects are **Variable**, the **Find** property must be defined. The **Find** property determines whether the value of syntax object is set on each occurrence or whether the current setting (or default value) is used.

When the **Initiator**, **Terminator**, **Release**, or **Delimiter** property value is **Variable**, select one of the following from the drop-down list in the **Value** column:

Yes

Determine the value of the syntax object each time an occurrence of that type is found. After the value of that syntax object is found, that particular value is used until it is reset by another **Find** or by the occurrence of that syntax item as a component.

INPUT: The value of the object in the input data is determined by the location in the data stream and the restrictions of the syntax item.

OUTPUT: The default value is used for building the syntax object in the output data.

No

The variable syntax object is defined as the current value or, if it is not set, as the default value.

INPUT: If the syntax object is not encountered in the data stream, the value of the syntax object is the default value.

OUTPUT: If the value of the syntax item has *not* been previously set, the default value is used.

Group properties

Group properties include the group's **Subclass** and **Format**, which describes how to distinguish one component of that group from another component of that group.

- [Group subclass](#)
- [Sequence group formats](#)
- [Explicit format](#)
- [Implicit format](#)
- [Specifying a delimiter](#)
- [Defining exclude characters](#)

During map run time, the data validation process uses the Exclude Character List group property to define a set of characters that are not allowed to exist in the data stream as data content.

- [Escaping an excluded character in the data content](#)

Select Release exclude characters when you configure the exclude character list to enable the release character to escape excluded characters. When enabled, a release character that precedes an excluded character in data content escapes the excluded character, and the data content passes validation. Likewise, Link precedes an excluded character with the release character when building the output stream.

Group subclass

Group types have a subclass of **Sequence**, **Choice**, or **Unordered**.

Property	Description
Sequence	A partially-ordered or sequenced group of data objects. Each component of a Sequence group is validated sequentially.
Choice	Choice groups provide the ability to define a selection from a set of components like a multiple-choice question on a test. A Choice group is valid when the data matches one of the components of the choice group. Validation of a Choice group is attempted in the order of the components until a single component is validated. If the Choice group has an initiator, the initiator is validated first.

Property	Description
Unordered	An unordered group has one or more components. Unordered groups can only have an Implicit format property, with the same syntax options as sequence groups: None or Delimited .

- [Properties of group subclasses](#)
- [Choice group components](#)
- [Unordered group components](#)

Properties of group subclasses

The distinction between Sequence and Choice group subclasses is that Choice groups have no **Partition** or **Format** properties.

Type syntax properties such as **Initiator**, **Terminator**, **Release**, and **Empty** can be applied to **Choice** groups. If a release character is defined, by default it applies to the **Terminator**.

Choice group components

A Choice group can have both items and groups as components. A partitioned Sequence group can only have group subtypes.

Components of a Choice group must be distinguishable from each other. The components of a Choice group cannot have a component range other than (1:1). Only one component of a Choice group built in the output data.

A Choice group data type is only one of the group components. For example, the data type **Record** is a group type with a **Group Subclass of Choice**. The group type **Record** has three components: **Order**, **Invoice**, and **Sales**. The data validation of **Record** will be only one of the components: **Order**, **Invoice**, or **Sales**. For this reason, the components of a Choice group must have a component range of (1:1).

Unordered group components

An unordered group has one or more components that can appear in the data stream in any order. They allow many SWIFT and FIX message types, for example, to be defined in a more natural way.

Unordered groups have no partitioned property. They have **Implicit** format properties with the same syntax options as sequence groups: **None** and **Delimited**.

When a group is defined as **Unordered**, any component can appear in the data stream. A component can be an item or a group.

Unordered group components have a range property. For example, if the unordered group, **A**, has the following component list:

```
B (1 : S)
C
D (S)
```

then **A** must have one **C**, at least one **B**, and possibly some **Ds**. They could appear in any order. For example, data for **A** could have the pattern: **CDBBDDD** or **BBBDDDCBD**.

Component rules of an unordered group cannot reference other components of the same group. They can only reference the component to which the rule refers and the objects contained in that component.

Sequence group formats

A sequence group has either an **Explicit** or **Implicit** format.

Explicit

The explicit format relies on syntax to separate components. Each component can be identified by its position or by a delimiter in the data. Delimiters appear for missing components.

Implicit

The implicit format relies on the properties of the component types. The format is not fixed. If delimiters separate components, they do not appear for missing components.

For example, if each component of a fixed group has a fixed size, the component is distinguished from the next component by its position in the data. Or, a group may have delimiters that appear for missing components. In these cases, the format is apparent; the group has an explicit format.

If a group does not have an explicit format, it has an implicit format. An implicit format relies on the properties of the component types. In this example, the components make some pattern in the data and it is possible to distinguish between them, but the format is not fixed and if delimiters separate components, they do not appear for missing components.

When deciding what format a group has, it may help to ask first whether it is clear where one component ends and another begins. Generally, a group has an explicit format if the position of each component in the data stream is always the same or if a delimiter always marks the place for each component.

Explicit format

To specify that a group has an explicit format, choose **Explicit** for the **Format** property. Select a setting for the **Track** property, and choose the group's syntax: **Fixed** or **Delimited**.

- [Track](#)
 - [Fixed syntax](#)
 - [Explicit delimited syntax](#)
-

Track

The **Track** property indicates whether the system should track only the components that have content or all components, including those that do not have content. The settings are **Content** and **Places**.

For example, if a group **StudyGroup** has the component **Name(s)**, and Places is specified for the Track property, any empty occurrences of **Name** are tracked.

Suppose **Name** has an * initiator and a space pad character. This is the data for **StudyGroup**:

*Carolyn * *Stuart *Margaret

Notice that the second **Name** is missing.

If Places is specified for the Track property, and you want to map the third **Name**, the empty **Name** would be counted as an occurrence, so the third **Name** would be Stuart. However, if Content is specified for the Track property, the empty **Name** would not be counted as an occurrence because it does not have content and the third **Name** would be Margaret.

Fixed syntax

If a group data object is always the same size (in bytes), it has a fixed syntax. For example, a record that is always 160 bytes has a fixed syntax.

Each component of a fixed group must be fixed. If you break down a fixed group, it ultimately consists of items that are fixed. Each is padded to a fixed size or its minimum and maximum content size are equal. Do not specify the size of a fixed group. The size is automatically calculated based on the size of the group's components.

- [Guidelines for defining a fixed group](#)
-

Guidelines for defining a fixed group

- Each component must be a group with a fixed syntax or a fixed item. The item is padded to a fixed size or its minimum and maximum content size are equal.
 - Each component must have a specified range maximum. The maximum cannot be s.
 - If a component range minimum is not equal to the maximum, content is not required for optional component occurrences. For example, if a component is the item **ShippingAddress** (0:1) and **ShippingAddress** has a minimum content size of two characters, data may either contain: 1) all pad characters, or 2) if content is in the data stream, there must be a minimum of two characters for a **ShippingAddress**. If a component is a group, no content is required for any of the items contained in an optional occurrence of that component.
-

Explicit delimited syntax

An explicit-format group with a delimited syntax is one whose components are separated by a delimiter and the delimiter appears as a placeholder even when a component has no content.

About delimiters and explicit-format groups:

- The only time a delimiter can be missing is when all components following the delimiter are optional and there is no data for the optional components.
 - A delimiter is a character or series of characters that separates data objects.
 - A delimiter cannot be longer than 500 bytes.
 - The delimiter of a group appears inside the group, separating its components. When a group is delimited, that indicates something about the components of the group. The delimiter inside a group is delimiting the components.
-

Example

The group **Employee** has an explicit-delimited format because a comma delimiter appears between **Employee's** components, the items that make up the **Employee** object. In addition, the delimiter is displayed when a component is missing and there is data for components following it.

The components of **Employee** are the items **ID#**, **Name**, **Department**, **Address**, and **Age**.

- [Delimiter](#)
-

Delimiter

Use the **Delimiter** property to specify the value and location of the delimiter. For specific information on specifying the delimiter, see "["Specifying a Delimiter"](#)".

In an explicit-delimited group, if the delimiter is whitespace <WSP>, the delimiter is interpreted as one byte long; each <WSP> character is interpreted as another delimiter. In the output, a <WSP> delimiter is one space.

The limit for <WSP> is 512 bytes.

Implicit format

In a group with an implicit format, the components are distinguishable not by delimiter or position, but by their pattern; something in the definition of the component types themselves. The group has no syntax property that distinguishes one component from another.

For example, the type **File** consists of **Record**(s). <CR><LF> appears at the end of each **Record**. It has been defined as the terminator of **Record**. **File**, however, has no syntax of its own. The **Record** terminator distinguishes one **Record** from another.

To specify that a group has an implicit format, choose **Implicit** for the **Format** property. Optionally, define a comment type, and choose the group's syntax: **Delimited** or **None**.

- [Floating component](#)
- [Implicit whitespace syntax](#)
- [Implicit delimited syntax](#)
- [No syntax](#)
- [Distinguishable components of an implicit group](#)

Floating component

The floating component represents an object that may appear after any component of the group.

An implicit group can have a floating component; an explicit group cannot. If the group is prefix or infix delimited, the floating component is displayed before the delimiter. If the group is postfix delimited, the floating component is displayed after the delimiter.

A floating component can be an optional component that may appear after any other component. However, it is not included in the component list because it does not appear at a specific location.

If a group has a floating component, a component must be distinguishable from a floating component. For example, components and floating component could start with different initiators.

Note: When a floating component appears in the input data, it is validated during mapping. If there are floating components in your output data, define them as actual components of the output.

A floating component can appear after the initiator (when the type has an initiator), after each component, or both. For EDI and other existing floating components, trees will be converted as "after each component".

A floating component can be specified for implicit sequence group, choice group, and unordered group definitions.

Implicit whitespace syntax

Select WhiteSpace for the **Component Syntax** value when white spaces are not allowed in the data. When you select the **WhiteSpace** option, define the **Build As** and **Character Set** properties.

Note: Helpful for XML data.

- [Build as](#)
- [Character set](#)

Build as

Enter the characters that will replace white spaces.

The Build As property is only available when the Component Syntax property is defined as WhiteSpace.

Character set

Select a character set for the component from the drop-down list.

The default value is Native, where the literal values use the native character set of the computer.

[Supported character sets \(code pages\)](#)

Implicit delimited syntax

If a delimiter separates the components of a group, but the delimiter does not appear when a component is missing, the group has an implicit format with a delimited syntax.

In certain data, the delimiter may not be a placeholder.

- [Delimiter](#)

Delimiter

Use the **Delimiter** property to specify the value and location of the delimiter. For specific information on specifying the delimiter, see "["Specifying a Delimiter"](#)".

In an implicit-delimited group, when the delimiter is whitespace <WSP>, all contiguous <WSP> characters are treated as one delimiter. In the output, a <WSP> delimiter is built as one space.

The limit for <WSP> is 512 bytes.

No syntax

To specify a group with an implicit format that has no syntax, choose **None** for the **Component Syntax** value.

Distinguishable components of an implicit group

Each component of an implicit group needs to be recognizable. If either of two different components appears at the same place in a data stream, there must be a distinguishable difference between one component and the other.

Sometimes components of an implicit group may be distinguished because there is something in the data that distinguishes them.

After the first item **Line** of the **Form**, the next data object could be another item **Line**. Or, it could be a **Trailer Line**. When looking at a particular **Line**, there is something in the data that identifies that **Line** either as a **Header Line**, an item **Line**, or a **Trailer Line**. The type **Line** has been partitioned to distinguish between the different kinds of **Lines**.

Specifying a delimiter

For the **Delimiter** property, specify whether the delimiter is a literal or a variable value.

- [Literal](#)
- [Variable](#)
- [Location](#)
- [Delimiter value appears as data](#)
- [Allow Excess Trailing Delimiters](#)

Literal

If the delimiter is a constant value, enter the delimiter value in the **Value** field. To enter a non-printable value, click the browse button and select a value from the Symbols dialog box.

- [National language](#)
- [Data language](#)

National language

The National language default value is Western. For initiator, terminator, and release character **Literal** values, you can optionally specify a "["Data language"](#)".

When the **Interpret as** value is defined as **Character**, the **National language** property is specific to the **Character** value and is not available as an option for a **Binary** value.

- [National language > data language](#)
- [Supported code pages](#)

Data language

Use the **National language** > **Data language** property to define the data language or character set.

[Supported code pages](#)

Variable

Sometimes you do not know what delimiter is used in the data source, especially if you receive that data from an outside source. However, you know all of the possible values that the delimiter could be. You can create an item to represent this delimiter and specify all of the possible values as restrictions of that item. The value of the delimiter in the data is found.

To specify an item as a Variable Delimiter:

1. In the Properties view for the delimited group, click in the Delimiter, Item value field.
2. Press Alt and drag the item from the schema editor into the **Item** field.

Location

The **Location** property specifies the location of the delimiter with respect to the components. The options are prefix (the delimiter appears before the component), postfix (the delimiter appears after the component), and infix (the delimiter appears between components).

The following table explains each option.

Property	Description	Example
Prefix	Before each component. Before each member of a component in a series.	$*a*a*b*c$
Postfix	After each component. After each member of a component in a series.	$a*a*b*c*$
Infix	Between components. Between members of a component in a series.	$a*a*b*c$

Delimiter value appears as data

Delimiters do not appear as part of the actual data. For example, if the delimiter is specified as a comma, the comma in the following text item would be considered a delimiter, rather than part of the data itself:

Tom Smith, Jr.

If the data does contain the delimiter value, there are ways to format the data so that both the data and the delimiter are distinguishable. For example, text items can be enclosed in quotation marks. Or, a release character may be used. For information about release characters, see ["Release Characters"](#).

Allow Excess Trailing Delimiters

The schema validation process allows data that contains excess trailing delimiters on sequence groups.

You can change the default setting for the Allow Excess Trailing Delimiters property to No so that the schema validation process, instead, fails data that contains excess trailing delimiters.

The schema validation process interprets a delimited sequence group that contains optional components at the end of its sequence, as having excess trailing delimiters.

For example, GROUPA contains the following components: COMPA (mandatory), COMPB (optional), COMPC (optional), and COMPD (optional). The group is infix-delimited by a tilde. The following data stream examples are valid for GROUPA:

A~B~C~D
A~B~C~
A~B~~
A~~~

For this example, you want the schema validation process to disallow all of the data stream examples that contain unnecessary or excess trailing delimiters. To disallow the excess trailing delimiters, you can change the setting for the Allow Excess Trailing Delimiters property to No. The result is that the validation process fails all of the examples except the first one.

Defining exclude characters

During map run time, the data validation process uses the Exclude Character List group property to define a set of characters that are not allowed to exist in the data stream as data content.

The data validation process allows these excluded characters to exist in the data stream as syntax, such as delimiters, if they are not being used as data content.

The group exclude characters might be derived from previously parsed values in the data stream or might be defined as literal values.

When you define exclude characters at the group level, the data validation process handles these specified characters as if they were in-scope data syntax.

For example, you have a schema which defines two groups, GROUPA and GROUPB. The tree defines the asterisk (*) character as a group delimiter for GROUPA. It defines the at-sign (@) character as a group delimiter for GROUPB. The tree also defines the FILE group, which contains both GROUPA records and GROUPB records.

The data stream contains content corresponding to the FILE group, which is composed of a series of both GROUPA and GROUPB records.

When a map begins to run, it parses and validates this data stream. Since the asterisk is the delimiter of GROUPA, the data content of GROUPA records is only allowed to contain asterisk characters that are escaped. If the data content contains non-escaped asterisk characters, those GROUPA records fail data validation. Similarly, since the at-sign is the delimiter of GROUPB, the data content of GROUPB records is not allowed to contain non-escaped at-sign characters. If it does, those GROUPB records fail data validation.

The schema defines the delimiters, or markup, for the GROUPA and GROUPB records. Asterisk characters are considered to be in-scope markup while the data validation process handles GROUPA records. At-sign characters are considered to be in-scope markup while the data validation process handles GROUPB records.

Conversely, GROUPA data content is allowed to contain at-sign characters, as the GROUPB at-sign delimiter does not apply to GROUPA records. Therefore, at-sign characters are considered out-of-scope markup for GROUPA records. GROUPB data content is allowed to contain asterisk characters, as the GROUPA asterisk delimiter does not apply to GROUPB records. Therefore, asterisk characters are considered out-of-scope markup for GROUPB records.

You might require the data validation process to exclude asterisk and at-sign characters in all of the data content for both GROUPA and GROUPB records, except when those characters are used as delimiters.

If so, use the Exclude Character List property to specify the asterisk and at-sign literal values at the FILE group level. When the validation process evaluates the data, it throws an exception if there is an asterisk (*) or an at-sign (@) character in the data content within the FILE group. The asterisk and at-sign characters are still valid if they are used as group delimiters; they are invalid if they are used in data content.

Performance tip: The Exclude Character List property causes the map validation process to use more resources as it searches for each of the exclude group characters in every data element under the group on which it is defined.

Open the Exclude Character List window by clicking the Value field on the Exclude Character List property, and then clicking the button that appears at the end of the field. Specify the characters in the list as literal characters or syntax items. You can use the Add Literal, Add Syntax Item, Edit, Remove, and Remove All functions to add literal characters and syntax items to the list, edit them, and remove them from the list.

Escaping an excluded character in the data content

Select Release exclude characters when you configure the exclude character list to enable the release character to escape excluded characters. When enabled, a release character that precedes an excluded character in data content escapes the excluded character, and the data content passes validation. Likewise, Link precedes an excluded character with the release character when building the output stream.

XML properties in the schema

When you open a schema in the Type Designer after you imported it from a DTD or XML Schema, the XML-specific properties are displayed as read-only fields.

For each type in the resulting schema, the Intent property is either General (indicating non-XML) or XML. All category types that are created during the import process are considered non-XML properties. All group and item types that are created during the import process are considered XML properties.

Any types that you manually add to the XML type tree are considered non-XML and have General intent. In such a case where there are both XML and non-XML types present (such as EDI data), the appropriate method of validation is determined automatically.

See the Type Tree Maker for information about creating schemas by importing XML Schemas and DTDs.

See Utilities for XML for information about tools that can assist you with upgrading your XML schemas and maps to this version of IBM Transformation Extender.

- [Support for XML constructs](#)
- [XML schema datatypes](#)
- [Identity constraints](#)
- [Namespaces](#)
- [Element type declarations](#)
- [Element and attribute wildcards](#)

Support for XML constructs

IBM Transformation Extender validation supports the following XML constructs.

Character Data

During validation, character data is mapped by the XML parser to IBM Transformation Extender types. This data includes both parsed character data (PCDATA) and unparsed character data (CDATA).

Comments and Processor Instructions

XML comments and processing instructions (PI) are mapped to floating components in schemas.

Namespaces

The XML Schema importer supports the specification of arbitrary prefixes for namespaces declared in the input grammar.

XSDL Hints

The xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes are collectively known as XML Schema Definition Language (XSDL) hints. These attributes specify the location of the XML Schema(s) that the XML parser uses for validation.

An XML Schema allows either or both of these attributes to display within any element tag. But the XML parser respects the location values only when the XSDL hint is specified in the root element of the schema.

The Doc group type of schemas that are created with the XML Schema or XML DTD importer contains the location of the Xerces DTD or Xerces XML Schema that is used for Xerces XML validation. The Intent > Validate As > Location property can be modified. However, use the Schema > Type > Metadata card setting in the map to change the location of the DTD or Schema if needed.

Empty Elements

Only one set of initiators and terminators for the Empty element is required for validation.

Nillable Elements

A nillable element can have one of three states: absent, present with content, or present with nil content. Both the DTD and XML Schema allow the definition of optional elements in the instance document. Additionally, the XML Schema allows nillable elements where the content can be empty when it contains an xsi:nil attribute with a value of "true", despite the fact the element's content is mandatory.

The XML Schema Importer can create the content of a nillable element within a group with a range of (0:1), which makes the element content optional.

Mixed Content

When parsing elements with a mixed content model (containing both character data and child elements), the DTD and XML Schema importers generate text items within the mixed content (instead of character sequences).

Regular Expressions

An XML Schema allows the restriction of the values of simple types that are based on regular expressions or pattern facets. During XML validation, the parser enforces the pattern facet. The XML Schema Importer fills the appropriate type properties with pattern facets encountered in the input schema, which are viewable in the Type Designer.

XML schema datatypes

This section describes the schema constructs that correspond to XML Schema datatypes.

The following table lists some common XML Schema datatypes with their corresponding type property values in the Type Designer.

For detailed information about XML attributes and elements as type properties in the schema, refer to the Type Tree Importers documentation .

XML Schema Datatype	Type Property	Value
simpleType	Intent > Validate As	XML_SIMPLETYPE
complexType	Intent > Validate As	XML_COMPLEXTYPE
element	Intent > Validate As	XML_ELEMENT
attribute	Intent > Validate As	XML_ATTRIBUTE
group	Intent > Validate As	XML_GROUP

- [Simple types](#)
- [Complex types](#)
- [Elements](#)
- [Attributes](#)
- [Groups and substitution groups](#)

Simple types

Elements that have assigned simple types have character data content but not child elements or attributes.

Simple type elements are represented in the Type Designer type properties with the value XML_SIMPLETYPE.

Complex types

Elements that have assigned complex types can have both child elements and attributes. The order and structure of the child elements of a complex type are known as its content model. Content models are defined using a combination of model groups, element declarations or references, and wild cards. There are three kinds of model groups: **all**, **choice** and **sequence**.

Complex type elements, including the complex types using compositor elements, are represented in the type properties with the value XML_COMPLEXTYPE.

Elements

Element declarations are either local or global. Local elements are represented in the Type Designer type properties with the value: XML_ELEMENT.

When the schema defines several global elements, the generated schema includes a Global choice group that contains all of the global elements. A Global choice group is represented in the type properties with the value XML_BODY.

Attributes

Attributes are another building block of XML. The import process uses attribute declarations to name attributes and associate them to particular simple types. Attribute declarations can be either local or global.

Attributes, including both local and global, are represented in the type properties with the value XML_ATTRIBUTE.

Groups and substitution groups

One way an XML Schema allows the creation of reusable content is by using named model groups. These global groups can be referenced throughout a schema.

Substitution groups are a flexible way to designate element declarations as substitutes for other element declarations in a content model. New element declarations can easily be designated as substitutes from other schema documents or namespaces without changing the original content model.

Groups and substitution groups are represented in the type properties with the value XML_GROUP.

Identity constraints

The XML parser in IBM Transformation Extender enforces declared identity constraints. The XML Schema Importer sets these properties based on the XML Schema. In general, the identity constraint definition serves in one of the roles listed below:

Identity Constraint	Description
Unique	Enforces that a value (or combination of values) is unique within a given scope. For example, all product numbers must be unique within a catalogue.
Key	Enforces uniqueness and requires that all values be present. For example, every product must have a number and it must be unique within the catalogue.
Key References	Enforces that a value (or combination of values) corresponds to a value represented by a key or uniqueness constraint. For example, for every product number that is displayed as an item in a purchase order there must be a corresponding product number in the product description section.

Namespaces

The XML Schema Importer supports namespace and prefix properties for all elements and attributes. The importer assigns the values of these properties based on the input grammar. For each namespace in the input grammar, the importer allows you to specify the namespace prefix to be used for output documents.

During the import process, a **Location** value is specified in the schema without a fully qualified path. In this case, a map execution process would, by default, look for the XML Schema at this location. However, if you need to change this path, you can do so.

For example, if you refer to the proper location of the schema in the XML document, then you can manually remove the path location from the type properties. When the map execution process does not find a **Location** value specified in the schema, the process then looks to the "[XSDL Hints](#)" specified in the XML document. When XSDL hints are not present, validation fails.

The value specified in the schema takes precedence over the XML document.

Element type declarations

The XML DTD and XML Schema importers can generate a simple schema when encountering character content within mixed data. During the import process, when character data (CDATA/PCDATA) is encountered, the importer incorporates it into existing text items within the schema.

Element and attribute wildcards

DTDs and XML Schemas allow the specification of wildcard elements within a grammar. The IBM Transformation Extender XML Schema and DTD importers recognize element wildcards, build the appropriate types, and set the appropriate properties for those types to represent element wildcards in the schema.

During the import process, when a wildcard element resolves to an element that is not defined in the imported grammar, it is represented by a text item.

The value of these text items is the text string from the input buffer that runs from the start of the open tag to the end of the close tag for that element.

XML Schemas allow the specification of an attribute wildcard that matches any number of undeclared attributes within the element tag. The XML Schema Importer recognizes the attribute wildcard and creates a sequence of name and value text item pairs within the attribute list of the enclosing element. The XML validation library fills this sequence with the names and values of attributes that do not match any declared attributes in the attribute list.

Type propagation for Category, Group, and Item Properties

The Propagate option enables to propagate individual and its children property values of a type to its child types where applicable.

Note: This property can only propagate the changes from parent properties to its child properties. Child properties do not have the Propagate option. The Propagate option is disabled if the parent property gives the validation message.

- [To Propagate in Category/Group/Item property](#)
 - [To Propagate Restrictions in Category/Group/Item property](#)
-

To Propagate in Category/Group/Item property

To propagate the changes from the parent element to its child elements using Propagate option.

1. In the Schema workspace Dictionary, open the parent element where you want to propagate its changes to its child elements.
2. Make the desired changes to the property values combo box or text box of the Properties dialog.
3. Hover the cursor in the property values combo box or text box and click on the More icon.
4. Select Propagate.

This will propagate the property values in all the child elements.

To Propagate Restrictions in Category/Group/Item property

To propagate the changes from the parent element to its child elements using Propagate Restrictions option.

1. In the Schema workspace Dictionary, open the parent element where you want to propagate its changes to its child elements.
2. In the Properties dialog, select Restrictions from the drop down.
3. Make the Values from file field false.
4. Enter the text in the Include/Exclude and Description text field.
5. Hover the cursor in the Rule combo box and click on the More icon.
6. Select Propagate Restrictions.

This will propagate restrictions in the Include/Exclude and Description field of all the child elements.

Item restrictions

Item restrictions are an optional feature you can use to specify valid or invalid data objects for an item type. Item restrictions are grouped into three categories: **Value**, **Character**, and **Range**.

Restrictions of an item type are the valid or invalid values for that item. "Include" restrictions are all of the valid values for an item. "Exclude" restrictions specify all of the invalid values. For example, a unit of measure field in the data must be one of a set of values: CN, BX, PK, BR. These values should be defined as "include" restrictions of the item **UnitOfMeasure**.

Defining restrictions for an item restricts the valid data for that item. Partial lists of the valid values are not possible. For example, it is not possible to define the values for a certain item to be {A, B, C, "some other possible values"}.

While you can define restrictions for any item, most items will not have restrictions. For example, you would not want to restrict the valid values of a name field because you would probably want to accept any name as valid data for that field. However, you could assign restrictions to it if needed.

- [Restrictions settings](#)
 - [Ignoring restrictions](#)
-

Restrictions settings

Using the Restrictions property, you can create a "restriction list" to limit an item to a particular value or set of values. Depending on the Item Subclass, you can set value, character, or range restrictions.

- [Value restrictions](#)
 - [Character descriptions](#)
- In the character restrictions view for an item type, there is either an Include or Exclude column, depending on the Restrictions > Rule setting.
- [Range restrictions](#)
 - [Inserting symbols](#)
-

Value restrictions

In the value restrictions view for an item type, there is either an Include or Exclude column, depending on the Restrictions > Rule setting.

Include column

Use the Include column to specify the restrictions to use in determining if input data is valid or invalid for the item. One-to-many values are allowed. The order in which restrictions appear in the list is not relevant.

"Include" values are considered valid. An input item is considered invalid if a character other than those specified in the **Include** column appears in the data.

Exclude column

Use the Exclude column to specify the text character values to be excluded.

"Exclude" values are considered invalid. This option provides a means to specify a default set of restrictions.

To add value restrictions to an item:

1. Go to the Item Subclass  Restrictions property.
 2. Choose Value from the drop-down list.
 3. The restriction list is case-sensitive by default. If you do not want case-sensitivity, set the Ignore case subproperty to Yes to ignore case.
 4. Set the Rule subproperty to Include or Exclude the values that you will provide.
 5. Enter the value restrictions Include or Exclude column.
 6. (Optional) Enter corresponding descriptions in the Description column.
 7. Analyze the schema.
 8. Save changes.
-

Character descriptions

In the character restrictions view for an item type, there is either an Include or Exclude column, depending on the  Rule setting.

- Include character restrictions:
 - Include First column - Use this column to define the first character of the character list.
 - Include After column - Use this column to define the character list of the characters to follow the first character, as defined in the Include First column.
 - Exclude character restrictions:
 - Exclude column - Use this column to specify the substrings in the input data that must be excluded and replaced with the associated reference string.
 - Reference String column - Use this column to define the characters that are to replace the excluded character strings. On output, a character text item is built by using the corresponding reference string when the content contains any of the Exclude character substrings listed. For example, you can define XML item content that excludes markup delimiters by using the corresponding reference strings. This is because XML character text items cannot contain the markup delimiters <, > or & in the raw form.
- [To add character restrictions to an item](#)
-

To add character restrictions to an item

1. Go to the Item Subclass  Restrictions property.
 2. Choose Character from the drop-down list.
 3. The restriction list is case-sensitive by default. If you do not want case-sensitivity, set the Ignore case subproperty to Yes to ignore case.
 4. Set the Rule subproperty to Include or Exclude the values that you will provide.
 5. Enter the character restrictions in the Include First or Exclude column.
 6. Enter corresponding values in the Include After or Reference String column.
 7. Analyze the schema.
 8. Save changes.
-

Range restrictions

Include range restrictions define the minimum and maximum values valid values of a range. *Exclude range restrictions* define the minimum and maximum values of the range that are to be excluded or considered invalid.

Note: Unbound restrictions are not supported.

- [Value not in range](#)
 - [Value not in range](#)
The minimum value and the maximum values can be specified as not included in the range. For example, when a number in the Include Minimum field displayed the Value NOT In Range icon, it indicates that the number is not included as the minimum value.
 - [To add range restrictions to an item](#)
-

Value not in range

The minimum value and the maximum values can be specified as not included in the range. For example, when a number in an Include Minimum field displayed the **Value NOT In Range** icon, it indicates that the number is not included as the minimum value. The range will therefore extend from any value that is greater than that number to the maximum value specified. Similarly, if the **Include Maximum** value is designated as "not in range", the valid range would extend up to any value this is less than the maximum value.

To specify a value as "not in range":

1. Select the field (cell) that contains the value to be designated as "not in range".
 2. Right click on the value and choose the Value NOT In Range menu item.
-

Value not in range

The minimum value and the maximum values can be specified as not included in the range. For example, when a number in the Include Minimum field displayed the Value NOT in Range icon, it indicates that the number is not included as the minimum value.

The range will therefore extend from any value that is greater than the number to the maximum value specified. Similarly, if the Include Maximum value is designated as 'not in range', the valid range would extend up to any value that is less than the minimum value.

To add range restrictions to an item

1. Go to the Item Subclass \geq Restrictions property.
2. Choose Range from the drop-down list.
3. The restriction list is case-sensitive by default. If you do not want case-sensitivity, set the Ignore case subproperty to Yes to ignore case.
4. Set the Rule subproperty to Include or Exclude the values that you will provide.
5. Enter the range restrictions in the Include Minimum and Include Maximum or Exclude Minimum and Exclude Maximum columns.
6. (Optional) Enter corresponding descriptions in the Description column.
7. Analyze the schema.
8. Save changes.

Inserting symbols

Symbols are used to indicate non-printable characters. You can insert a symbol by typing it or by using the Symbols dialog.

For example, to define a carriage return/line feed as an item restriction, from the item restriction view area, right-click and select Insert Symbols from the context menu. From the list of symbols, double-click CR and double-click LF and select OK. The carriage return/line feed symbols are displayed in angle brackets in the item restriction view area: <CR><LF>

Ignoring restrictions

There might be instances when you do not require the data for an item to match any of its restrictions. Suppose you defined restrictions for your data, but you want to run a test on some test data, and you do not want to use the restrictions for this time only. You can ignore the restrictions for a given execution of a map.

In another example, you have a list of valid part numbers that can appear in any data circulated within your company. Suppose you receive data from some other company in the same format as your internal data. The other company may be using different part numbers, so you do not want to make their data conform to the restrictions. When you map the other company's data, you could ignore the restrictions.

For instructions on ignoring restrictions during map execution, see Map Designer and Command Server documentation.

Components

A component represents a data object that is part of another data object.

- [Components are required for group types](#)
- [Defining components](#)
- [Required and optional data](#)
- [Defining component rules](#)
- [Component attributes](#)

Components are required for group types

Categories and groups can have components. Components of group and category types display in the group and category views. Item types do not have components.

Group types represent actual data objects, so groups must have components. The one exception is a partitioned group which is explained in ["Partitioning"](#).

By contrast, a category is used for organizing types and for type property inheritance reasons. Categories do not define actual data objects in detail. A category does not need components.

Each group must have at least one component, unless it is partitioned.

IBM Transformation Extender supports large metadata. It supports more than 65,536 types and 65,536 components in a single schema. To reduce the number of types that maps that use large schemas must process, trim these schemas so that they contain only the required types.

- [Components must be in the same schema](#)
- [Importance of component order](#)
- [Component range](#)

Components must be in the same schema

A component must be a type in the same schema as the type that contains the component.

You cannot define the components of a type by opening up a different schema and dragging components from that tree. You can, however, copy types from one schema to another.

Importance of component order

In the group view, components are listed from top to bottom in the order they appear in the data stream. The component in the first cell appears first in the data stream. The component in the second cell appears next, and so forth.

Component range

A component range can be specified for any component. A component range defines the number of consecutive occurrences of that component. The range (s) represents some or any number greater than one.

When a component is selected, the component name is displayed in the rule bar. Click in the rule bar after the component name to type the component range.

The range is displayed in parentheses immediately after the component name. The range is two numbers separated by a colon. The first number indicates the minimum number of consecutive occurrences of that component. The second number indicates the maximum number of consecutive occurrences of that component. The syntax of the component name and range is:

Component (MIN:MAX)

To enter a range after a component name, type in the rule bar or use the **Set Range** command.

The maximum component range is 2147483647.

Whenever a component has a range, each occurrence of that component may be referred to as a "member" of a series. The words "occurrence" and "member" are used interchangeably in the documentation.

- [Indefinite number](#)
- [Single occurrence](#)

Indefinite number

When there is no maximum number of occurrences of a component (the maximum is indefinite) use the letter s to stand for "Some - you do not know how many". Therefore, a file that contains at least one record and has no maximum number of records has this component:

Record(1:s)

If the range minimum is zero, omit the 0 and only enter s. If a file has a minimum of zero records and no maximum number of records, it would have this as its component:

Record(s)

Remember that when you see (s), the minimum of zero is implied. Therefore,

Record(0:s) is the same as Record(s)

If you enter any number alone in the parentheses, the range changes to a minimum of 0 and a maximum of that number. For example, if you enter (5) for a range and save and close the group view, the next time you open it, you see the range displays:

(0:5)

Single occurrence

If there is a minimum and a maximum of one consecutive occurrence of a component, its range is (1:1). This is the default. If there is no range after a component name, the range (1:1) is implied. When you drag a type to make it a component, it is automatically created with the default component range of (1:1).

Defining components

Most groups need at least one component. Categories do not have components, however, you can define components for a category for inheritance purposes.

To determine the components of a group, ask the question: *This group type consists of what?*

For example, "The file consists of what?" The answer might be "records". So, **Record(s)** is a component of that group or category type.

Suppose you have a data file containing order records for an office supply store. You need to define the components of the type **File**.

- [Guidelines for defining components](#)
- [Complete type name](#)
- [Relative type names](#)

- [Ambiguous type names](#)

 - [Fixed and variable ranges](#)
 - [Specifying a component range](#)
 - [Variable component names](#)
-

Guidelines for defining components

The guidelines below are numbered to allow references to each other. The numbering does not suggest a priority or a sequence to be followed in observing the guidelines.

1. Categories cannot have components.
A category is only used for organizing your schema and for setting common properties.
 2. A partitioned group cannot have components.
A partitioned group always represents a choice among the subtypes of that group. You never map a partitioned group without its subtree, so it does not need components.

Note: A *subtree* is a branch of a schema that includes a type and all of the subtypes that stem underneath it.
 3. If a group is not partitioned, it must have at least one component.
Nonpartitioned groups are sequences of data objects rather than choices. A sequence must contain at least one component.
 4. A type and one of its subtypes cannot be in the same component list.
 5. If a type has components, a subtype can inherit any of those components or any type in the subtree of one of those components.
 6. If a type has no components, a subtype can inherit any type that could be in that type's component list.
 7. A type that has an initiator and a terminator can have itself or one of its ancestors as a component.
 8. A type cannot have one of its subtypes as a component.
-

Complete type name

The complete name of a group is displayed in the title bar of its window. A type's complete name is similar to a path name, beginning at the type and including all types in the path up to the root. Spaces appear between types in a complete type name.

You can have duplicate type names as long as they are not on the same level. Each type has a unique complete name, so there is no doubt as to which particular type is being referenced.

Relative type names

A component name is similar to a relative path name. Component names exclude types that the defined type and component type have in common in their complete names.

The relative type name excludes the names that appear in the complete names of both the type and the component type. For example, because **ROOT** is included in the complete type name of both **Row ROOT** and **Product Column ROOT**, it is excluded from the relative type name **Product Column**.

If more than one type in a schema has the same relative type name as another in a group, then the full path of the type is exported instead of the relative type name. No two types that have different full type names but identical relative type names can be added to a component list.

- [Moving types with the same relative type name](#)
-

Moving types with the same relative type name

In a schema, there could be two types with the same name that exist in different places within the tree. The relative type names could both evaluate to be the same, with respect to the component.

For example, the relative type **Group Category ROOT** might have a type named "Item" in both **ROOT** and **Category ROOT**. Both evaluate to "Item" with respect to the **Group** component. In this scenario, you can drag only one component named **Item** into the component list. An attempt to add a second component with the same name will be blocked.

Ambiguous type names

A component name can refer to more than one type. In this situation, you must change type names so that the component name is no longer ambiguous. The Type Designer does not allow components with the same relative type name to be added to component lists.

If you delete a type that is used as a component of another type, and then perform an "Undo", thus adding the type back, and the component name is ambiguous; the component name remains unresolved in the component list. In this scenario, the "Undo" operation does not result in a complete reversal of the action.

Specifying minimum and maximum consecutive occurrences in the component list

The following table contains examples of how to specify in the component list the minimum and maximum consecutive occurrences for specific data objects:

Data Object	Min	Max	How to Specify
DateField	1	5	DateField (1:5)
DetailRecord	1	100	DetailRecord (1:100)
AddressField	2	3	AddressField (2:3)

Fixed and variable ranges

Sometimes the range of a component is described as fixed or variable. As an example, a fixed range has the same minimum and maximum, (5:5). A variable range has a different minimum and maximum, (1:10) or (s) for example.

Specifying a component range

You can specify a component range by using Set Range to enter the minimum and maximum number of occurrences.

You can select multiple components and use Set Range to apply the same range to each component. A range of (1:s) means that there will always be at least 1 occurrence, but could occur an infinite number of times. A range of (0:s) means that an occurrence is optional, but could occur an infinite number of times.

Variable component names

A component can refer to more than one type. To refer to all possible types whose names could appear at a certain place in the component name, use the word ANY.

The word ANY is like a wild card. It represents any type whose name could appear in that place.

The use of ANY is restricted to **Categories** and partitioned groups. For more information about using ANY in a partitioned group, see "[Partitioning](#)". For a list of reserved words and symbols, see the Design Studio Introduction.

Required and optional data

Sometimes, a certain data object is optional; it does not have to be present in the data. For example, in purchase order data, there might be a billing address and a shipping address. If the company wants the items shipped to the billing address, the shipping address would not appear in the data. The shipping address would be optional; it might not appear in the data.

Another example is a middle name field. Some people do not have a middle name, so the middle name field might be optional.

The Type Designer needs to know what data is optional. This is evident from the component range. The range minimum tells how many occurrences of that object must be present in the data. These are the required occurrences. Optional occurrences are the ones that are not required.

For example, for the following component, the range minimum is zero. No occurrences must be present. It is optional data:

DateField (0:1)

Suppose the component looks like this:

DateField (1:5)

The range is between one and five occurrences. This means that one occurrence of **DateField** is required and the remaining four occurrences are optional.

The following table lists examples of components and explanations of their status.

Component	Status	Reason
LineItem (1:s)	1 occurrence required	Range minimum is 1
Note Field (5:5)	5 occurrences required	Range minimum is 5
RecordID	1 occurrence required	Range minimum is 1
ShipTo (0:1)	0 occurrences required (Optional)	Range minimum is 0
OrderRecord (s)	0 occurrences required (Optional)	Range minimum is 0

- [Significance of required data](#)

Significance of required data

If you define an occurrence of a component as required, you are saying that, for the data containing the component to be *valid*, this component must exist. If it does not exist, the data is *invalid*.

For example, if you define **Record** as having the component **Field (3:3)**, you are saying that there must be three **Fields** in the **Record**. If there are not three **Fields**, then either it is a **Record** in error or it is not a **Record**.

There are other factors, besides the existence of all required components that make data valid. The existence of required components is necessary, but not sufficient, for data to be valid.

Defining component rules

A component rule is an expression about one or more components. It indicates what must be true for that component to be valid. For given data, it evaluates to either "true" or "false". A component rule is similar to a test. If the data does not pass the test, it is invalid.

Component rules are used for validating data. Some important points about component rules are:

- Only components of a group can have component rules. Components of a category cannot have component rules.
- A component rule cannot be longer than 32K.
- If a component is optional and does not appear in the data, the component rule is evaluated after determining that the data is missing. In a component rule, you can specify relationships that depend on existence or nonexistence of data.

Sometimes components have relationships among each other. For example, an address field in purchase order data is preceded by a qualifier field which tells whether the address is a bill-to or a ship-to address. If the value of the qualifier field is `BT`, the address field following it is a bill-to address. If the value is `ST`, the following address is a ship-to address.

The qualifier and address fields are dependent on each other. They only make sense as a pair. If one of these fields is optional and is missing, the other field is not meaningful. If the qualifier is missing, you do not know whether the address is a bill-to or a ship-to. If the address is missing, the qualifier does not qualify anything!

You might want to define this kind of relationship and other relationships among data objects. To do this, use a component rule. For example, use a rule on the address field component to indicate that the qualifier must be present if the address is present.

- [Examples of component rules](#)
- [Component rule syntax](#)
- [Entering object names in component rules](#)
- [Shorthand notation](#)
- [Component rules are context-sensitive](#)
- [Special characters in component rules](#)
- [Comments in component rules](#)

Examples of component rules

A component rule can limit the acceptable values of a component as shown in the following example:

```
Quantity < 10000
Interest Rate > .13 & Interest Rate < .20
WHEN (PurposeCode != "PF", ShipValue = 200|ShipCode < 0)
```

The following example illustrates how a component rule can make the presence of one component mandatory, if another component is present:

```
WHEN (PRESENT (Address Field), PRESENT (Qualifier Field))
WHEN (PRESENT (PhoneNumber), PRESENT (AreaCode), ABSENT (AreaCode))
```

A component rule can compare a component to the result of an arithmetic operation as shown in the following example:

```
SUM (((QuantityOrdered:Item Record:Detail) = TotalQuantity:Summary Record:Detail
Account Balance = Credits - Debits
Extension = Quantity*Price
#Items Field = COUNT (Item Record IN Invoice)
```

Component rule syntax

A component rule is a complete expression that evaluates to either "true" or "false". It can contain functions (for example, PRESENT, COUNT, and SUM). It can also contain arithmetic operators (such as `- + * /`).

A component rule is a statement, so it does not start with an equal sign.

For more information about the syntax of expressions, see the Functions and Expressions documentation.

Entering object names in component rules

A component rule can refer to a component within a component. The syntax for a component is the component name, followed by a colon (`:`), followed by the object of which the component is a part. Whenever you see the colon (`:`) in an expression, it can be interpreted as "component of" or simply "of".

For example, the following expression means "The item number of the order record of the order":

```
Item#:OrderRecord:Order
```

All of the objects that can be used in component rules are shown in the group view. You can enter an object name into a component rule by pressing `Alt` and dragging the object into the edit area. The complete object name is automatically entered.

A component rule can refer to:

- The component it applies to and any nested components.
- Any component above the given component in the component list, and its nested components.
You can enter an object name in a component rule by typing it; however, the recommended method is to press Alt and drag the component into the edit area.

Shorthand notation

In a component rule, the dollar sign (\$) represents the component itself. When you enter an object name in a rule by pressing Alt and dragging the object, the dollar sign is automatically entered in the rule to represent the given component.

Component rules are context-sensitive

Component rules apply to components, not types. It applies to data in a certain context when the data is a component of a given group.

Suppose you have some order data that contains two kinds of records: a regular order record and a bulk order record. In the bulk order record, the quantity ordered must be greater than 1000. In the regular order record, the quantity can be any number. You could put a rule on the quantity ordered component of a bulk order, but not on the quantity ordered of a regular order.

Special characters in component rules

To enter the actual value of a special character in a component rule, you must enter the Hex value for one of the characters. For example, to enter the text value <WSP>, enter the Hex value for the less than sign <<3C>>, and then the rest:

<<3C>>WSP>

See the Design Studio Introduction for a list of non-printable Hex and decimal values.

Comments in component rules

You can add comments to component rules. Comments do not affect how component rules are evaluated.

A comment begins with the characters /* and ends with the characters */. A comment can appear anywhere in a rule as long as it does not separate object names.

For example, the following component rule has a comment:

```
SIZE (Phone# Field:$) >=7
/* Phone numbers must include area code */
```

Component attributes

Attributes can be assigned to a component in a component list.

- [Identifier attribute](#)
- [Restart attribute](#)
- [Sized attribute](#)
- [Include self in size](#)

Identifier attribute

The identifier attribute can be used on a component of a group. The identifier indicates the components that can be used to identify the type to which a data object belongs. All the components, from the first, up to and including the component with the identifier attribute, are used for type identification.

When this data is validated, it knows that, when it reaches the identifier, it has found a specific group. That group, therefore, is known to exist, even if part of the group following the identifier is missing. The Map Designer documentation discusses how data validation occurs.

The identifier attribute is also useful when identifying an object of a partitioned group. For information about using an identifier with partitioned data, see ["Partitioning"](#).

In a component list, there can be only one identifier attribute.

Restart attribute

To continue processing your input data when a data object of a component is invalid, assign the restart attribute to that component.

Do not put the restart attribute on a required component. There must be a sufficient number of valid instances to cover all required components. If you have a required component that is not valid, the restart attribute does not validate the data.

For additional information about using the **Restart** attribute , see the Map Designer documentation.

Sized attribute

The sized attribute is used on a component in which the value specifies the size (in bytes) of the component immediately following it. The sized attribute can be used on more than one component of a group.

For example, you might have a variable length component with a number immediately preceding it that indicates the length of the component: **10Washington**. The size of the component would be 10.

Some important points about using the sized attribute are:

- The component with the sized attribute must be defined as an unsigned integer.
- If a binary byte stream item does not have a fixed size, the component preceding it must specify its size and the sized attribute must be used on that component.

The size of a component is the number of bytes from the beginning of that component, up to and including the end of the component. If a component has a series range (such as [1:3]), the size includes all of the members in the series of that component. If a delimiter separates each member of that series, the delimiters must be included in the size. Also, if release characters appear in the component, they must be included in the size.

The size does *not* include delimiters that separate one component type from the next.

Include self in size

If the value of the component with the sized attribute includes the size of the component, use the **Include Self in Size** option. For example, suppose the component with the sized attribute has a length of seven bytes. The value of the component with the sized attribute would be seven. So, its data would be one byte long, to hold the character seven. If its value includes the length of itself, its value would be $7 + 1 = 8$.

For example, a sized component is 7 bytes.

+ 1 byte (the length of the character 7)

If **Include Self in Size** is selected: 8 bytes

Partitioning

By partitioning, you can define your data to distinguish the difference between data objects based on values in the data or differences in the syntax.

Partitioning is a method of subdividing objects into mutually exclusive subtypes. The partitioned type maintains the same class.

- [Determining when to partition](#)
- [Partitioning types](#)

Determining when to partition

There are some cases in which you will *need* to partition your data and others in which you will *want* to partition your data. You are *required* to partition for unordered data when a data object at a certain place in the data stream can be any number of types and each type has different definitions. Choose to partition for convenience, either to simplify mapping rules or to put additional logic into your data's definition.

- [Required partitioning](#)
- [Partitioning for convenience](#)
- [Benefits of partitioning](#)

Required partitioning

Partitioning is required when components are randomly or partially ordered. The following example represents unordered data:

BGI - 13100,REM,931104,19970424...

AXR - 10930,INV,003X114,19970422...

PVY - 19496,ORD,PO-104-1499,19970425...

BGI - 13100,ORD,PO-182-2587,19970425...

AXR - 10930,INV,003X-114,19970422...

PVY - 19496,REM,931104,19970424...

The file would contain three different types of transactions: **Invoice**, **Order**, and **Remittance**. Each transaction has a different definition based on the type of information it represents.

Partitioning for convenience

You might decide to use partitioning in your schema to build additional logic into the definition of your data. You may also use partitioning to simplify the rules needed in your map.

The following is an example of partitioning to simplify rules. The example compares the differences between rules needed *with* and *without* partitioning. In the rule without partitioning, you would specify a condition for each state abbreviation in each region. This could make your mapping rules long, difficult to read, and difficult to maintain. The mapping rule with partitioning is more concise, self-documenting, and easier to maintain.

Map rule without partitioning:

```
=IF(ShipToCode Field::Input="NY" |  
    ShipToCode Field::Input="NJ" |  
    ShipToCode Field::Input="PA",  
    F_MapEast (Record:Input), NONE)
```

Map rule with partitioning:

```
=F_MapEast (EXTRACT (Record:Input,  
PARTITION (ShipToCode Field::Input, East)))
```

Benefits of partitioning

Using the [previous example](#), explore the benefits of partitioning.

- The rule is shorter than the rule without partitioning. The knowledge of which states belong to each region is maintained in the type tree rather than the map rule.
- It is easy to read this map rule and understand the mapping function being performed. For example, if the state belongs to the list of states in the eastern region, execute the **MapEast** functional map.
- The partitioning method is easier to maintain. If a value for **State** is added or moves from one region to another, it can be easily changed in the schema and automatically reflected in any mapping rules that reference the partitioned object.
- Partitioning using a restriction list used with the **Ignore Case** setting eliminates the need for PROPER, LOWERCASE, or UPPERCASE functions to compare each state with a literal.

Partitioning types

When data objects of different types appear in the same place in the data, the types must be distinguishable. This means that the data needs to be distinguishable by their definitions in the schema.

When the data object at any given point in the data may belong to any of a number of different types, there must be some way to tell the difference between them. To do this, you create a type and define a mutually exclusive subtype for each data object that may appear in the same place in the data. Once the subtypes are created, the subtypes also need to be distinguishable. Subtypes are distinguishable based on a value in the data or in the syntax of the different types.

- [Partitioning items](#)
- [Partitioning an item type using initiators](#)
- [Partitioning an item type using restrictions](#)
- [Partitioning an item type by format](#)
- [Partitioning groups](#)

Partitioning items

Use one of the following three methods to partition items in schemas:

- Initiators
- Restrictions
- Format

Partitioning an item type using initiators

To partition by initiator, each subtype must have an initiator and the value of the initiator must be unique for each subtype.

Partitioning by initiator is the most efficient method of partitioning.

Partitioning an item type using restrictions

If an item has restrictions, you can partition that type, create mutually exclusive subtypes, and divide the restrictions between subtypes. A restriction cannot appear in more than one subtype of that item.

- [Example of using restrictions](#)

Example of using restrictions

You have new data that needs to be entered into the schema designer. Each new record contains the name of the employee and his or her department.

The **Employee List** schema illustrates components of **Record**.

The following is the new data containing the name of the employee and the department.

Steven Barlow,Doc

Heather Proust,Qa

Mary Whiting,Doc

Genie Elks,Sup

Francine Maxwell,Dev

Mark Brown,Sup

Daryl Schwartz,Acc

Harry O'Brian,Sal

Ellen Randolph,Dev

Paula Keller,Qa

Define the values of **Department** as a character text item.

Define the example data as valid restrictions (enter in the **Include** column) of **Department**:

If the departments are located in different offices, you can divide the data into separate files; one file per office. To do this, map the data from the main office to one file, the data from the development office to one file, and the data from the support office to another file. Then create subtypes of **Department: MainOffice**, **DevelopmentOffice**, and **SupportOffice** and partition **Department**. When you partition **Department** and create subtypes, you are saying that a given department data object belongs to only one of the subtypes based on its value.

The subtypes of **Department** inherit the restrictions of **Department**. Now allocate restrictions among subtypes. To do this, delete the restrictions from the subtype that do not apply to that particular office. For example, the **MainOffice** item has only the departments in that office, **DevelopmentOffice** item has only the departments in that office, and the **SupportOffice** item has only the departments in that office.

Partitioning an item type by format

Subtypes that differ by their format are distinguishable from each other.

Partitioning groups

Use one of the following three methods to partition groups in schemas:

- Initiators
- Identifiers
- Component rules
- [Partitioning a group type using initiators](#)
- [Partitioning a group type using identifiers](#)
- [Partitioning a group type using component rules](#)

Partitioning a group type using initiators

To partition by initiator, each subtype must have an initiator and the value of the initiator must be unique for each subtype.

The method of partitioning by initiators for group types is similar to item types.

Partitioning a group type using identifiers

In a component list, only one component can have the identifier attribute.

The identifier attribute distinguishes the components that can be used to identify the type to which a data object belongs. Typically, use this technique to distinguish group partitions when components following the identifier are different for each partition, or, if you have a multilevel partitioned subtree. In the latter case, using an identifier accelerates data validation.

A partition is valid when each component up to and including the identifier is validated. If the set of components is valid, the partition exists.

If the identifier set of components is not valid, the partition is determined not to exist. Either validation occurs for the next partition at the same level (if there is one) or it is determined that the partitioned group does not exist.

If the partition exists, what occurs next depends on the position of the partition type in the subtree.

- If the partition is partitioned (that is, it has subtypes), the rest of the components are skipped and the process begins to validate subtypes until a subtype is valid, exists and is in error, or does not exist.
- If the partition has no subtypes, the remaining components are validated. If all remaining components are valid, the partition not only exists, but also is valid. If one or more components are found to be in error, the partition exists, but its type is in error. If the partition exists, but its type is in error, the error is propagated back up the partitioned subtree until the group being validated is reached. When a partition is found to exist, the system will not continue to search for partitions.

To specify a component as the identifier:

1. From the schema editor, double-click a component.
The Component view opens.
2. In the Component column, right-click on the component and choose Identifier from the context menu.

The identifier symbol appears in the component column next to the component name.

Partitioning a group type using component rules

Component rules are used to partition data when a value or range of values can be used to distinguish one partition from another.

Type inheritance

Properties, components, and restrictions of a type can be inherited by the types created as subtypes under it. Some properties of a type can also be propagated to already existing subtypes.

When you create a type, it becomes a subtype of whatever type is selected at the time. Everything that defines a type gets passed down: properties (with the exception of the Partitioned property), components, and restrictions. After a type is created, you can then modify any aspect of its definition.

When a group is created within a category, the item properties do not apply, so they are not inherited. When an item is created under a category, the group properties are not inherited.

- [Inheritance of item properties and restrictions](#)
- [Inheritance of category properties and components](#)
- [Propagation of type properties](#)

Creation time is not the only time type properties can be passed from a type to its subtypes. You can use propagation to pass along certain type properties.

Inheritance of item properties and restrictions

Properties and restrictions of items are inherited when a new item is created.

For example, an item named **Department** is defined as a character text item that has a content size minimum of 2 and maximum of 3. Department has a list of "include" restrictions that consists of valid departments: ACC (Accounting), SLS (Sales), and MKT (Marketing).

The type **MainOffice** is created as a subtype of **Department**. **MainOffice** inherits the properties and restrictions of **Department**.

You can delete any restrictions that are not applicable to **MainOffice**.

Inheritance of category properties and components

Categories can be used for organizing types and for inheritance reasons. Generally, you would use categories when you want to put items, groups, and possibly other categories under it as subtypes.

- [Organizing types under a category](#)
- [Using categories for inheritance](#)
- [When not to use categories](#)

Organizing types under a category

If you have two tables defined in one schema, you could divide the types of the two tables into different categories. A benefit of using a category type is that you can have any class of subtype: groups, items, and other categories.

Using categories for inheritance

The properties of a category include group and item properties. Assign properties to a category that you want types beneath the category to inherit.

Any group created under a category inherits the property of the category. Any item created under a category inherits the category's item properties. A category created under a category inherits both the group and item properties. Each type created under a category inherits the other properties of the category, such as initiator and terminator.

As an example, if most groups in your **LabInfo** data are infix delimited with ~ and most items in your **LabInfo** data are unsigned integers, you can define these as the properties of the category **LabInfo**. Any types you create under **LabInfo** inherit its properties.

You can change the properties of the root type, which is a category. Categories can have components, so you can also use them for inheriting components.

When not to use categories

It is best not to use a category type when the subtypes will specifically be item types or specifically be group types.

For example, you have a type named **Field** for which the only subtypes will be items. If you make **Field** a category type, each time you create a subtype, the new type will also be a category type by default. You will have to change the **Class** property from **Category** to **Item** for each subtype that you create. Instead, make **Field** an item type so that the **Class** property for any subtypes you create will automatically be defined as item types.

Propagation of type properties

Creation time is not the only time type properties can be passed from a type to its subtypes. You can use propagation to pass along certain type properties.

Propagation passes the setting of a particular type property from the given type to all of the types in the subtree as applicable and defined by their context. When you select a type property for propagation that does not apply to a given subtype, it is not propagated.

- [**Propagation of type properties common to all types**](#)

You can propagate some type properties that are common to all types such as Item Subclass, Description and Type Syntax, to each of its subtypes, without the process checking additional criteria to determine if the type property can be propagated.

- [**Propagation of type properties for specific types**](#)

You can propagate some other type properties such as Separators and Restrictions, to each of its subtypes for specific types, with the process checking additional criteria to determine if the type property can be propagated.

Propagation of type properties common to all types

You can propagate some type properties that are common to all types such as Item Subclass, Description and Type Syntax, to each of its subtypes, without the process checking additional criteria to determine if the type property can be propagated.

The type properties that fall into this category are the properties in the root of the tree, or are children properties that apply to all types to which their parent property is set, and are global in that these properties apply to all items.

The propagation process checks that the settings for some type properties such as the Item Subclass property, the Interpret as property, and if applicable, the Presentation property in a type, match the settings for these same properties in its subtypes, and if they match, the selected property is propagated. But, the propagation process does not check the settings of other properties to determine if the selected property exists in the item, because the selected property in this case, applies to all item types.

Examples of propagating a type property that has no children properties

A given category type that is in the root of the tree has the following type property setting: Description. \geq An example. The Description type property has no children properties. When you select the Description type property setting of An example to be propagated, the process propagates the Description setting of An example to all types in the tree. The Description property is a type property that is common to all types.

A given category type has the following type property settings: Item Subclass. \geq Text and for its child property, Interpret as. \geq Character. When you select the child Interpret as type property to be propagated, the process propagates the Interpret as setting of Character to each subtype of that category that also has the same Text type property setting. The Interpret as property is a type property that is common to all types except syntax types.

Examples of propagating a type property that has children properties

A given category type has the following type property settings: Item Subclass. \geq Number, and for its children properties, Interpret as. \geq Binary, and Presentation. \geq Integer. When you select the parent Item Subclass type property to be propagated, the process propagates the Item Subclass setting of Number, as well as the settings for its children properties, Interpret as setting of Binary, and the Presentation setting of Integer, to each subtype of that category. The Item Subclass property is a type property that is common to all types.

A given category type has the following type property settings: Item Subclass. \geq Text and for its child property, Interpret as. \geq Character. When you select the parent Item Subclass type property to be propagated, the process propagates the Item Subclass setting of Text, as well as the setting for its child property, Interpret as setting of Character, to each subtype of that category. The Item Subclass property is a type property that is common to all types.

Propagation of type properties for specific types

You can propagate some other type properties such as Separators and Restrictions, to each of its subtypes for specific types, with the process checking additional criteria to determine if the type property can be propagated.

The type properties that fall into this category are children properties that do not apply to all types to which their parent property is set, and are specific to a type, in that these properties do not apply to all item types.

The propagation process checks that the settings for some type properties such as the Item Subclass property, the Interpret as property, and if applicable, the Presentation property in a type, match the settings for these same properties in its subtypes, and if they match, the selected property is propagated. But, depending on the property being propagated and the context, the process also checks other property settings. If you are propagating a child property, depending on the context, the process also checks the settings of the parent property, because the selected property might only apply to specific item types.

Examples of propagating a type property that applies to a specific type

A given category type has the following type property settings: Item Subclass. \geq Number, and for its children properties, Interpret as. \geq Character, and Presentation. \geq Decimal. When you propagate the Separators child property, the process affects only types in the schema that also have those same Number, Character, Decimal type property settings. The Separators property is a type property that applies to the specific Presentation types, Decimal and Integer. For those types that have the Presentation type property setting of Zoned, the Separators property does not apply; it is not an available type property.

A given category type has the following type property settings: Restrictions. \geq Value and for its child property, Ignore case. \geq No. The Ignore case type property has no children properties. When you select the child Ignore case type property setting of No to be propagated, the process propagates the Ignore case setting of No to all types in the category whose parent Restrictions property setting is Value. The Ignore case property is a type property that applies to a specific Restrictions type, Value. For those types that have the Restrictions type property setting of Range, the Ignore case property does not apply; it is not an available type property.

Error detection

During map execution, the input data is compared to the data definition in the type tree. If the data does not match the definition, it is invalid or "in error".

To validate a data object as belonging to a certain type, the data must be matched to its type definition. For data to be valid, the following must be true:

- The data must have the properties that were defined for the type.
- If the type is an item that has restrictions, the data object must match one of the restrictions.
- If the type is a group, the components of the data object must match those defined in the group view, and each component rule must evaluate to "true" at map execution time.

Ultimately, all data objects, no matter how complex, consist of items because items represent the smallest unit of data. When all of the items that collectively comprise a component are found, the component has been "found."

When executing a map, invalid data is recorded in the trace file. You can decide what you want the system to do when errors are encountered: you can map the errors to an output and also have the system ignore invalid data. For methods on ignoring invalid data, see ["Restart attribute"](#).

- [How error detection works](#)
 - [Existence indicators](#)
 - [Existence versus presence of components](#)
-

How error detection works

When data is validated, the system may encounter data that does not match its type definition. A combination of how that type is defined and what data shows up determines what happens next. As data is validated, the system tracks valid data objects, data objects that exist but are in error, and data that cannot be recognized as belonging to any type.

If a data object is valid, the information is recorded, as needed, and validation continues.

If the system is looking for a data object of a particular type, and something in the data does not exactly match the type definition, the system bases the determination on whether to continue validation on whether that data object is known to exist.

If a data object contains enough information to determine its existence, errors associated with that data object are recorded and validation continues.

If a data object exists but contains errors, it is marked as an error. If a restart point is specified for the component of the type in error, these errors are ignored and validation continues.

If a data object does not contain enough information to determine its existence, the following occurs:

- If no validation recovery mechanism is specified, validation is stopped because it will get lost if it continues. Validation recovery mechanisms are discussed in the section ["Error Recovery"](#).
- If recovery mechanisms are specified, the system returns to the nearest restart point and resets what it is looking for. It proceeds by examining the data byte-by-byte until it either recognizes something or reaches the end of the data stream. All rejected bytes (from the first byte not associated with a type to the last unrecognizable byte) are collectively marked as an unidentified foreign object (UFO). A UFO is data in error with no valid data contained within it.

In summary, the data object of an input card could be valid, yet contain errors. If the data object of any input card is invalid, output data is not built. If all input card data objects are valid, the input is mapped to the output based on the map rules. Operators, most functions, and map references operate on valid data. To map invalid data, use the **REJECT** function.

Existence indicators

When the source or destination of a data object exists, the system knows that the entire data object of that source or destination exists. For example, if a source specified to contain a transaction is a file, and that file exists, the transaction exists. On the other hand, if you get a `Source not available` message, the data object of that source does not exist because the source itself does not exist.

When the data object of a source or destination exists, specific information about errors will appear in the data. For example, you might have any of the following:

- The data object is valid because it conforms to its type definition.
- The type of the data object exists, but has no content.
- The data object is in error because it does not conform to its type definition.
- The data object is valid but contains errors. You indicated that you wanted to ignore certain errors.

In addition to these conditions, the system can also tell if there is any unknown data remaining after the card object has been recognized. This can occur if there really is "junk" at the end. It may also be that enough data was identified to determine the status of the entire object and the data at the end could not, for some reason, be determined to have anything to do with the data object.

When a data object exists, the status of that object is determined by validating its type properties. If an entire data object is an item, it is easy to determine what the status is: whether it is valid or whether it does not match its item format, whether its value is not one of the specified restrictions, or whether it is missing an initiator or terminator. If the source or destination exists and the entire data object is an item, there is nothing else it could possibly be.

If the type of the entire data object is a group, the status of each component must be determined. The system uses existence indicators to determine whether a group component exists. If a component exists, the system can also tell you its status. If a component is required in another component that exists, the system will notify you if that required component is missing.

Existence versus presence of components

A component exists if the data object in which it is contained exists and if the component takes up space (if there is at least one byte in the data stream representing that component).

For example:

- If a delimiter appears as a placeholder for that component.
- If the type of that component has an initiator that distinguishes that component from any other component that may appear at that position in a data stream, the component exists if the initiator is there.
- If the type of that component is a group with an identifier and all components up to and including that identifier have been found to be valid.
- If the type of the component is an item with a restriction list and one of its restrictions appear in the data.
- If the type of the component is an item with a **Padded To** length specified and the item contains at least the number of bytes in the **Pad To** length.
- If the type of an optional component is valid, but the component rule evaluates to FALSE, the component only exists if there is a syntactic placeholder.

Data might exist, but might not be present. The presence of data is determined by whether the data has content. The following definitions are used in other parts of the documentation:

EXISTS

Something in the data represents that data object.

CONTENT

The data contains at least one byte other than a syntactical placeholder, such as a pad character or delimiter.

PRESENT

The data object exists and has content.

ABSENT

The data object does not exist or it exists and has no content.

Required components must exist. They do not necessarily have to be present. For example, a required item with no minimum content size can exist, be absent, and still be valid. However, if some minimum content size is specified, a required component is not valid if there is no minimum content.

The existence of optional components depends on the context in which they are used. For example:

- In a delimited group, an optional component must exist if data follows.
- In a fixed group, an optional component must exist if trailing white space is required. If no trailing white space is required, an optional component must exist if data follows.
- In an implicit group, an optional component is not required.

Unlike a required component, when an optional component exists, it might not have content - even when the minimum content specification is greater than zero bytes. The following table explains the conditions that must be met for required and optional components.

	EXISTS	CONTENT	PRESENT	ABSENT
Required Component	Must exist in any context	Must conform to content specification	Must be present if minimum content specification is greater than zero bytes.	Can be absent only if minimum content specification is zero.
Optional Component	Depends on context	Need not have content	Not necessary	Can be absent

Error recovery

It is good practice to map invalid data when it is encountered. For example, you have a file of records and some records are invalid. If your structure is designed to map invalid data when it is encountered, processing can continue without interruption.

To map invalid data of a particular object, you can assign the Restart attribute. The Restart attribute allows the processing of input data to continue when a data object of a component is invalid. Errors are ignored for invalid data object during validation. Using error-handling functions, you can map the invalid data.

- [Using the Restart attribute](#)
- [How the Restart attribute works](#)
- [Mapping invalid data](#)

Using the Restart attribute

The Restart attribute provides instructions for handling errors encountered in a data stream. The Restart attribute gets assigned to a component and takes effect during data validation.

During data validation, the Restart attribute identifies a "start over" point when an unidentified foreign object (UFO) is encountered in the data. All unrecognized data is considered an error of the type with the Restart attribute assigned.

If you are mapping data of a component with a Restart attribute in place, only the valid occurrences of that component are mapped. For example, suppose your input is a file of records, and the **Record** component of **File** has the Restart attribute. Suppose some of the records are invalid. When you map the **Record** objects, only the valid records are mapped. To map the invalid records (for example, to an error file) use an error-handling function, such as REJECT, in the map rule.

For information about error-handling functions, see the Functions and Expressions documentation.

Typically, you would assign the Restart attribute to a component that has a series range. For example, (1:20) or (s), and the objects in the series are independent of one another. If each record in your file is independent from the others, it makes sense to ignore an error if it encounters an invalid one. A bad record does not make the next record meaningless. But suppose the records are related. Maybe they are records related to one purchase order; if any record is bad, you want to stop after validation because it is important to have all records. Losing any records would make the overall data incomplete.

For additional information about using the **Restart** attribute, see the Map Designer documentation.

Tip: To capture all errors of the component using Restart, place the Restart attribute at the highest level possible in the schema.

How the Restart attribute works

The Restart attribute can do the following tasks:

- Identify valid data objects that contain objects in error.
- Tell the system where to start over when a unidentified foreign object (UFO) is encountered in the data during the validation process.
All unrecognized data is considered to be an error of the type with Restart assigned to it.
- Identify the UFOs and existing data objects in error that are ignored when mapping input to output.

When an invalid data object is a component that does not have the Restart attribute assigned, that component is marked in error. If components from the beginning of the data are marked in error because no Restart attribute is assigned, the following results occur. Processing stops after validation, and input data is not mapped to output.

Do not put the Restart attribute on a required component. There must be a number of valid instances that is enough to cover all of the required components. If you have a required component that is not valid, the Restart attribute does not validate the data.

When the Restart attribute is added to components that have only one mandatory element, it is ignored. Adding Restart to the parent level works only when there are no children that have one mandatory value. In this scenario, the ISERRORS and REJECT functions would report the first error. But if there are other errors, they are not captured because Restart stopped and restarted at the next parent level.

The Restart attribute is supported on components of Xerces schemas.

For more information about using the **Restart** attribute, see the Map Designer documentation.

Mapping invalid data

You can map the invalid or rejected data which you can use to determine what is wrong with the data. To do this, you use the restart attribute, in conjunction with the **REJECT**, **CONTAINSERRORS**, and **ISERROR** functions in map rules. For information on using these functions, see the Functions and Expressions documentation.

Schema analyzer

Use the schema analyzer to analyze your type definitions.

The schema analyzer analyzes type definitions and ensures internal consistency. For example, if you defined a group as fixed, but accidentally defined one of its items with no **Padded To** length, errors occur during analysis.

The analyzer checks your data definitions for logical consistency. It does not compare your definitions to your actual data. The resulting analyzer messages indicate whether your schema definitions are acceptable; not whether they match your data.

- [Mapping effects](#)
- [Internal consistency](#)
- [Logical analysis](#)
Logical analysis addresses the integrity of the relationships that you define.
- [Structural analysis](#)
Structural analysis addresses the integrity of the underlying database.
- [Error and warning messages](#)

Mapping effects

The analyzer helps you define your data by locating objects in your input data and creating the objects in your output data. The analysis indicates whether there is something in your definition that may prevent a correct mapping of your data.

If you do not analyze a tree before you map the data or you analyze a tree and do not resolve the errors, you will be warned that you may receive unpredictable results when you map.

Internal consistency

The analyzer checks the logic of your data definitions. For example, suppose you defined a group **PO** as fixed and consists of **Line(s)**. For the **PO** to be fixed, it cannot have an indefinite number of **Lines**. An analysis error would occur, indicating that you defined **PO** as fixed but it has a variable number of components.

Logical analysis

Logical analysis addresses the integrity of the relationships that you define.

Logical analysis detects, for example, undefined components, components that are not distinguishable from one another, item restrictions that do not match the properties of that item, and circular type definitions. The analyzer also checks delimiter relationships to each other and to components, undefined inherited relationships, and logic errors contained in component rules.

Structural analysis

Structural analysis addresses the integrity of the underlying database.

Generally, you should not encounter structural analysis errors. Structural analysis might be able to detect and possibly correct defects caused by system environment failures.

Error and warning messages

Analysis results might contain error and warning messages.

Warnings are relatively insignificant. They indicate an inconsistency that occurred when you changed something in the tree that was resolved. For example, if you change a group to an item, the analyzer removes the components of that type because items do not have components. To remind you of this change, the analyzer issues a warning.

Errors are important. An error is a problem in your type definitions that you should correct. An error may result in unpredictable results in your mapping.

Occasionally there are errors that prevent the analysis of the rest of your definitions (for example, when a component type cannot be found in the tree). **Analysis halted before completion** is displayed. This error might be due to one of the following:

- Undefined COMPONENTs found: ending analysis.
- Circular reference found in COMPONENT list: ending analysis.

When this occurs, correct the errors and analyze the tree again.

Distinguishable objects

Differences can be identified for objects in a data stream. This information is helpful when a schema analysis produced an error message concerning objects that are not distinguishable.

- [Objects in a data stream](#)
- [Schema analyzer and distinguishable objects](#)
- [Bound types](#)
- [Bound components](#)
- [Group starting set](#)
- [Group unbound set](#)
- [Initiator-distinguishable types](#)
- [Distinguishable objects of the same component](#)
- [Content-distinguishable components](#)
- [Content-distinguishable types](#)
- [Ending-distinguishable types](#)
- [Distinguishable data objects of an implicit group](#)
- [Distinguishable data objects of an explicit group](#)
- [Distinguishable syntax objects](#)

Objects in a data stream

A data stream is a byte-by-byte flow of data. Objects in a data stream include both data objects and syntax objects. Syntax objects indicate where a data object begins or ends. They include separators, initiators, terminators, delimiters, release characters, and pad characters. Sometimes, data values are used to identify where another data object begins or ends.

It might be necessary to distinguish between data objects in a component series, data objects of different types, or even syntax objects.

Schema analyzer and distinguishable objects

The schema analyzer indicates whether your data definitions are sufficient to distinguish the objects in your data stream. The following discussion explains how you can define your data so that the objects that need to be distinguishable are distinguishable. Chances are, if you analyzed your tree and received a message that involves distinguishable objects, you need to define the types differently or more specifically.

Bound types

A type is bound if its definition makes it clear where an instance of that type ends. If a type is bound, different objects of that type can be distinguished in a data stream. A bound type is easier to distinguish between an object of that type and an object of another type. The following tables describe how types may be bound.

An object of this type:

Is bound if any of the following is true:

Item

It is padded to a fixed size or its minimum and maximum content size are equal.
It has a terminator.

It has an include restriction list.

Partitioned item

Each non-partitioned item in the subtree is bound.

Sequence Group

It has an explicit fixed format.
It has a terminator.

Its last component is bound.

It is postfix delimited and its last component has a fixed range. For example, **Comment Field (3:3)** has a fixed range of **(3:3)**.

Partitioned Group

Each non-partitioned group in its subtree is bound.

Choice Group

It has a terminator.
The type of each selection component is bound.

Unordered Group

It has a terminator.

Bound components

A component is bound if it is possible to tell if a data object belongs to that component without comparing it to a component that follows it.

- [Component of a fixed group](#)
- [Component of an explicit delimited group](#)
- [Component of an implicit group](#)
- [Component of a choice group](#)
- [Component of an unordered group](#)

Component of a fixed group

Condition

Example

A range maximum is specified (it is not "s"), and its type is either a fixed group or an item whose length is fixed.

The component **InventorySection (0:3)** is bound because it is assumed there will be spaces in the data stream for 3 **InventorySections**.

Component of an explicit delimited group

Condition

Example

A range maximum is specified (it is not "s") if a component of the same group follows.

In the component list, **Security Sequence (0:10) Trailer** is bound in an explicit delimited group. It is assumed there will be a delimiter for all 10 **Security Sequences** in the data stream because **Trailer** is required.

The component is the last one and the explicit group has a terminator.

In the component list, **Security Sequence (s)** is bound in an explicit delimited group with a terminator. The system assumes the terminator will appear to indicate that there are no more **Security Sequences**.

Component of an implicit group

Condition

Example

Its range is fixed and its type is bound.

The component **Inventory Record (3:3)** is bound, if the type **Inventory Record** is bound according to any of the conditions listed under "[Bound Types](#)".

It has a component rule that binds it.

The component **PO Record (s)** is bound, if it has the following component rule which binds it:

PO# Field:PO Record = PO# Field:PO Record[LAST]

The schema analysis checks only that the component has a rule that refers to the component itself. The analysis does not check that the rule binds the component.
You must ensure that the rule is one that binds the component.

It is sized (using the Sized attribute) by the component that precedes it.

The component **Name Field (0:2)** is bound, if the previous component in the group has the Sized attribute.

Component of a choice group

Condition

Example

A component is bound if the type of a component is bound.

The component **Customer Record** is bound if the type **Customer Record** is bound.

Component of an unordered group

Condition

Example

A component is bound if its range is fixed and its type is bound.

The component **Address Field** is bound if its range is fixed, for example **(3:3)**, and the type **Address Field** is bound.

Group starting set

Data objects in a data stream need to be distinguishable when they could belong to two different groups. Specifically, the difference between the data that can come first in one group and the data that can come first in the other group. All of the possible types of data that may appear first in a group are referred to as the group's starting set.

The following describes the starting set of a group based on its group format:

Group Format	Starting Component Set
Explicit	Includes the type of its first component. <ul style="list-style-type: none">• Delimited• Fixed
Implicit	<ul style="list-style-type: none">• Includes the type of all components up to and including the first component that has a minimum range of at least one.• Includes the type of each component.
Choice	Includes the type of each component.

Group unbound set

Based on the nature of a bound group, the end of a bound group is determined without analyzing the data that follows it. However, if a group is not bound, the data that belongs to that group must be distinguishable from data that belongs to another type that might follow it in the data stream.

The unbound set of a choice or unordered group consists of the type of each component. The unbound set of a partitioned group consists of the unbound set of each unbound partition.

- [Unbound set of a sequence group](#)
-

Unbound set of a sequence group

The unbound set does not include a type that could come last, if that type is a required occurrence. For example, if the type **Comment Record** could appear last and the component is specified as **Comment Record (2:2)**, it is not in the unbound set, because the two occurrences of **Comment Record** are required. However, if **Comment Record** could appear last and the component is specified as **Comment Record (1:2)**, then **Comment Record** is in the unbound set, since its second occurrence is optional.

To determine the unbound set of a group, start with the last component of the group and proceed backward up the component list. If a component is unbound or has a minimum range of zero, continue up the list. Stop at the first component that is bound or that is unbound but has a minimum range greater than zero. Essentially, a group's unbound set is everything that is not clearly defined at the end of the group.

Initiator-distinguishable types

Initiator-distinguishable types are used during validation to determine existence of a type object based on the existence of its initiator.

- [Determining if a component is initiator-distinguishable from its following set](#)
- [Determining if a partition is initiator-distinguishable from its following set](#)
- [Determining if two types are initiator-distinguishable](#)

Determining if a component is initiator-distinguishable from its following set

A component is initiator-distinguishable from its following set if:

- The component is not a member of the identifier set and
- The type of the component has an initiator and
- The following set is empty or
- The type of the component is initiator-distinguishable from each type in its following set.

Schemas are analyzed to determine if components are initiator-distinguishable. Each implicit sequence group, choice group, and unordered group is analyzed to determine if their components are initiator-distinguishable. A component is marked as initiator-distinguishable when that component is initiator-distinguishable from its following set. The basis for this determination is found in ["Determining If Two Types are Initiator-Distinguishable"](#).

Determining if a partition is initiator-distinguishable from its following set

In a partitioned type, a partition is initiator-distinguishable from its following set if:

- The type of a partition has an initiator and
- The following set is empty or
- The type of the partition is initiator-distinguishable from each partition in its following set and the following set of a partition is the type of each partition that may follow.

Schemas are analyzed to determine if partitions are initiator-distinguishable. Each partitioned type is analyzed to determine if its partitions are initiator-distinguishable.

Determining if two types are initiator-distinguishable

The following table lists ways two types may be initiator-distinguishable. This is helpful if data validation errors indicate a type does not exist.

Type1	Type2	How to define them as initiator-distinguishable
item	item	If Type1 and Type2 have an initiator, and the initiators are different.
item	sequence group	Either: <ul style="list-style-type: none">• Type1 and Type2 both have an initiator and the initiators are different.or• Type1 has an initiator, Type2 does not, Type2 has no delimiter, and Type1 is initiator distinguishable from type of each component in the starting component set of Type2.
item	choice group or unordered group	Either: <ul style="list-style-type: none">• The Type1 and Type2 both have an initiator and the initiators are different.or• Type1 has an initiator, Type2 does not, Type2 has no delimiter, and Type1 is initiator distinguishable from type of each component of Type2.
item	partitioned item or partitioned group	Type1 has an initiator and is initiator distinguishable from each partition of Type2.
partitioned item	item or sequence group	Type1 has an initiator and each partition is initiator distinguishable from Type2.
partitioned item	partitioned item or partitioned group	Type1 has an initiator and each partition is initiator distinguishable from each partition of Type2.
sequence group	item	Type1 has no identifier, Type1 and Type2 both have initiators, and the initiators are different.

Type1	Type2	How to define them as initiator-distinguishable
sequence group	sequence group	Type1 has no identifier and or • Type1 and Type2 both have initiators and the initiators are different • Type1 has an initiator, Type2 does not have an initiator, Type2 has no delimiter, and Type1 is initiator distinguishable from the starting component set of Type2.
sequence group	choice group or unordered group	Type1 has no identifier and or • Type1 has an initiator, Type2 does not have an initiator, Type2 has no delimiter, and Type1 is initiator distinguishable from the type of each component of the Type2.
sequence group	partitioned item	Type1 has no identifier and Type1 must be initiator distinguishable from each partition of Type2.
sequence group	partitioned group	Type1 has no identifier and the Type1 must be initiator distinguishable from each partition of Type2.
partitioned group	partitioned item	Type1 has no identifier and each partition Type1 must be initiator distinguishable from Type2.
partitioned group	sequence group	Type1 has no identifier and each partition of the Type1 must be initiator distinguishable from Type2.
partitioned group	partitioned item	Type1 has no identifier and each partition of Type1 must be initiator distinguishable from each partition of Type2.
partitioned group	partitioned group	Type1 has no identifier and each partition of Type1 must be initiator distinguishable from each partition of Type2.
choice group or unordered group	item	Type1 and Type2 both have an initiator and the initiators are different.
choice group or unordered group	partitioned item	Type1 is initiator-distinguishable from each partition of Type2.
choice group or unordered group	choice group or unordered group	Either: • Type1 and Type2 both have an initiator and the initiators are different. or • Type1 has an initiator and Type2 does not, Type2 has no delimiter, and Type1 is initiator-distinguishable from the type of each component of Type2.
choice group or unordered group	sequence group	Either: • Type1 and Type2 both have an initiator and they are different. or • Type1 has an initiator and Type2 has no initiator and no delimiter, and Type1 is initiator-distinguishable from the type of each component in the starting component set of Type2.
choice group or unordered group	partitioned group	Type1 is initiator distinguishable from each partition of the Type2.

Distinguishable objects of the same component

When a component has a series range, for example, (1:10) or (s), one occurrence of that component must be distinguishable from the next occurrence of that same component.

Different data objects of a component are distinguishable if any of the following is true:

- The component type is bound.
- The component type is a non-partitioned group with an unbound set that is content distinguishable from the component type as a whole.
- The component type is a partitioned group and the unbound set of each non-partitioned group in its subtree is content-distinguishable from the component type as a whole.

Content-distinguishable components

A component is distinguishable from its following set when the component is:

- Initiator-distinguishable from its following set.

or

- Content- distinguishable from its following set.

A component is content-distinguishable from its following set when:

- The following set is empty.

or

- The type of the component is content-distinguishable from each component in its following set.

Content-distinguishable types

The following table lists the ways in which two types may be content-distinguishable. The table is helpful particularly if you analyzed your tree and received an error indicating that two types are not distinguishable. Look up the combination of types in the first two columns and read the list of ways to define them that would make them distinguishable.

For example, if you get an error indicating that **X** is not distinguishable from **Y**, where **X** is an item, and **Y** is a partitioned group, you would find the row in the table where **Type1** is an item and **Type2** is a partitioned group.

Remember that the order in which you compare two types matters. When you ask the question "Is type A content-distinguishable from type B?", this is not the same question as "Is type B content-distinguishable from type A?"

If you are trying to determine whether two types are distinguishable and you follow the guidelines in the following tables, you may encounter a situation in which you are comparing a type to itself. A type is never distinguishable from itself.

Another thing to keep in mind is that the context in which a type is used matters. When you ask the question, "Is type A, as a component of type C, content-distinguishable from type B?" this is not the same question as, "Is type A, as a component of type D, content-distinguishable from type B?"

The following table shows how to define types as content-distinguishable.

Type 1	Type 2	How to define them as content-distinguishable
item	item	<p>The first component or partition is either:</p> <ul style="list-style-type: none"> An item and marked as initiator distinguishable and <p>Both items are different partitions of the same partitioned subtree, or The second type has an initiator and those initiators are mutually exclusive, or Both types have the same initiator and the value of the first item is distinguishable from the value of the second item, or The second type has no initiator and the initiator of the first type is distinguishable from the value of the second type.</p> <ul style="list-style-type: none"> An item and not marked as initiator distinguishable and <p>Both items are different partitions of the same partitioned subtree, or The first item has an initiator, second has an initiator and initiator value of first is distinguishable from initiator value of the second. Both types have initiators and they are the same, or both types have no initiator and the value of the first item is distinguishable from the value of the second item. The first item has an initiator, second does not, and value of initiator distinguishable from the value of second item. The first item has no initiator, second does, and the first item's value is distinguishable from the value of the second item's initiator.</p>
item	sequence group, choice group, or unordered group	<p>The first component or partition is either:</p> <ul style="list-style-type: none"> An item marked as initiator distinguishable and <p>The second type has an initiator and those initiators are mutually exclusive, or The second type has no initiator and the item is initiator-distinguishable from each type in the starting component set of the group.</p> <ul style="list-style-type: none"> An item not marked as initiator distinguishable and <p>The item and group both have an initiator and the initiator of the item is distinguishable from the initiator of the group, or The item has no initiator, the group has an initiator, and the item's value is distinguishable from the value of group's initiator, or Both types have initiators and they are the same or both types have no initiator, and the item's value is distinguishable from the type of each component in the starting component set of the group, or The item has an initiator, the group has no initiator, and the item is content-distinguishable from the type of each component in the starting component set of the group, or The item has no initiator, the group has an initiator, and the item's value is distinguishable from each type in the starting component set of the group.</p>
item	partitioned item or partitioned group	The first component or partition is content-distinguishable from each partition of the second type.
partitioned item	item	Each partition of the first type is content-distinguishable from the second type.
partitioned item	sequence group	Each partition of the first type is content-distinguishable from the second type.
partitioned item	choice group	Each partition of the first type is content-distinguishable from second type.
partitioned item	unordered group	Each partition of the first type is content-distinguishable from second type.
partitioned item	item	Each partition of the first type is content-distinguishable from second type.
partitioned item	partitioned group	Each partition of the first type is content-distinguishable from second type.
group	item	Each partition of the partitioned group is content-distinguishable from the item.
partitioned group	partitioned item	Each partition of the partitioned group is content-distinguishable from each partition of the item.
partitioned group	sequence group	Each partition of the partitioned group is content-distinguishable from the second group.
partitioned group	partitioned group	Each partition of the first partitioned group is content-distinguishable from each partition of the second partitioned group.
partitioned group	choice group	Each partition of the partitioned group is content-distinguishable from the choice group.
partitioned group	unordered group	Each partition of the partitioned group is content-distinguishable from the unordered group.

Type 1	Type 2	How to define them as content-distinguishable
sequence group	item	<p>The first component is either:</p> <ul style="list-style-type: none"> • A group marked as initiator distinguishable and <p>The item has an initiator and the initiator value of the group is distinguishable from the initiator value of the item, or The second type has no initiator and the initiator value of the first type is distinguishable from the value of the second type.</p> <ul style="list-style-type: none"> • A group not marked as initiator distinguishable and <p>The group has an initiator, the item has an initiator and the initiator value of the group is distinguishable from initiator value of the item, or The group has an initiator, the item does not, and value of the initiator is distinguishable from value of the item, or Both types have initiators and they are the same, or both types have no initiator and each type in the starting component set of the group is content-distinguishable from the value of the second item.</p>
sequence group	sequence group	<p>The first component is either:</p> <ul style="list-style-type: none"> • A group marked as initiator distinguishable, and <p>Both groups are different partitions of the same partitioned subtree, or The second type has an initiator and those initiators are mutually exclusive, or The second type has no initiator and the first group is initiator-distinguishable from each type in the starting component set of the second group.</p> <ul style="list-style-type: none"> • A group not marked as initiator distinguishable, and <p>Both groups are different partitions of the same partitioned subtree, or Both groups have an initiator and the initiator value of the first group is distinguishable from the initiator value of the second group, or The first group has no initiator, the second group has an initiator and the type of each component in the starting component set of the first group is content-distinguishable from the second group, or The first group has an initiator, the second group has no initiator and the first group is content-distinguishable from the type of each component in the starting component set of the group. Both types have initiators and they are the same or both types have no initiator and The first group is content-distinguishable from the starting component set of the second group, or The second group is content-distinguishable from the starting component set of the first group, or The starting component set of the first group is content-distinguishable from the starting component set of the second group.</p>
sequence group	choice group or group	<p>The first component is either:</p> <ul style="list-style-type: none"> • A group marked as initiator distinguishable and <p>Both groups are different partitions of the same partitioned subtree, or The second type has an initiator and those initiators are mutually exclusive, or The second group has no initiator and the first group is initiator-distinguishable from the type of each component of the second group.</p> <ul style="list-style-type: none"> • A group not marked as initiator distinguishable and <p>Both groups are different partitions of the same partitioned subtree, or Both groups have an initiator and the initiator of the first group is distinguishable from the initiator of the second group, or The first group has an initiator, the second group has no initiator and the first group is content-distinguishable from the type of each component of the second group, or The first group has no initiator the second group has an initiator, and each component in the starting component set of the first group is distinguishable from the second group, or Both types have initiators, either the initiators are the same or both types have no initiator, and each component in the starting component set of the first group is content-distinguishable from the type of each component of the second group.</p>
sequence group	partitioned item or partitioned group	<p>The first component is either:</p> <ul style="list-style-type: none"> • A group marked as initiator-distinguishable and the group is initiator-distinguishable from each partition of the second type, or • A group not marked as initiator-distinguishable and the group is content-distinguishable from each partition of the second type.
choice group or unordered group	item	<p>The first component is either:</p> <ul style="list-style-type: none"> • A group marked as initiator distinguishable and The item has an initiator and the initiator value of the group is distinguishable from the initiator value of the item, or The second type has no initiator and the initiator value of the first type is distinguishable from the value of the second type. • A group not marked as initiator distinguishable and Both types have an initiator and the initiator value of the group is distinguishable from initiator value of the item, or The group has an initiator, the item does not, and the value of the initiator is distinguishable from value of the item, or The group has no initiator, the item has an initiator and the starting component set of the group is content-distinguishable from the item, or Both types have initiators and they are the same, both types have no initiator and the type of each component of the group is distinguishable from the value of the second item.

Type 1	Type 2	How to define them as content-distinguishable
choice group or group	sequence group	<p>The first component is either:</p> <ul style="list-style-type: none"> • A group marked as initiator distinguishable and <p>Both groups are different partitions of the same partitioned subtree, or The second type has an initiator and those initiators are mutually exclusive, or The second type has no initiator and the first group is initiator-distinguishable from each type in the starting set of the second group.</p> <ul style="list-style-type: none"> • A group not marked as initiator distinguishable, and <p>Both groups are different partitions of the same partitioned subtree, or Both groups have an initiator and the initiator value of the first group is distinguishable from the initiator value of the second group, or The first group has an initiator, the second group has no initiator and the first group is content-distinguishable from the type of each component in the starting component set of the second group. The first group has no initiator, the second group has an initiator and the type of each component of the first group is content-distinguishable from the second group, or. Both types have initiators and they are the same or both types have no initiator, and the type of each component of the first group is content-distinguishable from the type of each component in the starting component set of the second group.</p>
choice group or group	choice group or group	<p>The first component is either:</p> <ul style="list-style-type: none"> • A group marked as initiator distinguishable and <p>Both groups are different partitions of the same partitioned subtree, or The second type has an initiator and those initiators are mutually exclusive, or The second group has no initiator and the first group is initiator-distinguishable from the type of each component of the second group.</p> <ul style="list-style-type: none"> • A group not marked as initiator distinguishable and <p>Both groups are different partitions of the same partitioned subtree, or Both groups have an initiator and the initiator of the first group is distinguishable from the initiator of the second group, or The first group has an initiator, the second group has no initiator and the first group is content-distinguishable from the type of each component of the second group, or The first group has no initiator the second group has an initiator, and each component of the first group is distinguishable from the second group, or Both types have initiators and the initiators are the same or both types have no initiator, and the type of each component of the first group is content-distinguishable from the type of each component of the second group.</p>
choice group or group	partitioned item or partitioned group	<p>The first component is either:</p> <ul style="list-style-type: none"> • A group marked as initiator-distinguishable and the group is initiator-distinguishable from each partition of the second type, or • A group not marked as initiator-distinguishable and the group is content-distinguishable from each partition of the second type.

Ending-distinguishable types

Ending-distinguishability is used to determine if the end of a data object is distinguishable from the start of any other data object that could be next in the data.

The following table describes how two types may be ending-distinguishable. This is helpful if you are validating data and you receive a message that says a type exists, but it belongs to the wrong component.

Type1	Type2	How to define them as ending-distinguishable
item	item or sequence group or choice group or unordered group	Type1 is bound or the value of Type1 is content-distinguishable from Type2.
item	partitioned item or partitioned group	Type1 is bound or the value of Type1 is content-distinguishable from each partition of Type2.
sequence group	item or sequence group or choice group or unordered group	<p>Either:</p> <ul style="list-style-type: none"> • Type1 is bound. <p>or</p> <p>For each component in the unbound set of Type1</p> <ul style="list-style-type: none"> • If the component has a fixed range it must be ending-distinguishable from Type2. • If the component range is variable, it must be content-distinguishable from Type2 and ending-distinguishable from Type2.
sequence group	partitioned item or partitioned group	<p>Either:</p> <ul style="list-style-type: none"> • Type1 is bound. <p>or</p> <p>For each component in the unbound set of Type1</p> <ul style="list-style-type: none"> • If the component has a fixed range it must be ending-distinguishable from each partition of Type2. • If the component range is variable, it must be content-distinguishable from each partition of Type2 and ending-distinguishable from each partition of Type2.

Type1	Type2	How to define them as ending-distinguishable
choice group or unordered group	item or sequence group or choice group or unordered group	<p>Either:</p> <ul style="list-style-type: none"> • Type1 is bound. <p>or</p> <ul style="list-style-type: none"> • For each component of Type1, <p>The type of that component is bound, or The type of that component is unbound, and that type must be ending-distinguishable from Type2.</p>
choice group or unordered group	partitioned item or partitioned group	<p>Either:</p> <ul style="list-style-type: none"> • Type1 is bound. <p>or</p> <ul style="list-style-type: none"> • For each component of Type1, <p>The type of that component is bound, or The type of that component is unbound, and that type must be ending-distinguishable from each partition of Type2.</p>
partitioned item or partitioned group	item, sequence group, choice group, or unordered group	<p>For each partition of Type1, either:</p> <ul style="list-style-type: none"> • The partition is a partitioned type and ending-distinguishable from the second type, or • The partition of the first type is bound, or • The partition of the first type is unbound and ending-distinguishable from the second type.
partitioned item or partitioned group	partitioned item or partitioned group	<p>For each partition of the first type, either:</p> <ul style="list-style-type: none"> • The partition is a partitioned type and ending-distinguishable from the second type, or • The partition of the first type is bound, or • The partition of the first type is unbound and ending-distinguishable from the second type.

Distinguishable data objects of an implicit group

When a data object belongs to an implicit sequence, determining the component a data object belongs to depends on the format of the sequence, the type definition of a component, and the component properties.

- [Guidelines for defining an implicit delimited sequence](#)
- [Guidelines for defining an implicit sequence that has no delimiter](#)
- [Guidelines for defining an implicit unordered group that is delimited](#)
- [Guidelines for defining an implicit unordered group that has no delimiter](#)

Guidelines for defining an implicit delimited sequence

- If the type of a component has a terminator, that terminator must be different from the delimiter of the explicit group. If the delimiter and terminator are both defined as literal values, a type analysis confirms both have different values.
- The type of a component cannot be a binary item whose length is not fixed or sized.
- If the type of a component or a contained component is not bound, the type of the component cannot have a delimiter that is the same as the delimiter of the implicit sequence.
- If the range of a component is not bound, the type of that component must be content-distinguishable from the type of each component in the following set of that component.
- If the type of a component has both an initiator and terminator, the nested delimiters do not have restrictions. If this is not the case, all contained delimiters must be different.

Guidelines for defining an implicit sequence that has no delimiter

- The type of a component cannot be a binary item whose length is not fixed or sized.
- If the range of a component is bound, but the type of the component is unbound, the type must be ending-distinguishable from each type in the component's following set.
- If the range of a component is not bound, all the following rules apply:
 - The type of the component must be content-distinguishable from each type in the component's following set.
 - If the maximum range for that component is greater than one, and the type is unbound, the type must be ending-distinguishable from itself.
 - If the type of the component is unbound, the type must be end-distinguishable from each type in the component's following set.

Guidelines for defining an implicit unordered group that is delimited

- The type of a component cannot be a binary item whose length is not fixed.

- The type of a component must be content-distinguishable from the type of each other component.
- If the type of a component has both an initiator and terminator, the nested delimiters do not have restrictions. If this is not the case, all contained delimiters must be different.

Guidelines for defining an implicit unordered group that has no delimiter

- The type of a component cannot be a binary item whose length is not fixed.
- The type of a component must be content-distinguishable from the type of each other component.
- If the type of a component is unbound, the type must be ending-distinguishable from the type of each other component.
- If the maximum range is greater than one and the type is unbound, the type must be ending-distinguishable from itself.

Distinguishable data objects of an explicit group

When a data object belongs to an unordered group, distinguishing one data object from another depends on the format of the unordered group and the type definition of each component.

- [Guidelines for defining an explicit fixed group](#)
- [Guidelines for defining an explicit delimited group](#)
- [Objects of a choice group](#)
- [Objects of a partitioned type](#)

Guidelines for defining an explicit fixed group

- In a fixed group, each component must be either an item of fixed size, an item padded to a fixed length, or an explicit fixed group.
- The range maximum for each component must have a specific value; it cannot be **s**. A fixed amount of space is assumed in the data stream for each series member of a component in a fixed group.

Guidelines for defining an explicit delimited group

A component of an explicit delimited group can be a group or item, with the following restrictions:

- If the type of a component has a terminator, that terminator must be different from the delimiter of the explicit group. If the delimiter and terminator are both defined as a literal, analysis confirms if both have different values.
- If a component of an explicit delimited group is a binary item whose length is not fixed, that component must be sized by the component that precedes it.
- If the type of a component, or a contained component, does not have a terminator and the type of the component has a delimiter that is the same as the delimiter of the explicit group, the type of the component *must* be an explicit sequence. In this case, the delimiter appears as a placeholder for every data object if data of the same delimiter follows it.
- If an explicit group has a delimiter, the range maximum of any component other than the last one must have a specific value; it cannot be **s**. A delimiter is assumed in the data stream for each series member of a component of an explicit group with a delimiter.

Objects of a choice group

When a data object belongs to a choice group, which component the data object belongs to is based on the order the components appear in the type definition.

In a choice group, if a component is unbound it must be content-distinguishable from the type of each component that follows it in the component list.

Objects of a partitioned type

When data objects of different types appear in the same place in the data, the types must be distinguishable. The data must be distinguishable in the type definition. When a partition is part of a partitioned object, the process of cycling through the partitioned subtree begins to make the determination of which partition the data object belongs to.

In a partitioned type, each partition must be content-distinguishable from the type of each partition that follows it.

Distinguishable syntax objects

The system must be able to distinguish between different syntax objects contained within a group. To ensure that the syntax objects are distinguishable, use the following guidelines:

- If a component is unbound, make sure its delimiter and any delimiter contained in it is distinguishable from the delimiter of the group. If you get an analysis error, look for missing placeholders or components with a range maximum of **s**.

In a component or a contained component with the same delimiter as the type delimiter, the system assumes that the delimiter appears as a placeholder for every data object if data with the same delimiter follows it.

- If the delimited group has a terminator, make sure that the delimiter and any contained delimiter is distinguishable from the terminator.
The schema analysis verifies if the above requirement is met in a non-partitioned group.

Return codes and error messages

- [Type Tree Analyzer errors and warnings](#)
- [Schema analysis logic error messages](#)
- [Logic error and warning messages](#)
- [Schema analysis structure error messages](#)
- [Schema analysis structure warning messages](#)

Type Tree Analyzer errors and warnings

The Type Tree Analyzer checks the logic and internal consistency of your data definitions. Schema analyzer error and warnings messages are issued on the type of analysis that is performed: logic and structural.

- Logical analysis addresses the integrity of the relationships that you define in the schema.
- Structural analysis addresses the integrity of the underlying database.

Warnings indicate a successful analysis and are relatively insignificant. Warning messages provide information about inconsistencies that occurred, when the schema was changed, and were automatically resolved.

Errors are important. Error messages provide information about errors in your type definitions that you should correct. An error may result in unpredictable results in your mapping.

Words in italics represent information that varies, indicating information specific to the type for which the message is generated.

Schema analysis logic error messages

The following table lists the logic error messages that result from a logical analysis of a schema:

Return Code	Message
L100	COMPONENT neither inherited nor local: ` <i>type name</i> ` of TYPE: ` <i>type name</i> ` Hint: Look at the super-type's component list. The component is a valid type, but the supertype has a component list that restricts you from using this type as a component. You may have added subtype components before adding supertype components. Either remove all supertype components or add the components in error to the component list of the supertype.
L101	This GROUP must have at least one component - TYPE: ` <i>type name</i> ` Hint: If you want to map this group, add components. If you do not want to map it, make it a category.
L102	Circular reference found in COMPONENT # (` <i>type name</i> `) - TYPE: ` <i>type name</i> ' Hint: Look at the type of the component in error. It is probably missing an initiator or terminator.
L103	Circular reference found in Floating Component type - TYPE: ` <i>type name</i> ' Hint: Look at the floating component type in error. It is probably missing an initiator or terminator.
L104	DELIMITER for TYPE - ` <i>type name</i> ` must have a value Hint: All delimited groups need a delimiter. Edit delimited group properties to insert the missing delimiter.
L105	DELIMITER type neither inherited nor local - TYPE: ` <i>type name</i> ' Hint: The delimiter name has been entered incorrectly. It should be the name of a local type, or the name of an inherited delimiter, or the name of a type in the subtree of the inherited delimiter.
L106	Default DELIMITER not specified - TYPE: ` <i>type name</i> ' Hint: This Type was specified with a FIND option for its delimiter. Please add a default value to define what to use for building outputs.
L107	Default DELIMITER not in restriction list - TYPE: ` <i>type name</i> ' Hint: This delimiter was specified as a syntax item. Add the default value to the restriction list for that syntax item.
L108	DELIMITER type is not a SYNTAX ITEM - TYPE: ` <i>type name</i> ' Hint: Delimiters specified as an item must be specified to be interpreted as SYNTAX to set the value of the delimiter if it appears as a component in a data stream.

- L109
 DELIMITER type has no restriction list - TYPE: 'type name'
 Hint: All syntax items need a restriction list.
- L110
 RELEASE CHARACTER neither inherited nor local - TYPE: 'type name'
 Hint: The release character name has been entered incorrectly. It should be either the name of a local type, the name of an inherited release character, or the name of a type in the sub-tree of the inherited release character.
- L111
 Default RELEASE CHARACTER not specified - TYPE: 'type name'
 Hint: This Type was specified with a syntax item for its release character. Please add a default value to define a value for the release character that has not been encountered in the data.
- L112
 Default RELEASE CHARACTER not in restriction list - TYPE: 'type name'
 Hint: This Type was specified with a syntax item for its release character. Please add the default value to the restriction list of that syntax item.
- L113
 RELEASE CHARACTER type is not a SYNTAX ITEM - TYPE: 'type name'
 Hint: Release characters specified as an item must be specified to be interpreted as SYNTAX to set the value of the release character if it appears as a component in a data stream.
- L114
 RELEASE CHARACTER type has no restriction list - TYPE: 'type name'
 Hint: All syntax items need a restriction list.
- L115
 Floating Component TYPE neither inherited nor local - TYPE: 'type name'
 Hint: The floating component name has been entered incorrectly. It should be either the name of a local type, the name of an inherited floating component, or the name of a type in the sub-tree of the inherited floating component.
- L116
 INITIATOR type neither inherited nor local - TYPE: 'type name'
 Hint: The initiator name has been entered incorrectly. It should be either the name of a local type, the name of an inherited initiator, or the name of a type in the sub-tree of the inherited initiator.
- L117
 Default INITIATOR not specified - TYPE: 'type name'
 Hint: This Type was specified with a syntax item for its initiator. Add a default value to define a value for that initiator has not been encountered in the data.
- L118
 Default INITIATOR not in restriction list - TYPE: 'type name'
 Hint: This Type was specified with a syntax item for its initiator. Add the default value to the restriction list of that syntax item.
- L119
 INITIATOR type is not a SYNTAX ITEM - TYPE: 'type name'
 Hint: Initiators specified as an item must be specified to be interpreted as SYNTAX to set the value of the initiator if it appears as a component in a data stream.
- L120
 INITIATOR type has no restriction list - TYPE: 'type name'
 Hint: All syntax items need a restriction list.
- L121
 TERMINATOR type neither inherited nor local - TYPE: 'type name'
 Hint: The terminator name has been entered incorrectly. It should be either the name of a local type, the name of an inherited terminator, or the name of a type in the sub-tree of the inherited terminator.
- L122
 Default TERMINATOR not specified - TYPE: 'type name'
 Hint: This Type was specified with a syntax item for its terminator. Add a default value to define a value for that terminator has not been encountered in the data.
- L123
 Default TERMINATOR not in restriction list - TYPE: 'type name'
 Hint: This Type was specified with a syntax item for its terminator. Please add the default value to the restriction list of that syntax item.
- L124
 TERMINATOR type is not a SYNTAX ITEM - TYPE: 'type name'
 Hint: Terminators specified as an item must be specified to be interpreted as SYNTAX to set the value of the terminator if it appears as a component in a data stream.
- L125
 TERMINATOR type has no restriction list - TYPE: 'type name'
 Hint: All syntax items need a restriction list.
- L126
 COMPONENT range minimum (#) greater than range maximum (#) - COMPONENT 'type name' - TYPE: 'type name'
 Hint: The minimum range must be less than or equal to the maximum range.
- L127
 COMPONENT range minimum (#) less than inherited range minimum(#) - COMPONENT 'type name' - TYPE: 'type name'
 Hint: The component in error has been inherited. Look at the range of the component with the same name in the super-type's component list.
- L128

COMPONENT range maximum (#) greater than inherited range maximum(#)- COMPONENT `type name` - TYPE: `type name`
Hint: The component in error has been inherited. Look at the range of the component with the same name in the super-type's component list.

L129

COMPONENT RULE references a COMPONENT later in the component list - `type name` - TYPE: `type name`
Hint: Move the component rule to the component later in the list.

L130

COMPONENT RULE references undefined type - COMPONENT # of TYPE: `type name`
Hint: Verify the spelling of the data object name. The rule should reference a data object name of the component or a data object name of a component earlier in the component list.

L131

COMPONENT RULE references components of a partitioned group - COMPONENT # of TYPE type name

L132

Invalid partitioning: TYPE has no SUBTYPES - TYPE: `type name`
Hint: Remove the partitioned option from the class window or add sub-types to the Type in error.

L133

Type of COMPONENT exists, but its relative name is not valid: `type name` in TYPE: `type name`
Hint: To get the correct relative name, drag the type you want to use as a component and drop it in the component list of the Type. (Remember to delete the invalid component!)

L134

Reference to 'ANY' not allowed: COMPONENT number # of TYPE: `type name`
Hint: In this case, the Type in error is a group and it is not the root of a partitioned tree. ANY cannot be used if that component needs to be validated. So, if that group is partitioned, you cannot use ANY for a component up to and including the identifier (if there is one). If that group is not partitioned, you cannot use ANY at all.

L135

COMPONENT number # cannot reference a CATEGORY in TYPE: `type name` (because group is not partitioned)
Hint: In this case, the Type in error is a group and it's not the root of a partitioned tree. A category cannot be used if the component must be validated. So, if that group is partitioned, you cannot use a category for a component up to and including the identifier (if there is one). If that group is not partitioned, you cannot use a category as a component at all.

L136

COMPONENT `type name` occurs more than once in list - TYPE: `type name`
Hint: Each component in the same component list must have a unique type name. Try to make sub-types of the type name in error and replace each non-unique component with one of the new sub-types.

L137

COMPONENT `type name` and its super-type cannot be in same COMPONENT LIST (in TYPE: `type name`)
Hint: Try making another sub-type of the super-type and replace the super-type reference with the new sub-type.

L138

COMPONENT `type name` is same type as delimiter - TYPE: `type name`
Hint: A component and a delimiter cannot have the same name. You may need to add sub-types to the type name used in error to resolve this one.

L139

COMPONENT `type name` is sub-type of delimiter - TYPE: `type name`
Hint: This occurs when a syntax item is used to specify a delimiter. You can add another sub-type to the syntax item and replace the delimiter name with the new sub-type name.

L140

COMPONENT `type name` is super-type of delimiter - TYPE: `type name`
Hint: This occurs when a syntax item is used to specify a delimiter. You can add another sub-type to the syntax item and replace the component name with the new sub-type name.

L141

COMPONENT `type name` is same type as initiator - TYPE: `type name`
Hint: A component and an initiator cannot have the same name. You can add sub-types to the type name used in error and replace both the component name and the initiator name.

L142

COMPONENT `type name` is sub-type of initiator - TYPE: `type name`
Hint: This occurs when a syntax item is used to specify an initiator. You can add another sub-type to the syntax item and replace the initiator name with the new sub-type name.

L143

COMPONENT `type name` is super-type of initiator - TYPE: `type name`
Hint: This occurs when a syntax item is used to specify an initiator. You can add another sub-type to the syntax item and replace the component name with the new sub-type name.

L144

COMPONENT `type name` is same type as terminator - TYPE: `type name`
Hint: A component and a terminator cannot have the same name. Try adding sub-types to the type name used in error and replace both the component name and the terminator name with one of the new sub-types.

L145

COMPONENT `type name` is sub-type of terminator - TYPE: `type name`
Hint: This occurs when a syntax item is used to specify a terminator. You can add another sub-type to the syntax item and replace the terminator name with the new sub-type name.

L146

COMPONENT '*type name*' is super-type of terminator - TYPE: '*type name*'
Hint: This occurs when a syntax item is used to specify a terminator. You can add another sub-type to the syntax item and replace the component name with the new sub-type name.

L147
COMPONENT '*type name*' is same type as Floating Component - TYPE: '*type name*'
Hint: Make both the floating component name and the component name sub-types of the floating component.

L148
COMPONENT '*type name*' is sub-type of Floating Component - TYPE: '*type name*'
Hint: Make both the floating component name and the component name sub-types of the floating component.

L149
COMPONENT '*type name*' is super-type of Floating Component - TYPE: '*type name*'
Hint: Make both the floating component name and the component name sub-types of the floating component.

L150
COMPONENT '*type name*' is same type as release character - TYPE: '*type name*'
Hint: This occurs when a syntax item is used to specify a release character. You can add sub-types to the syntax item and replace both the component name and the release character name with the new sub-type names.

L151
COMPONENT '*type name*' is sub-type of release character - TYPE: '*type name*'
Hint: This occurs when a syntax item is used to specify a release character. You can add another sub-type to the syntax item and replace the release character name with the new sub-type name.

L152
COMPONENT '*type name*' is super-type of release character - TYPE: '*type name*'
Hint: This occurs when a syntax item is used to specify a release character. You can add sub-types to the syntax item and replace the component name with the new sub-type name.

L153
DELIMITER '*type name*' is same type as initiator - TYPE: '*type name*'
Hint: A delimiter and an initiator cannot have the same name. You may need to add sub-types to the type name used in error and replace both the delimiter and initiator names to refer to the new sub-types.

L154
DELIMITER '*type name*' is sub-type of initiator - TYPE: '*type name*'
Hint: This occurs when a syntax item is used to specify both an initiator and a delimiter. You can add another sub-type to the syntax item and replace the initiator name with the new sub-type name.

L155
DELIMITER '*type name*' is super-type of initiator - TYPE: '*type name*'
Hint: This occurs when a syntax item is used to specify both an initiator and a delimiter. You can add another sub-type to the syntax item and replace the delimiter name with the new sub-type name.

L156
DELIMITER '*type name*' is same type as terminator - TYPE: '*type name*'
Hint: A delimiter and a terminator cannot have the same name. You may need to add sub-types to the type name used in error and replace both the delimiter and terminator names to refer to the new sub-types.

L157
DELIMITER '*type name*' is sub-type of terminator - TYPE: '*type name*'
Hint: This occurs when a syntax item is used to specify both a delimiter and a terminator. You can add another sub-type to the syntax item and replace the terminator name with the new sub-type name.

L158
DELIMITER '*type name*' is super-type of terminator - TYPE: '*type name*'
Hint: This occurs when a syntax item is used to specify both a delimiter and a terminator. You can add another sub-type to the syntax item and replace the delimiter name with the new sub-type name.

L159
DELIMITER '*type name*' is same type as release character - TYPE: '*type name*'
Hint: A delimiter and a release character cannot have the same name. You may need to add sub-types to the type name used in error and replace both the delimiter and release character names to refer to the new sub-types.

L160
DELIMITER '*type name*' is sub-type of release character - TYPE: '*type name*'
Hint: This occurs when a syntax item is used to specify both a delimiter and a release character. You can add another sub-type to the syntax item and replace the release character name with the new sub-type name.

L161
DELIMITER '*type name*' is super-type of release character - TYPE: '*type name*'
Hint: This occurs when a syntax item is used to specify both a delimiter and a release character. You can add another sub-type to the syntax item and replace the delimiter name with the new sub-type name.

L162
DELIMITER '*type name*' is same type as Floating Component - TYPE: '*type name*'
Hint: A delimiter and a floating component cannot have the same name. Try adding sub-types to the type name used in error and replace both the delimiter and floating component names to refer to the new sub-types.

L163
DELIMITER '*type name*' is sub-type of Floating Component - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify both a delimiter and a floating component. You can add another sub-type to the syntax item and replace the floating component name with the new sub-type name.

L164

DELIMITER '*type name*' is super-type of Floating Component - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify both a delimiter and a floating component. You can add another sub-type to the syntax item and replace the delimiter name with the new sub-type name.

L165

INITIATOR '*type name*' is same type as terminator - TYPE: '*type name*'

Hint: An initiator and a terminator cannot have the same name. You may need to add sub-types to the type name used in error and replace both the initiator and terminator names to refer to the new sub-types.

L166

INITIATOR '*type name*' is sub-type of terminator - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify both an initiator and a terminator. You can add another sub-type to the syntax item and replace the terminator name with the new sub-type name.

L167

INITIATOR '*type name*' is super-type of terminator - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify both an initiator and a terminator. You can add another sub-type to the syntax item and replace the initiator name with the new sub-type name.

L168

INITIATOR '*type name*' is same type as release character - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify both an initiator and a release character. You can add sub-types to the syntax item and replace both the initiator name and the release character name with a new sub-type name.

L169

INITIATOR '*type name*' is sub-type of release character - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify both an initiator and a release character. You can add another sub-type to the syntax item and replace the release character name with the new sub-type name.

L170

INITIATOR '*type name*' is super-type of release character - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify both an initiator and a release character. You can add another sub-type to the syntax item and replace the initiator name with the new sub-type name.

L171

INITIATOR '*type name*' is same type as Floating Component - TYPE: '*type name*'

Hint: An initiator and a floating component cannot have the same name. Try adding sub-types to the type name used in error and replace both the initiator and floating component names with the new sub-types.

L172

INITIATOR '*type name*' is sub-type of Floating Component - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify both an initiator and a floating component. You can add another sub-type to the syntax item and replace the floating component name with the new sub-type name.

L173

INITIATOR '*type name*' is super-type of Floating Component - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify both an initiator and a floating component. You can add another sub-type to the syntax item and replace the initiator name with the new sub-type name.

L174

TERMINATOR '*type name*' is same type as release character - TYPE: '*type name*'

Hint: A terminator and a release character cannot have the same name. You may need to add sub-types to the type name used in error and replace both the terminator and release character names with the new sub-types.

L175

TERMINATOR '*type name*' is sub-type of release character - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify both a terminator and a release character. You can add another sub-type to the syntax item and replace the release character name with the new sub-type name.

L176

TERMINATOR '*type name*' is super-type of release character - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify both a terminator and a release character. You can add another sub-type to the syntax item and replace the terminator name with the new sub-type name.

L177

TERMINATOR '*type name*' is same type as Floating Component - TYPE: '*type name*'

Hint: A terminator and a floating component cannot have the same name. You may need to add sub-types to the type name used in error and replace both the terminator and floating component names with the new sub-types.

L178

TERMINATOR '*type name*' is sub-type of Floating Component - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify both a terminator and a floating component. You can add another sub-type to the syntax item and replace the floating component name with the new sub-type name.

L179

TERMINATOR '*type name*' is super-type of Floating Component - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify both a terminator and a floating component. You can add another sub-type to the syntax item and replace the terminator name with the new sub-type name.

L180

RELEASE CHARACTER `type name' is same type as Floating Component - TYPE: `type name'

Hint: A release character and a floating component cannot have the same name. You may need to add sub-types to the type name used in error and replace both the release character and floating component names to refer to the new sub-types.

L181

RELEASE CHARACTER `type name' is sub-type of Floating Component - TYPE: `type name'

Hint: This occurs when a syntax item is used to specify both a release character and a floating component. You can add another sub-type to the syntax item and replace the floating component name with the new sub-type name.

L182

RELEASE CHARACTER `type name' is super-type of Floating Component - TYPE: `type name'

Hint: This occurs when a syntax item is used to specify both a release character and a floating component. You can add another sub-type to the syntax item and replace the release character name with the new sub-type name.

L183

COMPONENT NAME ambiguous: `type name' in TYPE: `type name'

Hint: This type has a component whose relative name can be associated with more than one type in the schema. Rename the conflicting types.

L184

RESTRICTION longer than max TYPE size - RESTRICTION # of TYPE: `type name'

Hint: The Type in error is an item. Either change the maximum size of the item or remove the restriction.

L185

RESTRICTION used in an earlier partition - RESTRICTION # of TYPE: `type name'

Hint: Item Partitions must have mutually exclusive restrictions. Remove the restriction from one of the partition restriction lists.

L186

Type of COMPONENT does not exist - `type name' in TYPE: `type name'

Hint: You probably entered an incorrect type name. Try the drag and drop approach to get the correct one.

L187

TYPE must be partitioned (since in a partitioned tree and has sub-types) - TYPE: `type name'

Hint: All types in a partitioned sub-type must have mutually exclusive data objects. Set the partitioned property for the type in error.

L188

TYPE is FIXED, COMPONENT # must have a maximum range value - TYPE type name

L189

TYPE is FIXED, but COMPONENT # is not fixed - TYPE: `type name'

Hint: If the component is not intended to be fixed in size, change the group format for the Type to implicit. If the group format is intended to be fixed, check the component: if that component is an item, make sure it has a Padded To length; if that component is a group, change its type to be of fixed syntax.

L190

BINARY text ITEM used as COMPONENT neither FIXED nor SIZED - COMPONENT # of TYPE: `type name'

Hint: The size of a binary text item must either have a Padded To length or it must be sized by the previous component.

L191

COMPONENT with SIZED attribute is not an UNSIGNED INTEGER ITEM TYPE - COMPONENT # of TYPE: `type name'

Hint: A component used to size the component that follows it must be defined as an unsigned integer item type.

L192

The last COMPONENT in the COMPONENT LIST may not have a SIZED attribute: TYPE: `type name'

Hint: Specify a component to follow the one with the sized attribute.

L193

Range of COMPONENT # must have a maximum value to indicate how many placeholders are needed for its series in TYPE: `type name'.

Hint: Change the range maximum to a specific value (not "s") if you may re-define the data this way.

L194

Cannot distinguish delimiter from terminator in TYPE: `type name'.

Hint: Make the range of the last component in the type fixed or make the delimiter of the type different from its terminator.

L195

Cannot distinguish delimiter contained in COMPONENT # from terminator of TYPE: `type name'.

Hint: Make that component bound or make that contained delimiter different from the type terminator.

L196

Cannot distinguish delimiter of COMPONENT # from delimiter of TYPE: type name because COMPONENT # has no placeholder.

Hint: Make that component bound or make that component's delimiter different from the type delimiter.

L197

Cannot distinguish delimiter of COMPONENT # from delimiter of TYPE: type name because COMPONENT # has no range maximum.

Hint: Make that component bound, or make that component's delimiter different from the type delimiter, or specify a range maximum that has a specific value (not "s") for the last component of COMPONENT #.

L198

Cannot distinguish delimiter contained in COMPONENT # from delimiter of TYPE: `type name'.

Hint: Make that contained component bound or make that contained component's delimiter different from the type delimiter.

L200

Cannot distinguish delimiter contained in COMPONENT # from delimiter of TYPE: `type name'.

Hint: Either make that contained component bound, make that contained component's delimiter different from the type delimiter, or specify a range maximum that has a specific value (not "s") for the last component of the contained component.

Logic error and warning messages

The tables in this section list the logic warning messages that result from a logic analysis of a schema.

The following table lists the warnings than can result when a map is compiled.

Warnings should be resolved because they may produce unpredictable results at mapping time.

Return Code	Message
L199	COMPONENT # is not distinguishable from COMPONENT # that may follow in TYPE: `type name'. Hint: Make the first COMPONENT bound, or look at the tables in " Distinguishable objects " to see how you can define the two component types as distinguishable.
L201	Different data objects of COMPONENT # are not distinguishable in TYPE: `type name'. Hint: See " Distinguishable objects " for more information about distinguishable objects.
L202	RESTRICTION list deleted: TYPE is not an ITEM - TYPE: `type name' Hint: Type class was changed from an item to a group or category, so the restriction list was deleted. If this was not your intent, change it back to the way it was.
L203	COMPONENT list deleted: TYPE is an ITEM - TYPE: `type name' Hint: Type class was changed from a group to a item or category, so the program deleted its component list. If this was not your intent, change it back to the way it was.
L204	DELIMITER deleted: TYPE is not a DELIMITED GROUP - TYPE: `type name' Hint: Group format was changed from delimited to something else, so the program deleted its delimiter. If this was not your intent, change it back to the way it was.
L205	COMPONENT RULE deleted: TYPE is a CATEGORY - TYPE: `type name' (warning) Hint: Type class was changed from a group to a category, so its component rule was deleted. If this was not your intent, change it back to the way it was.
L206	DELIMITER cannot be found (because first component is not required) - TYPE: `type name' (warning) Hint: If the delimiter is missing, a previously set initiator value or the default value is used.
L251	COMPONENT NAME could apply to more than one type:'type name' in TYPE: `type name' (warning).

Schema analysis structure error messages

The following table lists the structure error messages that result from a structural analysis of a schema:

Return Code	Message
S100	Invalid TYPE Name: SubTYPE # of TYPE: `type name'
S101	Invalid TYPE chain: SubTYPE # of TYPE: `type name'
S118	Invalid TYPE NAME WhereUsed chain - TYPE NAME: `type name' (error).
S133	Referenced COMPONENT not 'InUse' - COMPONENT # of TYPE: `type name' (error).
S134	COMPONENT previously referenced - COMPONENT # (COMP #) of TYPE: `type name' (error).
S149	Bad Parent COMPONENT Index - COMPONENT `type name' - TYPE: `type name' (error)

Schema analysis structure warning messages

The following table lists the structure warning messages that result from a structural analysis of a schema:

Return Code	Message
S102	Unused DELIMITER deleted: `type name' (at index #)
S103	Invalid DELIMITER pointer deleted - TYPE: `type name'
S104	Invalid default DELIMITER pointer deleted - TYPE: `type name'
S105	Invalid RELEASE Char pointer deleted - TYPE: `type name'

S106 Invalid default RELEASE Char pointer deleted - TYPE: `type name'
S107 Invalid INITIATOR pointer deleted - TYPE: `type name'
S108 Invalid default INITIATOR pointer deleted - TYPE: `type name'
S109 Invalid TERMINATOR pointer deleted - TYPE: `type name'
S110 Invalid default TERMINATOR pointer deleted - TYPE: `type name'
S111 Resetting DELIMITER Use Count (was # now #) - DELIMITER: `type name'
S112 Unused DESCRIPTION deleted: `type name' (at index #)
S113 Invalid DESCRIPTION pointer deleted - TYPE: `type name'
S114 Resetting DESCRIPTION Use Count (was # now #) - DESCRIPTION: `type name'
S115 Invalid Floating Component TYPE pointer deleted - TYPE: `type name'
S116 Invalid TYPE UsedInComp chain repaired - TYPE: `type name'
S117 Unused TYPE NAME deleted - TYPE NAME: `type name' (at index #)
S119 Resetting TYPE NAME use count (was # now #) - TYPE NAME: `type name'
S120 Repaired empty TYPE NAME WhereUsed chain - TYPE NAME: `type name'
S121 Unused RESTRICTION NAME deleted: `type name' (at index #)
S122 Invalid RESTRICTION NAME deleted no DESCRIPTION was available - TYPE: `type name'.
S123 Invalid RESTRICTION NAME deleted DESCRIPTION was `type name` - TYPE: `type name'
S124 Resetting RESTRICTION NAME Use Count (was # now #) - RESTRICTIONS: `type name'
S125 Unused RESTRICTION DESCRIPTION deleted: `type name' (at index #)
S126 Invalid RESTRICTION DESCRIPTION deleted - TYPE: `type name'
S127 Resetting RESTRICTION DESCRIPTION Use Count (was # now #) - RESTRICTIONS: `type name'
S128 Unused RULE deleted: `type name' (at index #)
S129 Invalid RULE pointer deleted - COMPONENT # of TYPE: `type name'
S130 Resetting RULE Use Count (was # now #) - RULE: `type name'
S131 Invalid COMPONENT TYPE Description pointer - COMPONENT #
S132 COMPONENT marked 'InUse' found in Free Chain- COMPONENT #
S135 COMPONENT in Free Chain referenced by a TYPE - COMPONENT #
S136 COMPONENT recovered and added to Free Chain - COMPONENT #
S137 TYPE in Free Chain referenced by another TYPE - TYPE #
S138 TYPE recovered and added to Free Chain - TYPE X'%04X'
S139 TYPE marked 'InUse' but not referenced - TYPE #
S140 Referenced TYPE not marked 'InUse' - TYPE #
S141 TYPE Free Chain not in order: sorting
S142 COMPONENT Free Chain not in order: sorting
S143 Overlap found in LIST Free Chain
S144 Free Chain extends into unallocated region
S145 Overlap found in COMPONENT LIST SPACE: list cleared COMPONENTS will be deleted
S146 Invalid COMPONENT LIST pointer: all COMPONENTS DELETED - TYPE: `type name'
S147 Resetting COUNT in COMPONENT LIST: some COMPONENTS may be lost
S148 RULE truncated (due to internal error): `type name' (at index #)

- S150 CATEGORY 'type name' was missing GROUP and/or ITEM attributes
S151 GROUP 'type name' was missing GROUP attributes
S152 ITEM 'type name' was missing ITEM attributes
-

Maps

A map node invokes a map within a flow.

Map design

Use the Map Designer to develop maps that define input and output specifications and mapping rules for data transformation.

- [Introduction to the Map Designer](#)

- [Auto Map preferences](#)

Use the Auto Map preferences to select the options for the Auto Map to use for mapping source and target objects.

- [Profiler preferences](#)

Use the Profiler preferences to configure the default Map Profiler utility settings.

- [Where Used view](#)

You can see all the locations in a map source (.mms) file where a particular map is called in rules, where a particular type is used in rules, or where the maps and types are used by a rule, in the Where Used view.

- [Search options](#)

The Design Studio supports standard search options.

- [Maps and map source files](#)

- [Input and output cards](#)

- [Card settings](#)

- [Map events](#)

When you run Design Server Maps using the Design Server runtime REST API, the related Map execution events are sent to the specified Elasticsearch server.

- [Map rules](#)

- [Search functionality](#)

The search functionality in the Map designer allows to search for a specific text within all rules in a current executable map and all its corresponding functional maps.

- [Formulating map rules](#)

- [Functional map basics](#)

- [Rename a functional map](#)

The functional map of an execution map can now be renamed. To rename a functional map follow the below procedure:

- [Map settings](#)

- [Configuring bursts](#)

- [Building maps](#)

- [Running a map](#)

- [Map Profiler](#)

The Map Profiler is a user-configurable utility that captures and reports map execution statistics.

- [Map performance](#)

- [Managing invalid data](#)

- [Troubleshooting](#)

- [Error and warning messages](#)

Introduction to the Map Designer

Use the Map Designer to develop maps that define input and output specifications and mapping rules for data transformation.

The Map Designer uses the definitions of data stored in the schemas (that are created using the Type Designer) to specify the transformation logic in the form of map rules. Map rules operate on input data objects and build output data objects. The map can be built for specific platforms, and then run on that platform to perform the transformation of the data.

During the design phase, you build and run maps from within the Map Designer. You can view the results of a map in the Map Designer. You can also use the Map Designer to build a map to be run on supported platforms.

If you have built a map to be run on a WebSphere DataPower SOA Appliance platform, to test it from the Map Designer, you must also install the test domain on the appliance.

If you are testing IBM Transformation Extender maps that you can run on a Sterling B2B Integrator server, or deploy to a Sterling B2B Integrator server map repository, you must first complete the installation and configuration requirements. Install the IBM Transformation Extender for Integration Servers on both the machine where the Design Studio is installed, and on the machine where the Sterling B2B Integrator server is installed. Configure the Design Studio connection properties for IBM Transformation Extender maps in the Sterling B2B Integrator preferences pane.

- [Using the Map Designer](#)

- [Define data objects and properties](#)

- [Create maps to specify sources and targets](#)

Using the Map Designer

To use the Map Designer, you must already have the schemas that define your data. The Map Designer uses the data object definitions that are stored in the schemas.

The Map Designer is used to:

- Create maps to specify the logic necessary to transform the input data to the desired output data.
- Identify the source and data objects of the input data.
- Validate and resolve the source data type properties defined in the Type Designer.
- Identify the target and data objects of the output data.
- Specify and build the output data according to the map rules.
- Provide information about data validation by generating trace files.
- View the run results of the map execution.

After defining data objects and their properties in the Type Designer, you define a map in the Map Designer where map cards specify the input source and the output target.

Define data objects and properties

The schemas are defined with the Type Designer. You can also import them from a project.

To define data:

1. Use the Type Designer or import operation to create or generate a schema.
2. Define the type properties of input and output data.
3. Specify restrictions of input data for item types.
4. Specify desired validation of input data in component rules.
5. Save and analyze the schema.

Create maps to specify sources and targets

After defining data objects and their properties in the Type Designer, you specify the source of the input and the target of the output in the Map Designer. Sources and targets are specified with map cards. Each map can have none or more input cards, and one or more output cards.

To create maps: in the Transformation Extender Development perspective:

1. Create a map source file.
2. Create required executable map(s) in the map source file.
3. Create an input card that represents your input data.
4. Create an output card that represents your desired output.
5. In the output card map rules, specify the logic necessary to transform the input data to the desired output data.
6. Build the map.
7. Run the map.

Auto Map preferences

Use the Auto Map preferences to select the options for the Auto Map to use for mapping source and target objects.

To access Auto Map preferences, in the Map Designer, click Window > Preferences > Transformation Extender > Map > Auto Map.

- **Mapping Scope**
To specify the level of map objects that the Auto Map operation maps, you must configure the mapping scope.
- **Rule Creation Option**
To specify that the Auto Map overwrite existing rules on objects of the map that the Auto Map creates, configure the option for rule creation.
- **Name Matching Options**
To specify the options that the Auto Map uses to match the object names on the source with the object names on the target, configure the Name Matching Options.
- **Mapping Criteria**
To specify the conditions that the Auto Map uses for creating rules, you must configure the mapping criteria.
- **Match percent examples**
Here are examples of the minimum percent amount that the source and target names must match each other for the Auto Map operation to create rules.

Mapping Scope

To specify the level of map objects that the Auto Map operation maps, you must configure the mapping scope.

Configure the mapping scope in the Auto Map preferences in the Map Designer.

Option

Definition

Map only immediate items

Automatically maps the child items in the target. The child items are the items directly under the group that you selected.

Map only immediate items and groups

Automatically maps both the child items and groups in the target. On the groups, though, the process creates only functional maps, and does not map the child items that are under the group.

Map all descendants

Maps all levels of the child items and groups in the target. Creates the functional maps. Maps the children of the functional maps and continues mapping lower levels until there is nothing else for the process to map. This mapping scope option is the default configuration.

Rule Creation Option

To specify that the Auto Map overwrite existing rules on objects of the map that the Auto Map creates, configure the option for rule creation.

Configure the rule creation option in the Auto Map preferences in the Map Designer.

Option

Definition

Overwrite existing rules

The Auto Map operation maps objects that have existing rules. When you check this option, the Auto Map operation overwrites those rules.

Name Matching Options

To specify the options that the Auto Map uses to match the object names on the source with the object names on the target, configure the Name Matching Options.

Configure the Name Matching Options in the Auto Map preferences in the Map Designer.

Option

Definition

Case sensitive

The Auto Map operation compares those source and target object names with the same case.

Alphanumeric characters (letters and digits only)

The Auto Map operation ignores the nonalphanumeric characters when it compares the source and target object names.

Example:

- Name Matching Options: The Alphanumeric characters (letters and digits only) option for matching name is selected.
- Mapping Criteria: The Create rules when the names of the sources and targets match mapping criterion is selected.
- Source: abc_dEf
- Target: abcdEf
- Operation: The Auto Map compare operation ignores the underscore symbol that is in the source object name. It compares the resulting abcdEf characters from the source object name with the abcdEf characters of the target object name.
- Result: There is a 100% match between the resulting abcdEf characters from the source object name and the abcdEf characters of the target object name.

Mapping Criteria

To specify the conditions that the Auto Map uses for creating rules, you must configure the mapping criteria.

Configure the mapping criteria in the Auto Map preferences in the Map Designer.

Option

Definition

Create rules when the names of the sources and targets match

When you click this option, the Auto Map creates rules when the source and target object names match. The match criteria is defined by the Name Matching Options that you selected.

Create rules when the names of the sources and targets match by the specified percent

When you click this option, you must also click the % match arrows to specify a percent. The percent is the degree of match between the source and target object names that the Auto Map operation uses to determine whether it creates rules. The Auto Map operation uses the match criteria as defined by the Name Matching Options that you selected. It creates the rules when the source and target object names match according to those selected matching options and by the percent you specified.

Use the Number of characters field to specify the number of characters to compare. For example, when you specify the number of characters as 5:

- The following is a match:

`Date_424_PO<=>Date_411_PO`

- The following is not a match:

`PO_424_LineItems<=>PO_411_LineItems`

Match percent examples

Here are examples of the minimum percent amount that the source and target names must match each other for the Auto Map operation to create rules.

If you select the option to create rules when the source and target names match by a specified percent, you must specify that percent amount. You can go back to the Select the options to map source to target window and select different percent amounts. Repeat this process until you get the matching results that you want.

The following table lists examples of source and target object names and the percent amount that is used for the match process. The Auto Map operation uses this percent amount as the matching criterion, which determines whether the operation creates the rules. In these examples, all of the names of the source and target objects match each other by at least the specified percent. In example 1, firstName matches fName by a minimum of 15 percent. Since the matching criterion is met, the Auto Map operation can create the rules.

Example	Source object name	Target object name	Match percent
1	firstName	fName	15
2	lastName	lName	25
3	address	addressLine	25
4	account	acct	20
5	country	ctry	20
6	zipCode	zcode	50
7	birthDate	bDate	15
8	event	evt	30
9	telephone	phone	15
10	proj	project	15
11	record	rcrd	15

Profiler preferences

Use the Profiler preferences to configure the default Map Profiler utility settings.

Before profiling a map, you must enable a **Function Times** option or a **Type Times** option to see statistics in the output, otherwise the report is empty.

To access user preferences, click Window > Preferences > Transformation Extender > Map > Profiler.

To run a map using the Map Profiler utility to capture and report map execution statistics, you must configure the profiler settings in the Map Designer for the following profiler options:

Function times

Enable the **All** or **Above** option to view function time statistics in the profiler report.

Option	Description
None	(Default setting) When None is enabled, function time statistics are not reported.
All	When you select All, each function and each function call is provided in the profiler output. Every occurrence of every function is displayed with the depth (level), number of iterations, elapsed time, map name, and type name.
Above	Use the Above option to obtain a smaller output file. When you specify a value in 1/10 milliseconds (10000 = 1 second), function times are only recorded when they exceed that value.
Summary	When you choose the Summary option, the report contains a summary for each function instead of listing every occurrence. A function is listed once with the total number of iterations and total elapsed time for all iterations. Sample report .

Type times

Enable the **All** or **Above** option to view type time statistics in the profiler report.

Option	Description
None	(Default setting) When None is enabled, type time statistics are not reported.
All	When you select All, each type per rule is provided in the profiler output. For each rule, the time, map name, and type name are reported.
Above	Use the Above option to obtain a smaller output file. When you specify a value in 1/10 milliseconds (10000 = 1 second), types times are only recorded when they exceed that value.
Summary	When you choose the Summary option, the report contains a summary of types per rule. A type name is displayed once with the total number of iterations and total elapsed time for those iterations. Sample report

File output

Option	Description
Fixed Width	This option produces a readable, flat file output.
Comma Delimited	This option produces a comma-delimited output which is useful for exporting to spreadsheet programs.

Where Used view

You can see all the locations in a map source (.mms) file where a particular map is called in rules, where a particular type is used in rules, or where the maps and types are used by a rule, in the Where Used view.

Open the Where Used view by right-clicking a map in the Outline view, or a type in the Map editor, and selecting Where Used.

From the Where Used view, you can go directly to the location where the map source file references the type or the map in a rule by double-clicking any of the locations returned in the view.

Search options

The Design Studio supports standard search options.

Search and replace

- Use the search operation to search through a single map source file or schema file, or multiple map source files or schema files, within search scope parameters that you specify, such as workspace, working set, and so forth.
- Use the replace operation to first do the search, and then replace text in the search results.

Find and replace

- Use the find operation to search for matches on text within a single map source file or schema file that you have open in the editor.
- Use the replace operation to replace text in the matched find results. This option is only available for searches within a schema.
- You can also do these operations using search and replace.

- [**Search and replace**](#)

This topic describes the features of search and replace.

- [**Find and replace**](#)

This topic describes the features of find and replace.

Search and replace

This topic describes the features of search and replace.

You have the option to do a search, which does a search operation only, or a replace, which does both a search operation and a replace operation. The search option searches the entire contents of a single map source file or multiple map source files, or a single schema file or multiple schema files based on the criteria you selected. The replace option does the search, and replaces the values in the search string with a replacement value for the search result components that you select to be included in the replace operation.

Features of the search and replace options:

- Run through the Transformation Extender tab in the Search window navigated from the Search menu on the menu bar.
- Operates on an entire map source or schema file or files. You can set the scope of the **Search** operation to do the search within the workspace, a specific working set, or a specific directory. For map source files, you can also set the scope to do the search in a current Map editor.
- Within a map source file or files, searches on:
 - All schema names
 - All card names
 - All output objects
 - All map names
 - All card type names
 - All map rules
 - All reference files

For example, you can search through map cards within a map source file, and replace file names ending with .txt with .dat. You can replace all card types named Record Set Data with Record Data. You can find card names that include the word Test.

- Within a schema file or files, searches on:
 - Type properties
 - Component rules
 - Restrictions
 - Type names

For example, you can search through all schemas in your workspace, and replace those type names named month with mm.

- [**Search For**](#)
Search For: is used to set the entity on which search and replace operates.
- [**Scope**](#)
Scope: is used to set the range within which search and replace operates.
- [**Using search and replace**](#)
There are different criteria that you can set when you use search and replace in the Design Studio.

Search For

Search For: is used to set the entity on which search and replace operates.

The following list describes the search entity options you can choose:

Type Tree Name

 Searches schema names

Card Name

 Searches card names

Output

 Searches output objects that have map rules

If you are doing a replace operation, it cannot replace text for this selection.

Map Name

Searches map names

Card Type Name

Searches card type names

Rule

Searches map rules

Reference Files

Searches reference files

Scope

Scope: is used to set the range within which search and replace operates.

The following list describes the search scope options you can choose:

Workspace

Searches for the search entity you selected, within the entire Eclipse workspace, which is where your projects are stored on your local drive

Working set:

Searches for the search entity you selected, within an entire Eclipse work set, which you create containing a subset of resources in the workspace

Directory:

Searches for the search entity you selected, within an entire folder

Current editor:

Option is only available when you select Map Source Files under Search In:

Searches for the search entity you selected, within the map source file that is open in the Map editor

Selection options:

- All Maps (default)
- Current Map
- Current and Reference Maps

Using search and replace

There are different criteria that you can set when you use search and replace in the Design Studio.

To use search and replace:

1. Click **Search > Search** on the menu bar, or press **Ctrl+H**.
The Search window opens.
2. Click the Transformation Extender Search tab.
This is the view through which you make your search and replace selections.
3. Enter text or wildcard characters in the Search string field.
Case sensitive and Whole word are optional fields that you can select.
4. Under **Search In:** click **Map Source Files**.
5. Under **Search For:**, click one of the search entities.
6. Under **Scope:**, click one of the scope entities.
7. Click **Search** to do a search operation only, or **Replace** to do both a search and a replace operation.
8. If you clicked **Replace**, the Map Designer window opens and displays the following message: Changes made using replace can not be undone. Do you want to continue with replace? Respond to the message by clicking **OK**.
9. While the operation is running, it displays the Search Query window containing the **Operation in progress** message. If it is searching through a large number of resources, the window remains open. Click **Run in Background** so that you can continue to access the Design Studio graphical user interface (GUI).
You can monitor the operation's progress by opening the Progress view, and viewing the progress indicator. You can also cancel the operation in this view.
The operation completes and displays any matches in the lower pane under the **Search** tab.
10. Click a map source file listed in the search results to see the details of the matches.

Double-click any map name in the list to locate it in the Map editor.

11. If you clicked **Replace** to do both a search and a replace operation, do the following additional steps:

- a. Select the check box next to each map name in the search results details to include in the replace operation.
There are two options in Search view that you can use if there are many search results to include (**Select All**), or exclude (**Deselect All**) from the replace operation.

- **Select All** - automatically selects all of the maps
- **Deselect All** - automatically deselects all of the maps, which were previously selected

- b. Enter the replacement text in the **With:** field.

The **Replace:** field contains the text you entered in the Search string field of the Search window.

- c. Click **Replace**.

The operation replaces the text in the **Replace:** field with the text in the **With:** field in every search result you selected to be included in the operation. It cannot replace text if you selected **Output** under the **Search For:** pane. When the operation completes, the Map Designer window displays a message about how many replacements were made.

- d. Click **OK**.

Find and replace

This topic describes the features of find and replace.

You have the option to do a find, which does a find or a find next operation only, a replace, which does a replace operation, a replace/find, which does both a replace operation and a find next operation, and a replace all, which does a replace operation for all found text. The available options are dependent on the objects you are searching.

Features of the find and replace options:

- Run through the Find/Replace window navigated from the Edit menu on the menu bar, or from the Find/Replace option on the context menu of an object.
- Operates on selected objects in a map source or schema file.
- Within a map source file, searches on:
 - Object names in a map card
 - Map rules in a card
 - Map elements in the Organizer folder, which is in the Outline view

Only the Find option is available for searches within a map source file.

- Within a schema file, searches on:
 - Text characters associated with types
 - Text characters associated with components
 - Text characters associated with restrictions

All options are available for searches on types within a schema file.

Only the Find and the ReplaceAll options are available for searches on components within a schema file.

- [Using find and replace](#)

There are different criteria that you can set when you use find and replace in the Design Studio.

Using find and replace

There are different criteria that you can set when you use find and replace in the Design Studio.

To use find and replace:

1. Select the area in which you want to search. For example, select the card to be searched.
2. Click **Edit > Find/Replace**.
3. In the Find field, enter the text you want to find.
4. To customize your search, select additional options in the window pertaining to direction, scope, case-sensitivity, whole words, and so forth.
5. Click Find to begin the search.
When search criteria is found, it is highlighted within the area that you selected in Step 1.
6. At this point, you can select from the following options:
 - To skip this instance and find the next, click Find.
 - To cancel the search, click Close.

Maps and map source files

The tasks involved in creating and managing map files include:

- Creating map source files
- Creating maps in the map source file
- Creating input and output cards for the map
- Building compiled maps
- Running maps
- Viewing run results

A map defines how to generate a data object of a certain type or multiple independent data objects, each of a certain type. A map contains input and output cards that transform data content from source formats to destination formats according to rules contained in the map.

A map source file stores related maps and functional maps in source format.

The Extender Navigator view lists the folder and file name of one or more map source files.

You must build (compile) a map source file before you can execute it.

- [Map name guidelines](#)
There are guidelines for you to follow when you are naming a map.
- [Map source file differences](#)
Map source files contain maps, and maps contain cards. Map source file differences are compared for each map source file at the map and card levels.
- [Troubleshooting tip](#)

Map name guidelines

There are guidelines for you to follow when you are naming a map.

Name your map according to the following guidelines:

- A map name can be up to 32 bytes in length in UTF-8 encoding.

- A map name cannot be a reserved word.
 - A map name cannot contain only digits or periods, or both.
 - A map name can contain combinations of the following types of characters:
 - Letters
 - Digits
 - ASCII characters 128–255
 - These special characters: ~ # % \ ? _ . ; `
 - Double-byte characters
- It is helpful to use an action-oriented map name that describes the purpose of the map. For example: **CreatePO**.
-

Map source file differences

Map source files contain maps, and maps contain cards. Map source file differences are compared for each map source file at the map and card levels.

Map source files are considered "different" when:

- A map exists in one map source file and does not exist in the other map source file.
- Any of the maps are different.

Maps are considered different if any of the following differences exist:

- Any card is different
- Any card exists in the first map and does not exist in the second map
- Any audit setting is different
- Any remark is different
- Any unresolved rule is different
- The order of the cards in the map is different

Cards are considered different if:

- The card settings are different
- The map rules on output cards are different

In addition to the map source file differences, the source file differences feature identifies differences for schemas, system definition files, and database/query files. You can view the results of the map source file differences.

Compare map source files in the Map Designer.

Troubleshooting tip

If map differences are indicated but not viewable, there is a possibility that if the map was exported, the adapter specified in the map source file was no longer supported or not installed at the time of export. When the map source is imported and then compared, a difference is detected but is not viewable.

Input and output cards

A map defines how to generate data objects of a certain type. A map contains input and output cards that transform data content from source formats to target formats. This data transformation occurs according to mapping rules on the data objects in the output card in the map.

Input and output cards represent data objects. Each card represents one data object, which is defined as a particular type. There are two types of map cards: input cards and output cards.

- An input card contains the complete definition of an input for the map including information such as source identification, retrieval specifics, and the behavior that should occur during processing.
- An output card contains the complete definition of an output for the map including information such as target identification, destination specifics, and the behavior that should occur during processing.

Each input of data and each output of data requires content definition settings. The content of each card is specified as a type in a schema.

- [Card overview](#)

Each map can contain none or more input cards and none or more output cards.

- [Native XML schema support](#)

- [Native JSON schema support](#)

Native JSON schema type tree is created automatically when a valid JSON schema is entered in the type tree field of a card.

- [Static input cards](#)

You can reduce the processing overhead of a map that runs repeatedly by including static input files in the map. A *static* input file doesn't change during map processing, such as a configuration file or a lookup table. A static file in a compiled map is parsed and validated only once, when the map loads. Other inputs are validated each time the map runs.

- [Automatically mapping source to target](#)

The Auto Map is available for you to use from the Design Studio.

Card overview

Each map can contain none or more input cards and none or more output cards.

The maximum number of input cards in a map is 100. The maximum number of output cards in a map is 100.

Each card represents one data object, which is identified by selecting a type from a schema. A card can represent an object in a row, a row in a record, the entire record, or the entire file.

Each card specifies a schema and a type as part of the card definition. This type, and the schema that contains it, is the link between the Type Designer and the Map Designer that defines the structure and properties of the data in the card.

- The input card represents input data. Input data validation occurs in the Type Designer.
- The output card represents output data and contains the map rules that transform that data. Therefore, only the output card has a rule column.
- [Card specifics](#)
- [Compositional hierarchy](#)

Card specifics

- More than one card in a map can reference the same type but the cards must have different card names.
- Each card is assigned a number when it is created. Cards are numbered sequentially, beginning at 1. The card numbers determine the order in which the cards and the data in those cards is evaluated. The card number is important when a map is used as a functional map. To reorder the cards, use the **Reorder** command on the Card menu.
- The structure of the card object appears in the card. An icon represents each component that the entire card data object is composed of. Each icon in the input and output card represents a type that has been defined in the Type Designer.
- The output column in the output card shows the structure and the names of the components of the output data object.
- In the case of partitioned groups, the structure shown is the partitioned group and its subtypes. An icon is shown for each component and each partition that compose the entire card object.
- Each output name appears in a separate cell in the output card.
- The rule column contains a rule cell for each output object. Enter map rules to define how to generate the data object of this card.

Compositional hierarchy

The Composition view of the cards shows the contents of the type definitions. Types are arranged in a compositional hierarchy, which shows the structure, layout or composition of the data. This hierarchy is different from the hierarchy in a schema, which is a classification hierarchy.

The data is defined in the Type Designer according to specific properties. The types are arranged on the input and output cards in the order they appear in the data. This compositional hierarchy shows the structure of the data.

Native XML schema support

IBM Transformation Extender provides native XML schema support. It supports generating specified global elements, specifying data types to be validated by using xsi:type, and processing data that contains complex types with mixed content. The associated NativeXMLSchema properties are added when you specify a native XML Schema (.xsd) file in the TypeTree property on an input or output card. The added properties are Identifier, GlobalElements, XSITypes, and MixedContent.

If you want to change the default values for the NativeXMLSchema properties, use the Native XML Schema Customization wizard.

An output card includes the Type>Metadata>xsi:schemaLocation property and the Type>Metadata>xsi:noNamespaceSchemaLocation property when you specify an XML schema in the card's TypeTree and Type properties.

- [Input-card type requirements for XML documents](#)
- [Parsing native XML schemas](#)
The initial map open process fully parses and validates the schema and creates a read-only, intermediary native schema schema (.mtx) file. Subsequent open processes retrieve the Transformation Extender-specific information that is stored in the cached .mtx file, similar to retrieving the information from a schema (.mtt) file. Retrieving the information from the cached .mtx file is designed to improve the response time for opening maps that reference an XML Schema.
- [Running the Native XML Schema Customization wizard task flow](#)
Follow this task flow to run the Native XML Schema Customization wizard from the input or output card of your map.
- [Support for XSDL hints in output cards](#)
When the TypeTree and Type properties of an output card specify an XML schema, Map Designer includes the xsi:schemaLocation and xsi:noNamespaceSchemaLocation fields in the card properties. The XSDL hint that you specify in the xsi:schemaLocation or the xsi:noNamespaceSchemaLocation field is included in the output XML schema when the map runs. If you specify XSDL hints in both the xsi:schemaLocation and the xsi:noNamespaceSchemaLocation fields, only the xsi:schemaLocation hint is included in the output XML schema.

Input-card type requirements for XML documents

When a native XML schema has a prolog, the Type setting of the main input card must be XSD (the root of the XML document). A parser error results when the XML schema has a prolog and the Type setting specifies a sub-element of the root.

As a general practice, use XSD as the Type setting in the main input card of all native XML schemas. The XSD setting parses correctly regardless of whether the schema includes a prolog.

For all Xerces schemas, use Doc XSD as the Type setting of the main input card, regardless of whether the XML document has a prolog. Parsing errors can result if the XML document includes a prolog and you specify a sub-element of Doc XSD as the Type setting of the main input card.

Parsing native XML schemas

The initial map open process fully parses and validates the schema and creates a read-only, intermediary native schema schema (.mtx) file. Subsequent open processes retrieve the Transformation Extender-specific information that is stored in the cached .mtx file, similar to retrieving the information from a schema (.mtt) file. Retrieving the information from the cached .mtx file is designed to improve the response time for opening maps that reference an XML Schema.

Running the Native XML Schema Customization wizard task flow

Follow this task flow to run the Native XML Schema Customization wizard from the input or output card of your map.

Before you can run the wizard, make sure that a native XML schema (.xsd) file is specified for the TypeTree property and that the NativeXMLSchemaCustomization properties were added.

Use the Native XML Schema Customization wizard to change the default values for the NativeXMLSchema based on your mapping requirements. When you start the Native XML Schema Customization wizard, it takes you step-by-step through the process that updates the NativeXMLSchemaCustomization properties in the card.

To run the Native XML Schema Customization wizard:

1. Click the button next to NativeXMLSchemaCustomization under the Value column.
The Native XML Schema Customization wizard opens. Follow the wizard prompts that guide you through the different windows.
2. Select the global elements that you want to be generated in the card. The card is generated with these specified global elements. Click Next to continue. You can click Finish to save the settings and return to the card that displays in the Map editor.
You must select at least one global element to continue to the next window in the wizard.
3. Select the global types for which you want to enable the use of derived types on base types by using the xsi:type attribute. Click Next to continue. You can click Finish to save the settings and return to the card that displays in the Map editor.
You do not have to make a selection in this window to continue to the next window in the wizard.
4. Select Support complex types with mixed content if the map must process data that contains complex types with mixed content.
You do not have to make a selection in this window to continue.
5. Click Finish to save the settings.
The Edit Card window redisplays in the Map editor.

The Identifier, GlobalElements, XSITypes, MixedContent properties that are listed in the card under NativeXMLSchemaCustomization contain updated values, depending on your selections.

If you updated all of the NativeXMLSchemaCustomization properties, you would see the following settings:

- Identifier: a unique numeric identifier for the native XML schema
- GlobalElements: a numeric designation and *global_element_name {namespace}* value for each of the global elements you selected that you want to be generated in the card
- XSITypes: a numeric designation and *global_type_name {namespace}* value for each of the global types for which you want to enable the use of derived types on base types by using the xsi:type attribute
- MixedContent: value that is set to True

Support for XSDL hints in output cards

When the TypeTree and Type properties of an output card specify an XML schema, Map Designer includes the xsi:schemaLocation and xsi:noNamespaceSchemaLocation fields in the card properties. The XSDL hint that you specify in the xsi:schemaLocation or the xsi:noNamespaceSchemaLocation field is included in the output XML schema when the map runs. If you specify XSDL hints in both the xsi:schemaLocation and the xsi:noNamespaceSchemaLocation fields, only the xsi:schemaLocation hint is included in the output XML schema.

The xsi:schemaLocation and xsi:noNamespaceSchemaLocation properties are not available in input cards.

Native JSON schema support

Native JSON schema type tree is created automatically when a valid JSON schema is entered in the type tree field of a card.

The JSON document is determined to be a JSON schema when a field called \$schema is found in outermost group. If this element is not found in the JSON document will be treated as a template.

When you use native JSON to define the main input or output card, always select the main Type as the first JSON type.

Note: The main input or output card is the card that has the file or other source that defines how to parse or create the document.
This restriction does not apply to functional maps.

A card property called Data Language is present for output cards which use native JSON. This card property allows the text encoding of the JSON output to be selected. The following encodings are supported: UTF-8, UTF-16BE, UTF-16LE, UTF-32BE, UTF-32LE. Previously, an item type in a native JSON type tree named encoding was used for this purpose. The encoding item remains valid for type trees and maps which use it. Conversion of a rule on an encoding item is necessary if the rule becomes invalid due to the absence of an encoding item in a native JSON type tree.

The encoding field on input always returns the value NONE. On output, this field can be set to any valid JSON encoding and the JSON document is produced that uses that encoding. If you do not configure the encoding, the default encoding used is UTF-8.

Restrictions with JSON Schema:

- Tuple validation is not supported.

- Elements will be loaded into a string array, but not validated.

The target of "if" statement must appear in the data stream before fields in the Then or the Else. Out of order data will cause the "if" to fail.

Dependencies that alter the initial type is not be supported. Data will be loaded into fields but not validated.

For example: Field B is defined as string.

A dependency where if field A is present then field B now must be a date.

ITX will handle this, but no validation will be done.

Static input cards

You can reduce the processing overhead of a map that runs repeatedly by including static input files in the map. A *static* input file doesn't change during map processing, such as a configuration file or a lookup table. A static file in a compiled map is parsed and validated only once, when the map loads. Other inputs are validated each time the map runs.

No new-line conversion or character-set conversion takes place in the file when the map runs on any platform.

To include a file in a map, specify the static file adapter and the file name on the input card before you compile the map. The file must exist at the time when the map compiles, and must be less than 10 MB in size. For static files, the OnSuccess property is always Keep and the OnFailure property is always Rollback.

You can override a static file input in a compiled map with another adapter. The static file input must pass validation in order for the map to load, but the map uses the adapter override when it runs.

You cannot use the static file adapter to override an input card during map execution. Static file input must be compiled into the map.

To change the contents of a static file, you must recompile and redeploy the map. When you enable map caching, you must restart the process before the map can use the updated static file.

Note: The `tx_install_dir/data_dir/config/config.yaml` configuration file controls map caching for Launcher and **RUN** maps. See the related information links for details about map caching in other environments.

- [Static file validation and tracing](#)

Transformation Extender (TX) validates a static input file in a compiled map only once, when the map loads, and produces a trace file only if the static file fails validation. TX validates other map inputs each time the map runs, and logs them in the map trace file as specified by the map settings.

Related information

- [TX map caching with IBM Integration Bus](#)
- [TX map caching with IBM Sterling B2B Integrator](#)
- [TX map caching with IBM Business Process Manager Advanced](#)
- [Map caching with TX programming APIs](#)

Static file validation and tracing

Transformation Extender (TX) validates a static input file in a compiled map only once, when the map loads, and produces a trace file only if the static file fails validation. TX validates other map inputs each time the map runs, and logs them in the map trace file as specified by the map settings.

When a static input file fails validation, the map does not load. TX logs the validation error in the appropriate log for the runtime environment for example, the Launcher's CompoundSystem log or the IBM Integration Bus log. The error includes the location of the static input trace file. TX creates the static input trace file as `map_name.mtr` in the map directory. If the map loads from memory, TX creates the `map_name.mtr` file in the map working directory.

When a static input file fails validation on a z/OS® system running in batch, CICS® or IMS, the trace is written to the DD name DTX#TRCE. Because the trace is written as a byte stream, it lacks formatting if the DTX#TRCE is directed to SYSOUT. If formatting is required, direct the DD card to a zFS file. For example:

```
//DTX#TRCE DD PATH='/tmp/dtx#trce.mtr',
//           PATHDISP=(KEEP),
//           PATHOPTS=(ORDWR,OCREAT),
//           PATHMODE=(SIRWXU,SIRWXG,SIROTH)
```

When you trace a static input file and the static file passes validation, the map trace file describes the static input as an existing work file. For example, you might trace two map inputs. Input 1 is not a static file and the input is invalid. Input 2 is a static file that passed validation during load. The trace file includes messages similar to the following:

```
.
.
(Level 2: Offset 389, len 6, comp 3 of 3, #1, DI 000000000053:)
Data at offset 389 ('00000<CR>') is INVALID data of TYPE
  X'0012' (total_hours element example).

(Level 1: Offset 297, len 98, comp 1 of 1, #4, DI 000000000054:)
Data at offset 297 ('Work A.      ...') is INVALID data of TYPE
  X'0003' (timesheet example).

(Level 0: Offset 0, len 396, comp 1 of 0, #1, DI 000000000055:)
Data at offset 0 ('FirstName      ...') is INVALID data of TYPE
```

```
X'0002' (all_employees example).  
INPUT 1 exists, but its type is in error.  
End of Validation messages for INPUT CARD 1.  
Reusing an earlier work file for INPUT CARD 2.  
End of Execution messages.
```

Automatically mapping source to target

The Auto Map is available for you to use from the Design Studio.

- [Auto Map overview](#)

The Auto Map automatically maps selected source and target groups.

- [Running the Auto Map task flow](#)

Follow this task flow to run the Auto Map in the Design Studio.

- [Setting the Auto Map options](#)

You can optionally change the default settings that originate from IBM Transformation Extender, or that you set up in the Preferences window.

- [Selecting the rules to create](#)

You can optionally select the rules that you want the Auto Map operation to create.

- [Editing rule proposals](#)

You can optionally change the rules that IBM Transformation Extender proposed for the target objects.

- [Renaming the map](#)

You can optionally change the functional map name.

Auto Map overview

The Auto Map automatically maps selected source and target groups.

Your source groups and item names must match your target group and item names according to the match properties set under Auto Map preferences.

Use the Auto Map wizard when you want to automatically map selected groups of your map. You can also run the Auto Map without using the wizard, by pressing Ctrl+A. The Auto Map operation maps the objects that you select in the following ways:

- Maps the objects that you selected from an input card in your map to the objects that you selected from an output card in your map.
 - Maps the objects that you selected from an output card in your map to the objects that you selected from another output card in your map.
-

Running the Auto Map task flow

Follow this task flow to run the Auto Map in the Design Studio.

When you start the Auto Map wizard, it takes you step-by-step through the process that automatically maps selected source and target objects.

Before you start the Auto Map wizard, you can select options in the Auto Map Preferences. These options are the default selections that the Auto Map uses. As the Auto Map wizard takes you through the process step-by-step, you can change the default selections. However, any changes to the selections that you make in the Auto Map wizard, are not saved. Subsequent runs of the Auto Map use the original default selections that you made in the Auto Map Preferences window. You can, again, change the default selections dynamically in the wizard. But, you can always update the settings in the Auto Map Preferences so that they are saved and used by the Auto Map in subsequent runs. Then, you do not have to reselect the options when you rerun the wizard. You are not required to select the Auto Map Preferences before you run the Auto Map. But, you can avoid continually reselecting the options every time you run the wizard. At any point, you can set the options in the Auto Map Preferences.

If required, you might also want to back up your map before you run the Auto Map because the Auto Map operation does not support an **Undo** function.

To run the Auto Map:

1. Open the map in the Map editor.
2. Select two groups that you want to map automatically.
One of the groups that you select must be a group component in an output card. You can select choice groups. To toggle your group selections on and off, press Ctrl, and click the selection.
Also, select source and target objects at the levels that you want to map. If you select the top level, the Auto Map operation maps all the groups and nested groups. The Auto Map icon in the Map editor toolbar is enabled.
3. Click the Auto Map icon.
The Map Designer window opens and displays an informational message. It warns you that the Auto Map operation does not support Undo so that you can back up your map before you complete running the Auto Map.
4. Click OK in the Map Designer window.
The Auto Map wizard starts. The Auto Map window opens and displays objects under the source and target groups that you selected.
5. Follow the wizard prompts. You can set the various options that the Auto Map operation uses to automatically map the source and target objects.
6. Click Finish.

The Auto Map operation automatically maps the selected source and target objects that are based on the matching properties and the proposed rules that you selected. The operation does not map the rule from the source to the target for the following objects:

- Objects that you did not select to create a rule.
- Objects for which the mapping process did not find a match.

Tip: You can run the Auto Map without using the wizard, by pressing Ctrl+A after you select the two groups that you want to map automatically. The Auto Map operation uses the settings that originate from IBM Transformation Extender, or that you set up in the Preferences window.

Setting the Auto Map options

You can optionally change the default settings that originate from IBM Transformation Extender, or that you set up in the Preferences window.

After you click Next in the Automatically map source to target page of the Auto Map wizard, the Select the options to map source to target page opens. You have the option in that page to configure settings that the Auto Map operation uses for the mapping process. The updated settings however, are not saved; they are not available to subsequent runs of the Auto Map. If you want the settings to be saved, configure them in the Preferences window.

To set the Auto Map options:

1. In the Select the options to map source to target page of the Auto Map wizard, you can set any of the mapping process options.
2. Click Next to open the next page in which you can select more options, or click Finish to run the Auto Map.

If you returned to that page from a subsequent page and changed settings, and then clicked Next, the Map Designer window opens. You are prompted to answer Yes or No to the **Do you want to run the match operation again?** message.

After you click Next, the Select rules to create page opens. It lists the source and target objects that meet the matching criteria that are specified on that page.

Selecting the rules to create

You can optionally select the rules that you want the Auto Map operation to create.

After you click Next in the Select the options to map source to target page of the Auto Map wizard, the Select rules to create page opens. It lists the source and target objects that meet the matching criteria that are specified on the Select the options to map source to target page.

You can run the Auto Map operation with the default settings or make the following optional changes from that page:

- Change the selection of the target objects for which you want the Auto Map operation to create rules.
- Edit the proposed rules.
- Rename the functional maps.

You click Finish on that page to run the Auto Map operation and exit the wizard.

To change the target object selections and the rules that you want the Auto Map operation to create for those objects, do the following optional steps:

1. Change the selection of the target objects for which you want the Auto Map operation to create rules.
 - a. Select the check box of the target objects for which you want the Auto Map operation to create rules.
The default is that the target objects listed in that page are all selected. Therefore, you can clear the check box of those target objects for which you do not want the Auto Map operation to create rules. Another option is to clear the check box of a target object that is a group and then make your selections.
The result is that those target objects that you did not select, are listed in the output with no rule mapped to it.
2. Edit the proposed rules.
 - a. Select one of these target objects for which there is an i indicator that is displayed between the target object and its rule.
The information (i) indicator signals to you that there are more rule proposals that you can optionally select for the object.
 - b. Click Edit rule proposals to open the Rule Proposals window in which you can change the rule selections that IBM Transformation Extender proposed as a result of the matching criteria.
3. Rename the functional maps.
 - a. Select one of the target objects for which there is a rule that contains a functional map.
 - b. Click Rename map to open the Rename Map window in which you can change the functional map name.
4. Click Finish to run the Auto Map operation and exit the Auto Map wizard.

The Auto Map operation automatically maps the selected source and target objects that are based on the matching properties and the proposed rules that you selected. The rule from the source is not mapped to the target for the following objects:

- Objects that you did not select to create a rule.
- Objects for which the mapping process did not find a match.

Editing rule proposals

You can optionally change the rules that IBM Transformation Extender proposed for the target objects.

The information (i) indicator that is displayed between the target object and its rule, signals to you that there are more rule proposals that you can optionally select for the object. After you select one of these target objects for which there is an i indicator that is displayed, and click Edit rule proposals in the Select rules to create page of the Auto Map wizard, the Rule Proposals window opens. The window lists all of the source objects that are possible matches. When you select one of the source objects, the window lists all of the various proposed rules for that selected source object. You can select a source object, and one of the rules to change the rule that IBM Transformation Extender proposed.

To edit the rule proposals:

1. In the Rule Proposals window of the Auto Map wizard, select a source object under Possible Matches.
When you select the source object, the proposed rules for that object are listed under Proposed Rules.
2. Select one of the rules.
3. Click Finish.

The Rule Proposals window closes. In the Select rules to create page, the proposed rule on the target object you selected is replaced by the rule that you selected.

The Auto Map operation automatically maps the selected source and target objects that are based on the matching properties and the proposed rules that you selected. The rule from the source is not mapped to the target for the following objects:

- Objects that you did not select to create a rule.
- Objects for which the mapping process did not find a match.

Renaming the map

You can optionally change the functional map name.

After you select one of the target objects for which there is a rule that contains a functional map, and click Rename map in the Select rules to create page of the Auto Map wizard, the Rename Map window opens. The window displays the default functional map name in the Map Name field.

To rename the functional map:

1. In the Map Name field that is displayed in the Rename Map window of the Auto Map wizard, rename the functional map.
The default is the selected functional map.
2. Click OK.
The Rename Map window closes. In the Select rules to create page, the functional map name in the rule for the targeted object you selected is replaced by the changed map name.

The Auto Map operation automatically maps the selected source and target objects that are based on the matching properties and the proposed rules that you selected. The rule from the source is not mapped to the target for the following objects:

- Objects that you did not select to create a rule.
- Objects for which the mapping process did not find a match.

Card settings

You configure how to run a map by selecting the Map menu, choosing Settings, and specifying the settings in the Properties view. Define **SourceRule** card settings on the input card, and define **TargetRule** card settings on the output card. All of the card settings are in the Properties view, the Data Audit Settings view, and the Remarks view.

Each input of data and each output of data require content definition settings. Card settings define the data object the card represents, and how the data is retrieved or routed.

Card settings can be exported. See "[Exporting a Map Source File](#)" for details about exporting map card settings.

Schema

The Schema setting for input and output cards defines the card name, schema, type, and file.

- [CardName](#)
- [Schema](#)
- [Type](#)

CardName

Each card in a map has a unique name to distinguish cards in the map. Precise naming of the card is practical and useful. A good practice is to name the card the same name as the data object it represents. Follow the card name guidelines.

Although cards can be named most anything you want, typically you would want to use a name that describes the data, such as **InputFile**, **ClaimData**, **ItemMasterRow**, and **CreditApprovalMsg**.

- [CardName guidelines](#)

CardName guidelines

Card names follow these guidelines:

- A card name can be up to 32 bytes in length in UTF-8 encoding.
- A card name cannot be a reserved word.
- A card name cannot contain only digits and or periods.
- A card name can contain *only* the following:
 - Letters
 - Digits
 - ASCII characters 128-255
 - These special characters: ~ # % \ ? _ ' . ; `

Schema

Cards represent a particular data object. Therefore, each input card and each output card is associated with a type in a schema that describes the content of that data. Therefore, each card includes a schema and type name as part of its definition. This schema is the link between the Type Designer and the Map Designer that communicates the structure and properties of the data to the Map Designer.

If you select a .xsd file, the NativeXMLSchema properties are added to the card. In the Edit Card window, expand NativeXMLSchema to see the added Identifier, GlobalElements, XSITypes, and MixedContent properties, along with their default values, as shown in the following list.

- Identifier: <Default>
- GlobalElements: All
- XSITypes: None
- MixedContent: False

Change the default values for the properties by running the Native XML Schema Customization wizard.

- [NativeXMLSchemaCustomization](#)

NativeXMLSchemaCustomization

NativeXMLSchemaCustomization includes several properties that support the Native XML schema.

- [NativeXMLSchemaCustomization > Identifier](#)
Native XML schema support includes the ability to generate the identifier of the file that the schema generates.
- [NativeXMLSchemaCustomization > GlobalElements](#)
Native XML schema support includes the ability to select global elements to be generated.
- [NativeXMLSchemaCustomization > XSITypes](#)
Native XML schema support includes the ability to specify the global types for which you want to enable the use of derived types on base types by using the xsi:type attribute.
- [NativeXMLSchemaCustomization > MixedContent](#)
Native XML schema support includes the ability to use complex types with mixed content in the card.

NativeXMLSchemaCustomization > Identifier

Native XML schema support includes the ability to generate the identifier of the file that the schema generates.

When you specify a .xsd file for TypeTree, the generated identifier displays under the Identifier property under NativeXMLSchemaCustomization in input and output cards. The default value is Default. When you run the Native XML Schema Customization wizard to update the other NativeXMLSchemaCustomization properties, the wizard generates a numeric value for the identifier.

NativeXMLSchemaCustomization > GlobalElements

Native XML schema support includes the ability to select global elements to be generated.

When you specify a .xsd file for TypeTree, the generated GlobalElements property displays under NativeXMLSchemaCustomization in the input or output cards. The default value is All. You can run the Native XML Schema Customization wizard to select the specific global elements that you want to be generated in the card. When the global elements are specified, the NativeXMLSchemaCustomization.>.GlobalElements properties contain the numeric designation and *global_element_name {namespace}* value for each of the global elements you selected. As a result, instead of generating all of the global elements, IBM Transformation Extender generates only the global elements that you selected.

NativeXMLSchemaCustomization > XSITypes

Native XML schema support includes the ability to specify the global types for which you want to enable the use of derived types on base types by using the xsi:type attribute.

When you specify a .xsd file for TypeTree, the generated XSITypes property displays under NativeXMLSchemaCustomization in the input or output cards. The default value is None. You can run the Native XML Schema Customization wizard to enable the use of derived types on base types by using the xsi:type attribute. When the global types are specified, the NativeXMLSchemaCustomization.>.XSITypes properties contain the numeric designation and *global_type_name {namespace}* value for each of the global types you selected.

NativeXMLSchemaCustomization > MixedContent

Native XML schema support includes the ability to use complex types with mixed content in the card.

When you specify a .xsd file for TypeTree, the generated MixedContent property displays under NativeXMLSchemaCustomization in input or output cards. The default value is False. You can run the Native XML Schema Customization wizard to set support of mixed content for the card by selecting Support mixed content types. When the support is set, the Native XML Schema Customization > Mixed Content property in the card is set to True. As a result, the data that the card represents can contain complex types with mixed content.

Type

The Type Name setting specifies the name of the type in the schema that describes the data represented by the card. This type must exist in the schema specified with the Schema setting.

- [Metadata](#)

The Schema > Type > Metadata card setting is applicable to Xerces XML schemas.

Metadata

The Schema > Type > Metadata card setting is applicable to Xerces XML schemas.

The default location for metadata, XML Schema, or DTD, is the location that is specified in the Doc group of the XML schema (type property: Intent > Validate as > Location).

Use the Schema > Type > Metadata card setting to specify the XML Schema or DTD location in the map at the card level.

The Metadata card setting takes precedence over the location that is specified in the schema.

You can override the Metadata setting by using the command line (-M). However, it cannot be overridden at the system level by using the Integration Flow Designer.

Change the metadata location by using this card setting in the map instead of changing it in the schema. When the Schema > Type > Metadata card setting is not set, the XML Schema or DTD location is derived from the schema by default.

- [Metadata > NameSpaces](#)

The NameSpaces property lists all of the namespaces that are referenced in the schema that is used in the Metadata location in an input or output card.

Metadata > NameSpaces

The NameSpaces property lists all of the namespaces that are referenced in the schema that is used in the Metadata location in an input or output card.

On an input card, you can do the following processes:

- Delete
 - You can delete a namespace by right-clicking the specific namespace and clicking Delete.
- Reload
 - You can reload all of the namespaces that you deleted by right-clicking the NameSpaces property and clicking Reload.

On an output card, you can do the following processes:

- Add
 - You can add a namespace by right-clicking the NameSpaces property and clicking Add.
 - The Namespace Dialog window opens.
 - You define custom namespaces by specifying the URI in this window.
- Delete
 - You can delete a namespace by right-clicking the specific namespace that you want to delete, and clicking Delete.
- Reload
 - You can reload the namespaces that you deleted by right-clicking the NameSpaces property and clicking Reload.

If there are namespaces that are defined on the output cards, when the map runs, those namespaces are written to the beginning of the XML file.

For more information about namespaces, see the topics about XML schema datatypes in the Type Designer documentation.

SourceRule input card settings

SourceRule settings specify what data to retrieve, where to get it, how much to get, and what to do when an error occurs.

The **SourceRule** settings define how the input is retrieved. The data object specified in the input card defines what data is retrieved. The **SourceRule** settings define how the data is retrieved.

To define card-specific data retrieval behavior, specify the **SourceRule** settings for each input card. An input card represents an input source. The content of an input is a *data object* such as a table of patient records in a relational database, a message that contains a mortgage application, or a file of item master update records that is

transferred from another location using the FTP adapter.

The content of an input card is defined with the card **Name**, **Schema**, **Type Name** and Filesettings. These settings define what the data is, but do not specify how to retrieve the data. The **Source**, **FetchAs**, **WorkArea** and **FetchUnit** card settings are some of the **SourceRule** settings that define how the data is retrieved for each input card.

SourceRule Setting overrides

Input card settings are stored in the compiled map. You can override the setting for each option from other applications, including the Command Server, Launcher, and Integration Flow Designer.

Execution commands can be used to override the map settings or card settings compiled into the compiled map when a map is run. See the Execution Commands documentation for a complete description of the override execution commands.

The **SourceRule** card settings and their override execution commands are listed in the table below:

SourceRule Card Setting	Override Execution Command
FetchAs	Not available
Backup	Not available
WorkArea	Available (-W)
Source	Available (-IA), (-ID), (-IE), (-IF), (-IM)
FilePath	Available (-IA), (-ID), (-IE), (-IF), (-IM)
OnSuccess	Available (-I...X)
OnFailure	Available (-I...B)
Retry	Available (-I...XRcount:interval)
Warnings	Not available
Scope	Not available
FetchUnit	Not available

Input data retrieval

The **FetchAs** setting applies only to input cards. It indicates how the adapter retrieves the input data. By default, this setting is **Integral**, meaning that all of the input data is retrieved once from the source.

Setting this parameter to **Burst** means that the adapter will retrieve the input data in increments specified in the **FetchUnit** parameter. The units of data correspond to the highest-level repeating object in the schema. For example, a payroll file contains 105 records. Using **Burst** mode with the **FetchUnit** parameter set to 10, data will be sent in 11 "chunks". The first ten chunks will contain ten records each and the eleventh chunk will contain the remaining five records.

Despite the fact that bursts process some of the map data and that multiple sets of outputs are built, transactional integrity is not sacrificed. If desired, the **Scope** card setting can be set to **Map** to prevent any changes from being committed until *all* bursts have successfully completed.

There are several potential benefits to using **Burst** mode:

- A single map consumes a large quantity of input data.
However, only a small portion of that data is required to build an individual output. **Burst** mode can be used to minimize the size of the workspace (an internal index of types present in the data stream). In some cases, a smaller workspace can increase map performance.

- Coordinate multiple inputs together.
For example, the first unit of data for Input Card 1 must be coordinated with the first unit of data for Input Card 2, and so on. If **Burst** mode is not enabled, one input must then act as a "driver" that must search for matching outputs.
- Process a single logical unit of work at one time.
For example, you may want to process one row from a database table at one time or one message from a message queue at one time. This would equate to the **Burst** mode being enabled with the **FetchUnit** parameter set to 1.

FetchAs

The **FetchAs** setting on an input card specifies how the data will be retrieved when the map is executed.

Value

Description

Integral

Data is retrieved once (in its totality) from the data source. If another input is set to **Burst** mode, the same integral data for this card is used for each burst. When an input **FetchAs** is **Integral**, the **Source** is requested to retrieve data one time for the entire mapping.

Burst

Data is retrieved in incremental units from the data source. The unit of data retrieved for each burst is adapter-specific, and is specified as the **Source FetchUnit**. When an input **FetchAs** is **Burst**, the data is retrieved once per burst.

When an input **FetchAs** is **Integral**, any failure action causes the entire map to fail.

- When **FetchAs** is **Integral**, the maximum size of a file that a map can process is 2 GB.
- When **FetchAs** is **Burst**, the maximum size of a file that a map can process is much larger, but a maximum of 2 GB per burst.

FetchAs > WorkArea

Each time a map is executed, information about the data and map is kept in a workspace and is used as the input data is validated and the output data is built. This workspace information can either be stored in files or written to memory.

A card's **WorkArea** setting specifies whether to reuse that work area on subsequent executions of the same map. If you are repeatedly going to run the *same* map using the *same* input data more than once, setting the **WorkArea** card setting value to **Reuse** increases the speed of map execution because data validation for this input is not repeated. There are guidelines for reusing work areas.

Value

Description

Reuse

Reuse the work area. After a map runs for the first time, the work area that is created for the input card is not deleted. Then, on subsequent executions of the same map, the data for this input card is *not* validated, and the work area information for the card is retrieved from the existing work area.

!Reuse

Do not reuse the work area. The input card's **WorkArea** is created for each map execution.

- [Guidelines for reusing work areas](#)

Guidelines for reusing work areas

Use the following guidelines when defining whether to reuse workareas. The **WorkArea** card setting depends upon the map setting for **WorkSpace Location** and **PageSize** and **PageCount** settings.

- WorkSpace Location setting. If the map setting for **WorkSpace** is **File**, the input card's work area can be reused. If the map setting for **WorkSpace** is **Memory**, the input card's work area can be reused only when the map is initiated using the **RUN** function. It cannot be reused from an API.
- WorkSpace **PageSize** and **PageCount** settings. When reusing work files, the paging configuration (page size and number of pages) for the first execution and subsequent executions of the map *must* be the same.
For example, if the first execution (when the work files are created) uses a paging configuration of eight pages of 64K each, the subsequent executions (where the work files are reused) must use the same paging settings, in this case eight pages of 64K each.
- For One Map Only.** The **WorkArea** card setting applies to a given map only. For example, it does *not* apply to two different maps that use the same input.
- FetchAs = Integral.** When a map is executed and the input card **FetchAs = Integral**, the work area is automatically reused for each burst. If **WorkArea = Reuse**, that work area is saved on completion of the map execution.
- FetchAs = Burst.** When the input card has a **FetchAs of Burst**, a new work area is created for each burst. If **WorkArea = Reuse**, the last work area is saved on completion of the map execution.

FetchAs > FetchUnit

The **FetchUnit** setting only applies to input cards. The **FetchUnit** setting defines the number of units of data to retrieve each time a request for data is made to the adapter. **FetchUnit** is primarily used when the **FetchAs** setting is set to **Burst** although it may also be used in other situations. The default value for **FetchUnit** is **S** (unspecified all).

A specific **FetchUnit** value allows you to aggregate, or "batch", a set of physical units (such as messages on a queue) into a logical unit of work. The unit of data is adapter-specific.

Value

Description	
S	Get all objects, database rows, messages on a messaging queue, or files.
1 - nnnn	<p>Positive integer representing the logical or physical unit of data.</p> <p>For messaging adapters, FetchUnit defines the number of messages to retrieve.</p>
	<p>For File or Echo, FetchUnit defines the logical unit of data.</p> <p>For database adapters, FetchUnit defines the number of rows.</p> <ul style="list-style-type: none"> • FetchUnit details • FetchUnit with multiple input cards

FetchUnit details

The unit of data is adapter-specific.

- If the adapter is **File**, the **FetchUnit** refers to a logical unit of data and divides map execution into valid units of work based on a logical unit of data.

For other adapters, the **FetchUnit** refers to a physical unit of data.

- For messaging adapters, the **FetchUnit** setting determines the number of messages per burst.
- For database adapters, the **FetchUnit** setting determines the number of database rows.

When an input **FetchAs = Integral**, the **Source** is requested to retrieve data once for the entire mapping.

When an input **FetchAs = Burst**, the data is retrieved once per burst.

For example, a database has the rows sorted in reverse chronological order by date. You want to map only the first row because that row contains the most recent data. Set the input **FetchAs = Integral** and **FetchUnit = 1**. Only the first row in the database is accessed.

Using different **FetchUnit** values for the same data object on multiple input cards has limitations.

FetchUnit with multiple input cards

In a case where more than one input card in a map references the same data object, the values of the **FetchAs** and **FetchUnit** card settings must be the same on all cards that reference that data object. Only one instance of the schema component structure is stored with the compiled map, therefore the card settings that control that component structure must be the same on all cards using that data object. The schema component structure stored with the map has one number that represents the maximum instances of that component. The **FetchUnit** setting changes this number.

For example, a map contains two input cards that both reference the **ContactFile** data object. This data object may be the card object (as specified with the **TypeTree** (**Contact.MTT**) and **Type** (**ContactFile Data** settings, as shown below) or may be a component of the card object.

To achieve desired data retrieval results, you must set the **FetchAs** and **FetchUnit** values the same on both cards that use the same type (**ContactFile**).

If different **FetchAs** and **FetchUnit** values are specified for the same data object on two different input cards in the same map, the **FetchAs** and **FetchUnit** values specified in the first card are used.

GET

The **GET** settings define all of the input data settings.

Source

The **Source** card setting identifies the source of the input data. The data may be in a file, from a specific application, in a database, from a message queue, or from other possible sources. Defining the adapter source specifies where to go to get the data and specifics on which data to get.

The meaning of the various adapter source settings is specific to the adapter being used to get the input data.

The maximum size of a file that a map can process in integral mode is 2 GB. In burst mode, the maximum size is much larger, but can only be 2 GB in one burst.

Source > FilePath

When **Source = File**, the **FilePath** setting specifies the name and path of the input data file. Enter the filename or browse your file system to select the input file.

Source > Command

When **Source** = *various resource adapters*, the **Command** card setting provides the adapter-specific commands to connect to the data source and retrieve the input data. For example, if the input data is coming from a file, the **Command** specifies the name of the input file. If the input data is coming from a database, the **Command** might include the database name, user ID, password, and so on.

The command syntax for the source and target adapter commands is detailed in the adapter-specific documentation. The maximum length of a source or target adapter command is 2000 bytes. Limitations to the maximum adapter command length may apply to some adapters.

DatabaseQueryFile

When **Source** = **Database**, the **DatabaseQueryFile** settings are used to specify the database specific settings: the name of the desired database/query file, the database name, and the query.

DatabaseQueryFile > Database

Specify the database that contains the desired query definition.

DatabaseQueryFile > Query

Specify the name of the desired query.

DatabaseQueryFile > File

Specify the database/query file (.mdq) that contains the desired source database and query definition.

Transaction

The **Transaction** settings include the input data **OnSuccess**, **OnFailure**, and **Scope** settings.

OnSuccess

The **OnSuccess** setting specifies the location of the source data when a map, a burst, or a card successfully completes. The availability of the **OnSuccess** setting is adapter-specific.

The **OnSuccess** setting works with the **Scope** setting, which defines when to apply the action specified with the **OnSuccess** setting.

Value

Description

Keep

The input data should *not* be removed from its source.

For example, if the input is a messaging adapter, and the map successfully completes, do *not* remove the messages from the message queue.

KeepOnContent

The input data should not be removed unless it has no content.

For example, if the input is a file, and the map completes successfully, but the input file had no data (it was empty), delete the input file. Otherwise, keep the input file.

Delete

Delete the input data or remove it from its source.

For example, if the map completes successfully, remove the messages from the message queue.

OnFailure

The **OnFailure** setting specifies the location of the source data if the map, burst, or card does not successfully complete.

Note: The exact meaning and availability of the options for this setting is adapter-specific. See your adapter documentation for more information.

The **OnFailure** setting works with the **Scope** setting, which defines when to apply the action specified with the **OnFailure** setting.

Value

Description

Rollback

Any changes made during map processing are rolled back and the original state of the data is restored.

If the map, burst, or card does not complete successfully, rollback any changes that were made to the source data during map execution.

For example, if the source of the input data was a stored procedure in a database that changed the contents of one or more tables, such as with an INSERT or UPDATE statement, if the map fails, the **Rollback** option would restore the affected tables to their original state.

Commit

If the map, burst, or card does not complete successfully, commit any changes that were made to the source data during map execution.
If the map fails, send the message produced for the output card to the specified message queue.

For example, if the source of the data was a message on a message queue and the message is removed from the source message queue, regardless of whether the map succeeds or not.

Scope

The **Scope** card setting tells the source or target adapter at what point during map execution to apply **OnSuccess** and **OnFailure** actions. The default setting is **Map**.

Value

Description

Map

Apply the **OnSuccess** and **OnFailure** settings based on the success or failure of the entire map execution (which may be one or more bursts).
In a RUN map, the **Map** scope applies the **OnSuccess** and **OnFailure** actions based on the success or failure of the top-level map.

Burst

Apply the **OnSuccess** and **OnFailure** settings based on the success or failure of each burst.
In a RUN map, the **Burst** scope applies the **OnSuccess** and **OnFailure** actions based on the success or failure of the map that is specified on the **RUN** function.

Card

Apply the **OnSuccess** and **OnFailure** settings based on the success or failure of this input. In this case, when a rule fails or validation fails, the source adapter applies the **OnFailure** action. If validation completes successfully for the input card, the source adapter applies the **OnSuccess** action.

- [FetchAs and Scope actions](#)

FetchAs and Scope actions

The FetchAs setting and the Scope setting affect when an OnSuccess or OnFailure action occurs.

If an input **FetchAs** setting is Integral, any failure action causes the entire map to fail.

Table 1. Effect of Scope setting when FetchAs setting is Integral

Scope	Action specified by OnSuccess or OnFailure setting occurs:
Map	After all bursts
Burst	After each burst
Card	After input validation for that input for each burst

Table 2. Effect of Scope setting when FetchAs setting is Burst

Scope	Action specified by OnSuccess or OnFailure setting occurs:
Map	After all bursts
Burst	After the first burst
Card	After input validation for that input for the first burst

TargetRule output card settings

The **TargetRule** settings define how the output data is routed. The data object specified in the output card defines what data is output.

To define card-specific output data routing, define the **TargetRule** settings for each output card. **TargetRule** settings specify where to send the data, and what to do when an error occurs. An output card represents an output target. The content of an output is a *data object* such as a table of customer records in a database, or a message that contains a business transaction, or a file of records.

The content of an output card is defined with the **CardName**, **Schema**, **Type**, and **File** settings. These settings define what the data is, but does not specify how to route the data. The **Target**, **Retry**, and **Scope** card settings are some of the **TargetRule** settings that define how the output data is routed for each output card.

- [OnFailure](#)
- [Scope](#)

TargetRule Setting overrides

Output card settings are stored in the compiled map. It is possible to override the setting for each option from both the Command Server and the Integration Flow Designer, which are supplied with the Design Studio.

Execution commands can be used to override the map settings or card settings compiled into the compiled map when a map is run. See the execution commands list for a complete description of the override commands.

The **TargetRule** card settings and their override execution commands are listed in the table below:

TargetRule Card Setting

Override Execution Command

Backup

Not available

Target

Available (-OA), (-OD), (-OE), (-OF), (-OM)

OnSuccess

Available (-O...X)

OnFailure

Available (-O...B)

Retry

Available (-O...Rcount:interval)

Warnings

Not available

Scope

Not available

PUT

The **PUT** settings define all of the output data settings.

FilePath

When **Target = File**, the **FilePath** setting specifies the name and path of the output data file. Enter the filename or browse your file structure to select the output file.

Target > Command

The **Command** setting provides the adapter-specific commands to connect to the data target and process the output data.

For instance, if the output data is being put into a file, the **Command** specifies the name of the output file. If the output data is being sent to a message queue, the **Command** might include the name of the message queue and any other setting required to connect to the message queue and put the message there.

The command syntax for the source and target adapter commands is detailed in the adapter-specific documentation.

DatabaseQueryFile

When **Target = Database**, the **DatabaseQueryFile** settings are used to specify the database specific settings: the name of the desired database/query file, the database name, and the query.

DatabaseQueryFile > File

Specify the database/query file (.mdq) which contains the desired target database and query definition.

DatabaseQueryFile > Database

Specify the database that contains the desired query definition.

DatabaseQueryFile > Table

Specify the database/query file (.mdq) which contains the desired target database and query definition.

Transaction

The **Transaction** settings include the output data **OnSuccess**, **OnFailure**, and **Scope** settings.

OnSuccess

The **OnSuccess** setting specifies the location of the target data when a map, a burst, or a card completes successfully. The availability of the **OnSuccess** setting is adapter specific. The default value is **Create**.

The **OnSuccess** setting works in conjunction with the **Scope** setting, which defines when to apply the action specified with the **OnSuccess** setting.

Value

Value	Description
Create	Output data should be sent by the target adapter to its target. For example, if the map completes successfully, the message adapter should put the message on the specified queue.
CreateOnContent	Output data should be sent only if content exists. For example, a message adapter should put the message produced on the specified message queue. If no data was produced, no message should be sent.
!Create	Regardless of whether or not data content is produced, output data is not to be sent to its target. This option is available for temporary data storage as a map runs.
Append	The output data should be appended to an existing data file. If the data file does not exist, it should be created.

OnFailure

The **OnFailure** setting specifies the location of the target data if the map, burst, or card does not complete successfully.

The exact meaning and availability of the options for this setting are adapter specific. The default value is **Rollback**.

The **OnFailure** setting works in conjunction with the **Scope** setting, which defines when to apply the action specified with the **OnFailure** setting.

Value

Value	Description
Rollback	Any changes made during map processing are rolled-back and the original state of the data is restored. If the map, burst, or card does not complete successfully, reverses any changes made to the target data during map execution.
Commit	If the map, burst, or card does not complete successfully, commit any changes that were made to the target data during map execution. If the map fails, send the message produced for the output card to the specified message queue.

Scope

The **Scope** card setting tells the source or target adapter at what point during map execution to apply **OnSuccess** and **OnFailure** actions. The default setting is **Map**.

Value

Value	Description
Map	Apply the OnSuccess and OnFailure settings based on the success or failure of the entire map execution (which may be one or more bursts).
Burst	Apply the OnSuccess and OnFailure settings based on the success or failure of each burst.
Card	Apply the OnSuccess and OnFailure settings based on the success or failure of this output. In this case, when a rule fails or validation fails, the target adapter applies the OnFailure action. If validation completes successfully for the output card, the target adapter applies the OnSuccess action.

Input and output card settings

- [BackupLocation > Directory](#)
 - [Directory > Value](#)
 - [BackupLocation > Filename](#)
 - [BackupLocation > FileName > Action](#)
 - [BackupLocation > FileName > Value](#)
-

Retry

The **Retry** settings are defined for each input and output card. The Retry setting is compiled into the map, but may be overwritten by the execution settings defined in the Integration Flow Designer and the **AdapterRetry** (-Y) execution command.

If adapter errors occur (for example, failure to connect) and Retry Switch = On, the adapter process is retried at the interval specified with the **Interval** value up to as many times as defined with the **MaxAttempts** setting.

The **Retry** settings specify the number of times and the interval at which to attempt access an unavailable source or target.

Define the **Retry** settings for each input (or output) card as required.

Retry > Switch

The **Switch** setting determines whether **Retry** for the specific adapter is **ON** or **OFF**. The default value of the **Switch** setting is **OFF**.

Value	Description
OFF	Retry is inactive. No attempt is made to access an unavailable source or target.
ON	Retry is active. Attempts are made to access an unavailable source or target for the number of attempts specified with MaxAttempts and at the time interval specified with Interval .

Retry > MaxAttempts

The **MaxAttempts** setting specifies the maximum number of times to try access to a source or target for a map. The default value for the **MaxAttempts** setting is 0.

Value	Description
nnnnn	A number that represents the maximum number of times an attempt is made to access the source or target for a map. After the maximum number of attempts has been attempted without access, the map returns a return code and message. Valid entries are integers from 0 to 65535.

Retry > Interval

The **Interval** setting specifies the interval (in seconds) at which each attempt to access the source or target is made. The default value is 0.

Value	Description
n	A number that represents the number of seconds at which each attempt to access the source or target is made.

DocumentVerification

For non-Xerces input schemas, use the **DocumentVerification** setting for the supplemental parsing (validation) of XML documents during the standard data validation process. In addition to the standard data validation process that takes place when a map runs, enabling this setting instigates an external library to validate XML data according to the Schema or DTD selected.

At the output card level, you can choose the specific situations in which the verification process takes place.

- [Use of DocumentVerification](#)
 - [Use of DocumentVerification for output data](#)
-

Use of DocumentVerification

To use DocumentVerification for input or output, you must enable the **MapAudit > SettingsAudit > Data** setting and add the data types to the Data Audit Settings view.

Except for the Well-Formed option, the DocumentVerification card setting must not be used with Xerces schemas on input because it initiates an extra and unnecessary validation process.

When you use DocumentVerification, the schema object that is associated with the Document Type must have the following properties set:

- The Document Type property must be XML.
- The Document Type > Metadata value must be set to either DTD or Schema.
- A DTD or Schema file location must be specified (Document Type > Location).

In the map input card, the following properties must be set:

- The Schema > Type is set to the object you associated with the Document Type as described earlier.
- The SourceRule > GET > Source > DocumentVerification setting is set to Always, OnSuccess, OnFailure, or Well-Formed.

Based on these settings, when the map runs, an external parser (document verification program) validates the XML document. If there are no errors, the map completes successfully. If there are errors, the map fails and the error information is written to an audit or trace file (when enabled).

The supported formats are XML with a DTD and XML with an XML Schema.

DocumentVerification settings

Because this setting is at the card level, you can set different options for different input and output cards.

Schema Validation

(Default setting) The option is turned off, meaning that only the standard data validation process takes place.

Always

Validates an XML document whenever an instance of an object with XML as the Document Type property is found at the card level. This XML document validation takes place in addition to the standard data validation process by using an external validation program.

OnSuccess

Validates an XML document when an instance of an object has XML as the Document Type property at the card level and is considered valid during the standard data validation process. This supplemental validation takes place in addition to the standard data validation process by using an external validation program.

OnFailure

Validates an XML document only when an instance of an object has XML as the Document Type property at the card level and fails validation during the standard data validation process. This supplemental validation takes place in addition to the standard data validation process by using an external validation program.

Well Formed

For Xerces schemas, disables validation of the XML document against the Schema and instead parses it to verify that it is well-formed.

Ignore Undefined Constructs

Ignores any elements that are not defined in the Xerces schema or native XML schema. Undefined elements would otherwise fail well-formed parsing with an Element not found error. Ignored elements are not accessible for any type of mapping and are not valid input for the PACKAGE and CPACKAGE functions.

Use of DocumentVerification for output data

For output data, the **DocumentVerification** option only works if the MapAudit Settings Audit > Data setting is enabled for the output. This is because output data is only validated (by means of the standard validation process) if the MapAudit Settings Audit > Data map setting for the output is enabled and the output item is specified under **Data Audit Settings** in the **Organizer** as shown:

If the MapAudit Settings Audit > Data map setting is enabled for an output card, standard data validation occurs during the audit process, and the external verification program can run when specified.

Backup settings

The **Backup** settings, when enabled, control when, where, and how the data for input and output cards should be copied to a specified backup file.

You can define the **Backup** settings for each input or output card as needed.

Backup > Switch

Use the **Switch** setting to activate the **Backup** feature.

Value

Description

OFF

Data for the card is not copied to a backup file.

ON

Data for the card is copied to a backup file based on the subsetting values selected.

Backup > When

The **When** setting specifies when a backup file is created. The default setting is **Always**.

Value

Description

Always

Always create a backup of the data.

OnError

Create a backup only if a burst fails to complete successfully.

Backup > BackupLocation

The **BackupLocation** value indicates that backup data is copied to a file. There are subsettings that enable you to select information about the file, such as where and when it is created.

BackupLocation > Directory

BackupLocation Directory enables you to specify the directory into which the backup file is written. The file is written to the **Map** directory by default.

Value

Description

Map

Creates the backup file in the map directory.

Custom

Specifies the directory location for the backup file.

When you select Custom, a **Value** field appears where you can enter the file path.

Directory > Value

If you selected the **Custom** value for the BackupLocation Directory setting, type the file path in this field or browse for a file.

BackupLocation > Filename

The BackupLocation Filename setting is used to specify the type of naming scheme used for the backup file. **Custom** is the default setting.

Value

Description

Custom

Specifies a custom name for the backup file. When you select Custom, the **Value** field appears into which you can enter the custom file name.

Unique

Generates a unique audit log name in the following format:

Mer_mapname_processkey_mapcounter_hostname.extension

Run_mapname_processkey_mapcounter_hostname.extension

The prefix "Mer" is used with top-level maps while "Run" is used for run maps.

mapname

The executable map name.

processkey

Unique value for each process.

mapcounter

Unique value for each map instance (within the same process).

hostname

The host name of the computer where Transformation Extender is running.

extension

is the backup filename extension, which is *.Inn.bak* (for input cards) or *.Onn.bak* (for output cards), where *nn* represents the card number.

BackupLocation > FileName > Action

The **BackupFileAction** setting specifies how data should be written to the backup file. **Create** is the default setting.

Value

Description

Create

Creates the backup file at the start of map execution. If a file exists with the same file path, it is overwritten. If more than one burst is used, data will be appended to the same backup file.

Append

If a file exists with the same file path, the data is appended to the existing file. Otherwise, a new file is created. If more than one burst occurs, data for each burst is appended to that same backup file.

BackupLocation > FileName > Value

If the BackupLocation Filename setting is **Custom**, enter the file name in this field.

Effects of modifying a schema

When you modify a schema or any type definitions in that schema, the next time you open a map that uses that schema, the map is updated.

If you save the schema without making changes to it, you are still prompted to update the map.

Changing a type that is used for a card

If you delete, move, or rename a type, and that type is used as the type of a card, the type will appear as having no components. Viewing the **Properties** of the type shows that the type is an **Invalid type**.

SyntaxCard

The SyntaxCard setting defines the output card as a syntax card.

Configure an output card as a syntax card by using the card settings and selecting Yes for the SyntaxCard setting. The default value for the SyntaxCard setting is NO.

When you specify a card as a syntax card, the map passes any syntax items it created to the next card. A map uses a syntax card so that the delimiter structure defined for a variable syntax object persists as the data flows from one output card to the next output card in the map. The card that follows a syntax card inherits the delimiter structure that is set by a syntax card.

A syntax card works with other output cards in the following way:

1. Output card 1 is defined as a syntax card. The syntax card maps most elements to =NONE and maps only the syntax items. For example, an EDI X12 element delimiter value can be represented as ="*".
2. Output card 2 maps only the data. Output card 2 does not map the syntax items that are defined in output card 1. But the mapping process maps the data according to the output card 2 structure as if the syntax items have been set.

For example, when producing EDI such as X12 and EDIFACT documents, syntax elements define the syntax of the components in the EDI schema. The syntax can vary for each input. Without a syntax card, you must define the syntax elements in the envelope to use the syntax structure later on. When bursting, a map can produce many EDI transactions. Without a syntax card, the only way to initialize the syntax is to include an envelope in each burst. The service that reads the output from the map must strip the envelopes from the output.

When your map includes a syntax card, the syntax need not be initialized with each burst. Also, it is not necessary to strip the envelopes from the output.

There are additional requirements and considerations for using the SyntaxCard setting.

You might have a requirement to pass the syntax value on additional output cards that do not follow directly after the card that is configured as the syntax card. In this scenario, you must also set the SyntaxCard setting to Yes on all of the output cards in between the syntax card and the card that uses the syntax values defined on the syntax card. For example, output card 1 is the SyntaxCard. You need to use the syntax values on output card 3. Therefore, you must also set the SyntaxCard setting to Yes on output card 2.

On the syntax item in the schema where the Delimiter property value is Variable, you must set the FIND setting to NO. When the FIND setting is set to NO, the predefined or default value is mapped.

You must use the same schema for the output card defined as the syntax card and the output card that uses the syntax values defined on the syntax card.

Although you are not restricted from doing so, you should use only the output card that is defined as the syntax card to define the syntax items.

Editing a card

When you edit input and output cards, the map rules that were not affected by the change are retained. You can change anything specified in a map card: the card name, the schema, the type of the card, and the data source or target.

- [Changing a card name](#)
- [Changing the type of an input card](#)
- [Changing the type of an output card](#)
- [Changing the schema of a card](#)

Changing a card name

When a card name is changed, any reference to that card in any map rule is automatically changed to the new name.

In an example that has an input card named **Input**, which is referenced in two places in the map rule, if you change the name of the input card from **Input** to **GrowthReport**, the new card name is automatically changed.

The input card is edited and the name of the card is changed from **Input** to **GrowthReport**.

The instances of **Input** in the map rule are automatically changed to **GrowthReport**. All instances of the card name are changed in all map rules where it appears.

Changing the type of an input card

You can change the type (**TypeName**) of an input card. Note that when you change the type of an input card, if an object within that card is referenced in a map rule, the object name might now be invalid.

If a map rule contains the name of an object on an input card:

```
Flower:ProgressReading:Input
```

The type of the input card is **GrowthReport** and it is changed to **ProgressReading**, which is a component of **GrowthReport**. The object names in the map rule are now incorrect. **Flower** is a component of **ProgressReading**, which is now the type of the card. After the type of the card has changed, the correct name for **Flower** is **Flower:Input**.

To correct the object name in the map rule, drag the object name to the map rule again. If you change the type of a card and you have many map rules in that card, you might want to use search and replace by selecting the Replace option under the Transformation Extender Search tab in the Search window navigated from the Search menu on the menu bar instead.

Not all modifications to an input type will affect map rules. For example, if you add a component to an input type, map rules are not affected. Also, if you delete an input component that is not referenced in a map rule, the map rules are not affected.

Changing the type of an output card

You can change the type (**TypeName**) of an output card. Changing the type of an output card retains the map rules for the objects that still exist within the card object, even if they are in a different order.

- If there was a map rule on an object that no longer exists in the card object, that map rule becomes unresolved.
- If there is a map rule on a data object that still exists in the card object, the map rules are retained.

Even though the order of the output components changed, the map rules stay intact.

Changing the schema of a card

The schema of a card can be changed. Optionally, you can change the schema of all the cards in that map and in referenced maps that use the previous schema. When the schema for a card is changed, you can choose to replace all references to that schema with the new schema.

In some situations, you would not want to replace all references to the schema. For example, if only the input of the selected schema had changed, you would not want the output to change.

Map events

When you run Design Server Maps using the Design Server runtime REST API, the related Map execution events are sent to the specified Elasticsearch server.

Map execution events include these events:

- Execution details
- Map names
- Elapsed execution times
- Map start and stop information
- Map and its adapters return codes
- Error details

Map rules

Map rules are used in output cards of a map to define how output data is built. Map rules are required for output data generation. If there is no map rule, there is no output data. When no output is desired for a given data object, a map rule of =NONE is required.

A map is not complete until each rule cell has a map rule, or appears dimmed (the map rule is unavailable). Empty rule cells generate a build error when the map is built.

A map specifies how to generate a particular output data object, or multiple independent objects, each of a particular type. Each output card has a rule column in which you enter map rules. Color-coding of map rules provides visual ease of use in formulating and understanding rules. When color-coding is enabled, syntax errors in map rules are underlined.

Map rules are validated only when that map rule is changed.

- [Map rules overview](#)
- [Rule editor](#)
- [Color coding of map rules](#)
- [Map rules as expressions](#)

Map rules overview

Map rules are used to:

- Convert an object in the input data from one value to another value in the output data
- Perform conditional logic
- Execute another map to produce file with specific contents

A map rule is an expression that evaluates to data. The maximum length of a map rule is 32K characters (including non-printable characters).

Non-printable characters are not displayed in the Rule editor, but display in the rule cell on the output card in the Map editor as `o`.

Rule editor

Use the Rule editor display and enter map rules for the selected object on the output card in the Map Designer..

When you select a rule icon on the output card in the Map Designer, the rule displays in the Rule editor. Changes to map rules are made and committed in the Rule editor.

Non-printable characters do not display in the Rule editor, but display in the rule cell on the output card in the Map editor as `□`.

- The default Commit key in the map rule is `Enter`. To enter a new line hold down the `Ctrl` key and press `Enter`. If `Tab` is the commit key, simply press `Enter`.
- To enter the object name of any data object, drag it from the map card into the Rule editor.

You can type in extra spaces in a map rule to make it easier to read. Line feeds are not required, but may improve the way the rules are displayed. In addition, you can create a new line where you want one.

Text literals enclosed in quotation marks may not contain new lines.

Color coding of map rules

To aid in readability, map rules can be colored with user-configured colors. When color-coding is enabled, each element of a map rule can be configured with a different color.

The elements of map rules are categorized to allow color specification by category. Colors are assigned to:

- Unknown
- Syntax
- Number
- Type Name
- Map Name
- Reserved
- Literal
- Comment
- Background
- [Configuring colors for map rules](#)

Configuring colors for map rules

Enable color-coding by selecting a color for each category of map rule elements.

To configure map rule colors

1. Click Window > Preferences > Transformation Extender > Type Tree > Group Window.
The Group window appears.
2. From the Rule Color Specifications list, select one of the categories.
3. Click the color button.
The Color window appears.
4. Select a color from the color palette and click OK in the Color window and OK in the Group window.

To disable color coding

Remove the color selections you have made through the Group window.

Map rules as expressions

A map rule is an expression that evaluates to data. An expression is any valid combination of literals, data object names, operators, functions and map names. The expression in a map rule generates the desired data. For example:

- The expression Name Field:Input evaluates to the value of the data object Name, which is a subtype of Field, which is a component of the data object Input.
- The expression 500 evaluates to a data object with a value of 500.
- The expression COUNT (Record:OrderFile) evaluates to a data object that has a numeric value equal to the count of the Record objects in the data object OrderFile. A map rule has a maximum length of 32K characters. Rules in older maps might start with an equals (=) sign.

Some examples of simple expressions are shown in the following table.

Expression

This expression uses:

"ABC Company"
a literal
City Field:Record
a data object name
City Field:Record + State Field:Record + ZipCode Field:Record
operators (plus signs) and data object names
UPPERCASE (City Field:Record)
the UPPERCASE function and a data object name
RecordMap (Record:InputFile)
a map name (RecordMap) and data object names

An expression can be complex and have simpler expressions nested within it. Examples of more complex expressions using nested expressions are shown below:

```
IF (Qualifier = "ST", Address, NONE)
LOOKUP (ProductCode:LookupList, ItemCode:Data =
ItemCode:LookupList)
EXTRACT (Record:Input, Company Field:Record:Input = "My
Company")
COUNT (EXTRACT (Row:Input, Company Column:Row:Input = "My
Company"))
```

These examples use the functions **IF**, **LOOKUP**, **COUNT**, and **EXTRACT**. These functions are specific to the IBM Transformation Extender suite of products. Functions have their own syntax. For more information on functions, see the Functions and Expressions documentation.

Map rules define how to generate data objects

The object of an output card may be composed of components and partitions. Each object on the output card has a corresponding rule cell, where map rules that transform that data are entered.

A map rule evaluates to a particular data object. The data object is either a group type or an item type. The following rule evaluates to the data object **Record**, which is a group:

```
= LOOKUP (Record:Input, Company:Record:Input = "ABC Printing")
```

A map rule for a data object must evaluate to a data object with the same subclass. Objects with an Item Subclass of **Date & Time** must evaluate to an object with an Item Subclass of **Date & Time**.

For example, the output item ShipDate has the Item Subclass of **Date & Time**. The following map rule is valid when the data object ShipToDate also has an Item Subclass of **Date & Time**:

```
ShipDate = ShipToDate:PO:Input
```

The output CompanyName is defined with an Item Subclass of Text. The following map rule:

```
CompanyName = "Pop's Pizza Co."
```

assigns the value of a text literal to the output.

A text literal is text enclosed in double quotes and is interpreted as a text item. A rule that evaluates to something other than text, for example, CompanyName = 24 would be invalid.

To view the type properties of a data object in a card, right-click the type in the input or output card and click Show in Properties on the context menu. If the Properties view is shown, select the map rule to update the Properties view to show the properties of the object.

A map rule on a group type must evaluate to a data object of the same group. For example, the following map rule on the output group **Record** must evaluate to the group type **Record**:

```
Record = LOOKUP (Record:Input, Name:Record:Input = "Kathy")
```

The map rule is for the group type **Record**, so it must evaluate to the type **Record**. The rule shown above does evaluate to **Record** because the LOOKUP function returns a **Record**. The rule would be invalid, for example, if it evaluated to the group **Invoice**.

Map rules are evaluated independently in sequential order

Each map rule is evaluated independently from all other rules. Each output object with a rule is created independently from the others.

Map rules are evaluated in sequential order. When a map is executed, the first rule of the first output card is evaluated. Next, the second rule of the first output card is evaluated, and so on, until the last rule of the first output card. Then, the first rule of the second output card is evaluated, and so on, to the last rule of the last output card.

Generating no output

Each map rule cell requires a map rule. If an output is optional, you may not want to generate the output for that data object. For map rules for data objects for which you do not want to generate output, enter the following:

= **NONE**

The reserved word **NONE** specifies to generate none of the given output. The word **NONE** is case-sensitive.

You don't have to type in the rule = **NONE**. The command **Insert NONE if Empty** puts this rule into the empty rule cells on the active output card, including those empty cells that cannot be seen by the current view of the card.

Text literals as **NONE**

The use of "" as text literals in a map rule evaluates to "none". For example, the following two rules are equivalent:

```
= EXTRACT (Record:Input, Store:Record:Input = "")  
= EXTRACT (Record:Input, Store:Record:Input = NONE)
```

Special characters in map rules

To enter a Hexadecimal value of a special character in a map rule, enter the Hex value for the characters in double brackets (open and close carets).

For example, to enter the text value <WSP>, enter the Hex value for the open caret <<3C>>, and then the literal values for the rest: WSP

```
<<3C>>WSP>
```

Syntax errors in map rules

Syntax errors are reported when the map rule is committed. The default "commit" key is the **Enter** key. Pressing **Enter** on a map rule commits that rule and reports any syntax errors.

The cursor is automatically positioned at the first syntax error. When color coding is enabled, syntax errors can be configured to display with underline.

Data object names in map rules

The following examples show different kinds of data object names that can appear in a map rule. The following is a partial list of the possible data object names. For a detailed list of object names, see the Functions and Expressions documentation.

Data Object	Appears in map rules as:	Description
Card names	OrderFile	User-defined name of input or output card A unique name for each card in the map provides the ability to distinguish between card objects that may be used in more than one card.
Component	Record:OrderFil e Quantity:Record: OrderFile	Separated by colon (:) Interpret as "of": " Quantity of Record of OrderFile " Quantity is a component of Record . Record is a component of OrderFile .
Index	Note[3]:Report	Specific occurrence appears in square brackets [n] immediately after the type A particular occurrence of a data object indicated by the index
Partition	Customer<>Rec ord	Separated by <> When a type is partitioned, its subtypes, or partitions, appear in the card with <>.

Data Object	Appears in map rules as:	Description
Shortened data object name	Company Field::Input	A period (.) is used as an abbreviation of ellipses (...). The shortest object name that is different from all other object names in the same map is used. Some object names may not include ellipses, because the shortest unique name is the entire name.

Card names in map rules

A map rule can see the entire card data object. For example, if an input card name is **OrderFile**, the name for the entire card object is **OrderFile**.

The name of the card appears as the first data object of the card. In the example shown below, the card name is **OrderFile**. This name appears last in each object name:

Record:OrderFile

Quantity:Record:OrderFile

A unique name for each card in the map provides the ability to distinguish between card objects.

For example, if two input cards are defined by the same type, these two input cards may exist with the same type, but their card names are different. If the name of the first card is **Input1** and the second input card is **Input2**. If a component **Record** exists as data objects in both these cards, the difference is distinguishable **Record** in one input and **Record** in the other because the **Record** types in the different cards have different names **Record:Input1** and **Record:Input2**.

Component names in map rules

A component in a data object name is indicated by a colon (:). The colon is the separator between a data object and the group or category type it is a part of (or the card name it is contained in).

For example, **Record** is a component of the data object **OrderFile**. The object name for **Record** is **Record:OrderFile**.

When you see a colon (:), you can read it as "of". For example, the name of the component **Quantity** in the input card is **Quantity:Record:OrderFile**. You can read the data object name for **Quantity** as "The **Quantity** of **Record** of **OrderFile**".

Index in map rules

An object name can refer to a particular occurrence of a data object indicated by the index.

For example, the third **Note** in a series of **Note(s)** has an index of 3. In a data object name, an index appears in square brackets immediately after the type being indexed. The indexed third **Note** of **Report** is **Note[3]:Report**.

Partition in map rules

When a type is partitioned, its subtypes or partitions appear in the card.

In a map rule, a partition is referenced by the symbol <>.

For example, the partition **CallRecord** of the group type **SetofCallRecords** is **CallRecord<>SetofCallRecords**.

Think of a partition as a particular kind of the partitioned type. For example, in the name **Detail<>Record**, you can think of it as a **Detail** kind of **Record**.

An object name includes component references and partition references. For example, the partition **Back** of **OrderRecord**, on the input card **File**, appears in a map rule as **Store Field:CallRecord<>OrderRecord:File**

Comments in map rules

You can add inline comments to map rules. Comments do not affect how map rules are evaluated. A comment may appear anywhere in a rule, as long as it does not separate object names.

A comment is identified with the start characters /*. While the end characters */ can be present, they are not required. If the end characters are not present, everything up to the end of that rule is the comment.

The following map rule has two comments, which are indicated by blue text:

```
= EXTRACT (Record:Customers /*Extract the Records */,
State Field::Customers = "FL" /* Get only the customers in
Florida */) 
```

Using comments for map rules, or portions of map rules, is a convenient way to retain complex and lengthy map rules for future use without deleting them.

Unavailable rule cells

The output of a map produces each output card object. To produce a card object, the required objects that compose the card object must be produced. There is a rule cell for each object within the card object.

If an output object is an item, you must supply a rule for it. If an output object is a group, you have two options. Either you can enter a rule for the object as a whole, or you can expand the view of that object in the output card and enter rules for each data object.

Defining how each component of the output object as a whole must be produced is the equivalent of defining how to create the entire output object.

If map rules are entered for each component of the output object, map rules may not be entered for the entire output object. When you expand the entire output object, notice that the rule cell next to the output object is automatically unavailable (grayed out). Entering a rule for the entire output object would be redundant, because the individual components of the output object already have map rules.

When you expand a group that has a component range maximum greater than 1, the rule cells on the components of that group are unavailable.

Use ellipses

Enables the **Use ellipses** display option for subsequent object names dragged to the Rule editor. The **Use ellipses** options causes lengthy object names to display the shortest possible object name.

Rather than having the entire name appear, unique portions of the name are replaced with a period (.) that is used as an abbreviation of ellipses (...).

Complete object name: **Company Field:Record:Input**

Shortened name: **Company Field:.:Input**

If the **Use ellipses** option is enabled, the shortest object name that is different from all other object names in the same map is used. Some object names may not include ellipses, because the shortest unique name is the entire name.

The **Use ellipses** option does not affect object names that already exist in map rules; it only affects object names that are entered after the option is enabled.

Search functionality

The search functionality in the Map designer allows to search for a specific text within all rules in a current executable map and all its corresponding functional maps.

- [To search in a Map using Search icon](#)

To search in a Map using Search icon

1. On the Map toolbar, click on the Search icon.
The Map search panel opens.
2. In the Search panel, enter the text you want to search.
3. In the Search in section, select component to search within the input and output cards or select Map Rules to search in the Rule Editor.
4. Check the Search Submaps check box to search in the child maps.
5. Click the Search button.
The relevant search results display.

Formulating map rules

Implement map rules to build specific output results.

- [When input data is missing](#)
- [Mapping an input item to an output item](#)
- [Mapping a group to a group](#)
- [Outputs with maximum range greater than 1](#)
- [Indexing an output](#)
When you know the number of objects to generate for each map execution, index the number of occurrences of that output object. To *index an output* is to generate a specific number of occurrences of that output.
- [Mapping to multiple occurrences of a group](#)
- [Indexing an Input](#)
- [Mapping from a floating component type](#)

When input data is missing

If you map an input to an output, but the input is missing, either the output will have no content or it will not exist. The existence of the output depends on how the output is defined.

- [When portions of an input series are missing](#)
- [When an output evaluates to NONE](#)

When portions of an input series are missing

When portions of an input series are missing, the output to which it is mapped built according to the **Track** property of the type in the Type Designer. The **Track** property indicates whether to only track the components that have content (**Track = Content**) or all components, including those that do not have content (**Track = Places**).

If both the input data object and the output data object have the **Track = Places** property, the place holder is generated on output, even if there is no data. Example output data with a missing third item would be:

YES,YES,,YES

If the input data object has the **Track = Content** property, the empty occurrences of that data object are not mapped and the empty occurrences are not built. Example output data with a missing third item would be:

YES,YES,YES

When an output evaluates to NONE

If an output object evaluates to "none", the information appearing in the output depends on how the output has been defined. The following table defines how output is build when the output occurrence evaluates to "none":

Table 1. When a required item evaluates to "None"

Context	Output is built in this manner:
Always	The item's initiator and terminator are built.
Occurs within a fixed explicit group	If a special value for NONE has been assigned, NONE is built as the special value. Otherwise, NONE is built as the pad characters for the Padded to Length specified.
Occurs within a delimited explicit group	The group's delimiter appears in the output. If a special value for NONE has been assigned, NONE is built as the special value. Or, if a pad property is specified as applied in any context, NONE is built. Otherwise, NONE is not built.
Occurs within an implicit group	If the group has a delimiter, the group's delimiter appears in the output. If a special value for NONE has been assigned, NONE is built as the special value. Or, if a pad property is specified as applied in any context, NONE is built.

Table 2. When an optional item evaluates to "None"

Context	Output is built in this manner:
Always	The item's initiator and terminator are not built.
Occurs within a fixed explicit group	If a special value for NONE has been assigned, NONE is built as the special value. Otherwise, NONE is built as all pad characters for the specified length.
Occurs within a delimited explicit group	The group's delimiter appears in the output if data with the same delimiter follows.
Occurs within an implicit group	No output is built.

Table 3. When a required group evaluates to "None"

Context	Output is built in this manner:
Always	The group's initiator and terminator are built. Required components are built.

Table 4. When an optional group evaluates to "None"

Context	Output is built in this manner:
Always	The group's initiator and terminator are not built.
Occurs within a fixed explicit group	Each component is built, down to its items, building NONE for each item according to the special value for NONE and pad property specifications.
Occurs within a delimited explicit group	The group's delimiter appears if data with the same delimiter follows.
Occurs within an implicit group	No output is built.

An item within a fixed group must have the Padded to = Fixed Size property specified, or the size minimum must equal the size maximum. If an item is required, and content is specified as required, an output invalid message appears in the summary trace file.

Mapping an input item to an output item

You might want an output item to be equal to some input item. In that case, drag the input item into the rule cell of the output item.

- [Automatic item conversions](#)
- [Intermediate item conversions](#)
- [Concatenating text strings](#)

Automatic item conversions

When mapping an item to an item and the input items have the same subclass as the output items, the item type properties of the input item are automatically used as the item type properties of the output item.

For example, an item type is defined according to the following:

Item Subclass = Number

Presentation = Decimal with a required decimal separator

Pad = Yes

Padded to = Fixed Size

Padded to > Length = 7 bytes

Pad > Value = 0

Pad > Justify = Right

If an input type is defined as a decimal number, with no pad character, no separator, and two decimal places, the following table shows an example of input and output types of an item type definition.

Property	Input Type	Output Type
Presentation	Decimal	Decimal
Separators	No	Yes
Places > Decimal Min	2	2
Pad > Value	(none)	0
Padded to	(none)	7
Justify	(none)	Right

The input data is automatically converted to the format of the output data object. The output data will be in decimal format, right justified, padded to 7 bytes with a pad character of 0.

An input item mapped to an output item must have the same **Item Subclass**. For example, both items must have an **Item Subclass = Number** or both must have an **Item Subclass = Text**. To convert the **Item Subclass** of an item, use the conversion functions, such as **NUMBERTOTEXT**, **TEXTTODATE**, and so forth.

Intermediate item conversions

When using an item with an **Item Subclass** of **Number** or **Date & Time** as a text argument, use the **TEXT** function to convert that item to a text form.

Concatenating text strings

To concatenate text, use the plus symbol (+) between the objects to be concatenated.

For example, the output **Name Field** is defined in the map rule as the input **FirstName Field**, a space, and then the **LastName Field**.

```
=FirstName Field:EmployeeInfo + " " + LastName  
Field:EmployeeInfo
```

Mapping a group to a group

Desired output of an input group may be the same as an input group. If the output group is the same type and is defined in the same schema as the input group, drag the input group into the map rule cell of the output group. If the input group is a partition of the output group, you can drag the partition into the rule cell of the output group.

If the input group and output group are different types, you cannot drag the input group to the output group. Either expand the output group down to its item components, or use a functional map.

- [Automatic conversion of syntax items](#)
- [Mapping to a group with a maximum range of 1](#)

Automatic conversion of syntax items

Syntax items are automatically converted from an input group to the syntax items of the output group. If the delimiters, terminators, and release characters of a data object are variable, these values are defined in the input data stream. To convert these values to other values, you may drag the input group to the output group map rule. The output group is built using the default values or data values for the syntax items.

Mapping to a group with a maximum range of 1

Generally, do not drag a group from the input to the output. This is only possible if the input group and the output group are the exact same group, which is not very common. When the range of a group has a maximum of 1, expand that output group and map to its components.

Outputs with maximum range greater than 1

For outputs with a component range maximum greater than 1 - (for example, (1:10) or (s)), define how many of that particular output to generate. There are two possible situations:

- the number of objects to create is known, or
- the number of objects to create is based on the number of some other object in the input or output data.

When the number of objects to create is known, index that number of output occurrences.

When the number of output objects is based on the number of some other object, create a map rule that maps the output according to the number of occurrences of an input.

Indexing an output

When you know the number of objects to generate for each map execution, index the number of occurrences of that output object. To *index an output* is to generate a specific number of occurrences of that output.

Indexing an output adds an output object to the output card. This output object has the index number in square brackets. For example, [1].

The index number identifies the occurrence of the object. The index number [1] indicates the first occurrence. The index number [2] indicates the second occurrence, and so on. After you have indexed an output, you can enter a map rule for that indexed output. If you have indexed a group, you can then expand the group and add map rules at the component level.

Map to the first occurrence of an indexed object by dragging that object from the input card to the map rule of the item on the output card. Define the second occurrence of the output by dragging the desired object from the input card to the map rule of the item on the output card. If you do not want a third indexed data object, enter the map rule = NONE.

Mapping to multiple occurrences of a group

When an output group has a range with a maximum greater than 1 and you want to map a certain input group to that output group, there are two possibilities:

- If the input group is the *same* as the output group, drag the input object from the input card to the map rule of the object on the output card. The output is created up to its maximum range.
- If the input group is *different* from the output group, use a functional map.
To generate occurrences of an output group based on occurrences of input data, use a functional map.

Indexing an Input

When a map rule refers to a particular occurrence of an input, the input must be indexed. In the map rule of the output object, enter the index number in square brackets [] immediately after the input object you are indexing.

Mapping from a floating component type

If an input card data object is a group that has a floating component type, you can map from the floating component type. A floating component must be distinguishable from every component of the group it is assigned to. On input, a floating component can appear after the initiator and after each component. If a floating component is associated with an input data object, it can appear as the first component.

If a type object has content, a floating component is built as the specified literal after the initiator and after each component. If this feature is used, it is up to the user to include a literal that will validate as an object of the type of the floating component.

You cannot map to a floating component in the output. If you have a floating component in the output data to which you want to map, you must define them as components of the output.

Functional map basics

A functional map is like a subroutine; it maps a portion of data at a time. It takes one or more input objects and generates one output object. For example, you might have a functional map that maps one Message to one row in a database table. Or you might have a functional map that maps one Header and one Detail to one ItemRecord.

The result of the functional map is sent directly to the output card when the type of the output card is:

- A group

- A partitioned item, when more than one of the partitioned type's subtypes has a rule other than the =NONE rule. The functional map evaluates the rules in the order that they are specified, and when the result of a rule is not NONE, the functional map builds the output of that rule as the partition that the rule is on.

A functional map result that returns directly to the output card is not available to the calling map for use in subsequent operations.

When the output of a functional map is an item, you can use the **ASFUNCTION** general function to return the output of the functional map to the calling map instead of to the output card. The calling map can use the returned result in subsequent operations in the same map rule. With **ASFUNCTION**, the result of the functional map returns to the calling map rule when the type of the output card is:

- A non-partitioned item type
- A partitioned item, in one of the following conditions:
 - There is a rule on the partitioned item.
 - All of the subtypes for the partitioned type, except one, have the =NONE rule.

When you do not use **ASFUNCTION** to run a functional map, the item is sent directly to the output card.

- [When to use a functional map](#)
- [Similarities of input and output data](#)
- [Using a functional map](#)
- [Comparing executable and functional maps](#)
- [Syntax of a functional map expression](#)
- [Entering the map rule that references the functional map](#)
- [Input card types of a functional map](#)
- [Input arguments as data objects](#)
- [Output card type of a functional map](#)
- [Using multiple inputs in a functional map](#)

When to use a functional map

The use of functional maps is very common. Almost every executable map created will use at least one functional map.

To map a group in the input to a different group in the output, use a functional map.

For example, use a functional map to map an input row to an output row when the rows are defined differently. Or, use a functional map to map from a file containing many input rows, to generate a file of many output rows with one output row per input row. The first output row would correspond to the first input row, the second output row corresponds to the second input row, and so on.

A map defines how to generate the output data. One important factor to consider in determining when to use a functional map is the presence of an output component with a range of more than one. For example, ranges of (s) or (1:10). The number of this output object to be created is based on the number of some input object.

Another important factor in determining when to use a functional map is when you want to transform the data - mapping from one or more types to a *different* type. In the preceding example of the functional map that maps one **Message** to one row in a database table, the input row and the output row are two different types.

Use a functional map when the number of a certain output group that you want to create is based on the occurrences of some input or output data - and the types are different types.

Similarities of input and output data

Frequently, your input and output data contain very similar information, but the data is arranged differently.

For example, you have a file of invoices from your company's internal application and you want to map it to a file of invoices to send to another company. The input and output invoices are really reflections of one another. The layout of an invoice in the application file may be different from the layout of an invoice in the output file. The important point is that you want to make an output invoice for each input invoice.

Or you may receive health claims in a standard format, and you want to map them to a different standard format. The input claims are embedded in a hierarchical layout where data is not repeated. The output claims may be arranged so that each claim has the same key data repeated: the provider, the patient, and so on. To make an output claim for each input claim, use a functional map. There is a one-to-one relationship between an input claim and an output claim.

A good indication of when to use a functional map is when there is a one-to-one relationship between a group in the input and a different group in the output.

As an example, you have a data source with three input records. A functional map provides a way to map one input record to one output record. The functional map defines the first input record that generates the first output record. Next, the second input record generates the second output record. The third input record generates the third output record. The result is three output records.

Using a functional map

The basic steps to follow for using a functional map are as follows:

1. Determine the need for using a functional map.
2. Determine the input argument(s) of the functional map.
3. Enter the map rule that references the functional map.
4. Create the functional map.
5. Create the input card(s).
6. Create the output card(s).
7. Enter map rules in the functional map.

The Functional Map Wizard eliminates Steps 5 and 6.

- [Example scenario for using a functional map](#)

Example scenario for using a functional map

An example of a functional map is shown below.

A data file contains statistics for different kinds of cars. Each record in the file represents a car. For each car, there are fields for mileage, head room, rear seat, trunk room, and weight. Each field is padded to a specific length. The record is fixed. For example:

Marlin	22	2	27	11	2930
Pacer ZSX	17	3	26	11	3350
Wildcat	22	3	18	12	2640
Fantasia DX	17	3	27	15	2830
La Vella	23	2	28	11	2070
Blue Baron	25	2	26	12	2650
Cavalino	20	4	29	16	3250

The objective is to map this data to a file containing delimited records. The delimited record has only the car name and the weight. In the delimited record, the weight is in decimal format. The desired output data result is:

Marlin,29.30
Pacer ZSX,33.50
Wildcat,26.40
Fantasia DX,28.30
La Vella,20.70
Blue Baron,26.50
Cavalino,32.50

You want to generate one delimited record for each fixed record in the input file.

Input data					Output data
Marlin	22	2	27	11	2930
Pacer ZSX	17	3	26	11	3350
Wildcat	22	3	18	12	2640
Fantasia DX	17	3	27	15	2830
La Vella	23	2	28	11	2070
Blue Baron	25	2	26	12	2650
Cavalino	20	4	29	16	3250

Define the map rule for the output **CarRecord(s)**, with a range of (s). There is an indefinite number of **CarRecord(s)**.

Ask yourself "How many **CarRecord(s)** do I want to generate?" If you want a specific number, the answer would be that number. To generate two **CarRecord(s)**, index two occurrences of **CarRecord**, expand each occurrence, and map to its components. For more information on indexing, see "[Indexing an Output](#)".

If the number of **CarRecord(s)** is based on the number of **FixedRecord(s)** in the input, generate one **CarRecord** for each **FixedRecord**. So, the answer to your question of how many **CarRecord(s)** to generate is, "As many as there are **FixedRecord(s)** in the input."

Note: When you see an output group with a range, it is always a good idea to stop and ask yourself, "How many of these do I want to generate?" The answer will either be:

- A specific number - index the output.
or
- The number is based on the number of some input - use a functional map.

You need a mechanism that takes a single **FixedRecord** and creates a single **CarRecord**. To do this, create a functional map, which is similar to a user-defined function. This functional map maps a single **FixedRecord** to a single **CarRecord**. The map is called for every occurrence of a **FixedRecord** in the input. This generates exactly one **CarRecord** for each **FixedRecord**.

For example, if there are 23 **FixedRecord(s)**, 23 **CarRecord(s)** are generated. The first **CarRecord** corresponds to the first **FixedRecord**. The second **CarRecord** corresponds to the second **FixedRecord**, and so on.

Comparing executable and functional maps

There are two kinds of maps: executable maps and functional maps.

Executable Map

An *executable map* is a map responsible for the totality of your inputs and outputs. The sources and targets of an executable map are entire files, database tables, messages, applications, and so on. Think of an executable map as the main map, the top-level map. Executable maps are compiled and run.

Functional Map

A *functional map* is referenced by another map through a map rule. A functional map maps just a portion of the entire data. Data sources and targets are not specified in the cards of functional maps. Functional maps are not compiled and run.

Note: A given map can be used both as an executable and as a functional map. You may want to test small portions of your data and temporarily use a map you created as a functional map as an executable map on that portion of the data.

If a map is used as a functional map, the input data and output data settings specified in that map are ignored.

Syntax of a functional map expression

Map rules on executable map output cards specify the functional map name. The syntax of a functional map expression is similar to the syntax of a function.

Similar to a function, a functional map has one or more inputs, and one output.

The inputs and the output are data objects.

The syntax of a functional map expression is the following:

```
FunctionalMapName (argument1, argument2,...argumentn)
```

Where **n** is the argument number. The input arguments of a functional map appear between the parentheses in the functional map expression separated by commas.

An input argument of a functional map is any valid expression that evaluates to data, including data objects, functions, and literals. For example, an input argument may be any of the following:

Input argument

Example

data objects

```
FixedRecord:Input
```

functions that evaluate to data

```
EXTRACT (StoreInfo:Inventory, StoreName:Inventory = "Lee  
Furniture")  
INDEX (Record:File)
```

literals

```
"payroll"
```

Each of these expressions evaluates to data. For example, the following expression evaluates to the data object **FixedRecord**:

```
FixedRecord:Input
```

The following expression evaluates to **StoreInfo** data objects:

```
EXTRACT (StoreInfo:Inventory, StoreName:Inventory = "Lee Furniture")
```

The **INDEX (Record:File)** expression evaluates to an integer; the "**payroll**" expression evaluates to text.

For a detailed discussion of functions and expressions, see the Functions and Expressions documentation.

- [Determining the arguments of a functional map](#)

Determining the arguments of a functional map

The input arguments of a functional map are the objects necessary to create *one* occurrence of the output object where the map rule is.

To determine what the input argument(s) of a functional map should be, ask yourself, "What do I need to create this output?" Whatever is necessary in a functional map must be passed to it as an argument. There may be one or more input arguments. The arguments of a functional map can be thought of as triggers. The number of times a functional map is triggered depends on the number of occurrences of the input arguments in the data and the expressions used for each argument.

To determine the input arguments of a functional map, ask yourself what objects are necessary to create *one* occurrence of the output object.

- [Input argument to a functional map evaluates to NONE](#)

Input argument to a functional map evaluates to NONE

If an occurrence of input argument is missing, the functional map is not evaluated.

A file that has no content will still allow the functional map to execute.

For example, in the following functional map expression the **GroupInfo** object is optional with a component range of (0:3):

```
MakeForm (EntryForm:Input, GroupInfo:Input)
```

If there are no occurrences of **GroupInfo** in the source data object, the specified **MakeForm** functional map is not evaluated.

In the following map rule, the **OrderMap** functional map is specified with the (DetailRecord:Order:Input, SummaryRecord:Order:Input) arguments:

```
OrderMap (DetailRecord:Order:Input, SummaryRecord:Order:Input)
```

The data object **SummaryRecord** has an optional component range of (0:1). For the first **Order**, **SummaryRecord** is present. The functional map **OrderMap** is evaluated. In the second **Order**, **SummaryRecord** is missing. The map **OrderMap** is not evaluated for that second **Order**.

To evaluate the entire **OrderMap** if **SummaryRecord** may be absent from the source data, specify the entire **Order** as an input argument, rather than **SummaryRecord**. Specifying the entire **Order** ensures that **OrderMap** is evaluated, even when **SummaryRecord** is missing. Then, in the functional map **OrderMap**, you can still map from **SummaryRecord**.

Entering the map rule that references the functional map

Map rules that reference functional maps are entered in the rule cells on the output card of the executable map. Map rules belong in the rule cell of the data object that requires additional data processing. The number of times a functional map is triggered depends on the number of occurrences of the input arguments in the data and the expressions used for each argument.

This section explains how to manually create a functional map. You can also use the "[Functional Map Wizard](#)".

For the executable map for mapping the car data (see [Example Scenario for Using a Functional Map](#)), the executable map is **CarData**. The source data contains fixed records and the goal is to generate an output file containing one delimited record for each fixed record in the source data.

A functional map on the **CarRecord(s)** data object can generate one **CarRecord** for each **FixedRecord**. A suitable name for the functional map can be **RecordMap**, because the functional map maps one record at a time. In the **CarData** executable map, the map rule for the **CarRecord(s)** data object in the output card would contain an equal sign, the name of the functional map, and a set of parentheses:

```
=ListCars ( )
```

To map the fixed record input object to the map rule, drag the **FixedRecord(s)** data object from the input card into the rule cell inside the parentheses. Commit the map rule by pressing the **Enter** key.

A map rule specifies how to generate that certain output. The map rule on **CarRecord(s)** specifies how to create each **CarRecord**. Basically, the map rule specifies "to generate a **CarRecord** data object, use a functional map named **ListCars** on a **FixedRecord** data object." The functional map **RecordMap** uses the **FixedRecord** to create a **CarRecord**.

The functional map **ListCars** can be created before the executable map. The creation order for the map rule or functional map is not relevant. However, an error occurs at build time when a rule includes a nonexistent map name.

Input card types of a functional map

The input and output cards in a functional map must be in the same order as the data objects are specified in the map rule argument.

The input card type(s) in a functional map must be coordinated with the input argument(s).

For example, if the input arguments evaluate to **Record**, **Claim**, and **LookupFile**, in that order, then the input card types in the functional map must be **Record**, **Claim**, and **LookupFile**, in the same order.

Input arguments as data objects

Input arguments of a functional map can evaluate to **Item** or **Group** type data objects.

Item types

When an input argument of a functional map evaluates to an item type, the type of the corresponding input card must be an item type with the same **Item Subclass** (**Number**, **Text**, **Date & Time**, or **Syntax**).

An input argument might evaluate to a number. If the following input argument evaluates to a number, the corresponding input card type must be an item with an **Item Subclass of Number**:

```
INDEX (Record:File)
```

If the input argument is a text literal (for example, "`payroll`"), the input card type that corresponds to this argument must be an item with an **Item Subclass of Text**.

Group types

When an input argument of a functional map evaluates to a group type, the type of the corresponding input card must be the exact same group. For example, if the second input argument evaluates to **InvoiceSet**, the **TypeName** of input card #2 must be **InvoiceSet**.

If there is one argument of the functional map, there will be one input card. The **TypeName** on the input card must correspond to the data object specified in the argument for the functional map.

Functional maps do not require **InputData** and **OutputData** settings.

When **InputData** and **OutputData** settings exist in input and output cards in a functional map, they are ignored when the executable map is compiled.

Output card type of a functional map

The type of the output card in a functional map is the type whose map rule includes the functional map name. For example, if the functional map name is entered in the rule cell for **CarRecord(s)**, the output of that functional map must be **CarRecord**.

The output of a functional map must match the output data object (where the map rule that calls the functional map is), therefore a functional map has only *one* output card.

A functional map may have only *one* output card.

- [Entering map rules](#)

Entering map rules

Map rules of a functional map are entered to generate the desired output of the functional map. Similar to an executable map, output data is generated in the specified format. This specified format is determined by the type properties of the type on the output card.

Essentially, a function maps a single data object for every data object received from the input.

Using multiple inputs in a functional map

A functional map may require more than one input. For example, you are mapping an input purchase order to an output purchase order. The input **PO** consists of a header and multiple details. The output **PO** is composed of a series of item records. Each **ItemRecord** contains the **PO#** and the company name, which must be mapped from the **Header** of the input **PO**. Each **ItemRecord** also contains item, quantity and price information, which is mapped from a **Detail** in the input.

You need a functional map to generate an **ItemRecord**. The inputs of the functional map would be everything that is necessary to generate one **ItemRecord**: both the **Detail** and **Header** from the input. A suitable name for the functional map may be **MakeItemRecord**.

The input **PO** is composed of one **Header** and multiple **Details**. You want to generate one **ItemRecord** for each **Detail**.

The functional map **MakeItemRecord** takes one **Detail** at a time, along with the **Header**, and creates one **ItemRecord**.

The two input arguments of **MakeItemRecord** are **Detail** and **Header**. You would enter the following map rule for the output **ItemRecord(s)**:

```
= MakeItemRecord (Detail:Input, Header:Input)
```

In the map **MakeItemRecord**, you would create two input cards. The first input card corresponds to the first input argument, **Detail**. The second input card corresponds to the second input argument, **Header**.

- The input arguments must match the input card types, in the same order.
- The order of the arguments does not affect the number of times a rule is evaluated. However, it may affect the order in which the output objects appear and the performance at run time. For more information on how rules are evaluated, see the Functions and Expressions documentation.

In **MakeItemRecord**, map the **PO#** and **Company** from the **Header** into the components of **ItemRecord**. Map the **Item**, **Qty**, and **Price** from the **Detail**.

- [Input objects are triggers](#)

Input objects are triggers

A functional map is triggered by the presence of the input objects that are specified as the arguments of the functional map. Each time a new combination of input objects is evaluated, the functional map is executed.

The functional map **MakeItemRecord** has two inputs: **Detail** and **Header**. One output **ItemRecord** is produced for each combination of **Detail** and **Header** in the input. In this example, there is one **Header** for many **Details**. The same **Header** object is sent to the functional map again and again with each new **Detail**.

For a complete explanation of how map rules are evaluated, see the Functions and Expressions documentation.

Rename a functional map

The functional map of an execution map can now be renamed. To rename a functional map follow the below procedure:

1. In the Map workspace list, right click on the functional map you want to rename and select Edit option.
Edit Map window opens.
2. In the Edit Map window, enter the new name in the Name field.
3. Click OK.
The Edit Map window closes.

After renaming the functional map, the renamed map name should be reflected in below places:

1. Rule editor
2. Connection Rule
3. Map tab name
4. Map Navigator list
5. Map workspace list

Map settings

Map settings specify properties for map executions that are not specific to a particular input or output. These include settings for auditing a map, tracing data content, performance settings, validation settings, and map-specific warnings and errors.

Map settings are defined for a map during the design phase and are compiled with the map. Except for BurstRestart, the map settings compiled with a map can be overwritten at run time.

The default map settings can be defined or changed in the Map Designer options for Run Options by clicking Window > Preferences > Transformation Extender > Map > Run Options.

- [MapAudit settings](#)
 - [MapTrace settings](#)
 - [WorkSpace settings](#)
 - [Century settings](#)
 - [Validation settings](#)
 - [Retry settings](#)
 - [Warnings settings](#)
 - [CodePageFallback](#)
 - [MapRuntime setting](#)
-

MapAudit settings

MapAudit settings specify options for creating and storing map audit logs.

If the **MapAudit Switch** is set to **ON**, the audit log is created and can be appended. In addition, there are flexible sub-switches that allow for the audit log to be created or appended based on the following conditions:

- When a map fails.
- If the map has an error.
- If the map has a warning or error.

- [MapAudit > Switch](#)
 - [MapAudit > BurstAudit](#)
 - [BurstAudit > Data](#)
 - [BurstAudit > Execution](#)
 - [MapAudit > SummaryAudit](#)
 - [SummaryAudit > Execution](#)
 - [MapAudit > SettingsAudit](#)
 - [SettingsAudit > Data](#)
 - [SettingsAudit > Map](#)
 - [MapAudit > AuditLocation](#)
 - [AuditLocation > Directory](#)
 - [AuditLocation > FileName](#)
 - [AuditLocation > Sized](#)
-

MapAudit > Switch

The **Switch** setting enables or disables the map audit feature. The default value for the **Switch** setting is **OFF**.

Value	Description
OFF	Audit data for the map will not be created.
ON	Audit data for the map will be created based on the values of the related settings.

MapAudit > BurstAudit

Expand this setting to define the audit log BurstAudit Data and BurstAudit Execution settings.

BurstAudit > Data

The **Data** setting is used to include or exclude data information in the audit log. The burst audit data information includes a burst count, the card number, the object index, the audit log status code, the object level, the size of the object, and the object name. You can specify that you want to audit a particular object by including that object on the Data Audit Settings view.

The BurstAudit Data settings are listed in the following table. The default setting is **Never**.

Value	Description
Always	Write data to the audit log, regardless of the map execution outcome.
Never	Do not log data information.
OnBurstError	If the outcome of the execution of the burst meets a failure condition, write the burst data to the audit log.
OnBurstWarningOrError	If the outcome of the execution of the burst is a warning or meets a failure condition, write the burst data to the audit log.

- [Data > SizeValidation](#)

Data > SizeValidation

When BurstAudit Data is set to **Always**, **OnBurstError**, or **OnBurstWarningOrError**, the **SizeValidation** field becomes available. The input trace file will report when data fails to meet size requirements for the type.

TooLong TooShort

When you choose this option and the minimum or maximum size requirements are not met during data validation, one of the following size-specific messages will be indicated in the input trace file:

```
"fails minimum size requirements"  
"fails maximum size requirements"
```

Wrong Size

This is the default option for this setting. If the minimum or maximum size requirements are not met during data validation, it will be indicated in the input trace file with a generic message similar to the following example:

```
"data at offset xx ('DATA...') is the wrong size for the TYPE X' (02)  
(typename)"
```

When using the **TooLong TooShort** value for the BurstAdit Data **SizeValidation** setting and the data fails the minimum size requirement, the input trace file entry will look similar to the following example:

```
(Level 1: Offset 41, len 6, comp 5 of 7, #1, DI 00000005:  
Data at offset 41 ('SYNTAX...') fails minimum size requirements  
TYPE X'0007' (LongSyntaxItem ROOT).
```

BurstAudit > Execution

The **Execution** value determines whether to include audit execution information in the audit log.

The execution audit log includes the command used to run the map from a command line, the number of input and output objects, and information about data sources, data targets, work area size, and the time it took to run the map. The execution log does not include information about restarts.

The BurstAudit Execution settings are listed in the following table. The default setting is **Never**.

Value	Description
Always	Include burst audit execution information in the audit log, regardless of map execution outcome.
Never	Do not include burst audit execution information in the audit log, regardless of map execution outcome.
OnBurstError	If the burst execution outcome meets a failure condition, write burst audit execution information to the audit log.
OnBurstWarningOrError	If the burst execution outcome is a warning or meets a failure condition, write burst audit execution information to the audit log.

MapAudit > SummaryAudit

Expand this setting to define the summary audit **Execution** settings. Summary audit provides audit information on map execution without the detailed burst information.

SummaryAudit > Execution

The **Execution** value determines whether to include summary audit execution information in the audit log. Summary audit provides audit information on map execution without the detailed burst information.

The SummaryAudit Execution settings are listed in the following table. The default setting is **Always**.

Value	Description
Always	Include summary burst audit execution information in the audit log, regardless of the map execution outcome.
Never	Do not include summary burst audit execution information in the audit log, regardless of the map execution outcome.
OnError	If the map execution outcome meets a failure condition, write the execution information to the audit log.
OnWarningOrError	If the map execution outcome is a warning or meets a failure condition, write the execution information to the audit log.

MapAudit > SettingsAudit

Expand this setting to define which settings are included in the audit log.

SettingsAudit > Data

The **Data** value determines whether to include data settings in the audit log.

The SettingsAudit Data settings are listed in the following table. The default setting is **Never**.

Value	Description
Always	Include data settings in the audit log, regardless of the map execution outcome.
Never	Do not include data settings in the audit log, regardless of the map execution outcome.
OnError	If the map execution outcome meets a failure condition, include data settings in the audit log.
OnWarningOrError	If the map execution outcome is a warning or meets a failure condition, include data settings in the audit log.

SettingsAudit > Map

The **Map** setting is used to include or exclude the settings from the map in the audit log.

The SettingsAudit Map settings are listed in the following table. The default setting is **Never**.

Value	Description
Always	Include map settings in the audit log, regardless of map execution outcome.
Never	Do not include map settings in the audit log, regardless of map execution outcome.
OnError	If the map execution outcome meets a failure condition, write map setting information to the audit log.
OnWarningOrError	If map execution outcome is a warning or meets a failure condition, write map setting information to the audit log.

MapAudit > AuditLocation

The **AuditLocation** setting is used to specify where the audit information is stored.

The availability of additional settings (such as Directory, FileName, Action, or Sized) varies according to the AuditLocation setting.

The MapAudit AuditLocation values are listed in the following table. The default value is **File**.

Value	Description
File	Audit information is stored in a file. There is a maximum of 259 characters in the path and filename.
Memory	Audit information is stored in memory, and appended to the last set of data returned during map execution. The Memory value is used when the map is run by the RUN function or by an API.

When a map is run by a Command Server or Launcher, the **Memory** setting is ignored. The audit log is created in a file in the map directory, as specified with the AuditLocation **FileName** setting.

AuditLocation > Directory

The **Directory** setting is used to specify the same directory as the map or a user-defined directory. The default value for the **Directory** setting is **Map**.

Value	Description
Map	The same directory as the map.
Custom	The directory you specify using the Value setting.

- [Directory > Value](#)

Directory > Value

If you selected the **Custom** value for the AuditLocation > Directory setting of the MapAudit setting, enter the full path of the directory in the Value field, or browse to select the directory.

AuditLocation > FileName

Use the FileName setting to specify a default or custom name for the audit log file.

The default value is Unique.

Value

Description

Default

The file is automatically assigned an audit log file name based on the compiled map name with the .log file name extension.

Unique

Generates a unique audit log name in the following format:

Mer_mapname_processkey_mapcounter_hostname.log

Run_mapname_processkey_mapcounter_hostname.log

The "Mer" prefix is used with top-level maps while "Run" is used for run maps.

mapname

The executable map name.

processkey

Unique value for each process.

mapcounter

Unique value for each map instance (within the same process)

hostname

The host name of the computer where Transformation Extender is running.

You cannot view an audit log file that has a unique name from the Data Audit Settings view.

Custom

Use the FileName > Value setting to specify the custom name of the audit log file.

Use the Custom value if the log files produced for one map trigger another map, so that each log file triggers another instance of that other map. Be sure to specify different directories for the log files.

The number of characters allowed for the log file name is contingent on the number of characters in the directory path. The total number of characters in the path name and the file name is limited to a maximum of 255 characters.

- [FileName > Action](#)
- [FileName > Value](#)

FileName > Action

The **Action** setting for the AuditLocation > FileName setting of the MapAudit setting is used to create a new audit log file or to append the audit log to an existing audit log file. The default value for the **Action** setting is **Create**.

Value

Description

Create

The audit log file is created each time the map is run.

Append

The audit log is appended to an existing audit log file each time the map is run. If no audit log file exists at the start of map execution, an audit log file is created.

FileName > Value

If you selected the **Custom** value for the AuditLocation > FileName setting of the MapAudit setting, enter the file name in the Value field.

The amount of characters allowed for the audit log filename is contingent on the amount of characters in the directory path. The total number of characters in the path name and the file name is limited to a maximum of 255 characters.

AuditLocation > Sized

When **AuditLocation = Memory**, audit information is stored in memory and appended to the last set of data returned during map execution. The memory setting can be used only when the map is run by the **RUN** function or an API. Audit data is prefixed with a text number indicating the size of the audit data, followed by a <SP>.

Value	Description
ON	The audit data is sized.
OFF	Not sized: the audit data is returned with no size.

MapTrace settings

MapTrace settings specify properties for a trace file used to diagnose invalid data or incorrect type definitions.

- [MapTrace > Switch](#)
- [MapTrace > TraceLocation](#)
- [TraceLocation > Directory](#)
- [TraceLocation > Filename](#)

The FileName setting (Map Settings.>.TraceLocation.>.FileName) specifies how a map trace file is named. A map trace file with a default name is overwritten the next time the map is traced. Specify a custom name or a unique name to compare map trace files across multiple runs of the same map.

- [MapTrace > InputContentTrace](#)
- [InputContentTrace > CardNumber](#)
- [InputContentTrace > StartObject](#)
- [InputContentTrace > EndObject](#)
- [MapTrace > RulesTrace](#)
- [RulesTrace > CardNumber](#)
- [MapTrace > SummaryContentTrace](#)
- [MapTrace > Format](#)

The MapTrace.>.Format setting specifies whether the contents of the trace file are binary or text. Binary files are smaller than text files and are likely to have less impact on performance (however, never use tracing in a production environment).

MapTrace > Switch

Define whether map tracing is enabled. A trace file can be used for diagnosing invalid data or incorrect type definitions.

Value	Description
OFF	Trace data for the map will not be created.
ON	Trace data for the map will be created.

MapTrace > TraceLocation

Use the **TraceLocation** settings to specify where the trace file will reside. The **TraceLocation** is **File**, which specifies that trace information is written to a file as specified with the **Directory** and **FileName** settings.

TraceLocation > Directory

The **Directory** setting is used to specify the same directory as the map or a user-defined directory. The default value for the **Directory** setting is **Map**.

Value	Description
Map	The same directory as the map.
Custom	The directory you specify using the Value setting.

- [Directory > Value](#)

Directory > Value

If you selected the **Custom** value for the TraceLocation.>.Directory setting of the MapTrace setting, enter the full path of the directory in the Value field, or browse to select the directory.

TraceLocation > Filename

The **FileName** setting (Map Settings > TraceLocation > FileName) specifies how a map trace file is named. A map trace file with a default name is overwritten the next time the map is traced. Specify a custom name or a unique name to compare map trace files across multiple runs of the same map.

Default

The default map trace file name is *mapname.mtr*.

Custom

Specify a name for the map trace file in the **Custom > Value** field.

Unique

Automatically creates a unique map trace file name in the format:

`Mer_mapname_processKey_mapCounter_hostname.mtr`

MapTrace > InputContentTrace

Specify options of which input data is traced. The default value for the **InputContentTrace** setting is **All**.

Value

Description

OFF

Trace input data for the map will not be created

All

Trace all inputs.

Card

Trace a single input. Specify the input map card by typing the number of the map card into the value field of the **CardNumber** setting.

Range

Trace a range of input objects. Specify the beginning object by typing the number of the object into the value field of the **StartObject** setting. Specify the ending object by typing the number of the object into the value field of the **EndObject** setting.

InputContentTrace > CardNumber

To trace a single input trace, enter the card number. For example, to include only messages about card 2 in the trace file, enter 2.

InputContentTrace > StartObject

Enter the beginning object number to be traced. For example, to trace data objects 1000 to 2000, enter 1000 as the **StartObject** value.

InputContentTrace > EndObject

Enter the ending object number to be traced. For example, to trace data objects 1000 to 2000, enter 2000 as the **EndObject** value.

- [Using ranges for InputContentTrace](#)

Using ranges for InputContentTrace

The range specified for objects is not precise. The intention is to reduce the number of objects in the trace file, not to specify precise objects. To trace the first object, specify a **StartObject** range of 0, not 1.

The object number is not provided in the trace file. Providing a range is an attempt to trace less than the whole, not a precise range of objects.

MapTrace > RulesTrace

The **Detail** setting specifies options of which output data is traced. The default value for the **Detail** setting is **OFF**.

Value

Description

OFF

Trace output data for the map will not be created.

All

Trace all objects built.

Card

Trace a single output. Specify the output map card by typing the number of the map card into the value field of the **CardNumber** setting.

RulesTrace > CardNumber

To trace a single output trace, enter the card number. For example, to include only messages about card 2 in the trace file, enter 2.

MapTrace > SummaryContentTrace

The **SummaryContentTrace** setting is used to place a summary of the validation status of each input and the build status of each output after the map is built into the trace file. The default value for the **SummaryContentTrace** setting is **OFF**.

Value	Description
OFF	Do not include a summary in the trace file.
ON	Include a summary in the trace file.

MapTrace > Format

The MapTrace > Format setting specifies whether the contents of the trace file are binary or text. Binary files are smaller than text files and are likely to have less impact on performance (however, never use tracing in a production environment).

Option	Description
Text	Generates a text trace file. This is the default format.
Binary	Generates a binary trace file. Use the dtxmaptrace utility to convert a binary trace file to text. ASSERT messages in the binary trace file indicate which data type (from the schema) Transformation Extender is validating.

- [dtxmaptrace utility](#)

WorkSpace settings

WorkSpace settings specify the location (file or memory) of the workspace and **PageSize** and **PageCount** settings for configuring the page size. **WorkSpace** settings allow you to optimize the speed of map processing.

When a map is run, a paging scheme to access information about the data as efficiently as possible is used. Portions of both working data and actual data are paged, as needed. The workspace can be a combination of files and memory, or simply memory-based. When file-based workspace is used, the amount of memory accessed at a given time depends on the number of pages and the count of pages configured for a map to run.

The **WorkSpace** settings specify the location (file or memory) of the workspace and **PageSize** and **PageCount** settings for configuring the page size.

The default value for the **WorkSpace** setting is **File**.

Value	Description
File	A work file is created for each input card. Use the Directory setting to specify the directory.
Memory	A memory-based workspace is created.

The **WorkSpace** settings allow you to optimize the speed of map processing.

- When the size of the input data a map is processing is large, file-based workspace using default paging is recommended (**Workspace = File**).
- When small amounts of data are processed, smaller page sizes and memory-based workspace is recommended (**Workspace = Memory**).
- When using burst processing, adjust the workspace configuration for the size of burst data.
If a particular map card is not referenced by any map rules, no work area for that card will be created, and the audit log will indicate that the work area is not found.
- [WorkSpace > PageSize](#)
- [WorkSpace > PageCount](#)
- [WorkSpace > Directory](#)
- [WorkSpace > WorkFilePrefix](#)

WorkSpace > PageSize

The **PageSize** setting specifies the size of a memory page to be used for work files. For maps that include a large number of type references, you may want to increase the page size. The default value for the **PageSize** setting is 64.

Value	Description
n	

Enter a number that represents the size of a memory page in kilobytes. The page size should be a multiple of 2, between 2 and 1024.

WorkSpace > PageCount

The **PageCount** setting specifies the number of memory pages to use for work files. For large data files, you may want to increase the number of pages used. The default value for the **PageCount** setting is 8.

Value

Description

n

Enter a number that represents the number of memory pages to use for workspace. Valid numbers are 1 to 9999 (an integer greater than 0).

WorkSpace > Directory

The **Directory** setting is used to specify the same directory as the map or a user-defined directory. The default value for the **Directory** setting is **Map**.

Value

Description

Map

The same directory as the map.

Custom

The directory you specify using the **Value** setting.

- [Directory > Value](#)

Directory > Value

If you selected the **Custom** value for the **Directory** setting of the **WorkSpace** setting, enter the full path of the directory in the **Value** field, or browse to select the directory.

WorkSpace > WorkFilePrefix

Use the **WorkFilePrefix** setting to select a convention for naming work files.

The default value is **Unique**.

Value

Description

MapName

The name of a work file is the base name of the compiled map file. The extension is **.Inn**, for an input, and **.Onn** for an output, where *nn* is the card number. For example, the work file for input card number 3 has the extension **.I03**.

Unique

Generates unique work files with no conflict between work files each time a given map is run. If this option is turned on, work files are automatically deleted.

- [WorkFilePrefix > Action](#)

WorkFilePrefix > Action

Use the **WorkFileAction** setting to save or delete the work files. The default value for the **WorkFileAction** setting is **Delete**.

Value

Description

Delete

Delete the work files after a map is executed. All work files are deleted, except those being saved for reuse, as specified on the input cards for each map.

Create

Save the work files based on the **Value** and **FilePrefix** settings.

Century settings

Century settings specify the current or sliding century.

- [Century](#)
- [Century > CCLookup](#)

Century

The **Century** setting specifies the current or sliding century. The default value for the **Century** setting is **Current**.

Value	Description
Current	Missing century numbers are derived based on the current system date.
Sliding	Enables SlidingCentury options. Missing century numbers are derived based on the value of the CCLookup setting.

Century > CCLookup

The **CCLookup** setting specifies the first year in a 100-year range used to derive a missing century for a date item, using CCYY format. The default value for the **CCLookup** setting is **1950**.

For example, if the value of the **CCLookup** setting is **1960**, a YYMMDD formatted date between 1960 and 1999 is interpreted as having a century date of **19**, while dates between 2000 and 2059 are interpreted as having a century date of **20**. In this case,

- 600101 is assigned a century of 19
- 580101 is assigned a century of 20

Value	Description
n	Enter a number in CCYY format that represents the start of a 100-year range. Valid numbers are 1 to 9999.

Validation settings

Validation settings specify how strictly the data is validated by specifying response behavior for types of validation errors.

- [Validation](#)
- [Validation > OnValidationError](#)
- [Validation > RestrictionError](#)
- [Validation > SizeError](#)
- [Validation > PresentationError](#)
- [Validation > Ignore Component Rules](#)

Use the Ignore Component Rules map setting to run a map without validating component rules, for example, when your data does not conform exactly to a particular schema.

Validation

During map execution, the input data is validated to assure it matches the definition of that input. Specify how strictly the data is validated by specifying response behavior for types of validation errors.

Value	Description
Standard	Standard validation occurs when the map is run.
Custom	Enables custom validation options. Define these options in the OnValidationError , RestrictionError , SizeError , and PresentationError settings.

Validation > OnValidationError

Under certain circumstances, multiple errors are detected that occur during validation. The **OnValidationError** setting defines where to halt map execution. With either setting, if an error is found in the input, no output objects are built.

Value	Description
Stop	Only validate through the input card where the first error occurs. Stop executing the map after validating that input card, even if there are multiple input cards.
Continue	Continue validating data until all errors are found. Even when validation finds data errors in a given input card, map execution continues with the next input card.

Validation > RestrictionError

Define whether to validate the data with restrictions at run time. For example, if you are running some test data and you do not need the item values to match the restrictions, you might wish to ignore the restrictions.

Value

Description
Ignore
Ignore restrictions during validation.
Validate
Validate with restrictions.
Ignore (no warnings)
Allows restrictions to be fully ignored, in all situations other than when ignoring is required for object identification, such as when an item is partitioned by a restriction list.
Restrictions of syntax items are not ignored, because these are used in determining the value of the syntax object.

Validation > SizeError

Define whether to validate the data with size at run time.

Value	Description
Ignore	Ignore minimum and maximum size of items that appear in delimited data during validation.
Validate	Validate with size.
For example, if an item is defined as having a minimum of 3 bytes, but it only has 2 bytes in the data, the mapping process ignores the fact that it only has 2 bytes and accepts the data as valid.	

Validation > PresentationError

Define whether to validate the data with presentation settings at run time. For example, if a number is defined as an integer, but it appears in the data as a decimal number, the mapping process ignores the fact that the number appears as a decimal and accepts the data as valid anyway.

Value	Description
Ignore	If the item has an invalid presentation, the system cannot interpret it as an object of the defined type. Even if the data fails the item presentation check, the mapping process handles the data as if it were valid. Although the mapping process attempts to map the item, it might not produce the correct output.
Validate	Validate with presentation settings.

Validation > Ignore Component Rules

Use the Ignore Component Rules map setting to run a map without validating component rules, for example, when your data does not conform exactly to a particular schema.

The Validation map setting Ignore Component Rules prevents a component rule from being evaluated when either:

- The group does not include a component that has a group identifier attribute.
- The component rule occurs on a component that is after the component that has the group identifier attribute.

Retry settings

The **Retry** map settings define whether to try again if compiled map files, work files, audit log files, or trace files that are needed during map execution cannot be opened.

Specify the **Interval** and **MaxAttempts** to define how many times and at what interval attempts are made to access an unavailable file.

If adapter errors occur (for example, failure to connect) and Retry Switch = On, the adapter process is retried at the interval specified with the Interval value up to as many times as defined with the **MaxAttempts** setting.

- [Retry > Switch](#)
- [Retry > MaxAttempts](#)
- [Retry > Interval](#)

Retry > Switch

The **Switch** setting enables or disables **Retry** options. The default value for the **Switch** setting is **OFF**.

Value	Description
OFF	Disables Retry options. Only one attempt to access an unavailable file. If this fails, a return code and message (Could not open file) are returned by the map.

ON

Enables **Retry** options. Retry is enabled for the number of attempts specified by the value of the **MaxAttempts** setting at the interval specified by the value of the **Interval** setting.

Retry > MaxAttempts

Use the **MaxAttempts** setting to specify the maximum number of attempts to access an unavailable file referenced by the map. The default value is **10**.

Value

Description

n

Enter a number that represents the maximum number of attempts to access an unavailable file referenced by the map. After the maximum number of attempts has been exhausted unsuccessfully, a return code and message are returned by the map. Valid entries are integers 0 to 65535.

Retry > Interval

Use the **Interval** setting to specify the interval to wait between attempts to open a system file referenced by the map. The default value for the setting is 0.

Value

Description

n

Enter a number that represents the number of seconds to wait between attempts to access input data referenced by the map. Valid entries are integers 0 to 9999.

Warnings settings

Warnings settings specify that the map should fail when any of the selected warning codes are returned. The default value for the **Warnings** setting is **Every**.

Enabling the **Warnings** options impacts the transaction behavior specified for each card in the map.

If a map execution warning code occurs, the map fails after processing of that map is finished.

Maps called (from the failed map) with a **RUN** function, **PUT** function, or **GET** function will still process, and the behavior defined in that map's card settings for Transaction OnSuccess and Transaction OnFailure occurs.

If any warning is set to **Fail** the map, and the map fails due to the cause associated with the selected warning, the execution audit includes the map-failed message with the appropriate warning code preceded by a minus sign, for example: **Map failed on warning (-27)**.

Define your audit settings for each map, as the audit log of the main map may not reflect all failed map information if the failed maps are called with a RUN, PUT, or GET function.

Value

Description

Every

Map fails when any of the warning codes are returned. This setting treats every warning the same way, depending on the value of the **Return** setting. For **Return**, you can select **Warn**, **Ignore**, or **Fail**.

Custom

Map fails only when the user-selected warning codes are returned. The specific warnings are available only if the value of the **Warnings** setting is **Custom**.

- [Other Warnings settings](#)
- [Warnings > Return](#)

Other Warnings settings

If you selected the **Custom** value for the Warnings setting, specific warnings settings appear. For each warnings setting, you can select the specific map response to the warning. The default value for the each of these additional settings is **Warn**.

Value

Description

Warn

Issue a warning if any warning is returned.

Ignore

Ignore all warnings if any warning is returned.

Fail

Fail the map if any warning is returned.

Warnings > Return

The **Return** setting specifies the response for warnings. The default value for the **Return** setting is **Warn**.

Value	Description
Warn	Issue a warning if any warning is returned.
Ignore	Ignore all warnings if any warning is returned.
Fail	Fail the map if any warning is returned.

CodePageFallback

Use the CodePageFallback map setting to specify the code page conversion fallback behavior when mapping between objects with a specific data language set and there is a character found that is not defined in the target character set during the conversion process. The default value is Skip.

Value	Description
Skip	Skip a character that cannot be converted to the target code page. When a character is skipped, the result is that the content of the target data is a character shorter than the content of the source data.
Substitute	If you select Substitute, the Substitute Value property opens. Specify any value for the Substitute Value property. At run time, if a string contains a character that is not defined in the target character set, the mapping process replaces the character with the substitute character or string that you specified in the Substitute Value property. If you do not specify a value for the Substitute Value property, the mapping process replaces the character that is not defined in the target character set, with the International Components for Unicode (ICU) substitution character that is specified in the conversion tables.

MapRuntime setting

The MapRuntime setting determines the runtime platform of an executable map. The default value is Transformation Extender. The alternate option, DataPower, pertains to an WebSphere DataPower SOA Appliance.

To design and create DataPower maps in the Map Designer, which is during the pre-production phase, use the DataPower runtime option to build and test them. After you have successfully tested the maps, you can deploy the maps to a DataPower appliance during the production phase. Maps that are built specifically for a DataPower appliance do not support all of the features of the Transformation Extender. The limitations on the appliance are described in the [Limitations of appliances](#) topic. The DataPower run time requires a compiled map (.dpa) and the input files for the map to run.

Configuring bursts

For input card settings that have a **FetchAs** mode of **Burst**, the type of input object (as defined in the **Source** setting) and the **FetchUnit** work together to achieve the desired results.

For example, if an input type is one message, the **FetchUnit** should be 1. If the input type is a series of messages, the **FetchUnit** can be any integer.

- When the **Source** is a File of Messages
When the map is run, the first message in the file is found, and converted as specified. Consecutive messages in the file are encountered, and converted. And so on until all of the messages in the file are processed. A burst is identified by the definition of the input type - a message in this case.

If the target is a file, each message produced by a burst is appended to the same file. If you define the target as a message queue, each message produced is placed on the output queue after each burst.

- When the **Source** is a Queue of Messages
Change the source of the input to be a message queue. In this case, fetch the first message on the queue, convert it to the message, and route it to its target - which can be a file or another message queue, for example. Then, fetch the next message on the input queue and process it, and continue to fetch messages one at a time until the input message queue has no more messages.

Retrieval of data prior to the first burst is specific to the adapter.

- [Batching logical messages](#)
- [Using bursts for large files](#)
- [Configuring bursts for error recovery](#)
- [Configuring the RUN function and bursts](#)
- [Logical or adapter-specified FetchUnits](#)

Batching logical messages

You may process bursts of multiple messages. Under some conditions, this may improve performance. To do this, the logical input (that is, the type of the input card) is a series of messages. Then, adjust the **FetchUnit** to the quantity of messages to process for a given burst.

Automatic Logical Unit Adjustment: If the input type has one component, the range maximum is automatically adjusted for that component to match the FetchUnit. For example, the input type is a group with one component (could be a series of messages with a range maximum of 10) and the FetchUnit = 20. The series range maximum is automatically adjusted to 20 when the map runs.

If the input type has no components, or has more than one component, the type of that input is not automatically adjusted. In this case, if the amount of data retrieved for a burst does not match the input type definition, the input is either invalid or a burst warning is issued "Input valid, but unknown data found".

Using bursts for large files

To merge three inputs into one, the application takes the first row from the first input, the first row from the second input, and the first row from the third input, and constructs a new row from data of all three input rows. Then, take the second row of the first input, the second row of the second input, and the second row from the third input to construct a new second output row. Then, do the same with each matching input row, constructing a matching output row until all the input is consumed.

To configure the map to run coordinated bursts, set up each input's **CardMode** to **Burst** - and use the same **FetchUnit** for all three inputs.

When more than one input **CardMode** is set to **Burst**, and there is data for one burst and not another, the type definitions for the inputs determine the response. If the card object is required, and that card is set to Burst, data must be present if data for any other card set to **Burst** mode is present. In this case, the burst (and subsequently the map) will fail and the error message "One or more inputs is invalid" is displayed".

Configuring bursts for error recovery

Errors that occur during burst processing might be recoverable, or they can cause only a burst to fail, or they can be severe enough to cause the entire map to fail. Your card and map settings control many of these failure points.

If the following error occurs...	Card fails	Burst fails	Map fails
Any source connection fails	✓	✓	✓
The FAIL function causes a component rule to fail	✓	✓	✓
The type of an input is invalid	✓	If stop on first error is set, input validation fails, causing the burst to fail. If stop on first error is not set, input validation continues until all inputs are validated. Input validation as a whole causes a burst failure if any input type is invalid.	If the error limit is reached and a burst fails because one or more inputs are invalid, the map fails.
The FAIL function causes a transformation rule to fail	✓	✓	✓
If an output audit fails If output audit is used, it is recommended that Scope is set to burst or map.		✓	✓
If fail is set for an input or output Warnings.	✓	✓	✓
Any target connection fails.	✓	✓	✓

If an adapter is referenced as a function argument and no FAIL function is used, all operations rollback when a burst fails. When a burst is successful, any successful operations are committed.

Configuring the RUN function and bursts

When using the RUN function, a source or target used for the map that is run can be configured to be part of the transaction of the burst using the RUN function. To do this, set the **Scope** of the card in the map referenced in the RUN function to **Map**. In this case, if the map that contains the RUN rule fails, any adapter used in the map referenced in the RUN function whose scope is **Map** will exercise the **OnFailure** action.

If the **Scope** of a source or target is set to burst or card, that resource will act based on the appropriate completion status of the card or burst configured in the referenced RUN function.

When using nested RUN functions, if a source or target contained in a nested RUN has a **Scope** set to **Map**, any higher failure will cause that source or target to exercise its **OnFailure** action.

The rollback transaction behavior on maps called with the RUN function is achieved by using an output card, not the PUT function.

Logical or adapter-specified FetchUnits

All adapters have a **FetchUnit**. Some adapters have the capability to aggregate transactional data units. A transactional data unit refers to some unit of data that can be acted upon without affecting the state of another such data unit - for example, removing a message from a queue. Some adapters have the capability to divide one transactional unit into smaller discrete units of data. Some adapters cannot do either of the above. How the **FetchUnit** is interpreted depends on what the adapter's capabilities are.

When the data retrieved from a source adapter represents one transactional unit that cannot be subdivided into smaller discrete units of data without the adapter knowing the content of the data, the **FetchUnit** is interpreted as a logical unit. For example, if an input is a file, it is not a good idea to delete that file until a map completes its work

- a stream file is one transactional data unit that cannot be divided into physical units by the adapter. In this case, the **FetchUnit** is interpreted as logical by looking at the type definition of the input data to decide when a burst is complete.

When an adapter can aggregate transactional data units as one source, the **FetchUnit** is interpreted in terms of the transactional data unit. For example, if the data source is MQSeries, multiple messages can be aggregated, and the **FetchUnit** is the maximum number of messages to retrieve for a given burst. In this case, it is up to you to make sure the input type definition matches the amount of data retrieved for a single burst.

For database adapters, an input query represents one transactional unit that can be divided into rows by the adapter. In this case, the **FetchUnit** is the maximum number of rows to retrieve from the database for a given burst.

When the source adapter can only retrieve one transactional unit of data, the source **Scope** is limited to **Map** - this prevents you from trying to delete half a file, or half a buffer, for example. If the source adapter can retrieve multiple transactional units of data, the source **Scope** can be **Map**, **Burst** or **Card**.

Building maps

After you have entered map rules in an executable map, created necessary functional maps, and entered map rules for the desired output data objects, the next step is to build the executable map. A compiled map file is created when no build errors occur when the executable map, and all referenced maps, are analyzed.

An executable map has a data source or target specified for each of its cards. Executable maps are built. Functional maps are not built.

Data sources and targets specified for an executable map are defaults built into the compiled map file. Data sources and targets, and other map settings, can be overridden from the Integration Flow Designer or when a map is run using the Command Server.

- [Referenced maps](#)
- [Multi-platform maps](#)

You can compile a map to run on multiple platforms, for example, Microsoft Windows, AIX®, and Linux®. At run time, Transformation Extender runs the appropriate version of the map for the platform.

- [Including a static input file in a compiled map](#)

You can include a static input file in a compiled map to reduce processing overhead in maps that run multiple times.

- [Building a map](#)

Building a map compiles it into an executable map.

- [Rebuilding a map that has changed](#)

- [Building maps for a single platform](#)

To build a map that runs on a single platform, use Map>Build for Specific Platform and choose the platform you want the map to support. To build all maps in the map source file for a single platform, use Map>Build All for Specific Platform and choose the platform.

- [Sample JCL](#)

When you build a map for the IBM z/OS platform, a job control language (JCL) template is generated in the map directory.

- [Schema errors](#)

- [Map build analysis errors](#)

- [Map build warning messages](#)

- [Map build compile errors](#)

- [Compiled map files](#)

Referenced maps

When a map is built, the map and all of the functional maps that are referenced within that map are analyzed. For example, when the map called **MyMap**, which references **MakeRecord**, which references **ItemMap**, is built, all three maps are analyzed. If there are no build errors, a compiled map file is created. The referenced maps are compiled within this file. Referenced maps are not created as separate compiled maps.

Multi-platform maps

You can compile a map to run on multiple platforms, for example, Microsoft Windows, AIX®, and Linux®. At run time, Transformation Extender runs the appropriate version of the map for the platform.

In Design Studio, click Window > Preferences > Transformation Extender > Map > Build Options to select the platforms that you want your maps to support. Apply saves your choices. OK saves your choices and closes the window.

When you build maps with Map>Build or Map>Build All, the compiled maps support your selected platforms.

Including a static input file in a compiled map

You can include a static input file in a compiled map to reduce processing overhead in maps that run multiple times.

To include a file in a map, specify the static file adapter and the file name on the connection before you compile the map. The file must exist at the time when the map compiles, and must be less than 10 MB in size.

Note: No new-line conversion or character-set conversion takes place in the file when the map runs on any platform.

Building a map

Building a map compiles it into an executable map.

The build analyzes the logical interfaces within map rules, and if the analysis is successful, compiles the map. Analysis includes checking for missing rules, invalid rules, invalid card definitions, verifying map references, and verifying the arguments of functions. Analysis also looks for circular map references - maps that reference one another.

Remember: A map rule is required for each rule cell on an output card. When no data transformation is needed for an output object, a map rule is not required. In this case, enter = NONE as the map rule.

Rebuilding a map that has changed

After you have changed a map or updated it because you changed a schema used in it, build and save the map before running it again.

Building maps for a single platform

To build a map that runs on a single platform, use Map > Build for Specific Platform and choose the platform you want the map to support. To build all maps in the map source file for a single platform, use Map > Build All for Specific Platform and choose the platform.

A map that is compiled for a single platform has a platform-specific file extension. The compiled map name is the executable map name with the platform-specific extension, such as .aix. For example, building the map "MyMap" for the Linux® platform creates the file MyMap.lnx in the map directory. These default file extensions prevent you from inadvertently overwriting your original compiled map. They also help identify the compiled map file to transfer to the specific platform environment.

A map that is compiled for multiple platforms has the same .mmc file extension as maps that are compiled for a Windows platform.

When deploying systems that contain maps with XML types to non-windows platforms, the XML Schema, and XML input files must be transferred in binary format.

- [Platform-specific file name extensions](#)

Platform-specific file name extensions

Maps built for execution on Windows platforms use the default .mmc compiled map file name extension.

The **Build for Specific Platform** command creates a compiled map file in the format required for a specified platform, which accounts for byte-order and character set differences on that platform.

By default, the Map Designer assigns a platform-specific file name extension to maps built for specific platforms. You can change the default file name extension under Window > Preferences > Transformation Extender Compiled Map Extensions.

The default file name extensions for compiled maps are listed in the following table.

Platform	Extension
HP-UX (Itanium processor)	.hpi
IBM® AIX® (RS/6000® processor)	.aix
IBM z/OS®	.mvs
Linux® (Intel processor)	.lnx
Microsoft Windows	.mmc
pLinux	.pxn
Sun Solaris (SPARC processor)	.sun
zLinux	.znx

Create a folder exclusively for platform-specific maps.

To build a map for a specific platform:

1. Select the map in the Outline view or the Composition view.
2. Select the Build for Specific Platform option in one of the following ways:
 - From the menu bar, click Map > Build for Specific Platform.
 - Right-click the map and click Build for Specific Platform.
3. Select the specific platform on which you plan to run the map.

After the map is built for the specific platform, perform a binary file transfer of the compiled map file to the remote server environment. For example, to transfer the ported map to your UNIX server, you can use the File Transfer Protocol (FTP). You can also deploy the compiled maps from the Map Designer to the remote servers. Double-click the .dtxdeployment file that is under your project in the Navigator view, or in the Misc folder under your project in the Extender Navigator view. In the Deployment Editor, click Deploy to build and transfer the maps to the remote servers that you specified under Window > Preferences > Transformation Extender Deployment.

- A platform-specific build is not required if all of the items referenced in map rules have specific character sets and a specific byte order. No items have a native definition.
- For example, you might have a map whose only purpose is to convert data from ASCII to EBCDIC. However, to avoid mistakes, always use the Build for Specific Platform option when your target platform has a different byte order or character set than the byte order or character set in your map development environment.
- A platform-specific build is not required if you select a platform whose byte order and character set are the same as the byte order or character set on your development machine.

Sample JCL

When you build a map for the IBM z/OS platform, a job control language (JCL) template is generated in the map directory.

The JCL template is customized with information about the executable map (*mapname.jcl*), including the map name, input file name, and output file name. The following example JCL template was created by the Map Designer based on the following files:

```
//DTXSMJCL JOB
//***** Sample JCL to execute the SINKMAP map using the Transformation Extender Command Server for z/OS (OS/390).
//*
//***** MODIFY THE FOLLOWING GLOBAL VARIABLES FOR YOUR INSTALLATION
//*
// SET DTXLIB=DTX.SDTXLOAD           <== DTX LOAD LIB
// SET MAPLIB=DTX.SDTXSAMP          <== DTX MAP DSN
// SET EMPLOYEE=DTX.SDTXMAPS(DTXSMTXT) <== EMPLOYEE FILE
// SET ALLEMPS=DTX.SDTXMAPS(DTXAETXT) <== ALLEMPS FILE
// SET CLASS=*                      <== SYSOUT CLASS
//*
//*
//** NOTE: If the LE runtime library is not in the MVS LINKLIST,
//**        the LE runtime library must be added to the STEPLIB
//**        concatenation.
//*
//***** This job will execute the sample SINKMAP map using the
//** Transformation Extender Command server program.
//** The map output is directed to sysout.
//*
//DTX EXEC PGM=DTXCMDSV,REGION=48M,

//          UNIT=SYSDA,SPACE=(TRK,(20,1),RLSE)
*/

```

Schema errors

Each card in the map specifies a type and a schema. Schemas that are referenced by the map must be analyzed and saved. If you build a map, and a schema referenced by that map has not been analyzed, or it has been analyzed but produced at least one error, an error message displays.

You are not prevented from building the map. However, you may get unpredictable results when running the map. For example, if a group's components are not distinguishable, it is not clearly defined where one component ends and the next one begins. The data may not validate correctly.

A schema that has not been analyzed as error-free includes the following:

- A schema that was analyzed and produced at least one error.
- A schema that has been analyzed, but not saved.

Map build analysis errors

If build errors occur, view the errors, correct the problem(s), and build the map again. A map cannot be run if it has not been built.

Build results of a map provide information on errors and warnings that occur during the map build process.

During the map build process, the map and all of the functional maps that are referenced within that map are analyzed.

- Build errors prevent a map from being compiled
- Build warnings alert you of a condition that might be problematic.

You can ignore warnings to allow the map to be built even if there are warnings.

If you build a map and there are warnings, but no errors, the map is compiled.

Map build warning messages

A build warning alerts you about a potentially problematic condition. If you build a map with warnings, but no errors, the map is successfully compiled. You can ignore warnings.

Map build compile errors

Maps with compile errors may not be built. Maps that are not compiled may not be run.

For example, a compile error results when a map is built and the input contains a delimited group whose delimiter has not been specified. To correct this compile error, specify the delimiter in the schema, analyze it, and save the schema. Then build the map again.

Compiled map files

If no errors occur, invoking a **Build** option creates a compiled map file. The compiled map file is written to the location of the map source file (.mms). The name of the compiled map name is the source map name with a platform-appropriate file extension, or .mmc for a multi-platform map.

Note: If you have more than one executable map with the same name, make sure that you save the different map source files in different folders. A compiled map file is an input for the Command Server or Launcher. Running a map from a command line uses the compiled map file.

Running a map

When you run a map, the information in the compiled map file is used to create the output data.

To run a map, use the Map Designer, Launcher, Command Server, an integration or transformation server, or an API.

If you have a Launcher, use the Integration Flow Designer to configure maps to run.

You can run a map from within an application by using the TX programming interface. You can use the **RUN** function to run a map within another map. You can also run maps from any supported integration or transformation products with which IBM Transformation Extender is integrated.

- [Running in a multi-threaded environment](#)
You can run maps in a multi-threaded environment.
- [Run results](#)

Running in a multi-threaded environment

You can run maps in a multi-threaded environment.

- [Thread-safe map](#)
For a map to run optimally in a multi-threaded environment, when multiple occurrences of the map are instantiated, none of the resources that an individual instance of the map uses can be used by another instance of the map.
- [Verifying that the map meets basic thread-safe checks](#)
Before you run your map, you can verify that the map meets at least the basic thread-safe checks.

Thread-safe map

For a map to run optimally in a multi-threaded environment, when multiple occurrences of the map are instantiated, none of the resources that an individual instance of the map uses can be used by another instance of the map.

By default, map resources are managed. This helps facilitate the concurrent running of maps. However, you should specify unique names for the map's work files, audit logs, backup files, and trace logs, within each instance of the map.

Verifying that the map meets basic thread-safe checks

Before you run your map, you can verify that the map meets at least the basic thread-safe checks.

You can do some of the same checks of the map and card settings that these functions in the Design Studio do to find potential threading issues. Other map usages, such as when the map is working in a flow context, or if the map rules have the **RUN**, **GETANDSET**, or **PUT** functions, or if the **PUT** function has other overrides, might also cause threading issues.

Verify that the settings for the properties have specific values for map and card settings.

- [Map settings to optimize concurrent performance](#)
There are values for map settings properties that you can verify to optimize concurrent performance.
- [Card settings to optimize concurrent performance](#)
There are values for card setting properties that you can verify to optimize concurrent performance.

Map settings to optimize concurrent performance

There are values for map settings properties that you can verify to optimize concurrent performance.

Verify that the settings for the WorkSpace and AuditLocation properties for the map settings have these specific values.

Table 1. WorkSpace

Property	Value
WorkSpace	File or Memory
Directory	Map or Custom
WorkFilePrefix	Unique

Table 2. AuditLocation (If Switch is set to ON)

Property	Value
AuditLocation	File or Memory
Directory	Map or Custom
FileName	Unique

Card settings to optimize concurrent performance

There are values for card setting properties that you can verify to optimize concurrent performance.

Verify that the settings for the Backup properties for the card settings have these specific values.

Table 1. Backup (If Switch is set to ON)

Property	Value
BackUpLocation	File
Directory	Map or Custom
FileName	Unique

Run results

Run results are the input data used in the map and the output data generated by the map. The run results are the actual data as described by the data objects defined in the input and output cards.

Do not confuse run results with build results, which provide information about errors and warnings that occur during the map build process.

Map Profiler

The Map Profiler is a user-configurable utility that captures and reports map execution statistics.

The profiler focuses on component and mapping rules and the functions and types within those rules. The resulting information enables you to see where performance is lagging and in turn make improvements in your maps.

Map Profiler output

The profiler can capture the following statistics:

- Amount of time spent processing component and mapping rules and subordinate functions.
- Number of times rules and functions are executed (from validation through output).
- Number of times type objects are accessed.
- Depth (nesting level) of the object being profiled.
- [Configuring the Map Profiler in the Design Server UI](#)
Configure the Map Profiler in the Design Server UI:
- [Map Profile Settings](#)
To run a map using the Map Profiler utility to capture and report map execution statistics, you must configure the Map Profile settings in the Map Profile window as follows:

Configuring the Map Profiler in the Design Server UI

Configure the Map Profiler in the Design Server UI:

1. Open the project in Design Server UI.
2. Go to Maps and open a map that you want to build using Map Profiler utility.
3. Click the Build button on the top right corner to build the map.
4. Click the Profile Map button on the top right corner.
The Map Profile window displays.
5. In the Map Profile window, enable a Function Times option or a Type Times option to see statistics in the output (Otherwise the report will be empty).
You can also configure the settings to view more statistics, see "Map Profile Settings", for more details.
6. Click OK to run the map using the Map Profiler utility to capture and report map execution statistics.
The Profiler window opens with a full report with Download, Open New Tab and Search options. A full report contains both function and type information.
7. Click the Download button to download the map profile report.
Note: If the map profile report is big and exceed the expected limit, you cannot see the report in the Profile window. To see the map profile report, you must download it using Download button.
8. Click the Open New Tab button to see the map profile report in new tab.
9. Search the required content using Search option.

Map Profile Settings

To run a map using the Map Profiler utility to capture and report map execution statistics, you must configure the Map Profile settings in the Map Profile window as follows:

Function times

Enable the All or Above option to view function time statistics in the profiler report.

Table 1. Function times

Option	Description
--------	-------------

Option	Description
None	(Default setting) When None is enabled, function time statistics are not reported.
All	When you select All, each function and each function call is provided in the profiler output. Every occurrence of every function is displayed with the depth (level), number of iterations, elapsed time, map name, and type name.
Above	Use the Above option to obtain a smaller output file. When you specify a value in 1/10 milliseconds (10000 = 1 second), function times are only recorded when they exceed that value. You can reduce profiler output by specifying a time limit so that nothing is reported until it exceeds the time limit that you specify.
Summary	When you choose the Summary option, the report contains a summary for each function instead of listing every occurrence. A function is listed once with the total number of iterations and total elapsed time for all iterations.

Type times

Enable the All or Above option to view type time statistics in the profiler report.

Table 2. Type times

Option	Description
None	(Default setting) When None is enabled, function time statistics are not reported.
All	When you select All, each type per rule is provided in the profiler output. For each rule, the time, map name, and type name are reported.
Above	Use the Above option to obtain a smaller output file. When you specify a value in 1/10 milliseconds (10000 = 1 second), types times are only recorded when they exceed that value. You can reduce profiler output by specifying a time limit so that nothing is reported until it exceeds the time limit that you specify.
Summary	When you choose the Summary option, the report contains a summary of types per rule. A type name is displayed once with the total number of iterations and total elapsed time for those iterations.

File output

Table 3. File output

Option	Description
Fixed Width	This option produces a readable, flat file output.
Comma Delimited	This option produces a comma-delimited output which is useful for exporting to spreadsheet programs.

Map performance

You can use the Map Profiler to analyze map execution behavior.

- [Map Profiler overview](#)
- [Map Profiler output](#)

- [Profiler preferences](#)
Use the Profiler preferences to configure the default Map Profiler utility settings.
- [Command line](#)
- [Using the Map Profiler](#)
- [Profiler output example](#)
- [Profiler summary report example](#)
- [For best results...](#)

Map Profiler overview

The Map Profiler is a user-configurable utility that captures and reports map execution statistics. The profiler focuses on component and mapping rules and the functions and types within those rules. The resulting information enables you to see where performance is lagging and in turn make improvements in your maps.

For example, in the profile report you see that the processing time for a **LOOKUP** function is significantly more than other functions. You can modify the rule to use a better choice, such as the **SEARCHUP** function (because in this specific case the data in the **LOOKUP** is ascending), and as a result the processing time is greatly reduced.

Map Profiler output

The profiler can capture the following statistics:

- Amount of time spent processing component and mapping rules and subordinate functions.
- Number of times rules and functions are executed (from validation through output).
- Number of times type objects are accessed.
- Depth (nesting level) of the object being profiled.
- [Type names](#)
- [Function times](#)
- [RUN maps](#)

Type names

Similar to the map trace file, the type names referred to in the profile output represent the full type name in the original schema, not that of the type object that is visible in the Map Designer.

Function times

The processing time of any subfunctions rolls up into the processing time of the top level function. For example, if an EITHER function contains an IF function, the recorded time for the EITHER function would include the processing time of the IF function.

RUN maps

When a parent map contains a RUN map, the RUN map is not profiled. To profile a RUN map, it must be done outside of the RUN rule. (You can do this by running it as a top level executable map.)

Configuring the Map Profiler

The profiler can be configured and invoked from the Map Designer interface or from the command line.

From the Map Designer interface, you can enable or disable the profiler from the Map menu or the toolbar. Before running the map, you must open the Map Profiler options and enable either the **Function Times** option or **Type Times** option to see statistics in the output (otherwise the report is empty).

Profiler preferences

Use the Profiler preferences to configure the default Map Profiler utility settings.

Before profiling a map, you must enable a **Function Times** option or a **Type Times** option to see statistics in the output, otherwise the report is empty.

To access user preferences, click Window > Preferences > Transformation Extender > Map > Profiler.

To run a map using the Map Profiler utility to capture and report map execution statistics, you must configure the profiler settings in the Map Designer for the following profiler options:

Function times

Enable the **All** or **Above** option to view function time statistics in the profiler report.

Option	Description
None	(Default setting) When None is enabled, function time statistics are not reported.
All	When you select All, each function and each function call is provided in the profiler output. Every occurrence of every function is displayed with the depth (level), number of iterations, elapsed time, map name, and type name.
Above	Use the Above option to obtain a smaller output file. When you specify a value in 1/10 milliseconds (10000 = 1 second), function times are only recorded when they exceed that value.
Summary	When you choose the Summary option, the report contains a summary for each function instead of listing every occurrence. A function is listed once with the total number of iterations and total elapsed time for all iterations. Sample report .

Type times

Enable the **All** or **Above** option to view type time statistics in the profiler report.

Option	Description
None	(Default setting) When None is enabled, type time statistics are not reported.
All	When you select All, each type per rule is provided in the profiler output. For each rule, the time, map name, and type name are reported.
Above	Use the Above option to obtain a smaller output file. When you specify a value in 1/10 milliseconds (10000 = 1 second), types times are only recorded when they exceed that value.
Summary	When you choose the Summary option, the report contains a summary of types per rule. A type name is displayed once with the total number of iterations and total elapsed time for those iterations. Sample report

File output

Option	Description
Fixed Width	This option produces a readable, flat file output.
Comma Delimited	This option produces a comma-delimited output which is useful for exporting to spreadsheet programs.

Command line

The dstxprof console application enables you to profile maps from the command line.

See the Utility Commands documentation for information about using the dstxprof utility.

Using the Map Profiler

To profile a map:

1. Select a map and click Map>Enable Profiler.
2. Build and run the map.
3. Open the Organizer and select the Profile tab to view results.

You can also open Map Profiler results in a text editor from the map directory. The filename is a combination of the map name and a "PROF" extension. For example, *map_name.MPROF*.

Profiler output example

A full report contains both function and type information. The Profiler produces the following output when you run a full report against the sinkmap.mms file that is installed in *install_dir\examples\general\map\sinkmap* directory:

```
Profiling for install_dir 9.0.0\examples\general\map\SINKMAP\sinkmap.mmc
Total entries: 66
Total map sets: 1

Individual function breakdown

For best results...

- If you have a large amount of data, the profiler output could be very large or unmanageable. For this reason, it is best to profile only a subset of the original data.
- You can reduce profiler output by specifying a time limit so that nothing is reported until it exceeds the time limit that you specify. See section "[Configuring the Map Profiler](#)" for details.
- When running the profiler, always limit or terminate other processes running on your machine to avoid adverse results.

Managing invalid data

You can map invalid data to an output, just like any other data. For example, you can place all invalid data in a separate output for editing or debugging purposes. You can map invalid data to an error report.

To map invalid data, it must be contained in a valid object. A map does not run unless all input card objects are valid. For example, if you want to map an invalid purchase order in a file of many purchase orders, the file itself must be valid.

- [Using the Restart Attribute](#)
- [Using the REJECT function](#)
- [Using the ISERROR function](#)
- [Using the CONTAINSERRORS function](#)

Using the Restart Attribute

To map invalid data of a particular object, assign the **Restart** attribute at the component level. Errors must be ignored for invalid data objects during validation. You can then map the invalid data using any or all of the error functions **REJECT**, **ISERROR**, and **CONTAINSERRORS**.

IBM Transformation Extender information, including the **Restart** information, is stored in temporary, read-only native schema (.mtx) files. These files have the same name as the native schema, but with the .mtx extension. Any changes to schemas referenced in these .mtx files might cause the process that maps items from the schema, to update the .mtx file, and remove the **Restart** information that was stored there. If this occurs, or if the file gets deleted, you must recreate the **Restart** attribute by right-clicking the type in the card, and clicking Restart.

For additional information about the **Restart** attribute, see the Type Designer documentation.

Using the REJECT function

To map invalid data, use the **REJECT** function. The **REJECT** function is used in conjunction with the restart attribute. The **REJECT** function operates on an invalid data object contained within a valid object. The output of the **REJECT** function is a series of text items.

The syntax of the **REJECT** function is the following:

```
REJECT (component_with_restart_attribute)
```

Use the **REJECT** function with expressions that map valid data. For example, you can generate an error report that contains the invalid input data, in addition to the valid company name and date from the input.

Using the ISERROR function

You may conditionally map data based on whether or not a certain object is invalid using the **ISERROR** function. The **ISERROR** function has one input argument and returns a boolean value. It returns "true" if the argument is invalid or returns "false" if the argument is valid.

The **ISERROR** function is used with the **Restart** attribute. The **ISERROR** function operates on an invalid data object contained within a valid object.

In this input file of four customers, the third customer record is invalid:

```
Gisela,1252 S. Broward/Ft. Lauderdale,523-2622,22  
Dede,1513 Palatine Rd./Boca Raton,252-6560,86  
Lewis,74099 S. 67th Ave/Ft. Lauderdale,332-8665,3,3  
Eric,6933 Main St./South Miami Beach,291-7281,56
```

To generate a report that indicates whether each customer object is valid, assign a **Restart** attribute to **Customer(s)** in the input.

The output report is composed of **Line(s)**, where **Line** is defined as a text item. The map rule on **Line** uses the **ISERROR** function to check whether **Customer** is invalid. If **Customer** is invalid, the result is **INVALID Customer Data** and the **REJECT** of **Customer**. If **Customer** is valid, the result is **GOOD Customer Data** and the **TEXT** conversion of the **Customer** object itself.

Using the **CONTAINSERRORS** function

You may not want to map the input data if it contains any invalid data. In this example or situation, use the **CONTAINSERRORS** function. The **CONTAINSERRORS** function has one input argument that is the name of the object you want to test. The **CONTAINSERRORS** function returns "true" if the argument contains any invalid object or returns "false" if the argument does not contain any invalid object.

The **CONTAINSERRORS** function only operates on a valid object.

For example, if you have the same input file as in the example above, the third **Customer** record is invalid. You are mapping the input to the output file of **CustomerEntry(s)**. If the entire input contains any invalid object, do not produce any output. If the entire input is valid, map the **Customer(s)** to **CustomerEntry(s)**, using the functional map **MakeEntry**.

The map rule on **CustomerEntry(s)** uses the **CONTAINSERRORS** function to check if the entire **List** contains any errors. If **List** contains an error, no output is produced. If **List** does not contain errors, the **Customer(s)** will be mapped to **CustomerEntry(s)**.

The result is no output, because **List** does contain an error - the third **Customer** record is invalid.

Map audit overview

A map audit log is created when a map is executed. The log information is based on a particular map and provides information about map execution, map settings, card settings, and specific data objects. Map audit logs are in XML format and the contents can be mapped in such a way as to provide performance statistics and information about the content of your data.

- [Audit log contents](#)
- [Data settings in the audit log](#)
- [Map settings in the audit log](#)
- [Mapping from the audit log](#)

Audit log contents

A map can be configured to produce a map audit log consisting of the following:

- Execution statistics in summary or burst mode
- Burst information
- Map settings
- Data settings
- Data content information
- [Controlling audit log content](#)
The map settings that control the map audit. You can also specify audit options from the command line. See Execution Commands documentation for command options. The audit log can be stored in a file or returned in memory if you use the **RUN** function or an API.
- [Execution summary in the audit log](#)
- [Elapsed execution time in the audit log](#)
- [Source data report by card](#)
- [Target data report by card](#)
- [BurstAudit Data in the audit log](#)
- [Data content information in the audit log](#)

Controlling audit log content

The map settings that control the map audit. You can also specify audit options from the command line. See Execution Commands documentation for command options. The audit log can be stored in a file or returned in memory if you use the **RUN** function or an API.

Execution summary in the audit log

The MapAudit Switch = On and the SummaryAudit Execution = On map settings produce an audit log with execution summary information. The **ExecutionSummary** element of the audit log provides performance data for the map as a whole.

Execution summary information includes:

- Map status information
- Compiled map name
- Map return code
- Number of input objects found
- Elapsed execution time
- Number of output objects built
- Burst restart count
- Source data report by card
- Map return code message
- Target data report by card
- Work area information by card

The format of the elapsed time is presented differently on Windows platforms than on non-Windows platforms.

Some information is optional, and does not always appear in the **ExecutionSummary** element of the audit log. For example, information about objects found and built is provided only when using a command engine. **WorkArea** data is provided only when a work area is used during map processing.

Elapsed execution time in the audit log

The execution audit log records the elapsed time. The elapsed time format is presented differently on Windows platforms than on non-Windows platforms.

- On Windows platforms, the elapsed time of map execution is described to four decimal places.
- On non-Windows platforms, the elapsed time of map execution is presented in whole seconds only (rounded).

Source data report by card

In the audit log, the source data report by card provides information on:

- Value of the adapter **Source** card setting
- Source data byte count
- Adapter return code and message
- Adapter command line or file path
- Data source time stamp
- [Validation Errors in the Source Report Section of the Audit Log](#)

Validation Errors in the Source Report Section of the Audit Log

The Message section of the Source Report documents the validation errors generated by the engine for each card. This functionality enables users to conveniently review the validation errors after executing the map. It is essential to clarify that the recording of these error messages in the audit log does not require the enabling of engine trace.

To enable the audit option that reports the validation errors, in the Map audit settings set the SummaryAudit.Execution to Always, OnError or OnErrorOrWarning.

The number of error messages can be regulated through a setting in the config.yaml configuration file:

```
runtime:  
  validationErrors:  
    maximumCount: 20
```

The default value for this parameter is set at 20. If you wish to deactivate validation error reporting, simply set this configuration parameter to zero.

The following is a sample of the map audit when the validation fails for a choice group. SourceReport sections shows three validation error messages. The choice group had three types and all failed to validate.

```
<ExecutionSummary MapStatus="Error" mapreturn="8" ElapsedSec="0.0018" BurstRestartCount="0">  
  <Message>One or more inputs was invalid</Message>  
  <CommandLine>C:\maps\validationerrors\choicegroups\fix_tag.mmc</CommandLine>  
  
<SourceReport  card="1"    adapter="File"    bytes="6"    adapterreturn="0">  
  <Message>  
    Data read successfully  
    Data at offset 4 of size 1 failed RESTRICTION check for text [relative_size valid_values IOIQty Tag FIX]  
    Data at offset 4 of size 1 failed item presentation test for number [qty float DataTypes FIX]  
    Data at offset 4 of size 1 failed RESTRICTION check for text [a_b_or_c valid_values IOIQty Tag FIX]  
  </Message>  
<Settings>C:\maps\validationerrors\choicegroups\fix_tag_all_3_invalid.inp</Settings>  
<TimeStamp>2024-01-04T18:36:13Z</TimeStamp>
```

```
</SourceReport>
<WorkArea type="Memory">
<inputarea card="1" bytes="131344"/>
</WorkArea>
```

In addition to messages describing the validation error, the last known data that was correctly validated can be reported. In order to enable this message, user needs to set in the config.yaml file:

```
runtime:
  validationErrors:
    lastFound: true
```

The default value for lastFound is false. If the lastFound option is set to true, the example map audit file looks like:

```
<ExecutionSummary MapStatus="Error" mapreturn="8" ElapsedSec="0.0058" BurstRestartCount="0">
  <Message>One or more inputs was invalid</Message>
  <CommandLine>test.mmc</CommandLine>

<SourceReport card="1" adapter="File" bytes="91" adapterreturn="0">
  <Message>
    Data read successfully
    Data at offset 62 of size 0 is INVALID data for text [lastname textblobs Root] (A required object is missing.)
    Data at offset 89 of size 0 is INVALID data for text [lastname textblobs Root] (A required object is missing.)
    Data at offset 86 of size 2 was last found to be number [month textblobs Root]
  </Message>
  <Settings>inout.txt</Settings>
  <TimeStamp>2024-06-10T14:05:11Z</TimeStamp>
</SourceReport>
```

The last message points to the offset and size of data that was last found to be valid.

If the Audit data type validation is enabled on output cards, the engine validation errors audit report is not supported.

Target data report by card

In the audit log, the target data report by card provides information on:

- Value of the adapter **Target** card setting
- Target data byte count
- Adapter return code and message
- Adapter command line or file path
- Data target time stamp
- [Work area information by card](#)
- [Execution summary audit log sample](#)
- [BurstAudit execution in the audit log](#)

Work area information by card

In the audit log, the work area information includes:

- Work area type (file or memory)
- Work area file name and time stamp if applicable
- Work area byte count

Execution summary audit log sample

The following is a sample of the execution summary portion of the audit log.

```
<ExecutionSummary MapStatus="Valid" mapreturn="0" ElapsedSec="0.0373" BurstRestartCount="0">
  <Message>Map completed successfully</Message>
  <CommandLine>'install_dir\examples\CallsSummary.mmc'</CommandLine>
  <ObjectsFound>18</ObjectsFound>
  <ObjectsBuilt>12</ObjectsBuilt>
<SourceReport card="1" adapter="File" bytes="52" adapterreturn="0">
  <Message>Data read successfully</Message>
  <Settings>install_dir\examples\stores.txt</Settings>
  <TimeStamp>18:10:04 December 26, 2000</TimeStamp>
</SourceReport>
<SourceReport card="2" adapter="File" bytes="69" adapterreturn="0">
  <Message>Data read successfully</Message>
  <Settings>install_dir\examples\CALLS.TXT</Settings>
  <TimeStamp>18:10:04 December 26, 2000</TimeStamp>
</SourceReport>
<TargetReport card="1" adapter="File" bytes="119" adapterreturn="0">
  <Message>Data written successfully</Message>
  <Settings>install_dir\examples\summary.txt</Settings>
  <TimeStamp>10:14:34 April 27, 2001</TimeStamp>
</TargetReport>
```

```

<WorkArea type="File">
<inputarea card="1" Path="install_dir\examples\CallsSummary.I01"
TimeStamp="10:14:34 April 27,
2001" bytes="65695"/>
<inputarea card="2" Path="install_dir\examples\CallsSummary.I02"
TimeStamp="10:14:34 April 27,
2001" bytes="65695"/>
<outputarea card="1" Path="install_dir\examples\CallsSummary.O01"
TimeStamp="10:14:34 April
27, 2001" bytes="65695"/>
</WorkArea>
</ExecutionSummary>

```

BurstAudit execution in the audit log

The MapAudit Switch = On and the BurstAudit Execution = On map settings produce an audit log with burst execution information. The burst element provides information on the performance of the burst.

- If all input cards have the **FetchAs** mode of **Integral**, there is one burst element in the audit log.
- If any input card has the **FetchAs** mode of **Burst**, there is one element for each burst.

The execution log contains the return code of the burst, the amount of time it took to process the burst (in seconds), and a status of each input and output. The input and output status include the card number, the bytes processed, the adapter return code, and the content return code.

For example, if a burst fails because an adapter could not connect, the audit log defines which adapter failed. If an input is invalid, the content return code specifies which input is invalid. If an output rule fails, the content return code tells you which output failed.

A sample of the burst audit execution information in the audit log is:

```

<Burst count="1">
<ExecutionLog burstreturn="0" ElapsedSec="0.0118">
<inputstatus card="1" bytes="52" adapterreturn="0" contentreturn="0"/>
<inputstatus card="2" bytes="69" adapterreturn="0" contentreturn="0"/>
<outputstatus card="1" bytes="119" adapterreturn="0" contentreturn="0"/>
</ExecutionLog>
</Burst>

```

BurstAudit Data in the audit log

The MapAudit Switch = On and the BurstAudit Data = On map settings produce an audit log with burst audit data information. The burst audit data information includes a burst count, the card number, the object index, the audit log status code, the object level, the size of the object, and the object name.

A sample of the burst audit data information is:

```

<Burst count="1">
<DataLog>
<output card="1">
<object index="1" level="1" size="24" status="V00">Text1 Field</object>
</output>
</DataLog>
</Burst>

```

Data content information in the audit log

You can audit input and output data. The data audit settings determine what information about the data is written to the audit log.

Auditing data keeps track of specified objects in the input(s) and/or output(s) of a map. The burst audit data information in the audit log can track every occurrence of a record in a file and record the total count of records.

In the resulting audit log, the **<DataLog>** section follows the **</Burst>** tag. Within **<DataLog>**, there is an entry for the first input card. Within the input entry, there is an entry for each occurrence of the object.

If item data is specified in an audit setting, and the item is to be interpreted as binary, the line following the object line has the start tag **<Hex>** and the data is presented as pairs of hex digits for each byte.

In the audit log, the **<DataLog>** section follows the **</Burst>** tag. Within **<DataLog>**, there is an entry for the first input card. Within the input entry, there is an entry for each occurrence of the object.

If item data is specified in an audit setting, and the item is to be interpreted as binary, the line following the object line has the start tag **<Hex>** and the data is presented as pairs of hex digits for each byte.

Data settings in the audit log

The MapAudit Switch = On and the SettingsAudit Data = On map settings produce an audit log with input and output card setting information. Data settings are defined on the input and output cards of a map and include:

- Card number
 - Input card mode (as defined with the **FetchAs** card setting)
 - **WorkArea** reuse setting
 - Backup card settings
 - Source and target adapter settings
 - Transaction settings
 - Resource details
 - Retry settings
 - [Data settings in the audit log sample](#)
-

Data settings in the audit log sample

```
<DataSettings>
<InputData card="1" CardMode="Integral" WorkArea="!Reuse">
  <Backup switch="OFF"></Backup>
  <Source adapter="File" OnSuccess="Keep" OnFailure="Rollback" Scope="Map"
Warnings="Ignore">
    <Resource>install_dir\examples\stores.txt</Resource>
    <Retry switch="OFF"></Retry>
  </Source>
</InputData>
<InputData card="2" CardMode="Integral" WorkArea="!Reuse">
  <Backup switch="OFF"></Backup>
  <Source adapter="File" OnSuccess="Keep" OnFailure="Rollback" Scope="Map"
Warnings="Ignore">
    <Resource>install_dir\examples\CALLS.TXT</Resource>
    <Retry switch="OFF"></Retry>
  </Source>
</InputData>
<OutputData card="1">
  <Backup switch="OFF"></Backup>
  <Target adapter="File" OnSuccess="Keep" OnFailure="Rollback" Scope="Map"
Warnings="Ignore">
    <Resource>install_dir\examples\summary.txt</Resource>
    <Retry switch="OFF"></Retry>
  </Target>
</OutputData>
</DataSettings>
```

Map settings in the audit log

The MapAudit Switch = On and the SettingsAudit Map = On map settings produce an audit log with map setting information.

Map settings include:

- Map audit settings
- Map trace information
- Paging scheme
- Validation specifications
- Audit log location
- Work space information
- Century information

Map settings are viewable in the audit log:

```
<MapSettings>
<MapAudit switch="ON">
  <Log execution="OFF" data="OFF" mapsettings="ON" datasettings="OFF"/>
  <Location type="File" action="Create">
    <Directory type="Map">install_dir\examples</Directory>
    <FileName type="Default" prefix="MapName">CallsSummary.log</FileName>
  </Location>
</MapAudit>
<MapTrace switch="OFF"></MapTrace>
<WorkSpace>
  <Location type="Memory">
  </Location>
  <Paging>
    <PageSize>64</PageSize>
    <PageCount>8</PageCount>
  </Paging>
</WorkSpace>
<SlidingCentury switch="OFF"></SlidingCentury>
<CustomValidation switch="OFF"></CustomValidation>
<Retry switch="OFF"></Retry>
<BurstRestart switch="OFF"></BurstRestart>
<Warnings type="Every" action="Warn"></Warnings>
</MapSettings>
```

Mapping from the audit log

Mapping information from the audit log can provide useful performance statistics and information about the content of your data. For mapping purposes, the tryaudit.mtt schema provided in the **examples** directory defines the audit log data objects.

The format of the audit log is XML-based to enable use with other applications. The audit log is defined as a series of **MapAudit** elements. Each **MapAudit** element represents the log data for one map instance. You can get audit data for many map instances when the **AuditLocation** map setting for **FileName Action = Append**.

The **MapAudit** general element in the input card shown below displays the sequence of the information in the audit log.

- [ExecutionSummary in the Tryaudit schema](#)
- [Configuring data audit](#)
- [Status codes in the audit log](#)

ExecutionSummary in the Tryaudit schema

The audit log is created for a specific map. During map execution, after all bursts complete, the status of the map is summarized in the **ExecutionSummary**. The **ExecutionSummary** element in the audit log provides performance data for the map as a whole. This information appears in the audit log when the **SummaryAudit_Execution** map setting = **ON**.

Open *install_dir\examples\general\audit\tryaudit.mtt*, where *install_dir* refers to the path where IBM Transformation Extender is installed, to view the structure of **ExecutionSummary**.

The **ExecutionSummary** element contains:

- Map status
- Map return code
- Amount of map processing time
- **BurstRestartCount** indicator of how many times a burst restart occurred
- Return message for the map
- Command line that was used to re-configure any options compiled in the map
- Report for each source and target
- Work-area data

Summary information provides performance data for the map as a whole. For example, summary information might include the fact that all bursts succeeded, but the map failed because **Scope** was set to **Map**, and an adapter failed.

Summary source and target reports the adapter used for each, the total number of bytes processed over all bursts, and the final adapter return code.

Configuring data audit

Use the Data Audit Settings tab in the Organizer window to specify what information about the data to include in the audit log. Audit logs are for a single map.

To specify that you want to audit a particular object, drag that object from a card into the **Data Audit Settings** tab.

To audit a particular data object:

1. For the specific map with cards that contain the data object, define the **MapAudit** map settings in the Map Settings dialog box:
 - **MapAudit > Switch = On**
 - **BurstAudit > Data = On**

2. On the Map menu, click **Organizer**.
The **Organizer** window is displayed.

3. Drag the data object from the card into the **Audit** field on the Data Audit Settings tab.
4. From the **Track** list, select what information to track.
5. From the **Detail** list, select what information to report about the object's nested components.
6. If possible, from the **Item Data** list, specify when to show the item data of that object.

Data audit settings are compiled into the map file. If you change the audit settings in a map, you must build the map again for those settings to take effect.

The name of an object in the Data Audit Settings tab is the complete object name. Names are not entered with ellipses, even if the **Use Ellipses** option is enabled.

- [Detail](#)
- [Item data](#)

Detail

In the **Detail** list on the Data Audit Settings tab in the Organizer window, specify what information to include about an object's nested components.

Value

Description

Occurrence

A line appears in the audit log for each occurrence of that object of each nested component.

Warning

A line appears in the audit log for any nested component that causes a warning.

Error

A line appears in the audit log for any nested component that causes an error.

None

No information about nested components is included for that particular object.

Item data

In the **Item Data** list on the Data Audit Settings tab in the Organizer window, specify what actual *data* to show in the audit log. This applies to all items nested within the tracked object.

Value

Description

Occurrence

The data of each nested item within that object appears in the audit log.

Warning

The data of each nested item within that object that causes a warning appears in the audit log.

Error

A line appears in the audit log for each nested item within that object that causes an error.

None

No information about nested components is included for that particular object.

Status codes in the audit log

The status attribute in the Audit Log is a letter followed by a code number. The letter of the status attribute tells whether the data is valid V, or caused an error E, or caused a warning W.

Troubleshooting

There are various methods of troubleshooting that can assist you in situations where when running a map, the following types of errors occur regarding input or output data:

- Data is invalid
- Data contains invalid objects
- Unknown data exists

About data validation

When you run a map, the first thing that happens is the input data is validated by comparing the data to its definition in the schema. After validating data, the output card map rules are evaluated, and the output objects are built.

If you run a map and invalid or unknown input data is encountered, you can analyze what happened during the validation process. In addition, you can analyze the output data.

- [Run results](#)
- [Audit log](#)
- [Customized validation settings](#)
- [Map Debugger](#)
- [Trace files](#)

Overview of debugging aids

If you run a map and get a runtime error, or you do not get the expected output, use any or all of the following debugging tools:

- [Command Server window](#)
- [Run results](#)
- [Audit Log](#)
- [Customized validation settings](#)
- [Map Debugger](#)
- [Trace files](#)

Command Server window

After a map is run, a runtime message appears in the Command Server window. This message provides information about the map.

For example, the message "Map completed successfully" indicates that all inputs are valid. However, you might see the message "One or more inputs was invalid"- indicating that an input card object is invalid.

The message "One or more inputs was invalid" can occur even if you are absolutely sure that the input data is valid. In that case, there may be an error in the data definitions in the Type Designer. For example, if you mistakenly defined an item to be an integer but the data is actually a decimal number, that data object is considered invalid because it does not match its type definition. In general, when data is diagnosed as "invalid", either the data is invalid or the type definition is incorrect.

The Command Server window also displays the progress of the data being mapped. For example, you can see when input objects are found and when output objects are built.

Run results

Run results are the input data used in the map and the output data generated by the map. The run results are the actual data as described by the data objects defined in the input and output cards.

By viewing the results of a map execution, you can gain important information about how the data was mapped. For example, when no output objects are built, your input data might be invalid. Or, if you see only a portion of the output data, your input data might be valid but it could contain unknown data.

For more information about run results, see "[Run results](#)".

Audit log

The audit log stores the information about your data that you specify from within the map settings. For example, you can specify that the audit log only records failure information.

For a details about using the audit log, see the Map Audit topic.

Customized validation settings

Another way to troubleshoot a map is to customize the validation settings. Validation can be set to ignore certain aspects of the data during validation by setting custom options in the **Validation** map settings.

For example, you can choose that the validation process ignores item restrictions. This means that even if an item has restrictions defined, the restrictions are not considered when that item is validated.

Map Debugger

The debug functionality in the Map Designer can assist you in creating and troubleshooting maps. Use the Map Debugger when you have narrowed a problem down to a certain object or function call. For example, when you know that an object is not producing the correct output.

The map debug functionality allows you to break the execution of a map and inspect the current object values (both input and output objects) used within the currently executing output rule.

You cannot use the Map Debugger when the Map Profiler is enabled.

By enabling the Map Debugger, you can do the following:

- Identify breakpoints.
 - Step through rule execution.
 - View object values at a rule level.
- [Breakpoints](#)
 - [Rule execution](#)
 - [Viewing object values at a rule level](#)
 - [Running the Map Debugger](#)
 - [Remote debugging](#)

You can also use the Map Debugger to debug maps that run remotely on the supported operating systems.

Breakpoints

You can set breakpoints on the output objects of functional and executable maps.

- [Saving breakpoints](#)
- [Conditional BreakPoints](#)

To add a breakpoint

You can only add a breakpoint when the Map Debugger is enabled. See "[Running the Map Debugger](#)".

From an output card, right-click on an output object and select Add BreakPoint.
The output object rule with the breakpoint becomes highlighted.

To delete a breakpoint

Right-click on the output object and select Delete BreakPoint.

Saving breakpoints

When you save a map after adding breakpoints, the breakpoints are also saved. Therefore, the next time you open the map and enable the debugging option, the saved breakpoints will reappear. To remove the breakpoints, right-click on an object and select Delete All BreakPoints.

Conditional BreakPoints

You can configure the Map Debugger to stop on a specific iteration of a rule. For example, a rule repeats 99 times and the ninety-ninth occurrence is wrong. You can configure the Map Debugger to stop on the ninety-ninth iteration and subsequent iterations of the rule.

To set a conditional breakpoint:

1. Right-click on a card object and select Show BreakPoints.
The BreakPoints dialog box is displayed.
2. Select an object from the list and select Condition.
The BreakPoint Condition dialog box is displayed.
3. In the **Condition** field, select On Iteration.
4. In the **Value** field, enter a numeric value that represents the iteration of the rule that you want the Map Debugger to begin stopping at. For example, enter 99 for the Map Debugger to begin stopping on the ninety-ninth iteration of the rule.
5. Click OK.
When the map runs in this case, the Map Debugger stops at the ninety-ninth iteration of the rule and then every occurrence of the rule thereafter.

Rule execution

Starting from the first breakpoint, the debugging process can step through every rule on every card. The debugging process can step into functional maps and follow RUN maps that are defined within the same map source file (provided that the maps have been built with the Debug option turned on).

If any referenced functional maps or external RUN maps are found, the map enters step-over mode and stops at the end of the originating rule.

Viewing object values at a rule level

When processing a rule, the debugger displays relevant data. Relevant data is data that is read and written in the rule. The data currently being processed by a rule or function is displayed in the Debug Rule window.

The Rule editor in the Debug Rule window displays the current rule in a format of a hierarchical tree of objects, functions, and maps. At each breakpoint at which the map pauses, input and output values of objects, functions, and rules are shown.

Running the Map Debugger

When output from map execution is not what was expected, you can use the debug functionality to analyze each step of map execution.

To analyze map execution

1. In the Outline view, Composition view, Navigator view, or Extender Navigator view, select the specific map to debug.
 2. Click the Debug icon on the toolbar to enable debug mode.
 3. To set a breakpoint, right-click an output object and click Add BreakPoint on the context menu.
The object rule is highlighted in yellow or the color that you select in Preferences > Run/Debug.
 4. Build and run the map.
Map execution pauses when it encounters the object for which the break was positioned.
- The current rule is displayed in the Debug Rule window.
5. At this point, you can choose from the following options:
 - **Step In** to execute the next object or function in the rule. For objects, the current value appears. For functions, the output displays the result of the particular function.
 - At a rule level, the debug process proceeds to the next function or returns the value of the next object in the current rule.
 - At the function level, the object or map evaluated is updated, displaying the data that was returned.
 - At the object level, the value of the object is displayed.
 - At the function and map level, the result of the particular operation is displayed.
 - **Step Thru** to step through the rule until you recognize the problem. When the current rule executes the results are displayed. At a function level this option does not debug the remainder of the functions/objects in the rule.

- **Step Over** to move to the next rule in the current map.
 - **Continue** to continue map execution and stop at the next breakpoint if one exists, otherwise continue to the end of the map.
 - **Stop** to stop map execution. Execution will cease when all RUN maps have completed.
-

Remote debugging

You can also use the Map Debugger to debug maps that run remotely on the supported operating systems.

The following list includes the supported operating systems:

- HP-UX (Itanium processor)
- IBM® AIX® (RS/6000® processor)
- IBM z/OS®
- Linux® (Intel processor)
- Microsoft Windows
- Linux for Power Systems
- Linux for System z
- Sun Solaris (SPARC processor)

There are similarities between using the Map Debugger to debug maps that run locally on Windows, and remotely on the supported operating systems. You can set breakpoints on rules, inspect data during the transformation process, and use the same commands.

To use the Map Debugger, Design Studio (version 8.1 or later) is required on the local computer. Also, a minimum of Transformation Extender with Command Server (version 8.1 or later) must be installed on the remote computer where the executable map is run. The map must be built with version 8.1 or later of the Map Designer and then deployed to the remote computer.

On the remote computer, you must first start the debugging server (for example, with Telnet) before you can begin the debug process from the Map Designer. When you use Telnet, you can stop the debugging server by entering `Ctrl+C` in the Telnet command window.

- **Debugging a map remotely.**

These instructions assume that you have built a map using the Map Designer, version 8.1 or later, and have deployed the executable map file to the remote host.

Debugging a map remotely

These instructions assume that you have built a map using the Map Designer, version 8.1 or later, and have deployed the executable map file to the remote host.

Before you begin, access the remote host, for example, using Telnet, and set up your IBM Transformation Extender environment.

1. Start the debugging server by running the applicable file, located in the product installation directory:
 - `StartDebugServer.bat` (Windows)
 - `StartDebugServer.sh` (UNIX, z/OS UNIX)

By default, the debugging server uses port 2590. Specify `-PORT port_number` to use a different port. To resolve resource aliases while running a map under the debugger, use the `-MRC .mrc_file` option to specify the resource configuration file. For example, run `StartDebugServer -PORT 1234 -MRC MYALIASES.MRC`

To stop the debugging server, press `Ctrl+C`.

2. On the local computer, open the map source file for the remote executable map to be debugged.
3. In the Outline view, Composition view, Navigator view, or Extender Navigator view, select the specific map to debug.
4. Click the Debug icon on the toolbar to enable debug mode.
This also enables the Remote option.
5. Add one or more breakpoints to the output.
From an output card, right-click an output object and click Add BreakPoint.
6. Click Map>Remote.
The Remote Debugging window is displayed.
7. Under Remote Host, enter the remote computer information pertaining to the map to be debugged. In the Host field, enter the alias name or IP address of the remote computer. In the Port field, the default port number (2590) to be used by the debugging server is displayed.
8. Under Platform, select the platform of the remote host.
9. Under Security, enter a user name and password that provides access to the remote host where the executable map resides.
10. In the Map field, select the browse button and navigate to the executable map to debug.
11. Click OK to begin the remote debugging process.
Similar to the regular map debugging process, a Debug window is displayed from where you can select various options, such as Step In, Step Thru, Step Out, Step Over, or Continue, after a break point is reached.

Trace files

The trace file is a text or XML file that records the steps of map execution. You can use the information in the trace file to diagnose invalid data or incorrect type definitions.

- **Trace for general data**

The trace file records map execution progress. You can enable the trace option from the map settings or from the adapter command line. You can trace the input data, the output data, or both.

- **Static file validation and tracing**

Transformation Extender (TX) validates a static input file in a compiled map only once, when the map loads, and produces a trace file only if the static file fails validation. TX validates other map inputs each time the map runs, and logs them in the map trace file as specified by the map settings.

- **Trace for XML data**

- [Trace for XML parser errors only](#)

Related reference

- [MapTrace settings](#)

Trace for general data

The trace file records map execution progress. You can enable the trace option from the map settings or from the adapter command line. You can trace the input data, the output data, or both.

An input data trace file includes a message for each input data object. The trace file contains the sizes and counts of data objects, and the data object position in the data stream. If the data object is invalid, the trace file includes the reason the data is invalid.

Static input files produce a trace file only if the static input fails validation when the map loads. A map trace file describes a valid static input as a reused work file.

When output data is traced, the trace file specifies the objects that are built and the output objects that evaluate to `none`.

Because performance can be impacted, enable the trace option only during debugging.

- [Creating a trace file](#)

You specify the name and location of the trace file in the map settings. If you ran a map and got a message that an input was invalid, turn on the input trace only. If you got a message that an output was invalid, turn on the output trace only. If you trace both input and output, the input messages are at the beginning of the file, followed by the output messages.

Creating a trace file

You specify the name and location of the trace file in the map settings. If you ran a map and got a message that an input was invalid, turn on the input trace only. If you got a message that an output was invalid, turn on the output trace only. If you trace both input and output, the input messages are at the beginning of the file, followed by the output messages.

Trace file contents

A trace file of input messages contains a message for each input data object. A message gives a date and time stamp, describes the level of the object in the card, the offset of the data object in the data stream, the length of the data object in bytes, its component number, the index of the component, a portion of the actual data, and the name of the type to which it presumably belongs.

In the trace file, the symbol `\r` indicates a carriage return. The symbol `\n` indicates a linefeed.

The DI number and X number are not used for debugging purposes and can be ignored.

For example, shown below is trace message for the Name Data object. The length (`len`) of the data (`Nicole`) is 6 bytes.

```
18:22:17.837 Feb 13 2000
(Level 2: Offset 0, len 6, comp 1 of 2, #1, DI 00000001:)
Data at offset 0 ('Nicole') was found to be of TYPE
X'0004' (Name Data).
```

The level of an object indicates the position of the data object with respect to the entire card object. A card object has level 0; a component of the card object has level 1, and so on.

The trace file describes a static input card as a reused work file. See the static input card description for details.

Related concepts

- [Static input cards](#)

When data is valid

During data validation, a given data object is examined, and compared to its type definition. If a data object matches the type definition, the object is valid and the trace file indicates the object was found to be of that type. For example, in the trace message below, the data **Nicole** is a valid **Name** data object. It was found to be of the type **Name**.

```
18:22:17.837 Feb 13 2000
(Level 2: Offset 0, len 6, comp 1 of 2, #1, DI 00000001:)
Data at offset 0 ('Nicole') was found to be of TYPE
X'0004' (Name Data).
```

Group validation

A group is valid if the syntax is valid and all of its components are valid. A group is validated component-by-component. A component is valid if its type is valid, its component range is valid, and, if the component has a rule, the rule evaluates to "true".

When a component rule is evaluated, any invalid data used in a component rule is evaluated with a value of "none".

After all of the components of a group have been found, a message in the trace file indicates that the group itself was found.

For example, the components of **Row** are **Name** and **Phone#** and the data for **Row** is:

```
Nicole,352-2929
```

To find the object **Row** in the trace file, first the components of **Row** are found. The trace file contains a message for **Name**, then one for **Phone#**, and one for **Row**.

Valid card objects

If all of the objects that make up a card data object are found, the card object is valid. There is a trace message indicating this status. For example, if the data object for card 1 was valid, the trace message "INPUT 1 was valid" appears in the trace file. The message for a card object appears after all of the messages for the objects within that card.

For the Database object of an input card, the type **Database** is composed of **Row(s)**, and **Row** is composed of **Name** and **Phone#**.

The data for the entire input database is:

```
Nicole,352-2929
David,377-8098
```

In the trace file, there are messages for each **Row** and then there is a message for the entire card object, **Database**.

Invalid data

When a data object does *not* match the definition of the type to which it presumably belongs, it could be invalid.

Possible reasons for an invalid data object:

- Item value is not in restriction list
- Item failed the presentation test
- Item is the wrong size
- Data object has the wrong delimiter
- Data object has the wrong terminator
- Data object failed the component rule
- Group is missing a required component
- Group contains one or more invalid component(s)

Invalid card objects

If an entire card object is invalid, a runtime message appears in the Command Server window, indicating that the data is invalid. For example, if an input source is a file and the file is invalid, when the map is run, the message "One or more inputs was invalid" may appear.

If you trace the card containing the invalid object, a message in the trace file indicates that the card data object was invalid. If the data object of input card 1 is **File** and is invalid, the trace file would indicate this with the message "Input 1 exists, but it is invalid".

Prior to the message that the entire card object is invalid, there is an explanation of why it is invalid. For example, it might be that a required component of the card object is in error. The message about the invalid component will contain a negative word such as *not*, *failed*, *wrong*, or *invalid*.

Finding the important messages

The best way to read the trace file is to open it in a word processor and use the search facilities. The following tables explain the trace options to choose and what to look for in the trace file, based on the runtime message.

Table 1. Runtime message: One or more inputs was invalid

Limit trace to:	Read this in the trace file:
The summary	Read the card summaries to find out which card is invalid.
The invalid card	Start searching from the end of the trace file and look for the word <code>invalid</code> in the trace file.

Table 2. Runtime message: Input valid, but unknown data found

Limit trace to:	Read this in the trace file:
The summary	Read the card summaries to find out which card contains the unknown data.
The card containing the unknown data	Start searching from the end of the trace file, and look for the word <code>invalid</code> in the trace file.

Existence of data

When a certain data object is validated, determining the existence of that object occurs before fully validating all of the components within that object.

For example, if a data object is a partition and includes an initiator, as soon as the initiator is found, it is known that the data object exists. A message exists in the trace file, indicating that the data object is "known to exist."

The existence of a certain object can be determined if that object has certain properties. For a detailed explanation of how the existence of an object is detected, see the Type Designer documentation.

Example of existence of record objects

The following example shows how the existence of record objects can be determined. An input file is composed of records with three kinds of records: **A**, **B**, and **C**.

Record is partitioned into **A**, **B**, and **C**, the three types of records. Each record begins with a letter followed by an asterisk. The letter indicates the kind of record. This value is defined as the initiator for each record type. For example, an **A** Record begins with `A*`.

Shown below is the data:

A*couch,1
B*plate,12
A*chair,6
C*sweater,15
B*glass,8

Because the initiator partitions **Record**, as soon as the initiator of a given record is found, that record is known to exist.

Validation for invalid objects

If an object is determined to be invalid, and that object is known to exist, validation continues. For example, there was an error in the first **B Record**.

It is known that **B Record** exists. When **B Record** is found to be invalid, validation continues with the subsequent records.

If an object is *not* known to exist, the object is found as unknown data.

Unknown data

When input data is validated, additional data that does not validate as part of the input may also be found. This data is unknown data.

An example input is composed of **Product(s)** and **Product** is *not* defined with properties that allow its existence to be predetermined.

The second **Product** is invalid because the **Quantity** field is missing.

When the invalid **Product** is found, it is not known to exist. Therefore, it is assumed to be unknown data.

Sometimes a message about unknown data is not significant. You may get a message about unknown data because there are extra carriage returns or "junk" data at the end of an input file. You should read the trace file to determine whether all of the pertinent input data was found.

Negative messages not fatal

Sometimes validation of a given data object interprets the given data object as belonging to a type to which it does not really belong. In this situation, the data object will fail to belong to that type - but that is because the data does not belong.

In the following two situations, you may see messages that a data object fails to belong to a certain type because it is not really data of that type:

- When an optional occurrence of a component that does not exist in the data is sought during validation
- When an object of a partitioned type is sought during validation

Example of optional occurrences

If an occurrence of a component is optional, there may be more than one possibility for a given data object. For example, suppose a type has the following components:

A (1:3)

B

After **A** is found, the next object in the data stream can either be **A** or **B**. Suppose it is **B**. Therefore, the object fails to be **A**. A message in the trace file indicates that the object does not match the definition of **A** in some way. After the validation process has determined that the object is not **A**, validation occurs to determine whether it is **B**. Then the object is validated as **B**.

It is acceptable if an *optional* occurrence of a component does not exist in the data; it is optional. However, if a *required* occurrence of a component does not exist, the data object containing that component is invalid.

The optional **Message** is missing from the data. After finding the **Header**, the next data object searched for is **Message**. However, the next object in the data is not a **Message**, it is a **LineItem**.

The trace file indicates that the initiator of the data object is not **M** which is the initiator of a **Message**. After it is determined that the data object is not a **Message**, the **LineItem** is validated as a **LineItem**.

If you see a message in the trace file saying that a data object does not exist, this is not necessarily the error causing the entire input object to be invalid. Keep in mind the data being validated, and the optional data. Your understanding of optional data is important when reading the trace file.

Example of partitioned types

Another case in which a data object might fail to belong to a certain type is when the type is partitioned. If an object that is presumably a partition is validated, the validation process goes down the list of partitions to determine the partition to which the object belongs. You might see a message that indicates an object failed to be a certain partition. That means it does not belong to *that* partition, it may belong to one of the other partitions. The validation process checks to see whether it belongs to the next partition, and so on.

For example, suppose **Record** is partitioned into **A**, **B**, and **C**.

Each record begins with an initiator: **A***, **B*** or **C***.

First, validation checks the initiator to determine whether it is an **A Record**. The initiator will be the wrong value for an **A Record**. Next, validation checks the initiator to determine whether it is a **B Record**. The initiator will be the wrong value for a **B Record**. Next, validation checks to determine whether it is a **C Record** and the object is validated as a **C Record**.

Viewing results in hex mode

Run results can be viewed in hex mode, which displays the offset values of the data. This may be helpful if the trace file indicates a problem at a particular offset in the data. To view run results in hex mode, select the **Display In Hex Mode** check box in the **Run Results** dialog box.

Static file validation and tracing

Transformation Extender (TX) validates a static input file in a compiled map only once, when the map loads, and produces a trace file only if the static file fails validation. TX validates other map inputs each time the map runs, and logs them in the map trace file as specified by the map settings.

When a static input file fails validation, the map does not load. TX logs the validation error in the appropriate log for the runtime environment for example, the Launcher's CompoundSystem log or the IBM Integration Bus log. The error includes the location of the static input trace file. TX creates the static input trace file as *map_name.mtr* in the map directory. If the map loads from memory, TX creates the *map_name.mtr* file in the map working directory.

When a static input file fails validation on a z/OS® system running in batch, CICS® or IMS, the trace is written to the DD name DTX#TRCE. Because the trace is written as a byte stream, it lacks formatting if the DTX#TRCE is directed to SYSOUT. If formatting is required, direct the DD card to a zFS file. For example:

```
//DTX#TRCE DD PATH='/tmp/dtx#trce.mtr',
//          PATHDISP=(KEEP),
//          PATHOPTS=(ORDWR,OCREAT),
//          PATHMODE=(SIRWXU,SIRWXG,SIROTH)
```

When you trace a static input file and the static file passes validation, the map trace file describes the static input as an existing work file. For example, you might trace two map inputs. Input 1 is not a static file and the input is invalid. Input 2 is a static file that passed validation during load. The trace file includes messages similar to the following:

```
.
.
.

(Level 2: Offset 389, len 6, comp 3 of 3, #1, DI 000000000053:)
Data at offset 389 ('00000<CR>') is INVALID data of TYPE
  X'0012' (total_hours element example).

(Level 1: Offset 297, len 98, comp 1 of 1, #4, DI 000000000054:)
Data at offset 297 ('Work A.        ...') is INVALID data of TYPE
```

```

X'0003' (timesheet example).

(Level 0: Offset 0, len 396, comp 1 of 0, #1, DI 000000000055:)
Data at offset 0 ('FirstName      ...') is INVALID data of TYPE
X'0002' (all_employees example).

INPUT 1 exists, but its type is in error.

End of Validation messages for INPUT CARD 1.

Reusing an earlier work file for INPUT CARD 2.

End of Execution messages.

```

Trace for XML data

An XML-formatted trace file that contains XML validation information can be created during map execution for maps that contain XML schemas. When enabled, the XML trace file (*mapname_log.xml*) is generated in the map directory in addition to the general trace file. The XML trace file is not generated when no input card is present in the map.

For maps that contain XML schemas (created using Xerces), the input XML validation information that is generated to the regular trace file (.mtr) or that is viewable on the Trace tab of the Organizer is not valid. See the XML trace file (*mapname_log.xml*) for accurate XML input validation information.

When viewed with Microsoft Internet Explorer, the XML trace file:

- Contains a validation log.
 - Displays the XML validation sequence.
 - Presents validation results.
- When using a browser other than Microsoft Internet Explorer, only the content of the XML file is displayed.

Similar to the general trace, you must enable certain **MapTrace** settings to create an XML trace file.

- [Creating an XML trace file](#)
 - [XML validation log](#)
 - [Validation sequence](#)
 - [Validation results](#)
-

Creating an XML trace file

Enable certain **MapTrace** settings to create an XML trace file.

To create an XML trace file:

1. In the Extender Navigator view of the Design Studio, right-click the map that contains references to XML schema, and click Map Settings.
2. Set the MapTrace> Switch setting to ON.
3. Set the MapTrace> InputContentTrace setting to All.

After you run the map, the XML trace file is created. You can find the XML trace file (*mapname_log.xml*) in the map directory, unless otherwise specified. The file opens in your default browser. When you run the map again, the existing file is overwritten.

XML validation log

The Source tab displays the XML validation log. The XML validation log is a step-by-step representation of the XML validation process. This log presents the time of map execution, input file information, and other validation details.

Validation sequence

The Validation Sequence tab displays the reverted order in which the XML validation library identified the types from the XML input file.

The XML validation sequence can be useful in troubleshooting, for example, to see where (or on which type) the validation process stopped.

Validation results

The Validation Result tab displays the result of the XML validation process. When XML validation does not complete successfully, the applicable error messages are displayed. If map execution failed early in the validation process, this tab might not contain any information.

To locate the error, open the XML input file, go to the fourteenth line, and then 10 characters into the line.

The following XML code represents the XML input file for this example. The validation error is associated with **GenDate**. **GenDate** is required and there is no value present.

```

<?xml version="1.0" ?>
- <PO>
```

```

- <Header>
  <PONumber>C1234-3452545</PONumber>
  <PODate>08-08-01</PODate>
  <Contact Name="Darryl Brown" Phone="555-444-1212" />
- <Instruction Type="NONE">
  <Addressee>2000 E. Overlook Hwy</Addressee>
  <AddressLine />
  <City>Boca Raton</City>
  <State>FL</State>
  <Zip>33431</Zip>
</Instruction>
<GenDate />
</Header>
- <LineItem>
  <CatalogUPC />
</LineItem>
</PO>

```

Trace for XML parser errors only

At map run time, IBM Transformation Extender automatically generates an error log when an XML input file that the map is processing contains an XML error and the `DTX_XML_LOG_ON_ERROR=TRUE` environment variable is set. The error log file contains information about the XML parser error only. You can use the information to diagnose the invalid data or incorrect type definitions in the XML input file.

In distributed environments, the log file is called `wtxParserError_log.xml` and is created in the map directory. If the log file exists already, the error is appended to it.

In z/OS Batch environments, the log file is directed to the `DSTXXLOG` DD name.

Error and warning messages

- [Map execution error and warning messages](#)
- [Map execution warning messages](#)
- [Map build error messages](#)
- [Map build warning messages](#)
- [Map compile error messages](#)
- [Audit log status codes](#)

Map execution error and warning messages

After a map is executed, map execution messages indicate the execution results. If audit is enabled, these messages are also recorded in the appropriate audit log for the map.

The following list describes the codes and messages that can be returned as a result of running a map.

The return codes marked with an asterisk (*) are warning codes. See [Map Execution Warning Messages](#) for a consecutive list of the warning codes for a map.

The return codes marked with a dagger symbol (†) are those codes that, when returned from a failed WebSphere DataPower map, indicate that there are additional map failure causes specific to DataPower maps. See [Error messages for WebSphere DataPower maps](#) for a consecutive list of the error codes for a WebSphere DataPower map.

Return Code

Message

0	Map completed successfully
1†	User aborted map If you cancel the Server before the map completes, this message is displayed.
2	Not enough memory to execute map There is not enough memory to initialize the map. Try closing all other running applications.
3	Could not open map The .mmc file cannot be found. Ensure the file name or path is correct.
4†	Could not read map If you have ported your map and sent it with FTP to another platform, make sure you have done so using the BINARY option so the map's contents will not be corrupted.
5	Could not read inputs
6	Invalid map handle
7	Invalid card number was specified Your map may be corrupt.

- 8 One or more inputs was invalid
Turn the input trace on, run the map again and read the trace file.
- 9† Target not available
An incorrect file name or path for a target may be specified.
- 10† Internal error
- 11 Could not build one or more outputs
An attempt may have been made to write to a read-only directory, or an output file directory may be missing.
- 12† Source not available
An incorrect file name or command for a source may be specified.
- 13 Could not open work files
An invalid path for work files may be specified.
- 14* One or more outputs was invalid
A number produced an overflow condition. Enable the **Trace Output** option, run the map again, and read the trace file.
- 15 Map must be recompiled
You may be trying to run a map with a server that has a different version from the Map Designer version used to compile the map. Make sure the Map Designer and the Server versions match.
- 16 Disk write error
An attempt may have been made to write to a read-only directory or file. Also, check the amount of available disk space.
- 17 Disk read error
An attempt may have been made to access a file on a shared resource that is not accessible. Also, check the amount of available disk space.
- 18* Page usage count error
Your data mapped correctly; however, an internal paging problem exists.
- 19 Internal calling error
- 20 Reopen file failed
Your map did not run correctly.
- 21* Input valid but unknown data found
Enough of the input data to conform to the card definition was recognized, but there was more data at the end of the input stream. Enable the **Trace Input** setting, re-run the map and read the map trace file (.mtr).
- 22 Page size too small
Increase the page size or decrease the number of types in the schema that are used to define the input.
- 23 Unable to reuse work file
Use the same page settings that were used when you created the existing work file.
- 24 Database error
A problem was encountered attempting to write to an output database. Read the database trace file (.dbl) for information about possible causes.
- 25 File attribute error
The Command Server or Launcher failed to write data to either the work or data file. Check the output card definition on the map to see if it matches the platform-specific data definition specified for the file the map is attempting to create.
- 26* Output type in error
The entire card object is in error.
- 27* Output type contains errors
One or more components failed restrictions or a component rule.
- 28* Input type contains errors
This occurs when mapping data of a component that has a RESTART assigned to it, and at least one instance of the component in the input data is invalid.
- 29*

	Output valid, but unknown data found This occurs when enough of the output data is recognized to conform to the card definition, but there was more data at the end of the output stream.
30	FAIL function aborted map This occurs when the FAIL function is used within the map to cause map execution to cease. The return message specified as the second argument of the FAIL function appears in place of the xxx in the Execution Audit section of the Audit Log. See the Functions and Expressions documentation for more information about using the FAIL function.
31	(No longer used)
32	Invalid map instance handle
33	Map instance handle in use
34*	Too few pages requested, more allocated The map can complete but it can be better optimized by increasing the page count.
35	Insufficient number of pages to execute map The map could not complete because not enough pages were specified.
36	Could not open work files A scratch file for the HANDLEIN function could not be created.
37†	Operation is not supported on the platform
50	Not enough memory to execute map There is not enough memory to initialize the map. Try closing all open applications.
51	Card override failure There is a problem with the command line entered for an -I or -O option. (Applicable to Command Server)
52	I/O initialization failure A run map was called and could not allocate memory for input or output.
53†	Open audit failure The audit file was not accessible.
54	No command line There was no map or command line specified. (Applicable to run maps and the Command Server)
55	Recursive command files A command file was specified within a command file. (Applicable to run maps and the Command Server)
56	Invalid command line option - <option> An invalid argument was entered on the command line. (Applicable to run maps and the Command Server)
57	Invalid 'W' command line option An invalid parameter for the -W option was specified. (Applicable to run maps and the Command Server)
58	Invalid 'B' command line option An invalid parameter for the -B option was specified. (Applicable to run maps and the Command Server)
59	Invalid 'R' command line option An invalid parameter for the -R option was specified. (Applicable to run maps and the Command Server)
60	Invalid 'A' command line option

- An invalid parameter for the **-A** option was specified.
 (Applicable to run maps and the Command Server)
- 61 Invalid 'P' command line option
 An invalid parameter for the **-P** option was specified.
 (Applicable to run maps and the Command Server)
- 62 Invalid 'Y' command line option
 An invalid parameter for the **-Y** option was specified.
 (Applicable to run maps and the Command Server)
- 63 Invalid 'T' command line option
 An invalid parameter for the **-T** option was specified.
 (Applicable to run maps and the Command Server)
- 64 Invalid 'G' command line option
 An invalid parameter for the **-G** option was specified.
 (Applicable to run maps and the Command Server)
- 65 Invalid 'I' command line option for input <2>
 An invalid parameter for the **-I** option was specified for
 input card <number>.
 (Applicable to run maps and the Command Server)
- 66 Invalid size in echo command line for input < 2 >
 A size (nnn) was specified for **-IE2Snnn** that is outside of the boundaries for input card <number>.
 (Applicable to run maps and the Command Server)
- 67 Invalid adapter type in command line for input <2>
 Using the **-IAadapter_name** or **-IMadapter_name**, <adapter_name> is not a valid adapter type.
 (Applicable to run maps and the Command Server)
- 68 Invalid 'O' command line option for output <1>
 An invalid parameter for the **-O** option was specified for output card <number>.
 (Applicable to run maps and the Command Server)
- 69 Invalid adapter type in command line for output <1>
 Using the **-OAadapter_name** or **-OMadapter_name**, adapter_name is not a valid adapter type.
 (Applicable to run maps and the Command Server)
- 70 Command line memory failure
 Memory allocation failure during processing of command line.
 (Applicable to run maps and the Command Server)
- 71 Invalid 'D' command line option
 An invalid parameter for the **-D** option was specified.
 (Applicable to run maps and the Command Server)
- 72 Invalid 'F' command line option
 An invalid parameter for the **-F** option was specified.
 (Applicable to run maps and the Command Server)
- 73 Resource manager failure
 The resource manager could not reserve the resources (sources/targets) due to a resource contention that is most likely a run map.
 (Applicable to run maps and the Launcher)
- 74 Invalid 'Z' command line option
 An invalid parameter for the **-Z** option was specified.

(Applicable to run maps and the Command Server)

75	Adapter failed to get data on input During the commit/rollback phase, the source had a failure
76	Adapter failed to put data on output During the commit/rollback phase, the target had a failure.
77	Invalid map name: <map_name> The map path and name exceed 2000 bytes.

(Applicable to run maps and the Command Server)

Map execution warning messages

The following table lists the return codes that are warnings only - meaning that the map did complete, but some problems occurred. You can change the default behavior for the warning codes by specifying **Fail on Warnings** or **Ignore Warnings** through the map settings or by using the -F or -Z execution command.

The warning codes marked with an asterisk (*) are returned only when at least one output is listed in the **Data Audit Settings** of the **Organizer** and in the **Map Settings** dialog box, **MapAudit** is enabled with **Data** enabled for the **Log** setting.

Return Code	Message
14	One or more outputs was invalid A number produced an overflow condition. Enable the Trace Output option, run the map again, and read the trace file.
18	Page usage count error Your data mapped correctly; however, an internal paging problem exists.
21	Input valid but unknown data found Enough of the input data to conform to the card definition was recognized, but there was more data at the end of the input stream. Enable the Trace Input setting, run the map again and read the map trace file (.log).
26*	Output type in error The entire card object is in error.
27*	Output type contains errors One or more components failed restrictions or a component rule.
28	Input type contains errors This occurs when mapping data of a component that has a RESTART assigned to it, and at least one instance of the component in the input data is invalid.
29*	Output valid, but unknown data found This occurs when enough of the output data is recognized to conform to the card definition, but there was more data at the end of the output stream.
34	Too few pages requested, more allocated The map can complete but it can be better optimized by increasing the page count.

Map build error messages

Build errors prevent a map from being compiled. If build errors occur, view the errors, correct the problem(s), and build the map again. A map cannot be run if it has not been built.

In the following build messages; these letters are used as variables:

- x = the map where the error occurred
- y = the output that contains the rule in error
- w = number
- z = number

DataPower maps in addition to the ones listed below. See [Map build errors for DataPower maps](#) for a consecutive list of these additional map build error codes for a DataPower map.

Return Code	Message
M100	Analysis aborted by user.
M101	

Map: x
Unresolved rules exist.

Hint: Go to map x. If you want to use the unresolved rules, copy and paste them. Delete any unwanted unresolved rules.

M102

Map: x Output: y
Functional map referenced in rule must have one (and only one) output.

Map referenced: *map-name*.

Hint: Go to the functional map. Delete the extra card(s).

M103

Map: x Output: y
Number of arguments for functional map *map-name* is incorrect.

Number specified: #*specified* Number required: #*required*

Hint: Add or delete arguments from the rule, or add or delete input cards in the functional map.

M104

Map: x Output: y
Empty rule cell. Rule required.

Hint: Go to map x. Enter rules in each empty rule cell.

M105

Map: x Output: y
Rule references unknown type: *type name*.

Hint: You may have made a change in the schema. If the card object is unknown, edit the card, and choose a valid type. You may have incorrectly typed in the name. If you drag and drop the type, the correct name is automatically entered.

M106

Map: x
Circular map reference from map *map-name*.

Analysis must terminate.

Hint: Two different maps contain rules that reference each other. Remove the reference from one of the maps.

M107

Map: x Output: y
Rule syntax is invalid starting at character position: *position#*.

Rule

Hint: This error may occur if a previous version did not catch the syntax error. Generally, syntax errors are caught as rules are entered. See the [release notes](#) for any changes in rule syntax.

M108

Map: x Output: y
Rule references unknown map: *map-name*.

Hint: Re-enter the map name in the rule. You may have typed the map name incorrectly. Map names are case-sensitive. You may have forgotten to create the functional map. If so, create it.

M109

Map: x Card: *cardname*
Card is invalid.

Hint: The type name is either misspelled or you may have made a change in the schema by deleting or renaming the type. Edit the card, and choose a valid type.

M110

Map: x Card: *cardname*
Card type is not a group or item.

Hint: You probably changed your schema. Edit the card, and choose a group or item.

M111

Map: x Output: y
Argument #w for map *map-name* does not match type of input card #z.

Hint: Change argument #w so that it matches the type of input card #z, or change the type of input card #z so that it matches argument #w.

M112

Map: x Output: y
Argument #w for map *map-name* does not match item sub-class of card #z.

Hint: Change argument #w so that it matches the item sub-class of input card #z, or change the type of input card #z so that its item sub-class matches argument #w.

M113

Map: x Output: y
Argument #w for function *function name* is invalid.

Hint: Select the rule for output *y*. Right-click the map rule and choose Properties on the context menu. The Rule Properties dialog box allows you to view function arguments and object properties. You have either referenced an invalid object, or used the wrong type of argument.

M114

Map: *x* Output: *y*
Output argument of rule does not match output type: *rule*.

Hint: The map rule is resulting in a data object of the wrong type. Check the functions and the maps used within the map rule and make sure that the entire rule evaluates to the correct type.

You may have dragged and dropped a group that is a different type to this output. Use a functional map instead. If the rule contains the name of a functional map, go to the functional map and edit the output card. Make sure the type of the output card is the output *y*.

M115

Map: *x* Output: *y*
Output argument of rule does not match output item sub-class: *rule*.

Hint: Notice the output *y*. The output argument of the rule must have the same item sub-class as *y*.

M116

Map: *x* Output: *y*
Type Tree for this card is not used in executable map.

Hint: Edit the card and select a schema that is used in the executable map.

M117

Map: *x* Output: *y*
Cannot assign an output to itself.

Hint: You might have accidentally dragged and dropped an output into its own rule cell. Edit the rule.

M118

Map: *x* Output: *y*
Rule references unknown comment: *commentname @ inputname*

Hint: The input card type does not have a floating component, or you have incorrectly typed in the name. If the input card has a floating component, on the Card menu, the Show Floating Component Type option will be activated.

M119

Map: *x* Output: *y*
Output argument of rule is not a partition of output type.

Hint: If the rule contains the name of a functional map, go to the functional map and edit the output card. Make sure the type of the output card is the output *y*, or a partition of the output *y*.

M120

Map: *x* Output: *y*
Operand is an invalid *operand*.

Hint: For information on operands, see the Functions and Expressions documentation.

M121

Map: *x*
Input card #*cardnumber* uses invalid schema.

Hint: You may have moved the schema or map source from its original location. You may have incorrectly entered the name of the schema.

M122

Map: *x*
Output card #*cardnumber* uses invalid schema.

Hint: You may have moved the schema or map source from its original location. You may have incorrectly entered the name of the schema.

M123

Map: *x* Card: *cardname*
Card updates input, but card type and data file do not match an input.

Hint: Edit the card and re-define the update information.

M124

Map: *x* Output: *y*
Rule references type later in output: *rule*

Hint: If possible, enter an equivalent rule in a later output. An output referenced in a rule must appear above the rule within the output card.

M125

Map: *x*
Invalid audit: *audit statement*

Hint: Look at the Audit Settings window. An asterisk * appears next to any invalid audit statement. Re-enter the audit statement.

Map build warning messages

A build warning alerts you of a condition that might be problematic. If you build a map and there are warnings, but no errors, the map is compiled. You can ignore warnings. To ignore warnings, from Window > Preferences > Transformation Extender, select Suppress Build Warnings.

Return Code
Message

M200

Map: x Output: y
WARNING: Size of input item is greater than size of output item.

M201

WARNING: Functional maps that return groups or partitioned items must not be used as input to functions.

Map compile error messages

The compile errors display on the Build Results tab of the **Organizer**. Maps with compile errors may not be run. Correct all compile errors to run a map.

The following table lists the errors than can result when a map is built:

Return Code

Message

M1001

Compile aborted by user.
Hint: You cancelled the build process before it completed.

M1002

Not enough memory available to compile.
Hint: Close other applications that you have open, and build the map again.

M1003

Couldn't open the map source file.
Hint: The map may be corrupt. Please contact Technical Support.

M1004

Couldn't find the executable map.
Hint: The map source file may be corrupt. Please contact Technical Support.

M1005

Duplicate map names in output file.
Hint: If you get this error, please contact Technical Support.

M1006

Tree used in functional map not used by executable map.
Hint: Edit the card in the functional map or the executable map so both cards reference the same schema.

M1007

No delimiter defined for delimited type.
Hint: In the Type Designer, specify the delimiter value for the given type.

M1008

Unable to open the schema for input card.
Hint: The schema may not exist in the directory specified, or the schema may be corrupt. If your schema is corrupt, please contact Technical Support.

M1009

Unable to open the schema for output card.
Hint: The schema may not exist in the directory specified or the schema may be corrupt.

M1010

Unable to find a type in an input schema.
Hint: If you get this error, please contact Technical Support.

M1011

Unable to find a type in an output schema.
Hint: If you get this error, please contact Technical Support.

M1012

Could not retrieve query information.
Hint: Either you have not installed the Database Interface Designer or the .mdq file is incorrect.

M1013

Could not retrieve database information.
Hint: Either you have not installed the Database Interface Designer or the .mdq file is incorrect.

M1014

Input data file for executable map missing or invalid.
Hint: Check the file names used for sources and targets.

M1015

Output data file for executable map missing or invalid.
Hint: Check the file names used for sources and targets.

M1016

Parser found an invalid rule.

Hint: If you get this error, contact Technical Support.

M1017

Output card referenced in rule not found.

Hint: If you get this error, please contact Technical Support.

M1018

Invalid component or partition subtype encountered.

Hint: If you get this error, please contact Technical Support.

M1019

Unable to resolve type references in rule.

Hint: If you get this error, please contact Technical Support.

M1020

Couldn't open the compiled map file.

Hint: The compiled map file may be corrupt. Please contact Technical Support.

M1021

Error writing to the compiled map file. (Disk full?)

Hint: Delete unnecessary files from your hard disk.

M1022

Unable to resolve type references in audit.

Hint: If you get this error, please contact Technical Support.

M1023

Unable to open .MDQ file.

Hint: The .mdq file does not exist or is otherwise inaccessible.

M1024

Database not found.

Hint: The named database is not defined in the specified .mdq file.

M1025

Database Error.

Hint: An unexpected error occurred while processing and .mdq file.

M1026

Input MDQ file not found.

Hint: The .mdq file does not exist or is otherwise inaccessible.

M1027

Input query not found.

Hint: The named query is not defined in the specific .mdq file.

M1028

Output MDQ file not found.

Hint: The .mdq file does not exist or is otherwise inaccessible.

M1029

Output database not found.

Hint: The named database is not defined in the specified .mdq file.

M1030

At least one syntax object literal is too long.

Hint: Type Designer analysis is required.

Audit log status codes

The status attribute in the Audit Log is a letter followed by a code number. The letter of the status attribute tells whether the data is valid (V), or caused an error (E), or caused a warning (W).

- [Valid audit log status codes](#)
 - [Warning audit log status codes](#)
 - [Error audit log status codes](#)
-

Valid audit log status codes

The following table explains the number in the status code if the letter is V.

Status Code	Description
-------------	-------------

V00

The object and all contained objects are valid

V01

The object is valid, but it contains invalid object(s)

Warning audit log status codes

The following table explains the number in the status code if the letter is W.

Status Code	Description
W01	Object failed restriction
W02	Object failed presentation
W03	Object failed size check

Error audit log status codes

The following table explains the number in the status code if the letter is E.

Status Code	Description
E00	Object is an unidentified foreign object (UFO) - data not associated with any particular type
E01	Object failed restriction
E02	Object failed presentation
E03	Object failed size check
E04	Invalid or missing initiator
E05	Invalid or missing terminator
E06	Object missing required component
E07	Object is invalid because it contains components in error
E08	Object failed partitioning
E09	Object failed component rule
E10	This required object is missing
E11	Invalid or missing delimiter
E12	More instances of an object exist than have been specified (Only implemented for unordered groups)
E13	Object failed to meet minimum size requirement.
E14	Object failed to meet maximum size requirement.

Flows

A flow node invokes a sub flow within a flow. Sub-flows need not be wired to other nodes; it is valid to have a flow that is comprised of multiple sub-flows that each have listeners.

It is equally valid to wire up the flow -terminals of sub-flows to other sub-flows or other nodes.

Introduction to Flows

This documentation describes how Flows can be run from REST API, listeners, or they can be scheduled.

- [Nodes](#)
- [Terminals](#)
- [Flow terminals](#)
- [Scheduled flows](#)
- [Listener](#)
 - A Flow that has a Map node as its first node, and uses a File adapter for an input, can enable that node's input to be a Watch.
- [Flow audits](#)
 - Flow audits are a way to retrieve more verbose information about a flow instance.

Nodes

- [**Map**](#)
A Map node invokes a ITX map within a flow.
- [**Flow**](#)
A flow node invokes a sub flow within a flow. Sub-flows need not be wired to other nodes; it is valid to have a flow that is comprised of multiple sub-flows that each have listeners.
- [**Source and Target**](#)
Source and Target nodes provide IBM Transformation Extender Design Server with an outside-in approach to developing integrations. The inside-out approach means that you begin with a map, add inputs and outputs, and then configure these to access resources. Connections might be created in the process. The outside-in approach implements the integration from the opposite direction. You begin with the outside interfaces, then connects them to provide maps and other artifacts.
- [**Request node**](#)
The request node has a single input request terminal and a single output response terminal. Similarly, to the source node, it allows data to be retrieved from a data source. The request node differs from the source node in that it accepts input data from a request. This input data can influence or determine the data that is retrieved from the data source. The ability of the request node to accept request input is one way to introduce dynamic queries into the execution of a flow.
- [**Cache Read and Write**](#)
This documentation describes the function and use of the Cache Read and Cache Write nodes.
- [**Clone**](#)
The Clone node has one input and two output terminals. This node clones, or copies the input data from the single input terminal to both output terminals.
- [**Decision**](#)
The flow variable on which to make a decision.
- [**Fail**](#)
Fails the flow execution.
- [**Format Converter Node**](#)
The Format Converter Node can be used to quickly convert data from one format to another.
- [**JSON Read Node**](#)
This documentation describes the function and use of the JSON Read node.
- [**JSON Transform Node**](#)
This documentation describes the function and use of the JSON Transform node.
- [**JAVA**](#)
Invokes a java class, performing user defined functionality based on the properties specified for the java class to act on the input.
- [**Join**](#)
The Join node gathers the individual results and appends to a single output file or terminal.
- [**Log**](#)
This node logs the raw data from the node input into the file and propagates the data from the input to the output terminal.
- [**Passthrough**](#)
The Passthrough Node propagates data from the input to the output terminal.
- [**REST Client**](#)
The REST Client flow node provides a simple and powerful way to access REST services. It can be used to directly invoke REST APIs or can use prebuilt configurations that define the APIs of the service. The node supports:
- [**Route**](#)
The Route node provides a way to route data conditionally to one or more outputs of the node. The node bases decisions by evaluating a condition for a flow variable and determining whether to send the data to output 1 or 2 or both, based on the result of the condition.
- [**Sleep**](#)
This node suspends the execution of the flow for the specified number of milliseconds
- [**SOAP Client Node**](#)
- [**Split**](#)
A Split Node should be used when there is a need to split CSV or JSON data processing or when a map can run in a burst mode to process data in batches. This might occur when data processing becomes excessively time consuming.
- [**Status Node**](#)
A Status Node can only be used as the first node in a “status flow”, as that what makes a flow a status flow. Similar to an initialization flow, a status flow may be referenced from any other main flow. A status flow has a Status node as its first node which has Success, Error and Always output terminals that provide the flow status JSON to a downstream node.

Map

A Map node invokes a ITX map within a flow.

Using the Map node

Once the Map node is deployed to the flow canvas, you can select the map from the list of maps existing in the project. To replace a map in the Map node, use the Replace Node setting and select a different map from the list of maps. To control the map's behavior, use the Settings option. Map settings are explained in the map documentation under Project > Maps.

When the map is executed within the Map node, the transaction scope of adapters invoked from the map rules or from input and output cards that are not wired or are not attached to the flow terminals is set to map. This means that the adapters commit, or rollback transactions based on the Map node's status, not the flow's final status. If the input or output card is attached to the flow terminal, the transaction scope of that card is flow. This means that the transaction will be committed or rolled back based on the flow's status. The map audit is produced in JSON format and is part of the overall flow audit.

Map node Terminals

You can use the Edit Terminals option to show or hide map input or output terminals. If the terminal is shown, it can be wired to other nodes or set as a flow terminal. If the Map node is the first node, multiple map node terminals set as flow terminals. Multiple output map node terminals can also be set as flow terminals. Only one map

node input terminal can be wired to the previous node. If multiple map node input terminals are shown, those that are not wired can have the input card input modified. Multiple output terminals can be wired to other nodes.

When the input or output Map node terminal is wired, the adapter originally assigned to the map is overwritten with the internal stream adapter that passes data in memory in or out, depending on the terminal type. To control the maximum size of data being passed on this stream in memory, in megabytes, use the streamSize setting from the config.yaml file.

- Log terminal: Produces the full map audit in the JSON format.
- Status terminal: Produces the map status and values of flow variables attached to the Map node in the JSON format, if the map execution is successful. If the map fails, no data is produced on this terminal, and any downstream nodes wired to this terminal are not executed.
- Error terminal: Produces the map status and values of flow variables attached to the Map node, if the map execution is unsuccessful. If this terminal is shown, the map error code will not be propagated to the flow, and the map failure will not result in the flow's failure. Essentially, the error is captured within the Map node.

Types of Maps

The Map node supports both maps that have map source code and compiled maps. If the Map node uses a map that has the source code, the Open Map option can be used to modify the map. If the map is an existing compiled map, the Open Map option is not available.

Flow

A flow node invokes a sub flow within a flow. Sub-flows need not be wired to other nodes; it is valid to have a flow that is comprised of multiple sub-flows that each have listeners.

It is equally valid to wire up the flow-terminals of sub-flows to other sub-flows or other nodes.

Note: Flows are not supported on AIX and z/OS.

Source and Target

Source and Target nodes provide IBM Transformation Extender Design Server with an outside-in approach to developing integrations. The inside-out approach means that you begin with a map, add inputs and outputs, and then configure these to access resources. Connections might be created in the process. The outside-in approach implements the integration from the opposite direction. You begin with the outside interfaces, then connects them to provide maps and other artifacts.

- [Introduction to nodes](#)
The function of these nodes are as follows.
- [Node settings](#)
Access the node settings by right-clicking on the node in the flow.

Introduction to nodes

The function of these nodes are as follows.

- [Source Node](#)
- [Target Node](#)

Source Node

The source node has a single output terminal, and it supports watches if the selected connection type supports watches. Source node has an input terminal. By having an input terminal, it enables the existing watch mechanism and allows the input to be overridden, such as when running the flow from the designer when you want to bypass the node and pass data from a file instead. This node supports success, error, and log terminals.

Target Node

The Target node has a single input terminal and a single output terminal.

By having an output terminal, the output can be overridden when it is run. This node supports success, error, and log terminals.

Node settings

Access the node settings by right-clicking on the node in the flow.

The settings are not displayed in a modal dialog like other node settings. Instead settings are displayed in an accordion dialog. When displayed it looks like the card settings of a map. This should be like the edit card settings for a map card in a flow.

There are differences in the properties:

1. The action properties should not include map related properties such as transaction scope, backup, and retry. These properties are only available in the context of a map.
2. The schema allows you to select a schema or generate a schema for certain connection types (for example JDBC, and Salesforce). The schema page, however, is not required in order to specify a schema. This allows a map to be automatically generated between existing nodes.

Request node

The request node has a single input request terminal and a single output response terminal. Similarly, to the source node, it allows data to be retrieved from a data source. The request node differs from the source node in that it accepts input data from a request. This input data can influence or determine the data that is retrieved from the data source. The ability of the request node to accept request input is one way to introduce dynamic queries into the execution of a flow.

The request node is analogous to a map node whose map uses the GET function.

```
GET ("adapter-alias", "command-line", request-data)
```

Like the GET function in maps, the request node supports a variety of data source types.

As for the source and target nodes, the settings categories of the request node are Connection, Action Properties, and Schema. The Connection category allows an existing connection or a command line to be used. When a command line is used, the type of the data source of the request node must be elected. The syntax and meaning of the command line value depends on the data source type. The available options for the Action Properties category vary depending on the data source type.

The transactions are committed at the node level if the data was retrieved or modified successfully (adapter's GET operation was successful).

Example Use cases:

- REST APIs where the PUT or POST requires a body, and a response is returned in the HTTP response
- A SAP BAPI call has input parameters and a response to the BAPI call
- A converter that converts data from one form to another (e.g. SOAP adapter)
- A cipher adapter encrypts or decrypts the requested data

Process to create a request node

Request node can be placed as a first node, last node or between any other two nodes on canvas.

Node settings are:

- Connection: choose existing connection or select Use Command Line to specify the adapter and its command line.
- Define success and failure actions.
- Optimally, choose a schema that defines the node's data.

Logging

The node produces a log that consists of the node's internal messages and messages that underlying adapter generates. The adapter messages are prefix with the adapter name. The level of details depends of the flow execution log level.

Example log may look like (subject to change):

0: Called adapter EXCEL.
1: The adapter command line was: -WRKSHEET invoice1
2: The adapter success_action was set to: create
3: The adapter failure_action was set to: commit
4: EXCEL: Worksheet | invoice1
5: EXCEL: Excel Format | false
6: EXCEL: Trace file | __memory__
7: EXCEL: Trace append | true
8: EXCEL: Trace error | false
9: EXCEL: Trace verbose | false
10: EXCEL: Excel document data passed as GET parameter from the map
11: EXCEL: Reading Excel document data from the worksheet...
12: EXCEL: Total Rows in the Excel document: 5
13: EXCEL: Excel document data has been successfully passed to map!
14: EXCEL adapter performed the commit operation.
15: EXCEL retrieved 193 bytes.

Cache Read and Write

This documentation describes the function and use of the Cache Read and Cache Write nodes.

- [**Cache Read and Cache Write nodes configuration**](#)

This documentation describes how to configure the Cache Read node and the Cache Write node.

- [**Cache Read**](#)

The Cache Read node reads key/value pairs from the global cache, or from the flow variables. Optionally, it can delete keys and read from the cache.

- [**Cache Write**](#)

The Cache Write node writes key/value pairs to the global cache, or to the flow variables based on the scope property

Cache Read and Cache Write nodes configuration

This documentation describes how to configure the Cache Read node and the Cache Write node.

When a Cache Read or Cache Write node scope is set to Cache, Redis is used as an external cache to store the key/value pairs. In this case, the following are applicable:

<install_dir>/config.yaml file or environment variables are used to configure the cache.

<install_dir>/config.yaml file:

redis.host=localhost - defines the redis server hostname.

redis.port=6379 – defines the redis server port.

Environment variables can be used to override the settings from config.yaml file:

server.variableCacheType=External

redis.host=hip-server-redis

redis.port=6379

By default, the Cache is enabled, and it uses the local Redis server installed with the product.

Cache Read

The Cache Read node reads key/value pairs from the global cache, or from the flow variables. Optionally, it can delete keys and read from the cache.

The Cache Read node consists of one input terminal (Input) where the key values are passed in, and two output terminals (Matched and Unmatched).

The matched keys are written to the Matched terminal. Unmatched keys are written to the Unmatched terminal.

Data is sent to the Input terminal as a set of keys or a single key and each key is looked up and returned in the response. If the Key Prefix property is set, it is prepended to each key value to provide name-spacing. The input can optionally contain values, but they will be ignored.

Example 1: If the Data Format is delimited, and the delimiters are set to defaults, the data can either be sent as shown here:

Key1\n

Key2\n

or:

Key1,valA,ValB\n

Key1,valA,ValB\n

In the later case, everything between the first comma and the newline (value) is ignored.

Example 2: If the Data Format is JSON array:

```
[  
  {  
    "key": "Key1",  
    "value": "Value1"  
  },  
  {  
    "key": "Key2"  
  }]
```

The Key1 value set to Value1 is ignored.

Example 3: If the Data Format is None, the node could then be used as a source node, with no data passed to input terminal. A new property “Key1” is enabled to specify the name of the key.

Example 4: If the Key Pattern is specified, the node could then be used as a source node, with no data passed to input terminal. If the scope is Flow Variable, the pattern is a regular expression pattern (regex) and all keys that match the regex are retrieved. If the scope is Cache, the pattern is a glob style pattern and all keys that match the glob are retrieved.

Example regular expression:

a.b matches a1b or acb.

a*b matches acdefb

Example glob pattern:

a?b matches a1b or acb.

a*b matches acdefb

- **Settings**

This documentation describes the settings available for the Cache Read node.

- **Node Logging**

When executed the node reports matched keys into the log.

Settings

This documentation describes the settings available for the Cache Read node.

- **Cache Scope**

Determines whether to read values from flow variables, or from the Cache.

- **Data Format**

The format of the incoming input and output data.

- **Key Delimiter**

The Key Delimiter is enabled when the Data Format is Delimited.

- **Record Delimiter**

The Record Delimiter is enabled when Data Format is Delimited.

- **Include Key**

The Include Key is enabled when the Data Format is Delimited.

- **Key Prefix**

Prefix the key values with this value. This property can include flow variables.

- **Delete Key**

Determines whether or not to delete the matched keys from the cache after reading the value.

- **Default Key Value**

If the Default Key Value is set, nothing is ever sent to the unmatched terminal. All unmatched keys will be assigned the Default Key Value and sent to the matched terminal.

- **Key Pattern**

The key pattern meaning depends on the Cache Scope.

Cache Scope

Determines whether to read values from flow variables, or from the Cache.

If the Cache is selected, the node will fail if the connection to the external cache cannot be established.

Data Format

The format of the incoming input and output data.

Supported data formats are JSON, and Delimited and None. Whatever format is presented to the input terminal will be produced on the output terminal as well. For example, if a JSON array is sent to the input terminal, the output terminal will also produce a JSON array. If the Data Format is None, a new property "Key" is enabled to specify the name of the key to be retrieved and send to the output.

- **JSON data format**

JSON array and JSON object formats are described in this documentation.

- **Delimited data format**

The data sent to the input terminal is delimited according to the Record Delimiter properties.

JSON data format

JSON array and JSON object formats are described in this documentation.

JSON Array

If an array, each object in the array must have a key named **key**:

```
[  
  {"key": "MyKey1"},  
  {"key": "MyKey2"}  
]
```

The matched terminal produces an array of JSON objects with **key** and **value** keys:

```
[  
  {"key": "MyKey1", "value": "MyVal1"},  
  {"key": "MyKey2", "value": "MyVal2"}  
]
```

```
{"key": "MyKey2", "value": "MyVal2"}
```

The unmatched terminal produces an array of JSON objects with a single key named **key**:

```
[  
  {"key": "MyKey1"},  
  {"key": "MyKey2"}  
]
```

If there are no results on matched or unmatched terminals, an empty array will be returned.

JSON Object

If a JSON object is sent to the input terminal the names of the fields of the object specify which keys to lookup in the cache. The value of the keys is irrelevant and can be null, or any other value:

```
{  
  "MyKey1": null,  
  "MyKey2": 1  
}
```

The matched terminal will populate the values of the fields:

```
{  
  "MyKey1": "MyVal1",  
  "MyKey2": "MyVal2"  
}
```

The unmatched terminal will provide an object that has fields with null values:

```
{  
  "MyKey1": null,  
  "MyKey2": null  
}
```

If there are no results on matched or unmatched terminals, an empty object will be returned.

Delimited data format

The data sent to the input terminal is delimited according to the Record Delimiter properties.

It is comprised of one or more keys, for example:

```
MyKey1,MyVal1  
MyKey2,MyVal2
```

MyKey1

MyKey2

or if Include Key property is set to false, then the response will just be values:

```
MyVal1  
MyVal2
```

The data produced on the unmatched terminal will be a list of keys:

```
MyKey1  
MyKey2
```

Key Delimiter

The Key Delimiter is enabled when the Data Format is Delimited.

The Key Delimiter is the delimiter between the key and the value.

The default is a comma.

Record Delimiter

The Record Delimiter is enabled when Data Format is Delimited.

The Record Delimiter is the delimiter for each end of each record.

The default is newline.

Include Key

The Include Key is enabled when the Data Format is Delimited.

The Include Key determines whether or not the output should include the key.

Key Prefix

Prefix the key values with this value. This property can include flow variables.

For example: %_FLOWID_%

Delete Key

Determines whether or not to delete the matched keys from the cache after reading the value.

Default Key Value

If the Default Key Value is set, nothing is ever sent to the unmatched terminal. All unmatched keys will be assigned the Default Key Value and sent to the matched terminal.

Key Pattern

The key pattern meaning depends on the Cache Scope.

If the Cache Scope is Flow Variable, the pattern is a regular expression pattern (regex). If the scope is Cache, the key pattern is a glob style pattern. When the pattern is defined, the node can be a 1st node and the input data is not required. If the node is not a 1st node or the data exist on the node input terminal, the data is ignored. Matched keys in a format defined with Data Format property is sent to the Matched terminal. No data is sent to the Unmatched terminal. Consult online documentation for details about regex and glob style patterns.

Node Logging

When executed the node reports matched keys into the log.

Cache Write

The Cache Write node writes key/value pairs to the global cache, or to the flow variables based on the scope property

The Cache Write node consists of one input terminal, where the key values are passed, and one output terminal. The node propagates data from input terminal to the output terminal.

Data is sent to the Input terminal as a set of keys and values. If the Key Prefix property is set, it is prepended to each key value to provide name-spacing.

Example 1: If the Data Format is delimited, and the delimiters are set to defaults, and the data format is expressed as follows:

```
Key1,Value1\nKey2,Value2
```

The record delimiter is an option on the last record.

Example 2: If the Data Format is a JSON array

```
[  
  {  
    "key": "Key1",  
    "value": "Value1"  
  },  
  {  
    "key": "Key2",  
    "value": "Value2"  
  }]
```

Key1 is set to Value2 and so forth.

Example 3: If the Data Format is a JSON Object.

```
{"Key1":"Value1", Key2:123}
```

Key1 value is set to string "Value1" and Key2 integer value 123 is set to string "123".

All cache values are stored as strings, but the value provided could be in any format supported by JSON.

Example 4: If the Data Format is None, a new property Key is displayed. The entire input is written to the key. A flow variables can be used to define a key.

Scope = Cache

Key = Code%COLOR%

%COLOR% = "Red"

Input data sent to the terminal is: "Extremely Hot Temperature"

The node will create cache entry:

CodeRed="Extremely Hot Temperature"

- **Settings**

This documentation describes the settings that are available in the Cache Write node.

- **Node Logging**

When executed, the node reports the keys that are set in the cache.

Settings

This documentation describes the settings that are available in the Cache Write node.

- **Cache Scope**

Cache scope determines whether to write values to flow variables or to the cache.

- **Data Format**

The format for the incoming and output data. Supported data formats are JSON, Delimited and None.

- **Key Delimiter**

The Key Delimiter is enabled when the Data Format is Delimited.

- **Record Delimiter**

The Record Delimiter is the delimiter for the end of each record. The value is read from the Key Delimiter to the Record Delimiter.

- **Key Prefix**

Prefix the key values with this value. The property can include flow variables.

Cache Scope

Cache scope determines whether to write values to flow variables or to the cache.

If caching is only required within a single flow run, flow variables are used.

Data Format

The format for the incoming and output data. Supported data formats are JSON, Delimited and None.

If the Data Format is delimited, and the delimiters are set to defaults, the example data format is the following:

```
Key1,Value1\nKey2,Value2
```

The record delimiter is an option on the last record.

If the Data Format is a JSON array, for example the following:

```
[  
  {  
    "key": "Key1",  
    "value": "Value1"  
  },  
  {  
    "key": "Key2",  
    "value": "Value2"  
  }  
]
```

Key1 value is set to Value1, Key2 value is set to Value2.

If the Data Format is a JSON object, for example:

```
{ "Key1": "Value1", Key2: 123 }
```

Key1 value is set to string "Value1" and Key2 integer value 123 is set to string "123".

All cache values are stored as strings, but the value provided could be in any format supported by JSON.

If the Data Format is None, a new property Key is displayed. The entire input data is written to the key defined with the Key property.

Key Delimiter

The Key Delimiter is enabled when the Data Format is Delimited.

The Key Delimiter is the delimiter between the key and the value.

The default is a comma.

Record Delimiter

The Record Delimiter is the delimiter for the end of each record. The value is read from the Key Delimiter to the Record Delimiter.

Key Prefix

Prefix the key values with this value. The property can include flow variables.

For example: %_FLOWUID_%

Node Logging

When executed, the node reports the keys that are set in the cache.

Clone

The Clone node has one input and two output terminals. This node clones, or copies the input data from the single input terminal to both output terminals.

Decision

The flow variable on which to make a decision.

If the condition is met, routes the input data to the true terminal. If the condition is not met, routes the data to the false terminal. The decision is made based on the Flow Variable value and the operator.

- [Settings](#)

Settings

This section lists the settings available for the Decision node.

- [**Flow Variable**](#)
The decision is made based on the Flow Variable value.
- [**Operator**](#)
The decision is made based on the Operator.
- [**Case Sensitive**](#)
Whether to perform case sensitive or insensitive comparison.
- [**Value**](#)
Specifies the value of the property.

Flow Variable

The decision is made based on the Flow Variable value.

Operator

The decision is made based on the Operator.

Supported operators are:

- Equals
- Not equals
- In List
- Not In List

- Less Than
 - Greater Than
 - Less Than or Equal To
 - Greater Than or Equal To
-

Case Sensitive

Whether to perform case sensitive or insensitive comparison.

Value

Specifies the value of the property.

You can compare the Flow variable value using the Operator and Value of this property.

If the Operator is In List or Not In List, provide a comma-separated list of values.

Fail

Fails the flow execution.

When the Fail node executes, the flow fails immediately. The Error Message property provides the fail message. Flow variable substitution is supported in the flow message property.

- [Settings](#)
This section lists the settings available for the Fail node.
-

Settings

This section lists the settings available for the Fail node.

- [Error Message](#)
Provides the information text about the flow failure.
-

Error Message

Provides the information text about the flow failure.

The default error message is Fail from [nodename] node.

Format Converter Node

The Format Converter Node can be used to quickly convert data from one format to another.

The Format Converter Node supports these formats:

- CSV
- Delimited
- JSON
- YAML
- XML

When converting from JSON, YAML, or XML to CSV or delimited, there are limitations because CSV data is flat and cannot convey the hierarchical structures that may be in the JSON, YAML, or XML documents.

When converting from JSON or YAML to CSV or delimited the location of an array of objects is provided to the node by using the Input Array Path property. The node looks at the first element of the array to determine the set of fields that are included in the output CSV. This assumes that each object within the array has the same set of fields. If subsequent objects have more fields than the first node, these additional fields are ignored.

For example, given the JSON:

```
{  
    "addresses": [  
        {  
            "street": "10 Main St",  
            "city": "Smallville",  
            "state": "GA"  
        },
```

```

        {
            "street": "20 High St",
            "city": "Springville",
            "zip": "12345"
        }
    ]
}

```

The generated CSV is as shown:

```
street,city,state
10 Main St,Smallville,GA
20 High St,Smallville,
```

Since the second object does not contain a state key, that value is null additionally, although the second record contains a zip key, that is ignored because the fields are determined from the first object.

- [Converting from XML to CSV or Delimited](#)

When converting from XML to CSV or delimited, the XML elements to convert to CSV are selected by an XPath expression.

- [Using the Format Converter Node](#)

These instructions describe how to use the Format Converter Node in a flow.

Converting from XML to CSV or Delimited

When converting from XML to CSV or delimited, the XML elements to convert to CSV are selected by an XPath expression.

After obtaining a list of elements that are described by the XPath expression, the node looks at the first element it encountered to determine the set of fields that will be included in the output CSV.

The node first examines the element to see if it contains child elements. If it does, then these child elements define the set of CSV fields. If it does not contain child elements, the node examines the element to see if it contains attributes. If it does, then these attributes define the set of CSV fields. This assumes that each element within the set of elements has the same set of child elements or attributes. If subsequent objects have more fields than the first node, these additional fields are ignored.

For example, either of these XML documents produce the save CSV as shown in the JSON example:

XML with child elements:

```
<addresses>
    <address>
        <street>10 Main St</street>
        <city>Smallville</city>
        <state>GA</state>
    </address>
    <address>
        <street>20 High St</street>
        <city>Springville</city>
        <zip>12345</zip>
    </address>
</addresses>
```

XML with attributes:

```
<addresses>
    <address street="10 Main St" city="Smallville" state="GA"/>
    <address street="20 High St" city="Springville" zip="12345"/>
</addresses>
```

Using the Format Converter Node

These instructions describe how to use the Format Converter Node in a flow.

To use the Format Converter Node:

1. Select the Format Converter Node from the palette and drag it onto the canvas.
 2. Right-click on the node to select Settings.
 3. Configure the node as required, depending upon the data being converted. The following common properties are available:
 - Input Format - Select CSV, JSON, YAML, XML or Delimited to correspond to the format of the data that you want to pass to the input terminal of the node.
 - Output Format - Select CSV, JSON, YAML, XML or Delimited to correspond to the format of the data that you want to pass to the output terminal of the node.
- [CSV input format - available properties](#)
These properties are available if the desired input format is CSV
 - [CSV input format Delimited - available properties](#)
These properties are available if the input format is Delimited:
 - [CSV output format - available property](#)
One property is available if the output format is CSV.
 - [CSV output format delimited - available properties](#)
These properties are available if the output format is Delimited:
 - [JSON or YAML input, CSV output - available properties](#)
One property is available if the input format is JSON or YAML and the output format is CSV.
 - [JSON or YAML output, CSV input or delimited- available properties](#)
This property is available if the output format is JSON or YAML and the input format is CSV or Delimited:

- [XML input, CSV output or delimited- available properties](#)

This property is available if the input format is XML and the output format is CSV or delimited:

CSV input format - available properties

These properties are available if the desired input format is CSV

- Input Has Header - Set this property if the CSV data contains a header row in the first row of the data.
- Fields - If the CSV data does not contain a header row, the header can be specified in this property as a comma-separated list. This provides a means of specifying the header if it is not in the incoming data.

CSV input format Delimited - available properties

These properties are available if the input format is Delimited:

- Fields - Specify the names of the fields that are in the delimited data as a comma-separated list of field names, e.g. "id,name,age".
- Input Field Delimiter - The character or string that delimits fields. If not specified, the default is the pipe character '|'.
- Input Row Delimiter - The character or string that terminates a row. If not specified, the default is the newline character '\n'.
- Input Escape Character - The character to escape field and row delimiters if they appear in the data. By default, there is no escape character. If the field and row delimiters cannot appear in your data, do not define an escape character, since doing so adds processing overhead.

CSV output format - available property

One property is available if the output format is CSV.

Available property:

- Output Has Header - Set this property if you want the output data to include a header row.

CSV output format delimited - available properties

These properties are available if the output format is Delimited:

- Output Field Delimiter - The character or string that delimits fields. If not specified, the default is the pipe character '|'.
- Output Row Delimiter - The character or string that terminates a row. If not specified, the default is the newline character '\n'.
- Output Escape Character - The character to escape field and row delimiters if they appear in the data. By default, there is no escape character. If the field and row delimiters cannot appear in your data, do not define an escape character, since doing so adds processing overhead.

JSON or YAML input, CSV output - available properties

One property is available if the input format is JSON or YAML and the output format is CSV.

Property available:

- Input Array Path - When you convert from JSON or YAML to CSV, the incoming JSON or YAML must contain an array of JSON or YAML objects. This array can either be at the root of the document, or elsewhere in the document. If the entire document is an array of objects, the Input Array Path should not be set. Otherwise, specify the path of the array using dot-notation. For example, if the JSON data is:

```
{  
    "data": {  
        "id": 1,  
        "people": [  
            {  
                "name": "Fred",  
                "sex": "male"  
            },  
            {  
                "name": "Susan",  
                "sex": "female"  
            }  
        ]  
    }  
}
```

the path is specified as data.people.

JSON or YAML output, CSV input or delimited- available properties

This property is available if the output format is JSON or YAML and the input format is CSV or Delimited:

Property available:

- Output Array Path - When converting from CSV or delimited to JSON or YAML the output that is produced will convert the input rows to an array of JSON or YAML objects. This property determines the location of that array in the produced JSON or YAML. If the property is not set, the JSON or YAML array will be at the root of the document. If a path is specified, intermediate JSON or YAML objects will be created. For example, if the output array path is specified as "people", the produced JSON will look like this:

```
{  
    "people": [  
        {  
            "name": "Fred",  
            "sex": "male"  
        },  
        {  
            "name": "Susan",  
            "sex": "female"  
        }  
    ]  
}
```

XML input, CSV output or delimited- available properties

This property is available if the input format is XML and the output format is CSV or delimited:

Property available:

- Input XML XPath - When converting from XML to CSV or delimited, the output will be created from repeating node elements in the XML. The Input XML XPath property is an XPath expression that selects nodes from the XML to be converted to the output. The path can either be an absolute path or some other valid XPath specification. For example, consider this XML:

```
<XML>  
    <Winners>  
        <Winner>  
            <Name>Janet Gaynor</Name>  
            <Movie>Seventh Heaven</Movie>  
        </Winner>  
        <Winner>  
            <Name>Mary Pickford</Name>  
            <Movie>Coquette</Movie>  
        </Winner>  
    </Winners>  
</XML>
```

If we want to create CSV or delimited data that contains the Winner nodes the Input XML XPath can be set to:

- /Winners/Winner – this is an absolute path that navigates to a specific location in the XML
- //Winner – this XPath expression will find Winner elements anywhere in the XML document

JSON Read Node

This documentation describes the function and use of the JSON Read node.

The JSON Read node is used to set flow variables or cache variables to the value of elements extracted from a JSON document. It can also be used to extract elements from a larger JSON document, to perform simple JSON transformation.

The JSON Read node performs following:

- Examine the JSON document that is sent to the node's input link. It then processes each path or query expression that is provided in the node's Paths property to find the specified JSON element in the input document.
- If the Variable Scope property is set to Flow Variables, the named flow variables are set with the value of the JSON element. Alternatively, if the Variable Scope property is set to Cache, the named cache variables are set with the value of the JSON element.
- If the Output Content property is set to Filter the Input, the node's output is a JSON object with fields containing the JSON elements specified by the Paths. Alternatively, if the Output Content property is set to Propagate the Input, the input JSON is copied to the output terminal without modification.
- **Settings**
This documentation describes the settings available for the JSON Read node.
- **Examples**
These examples show the functionality of JSON Read node.

Settings

This documentation describes the settings available for the JSON Read node.

- **Paths**
Specifies as a table of paths to find in the input JSON document.
- **Variable Scope**
Variable Scope specifies the target for the path expressions.

- **Output Content**

Output Content specifies whether to propagate the input JSON document to the output, or whether to output a new JSON object that contains just the elements specified by the paths.

Paths

Specifies as a table of paths to find in the input JSON document.

The table has two columns:

- Path – The path or query expression that references elements in the JSON input document. Such expressions should comply with the syntax defined by Stefan Goessner's de-facto standard defined here: <https://tools.ietf.org/id/draft-goessner-dispatch-jsonpath-00.html>. Filter expressions are supported. The path might reference either a JSON text, numeric or boolean primitive, or can specify an object or array.
- Variable/Key – The name of the flow variable or cache variable. If filtering the output, this also specifies the name of the field in the filtered output. The specified name can include flow variable references which are resolved when the flow is run. For example, if you specify %_FLOWUUID_%_id to prefix the name of the variable with the ID of the flow run.

Variable Scope

Variable Scope specifies the target for the path expressions.

It can be set to one of these values:

- Flow Variables – Set flow variables.
- Cache – Set cache variables.
- Set no Variables – Do not set any variables. Use this option if you want to filter the input JSON and have no need to set flow variables or cache variables.

Output Content

Output Content specifies whether to propagate the input JSON document to the output, or whether to output a new JSON object that contains just the elements specified by the paths.

Simple JSON transformation can be accomplished by specifying this setting as Filter the Input and Variable Scope to Set no Variables.

Examples

These examples show the functionality of JSON Read node.

Example 1: The use case is to set a flow or cache variable variables to the Person_ID, City and Full_Address of some record.

The input data is:

```
{  
  "id": 123,  
  "name": "fred",  
  "address": {  
    "street": "101 Main St",  
    "city": "London"  
  }  
}
```

and the Paths table is set as:

Path	Variable/Key
\$.id	Person_ID
\$.address.city	City
\$.address	Full_Address

If the Variable Scope is set to flow or cache variables it will set these 3 variables:

Path	Variable/Key
Person_ID	123
City	London
Full_Address	{"street": "101 Main St", "city": "London"}

Note: If the path returns a JSON object or array, the value is the serialized form of that object or array.

If the Output Content property is set to filter the input, then the output in this example will be:

```
{  
  "Person_ID": 123,  
  "City": "London",  
  "Full_Address": {  
    "street": "101 Main St",  
    "city": "London"  
  }  
}
```

Example 2: This example demonstrates the query expressions.

The use case is to set a flow variable to the mobile phone number of some record.

The input data is:

```
{  
  "phones": [  
    {  
      "type": "mobile",  
      "number": "111-222-3333"  
    },  
    {  
      "type": "home",  
      "number": "444-444-5555"  
    }  
  ]  
}
```

The path expression to achieve this is:

Path	Variable/Key
<code>\$.phones[?(@.type == "mobile")].number</code>	mobile

This means in the "phones" array, find the object whose "type" field is "mobile" and then return the "number" field from this object. This will result in this flow variable:

Name	Value
mobile	111-222-3333

If the Output Content property is set to filter the input, then the output in this example will be:

```
{  
  "mobile": "111-222-3333"  
}
```

JSON Transform Node

This documentation describes the function and use of the JSON Transform node.

The JSON Transform node is used to transform JSON documents from one form to another. The JSON Transform node uses JSON path expressions embedded within a JSON template to build the output document. The template is specified as a property of the node and describes what the output data should be, and where the contents of the JSON should come from.

The JSON Transform node also supports setting the value of fields to the value of flow variables.

- [JSON Template Property](#)
The JSON template property must be a valid JSON. It can be either a JSON object or a JSON array. The template property can be specified as %variable-name%, in which case the template will be obtained from the named flow variable or configuration variable.
- [Examples](#)
These examples show the functionality of JSON Transform node.

JSON Template Property

The JSON template property must be a valid JSON. It can be either a JSON object or a JSON array. The template property can be specified as %variable-name%, in which case the template will be obtained from the named flow variable or configuration variable.

The template can include any arrays, objects, primitives, and these can also be specified as JSON path expressions. Such expressions should comply to the syntax defined by Stefan Goessner's de-facto standard defined here: <https://tools.ietf.org/id/draft-goessner-dispatch-jsonpath-00.html>.

The JSON Transform node uses the syntax "@@path" to indicate that the string contains a JSON path expression. The path is then evaluated, and its results are included in the output document to replace the path expression in the template.

As can be seen from the examples, where the JSON path expression is specified in the template determines the expected result of the JSON path expression.

- [Path to a Primitive](#)
To fetch a field that is a primitive (string, number, boolean) specify the JSON path as a string primitive:
- [Path to an Object](#)
There are two ways to specify an object in the template.
- [Path to an Array](#)
If the path is specified as a string member of an array, then the path will return an array.

Path to a Primitive

To fetch a field that is a primitive (string, number, boolean) specify the JSON path as a string primitive:

```
"field": "@@$.id",
```

The value of field will be set to whatever is returned from the specified path.

Path to an Object

There are two ways to specify an object in the template.

The first is to use the special field value "*":

```
"object": { "*": "@@$.address" }
```

The special field value causes the node to replace the entire object in the template with object specified by the JSON path.

Specifying the object as shown has the exact same result.

```
"object": "@@$.address"
```

The former may be preferable since it is clearer from looking at the template that the expected type that the JSON Path references is an object.

Path to an Array

If the path is specified as a string member of an array, then the path will return an array.

For example:

```
"array_of_objects": [ "@@$.phones" ],
"array_of_primitives": [ "@@$.numbers" ],
```

This indicates that the phones field and numbers fields return arrays. Even if the path points to something that is not an array, the result will be an array because it was specified that way in the template.

If the path references an array, and the template element is not an array, then only the first element in the array will be returned. To include all elements in the array, specify the [`<path>`].

Examples

These examples show the functionality of JSON Transform node.

Example 1: If the template is set as

```
{
  "literal": "a literal",
  "field": "@@$.id",
  "var": "%my_var%",
  "array_of_objects": [ "@@$.phones" ],
  "array_of_primitives": [ "@@$.numbers" ],
  "object": { "*": "@@$.address" }
}
```

and the given JSON expression passed to the input of the node:

```
{
  "id": 123,
  "name": "fred",
  "address": {
    "street": "101 Main St",
    "city": "London"
  },
  "numbers": [ 1, 2, 3 ],
  "phones": [
    {
      "type": "mobile",
      "number": "111-222-3333"
    },
    {
      "type": "home",
      "number": "444-444-5555"
    }
  ]
}
```

the node will generate this as the output:

```
"literal": "a literal",
"field": 123,
"var": "Value of my_var",
"array_of_objects": [
  {
    "type": "mobile",
    "number": "111-222-3333"
  },
  {
    "type": "home",
    "number": "444-444-5555"
  }
],
```

```

"array_of_primitives": [
  1,
  2,
  3
],
"object": {
  "street": "101 Main St",
  "city": "London"
}
}

```

To create this output, the node traversed the template to build the output. It produced these fields:

- literal – The value was set to a literal value.
- field – The value of the field is obtained from the path expression `$.id`, which has the value 123 in the input document.
- var – The value is specified as the name of a flow variable named city, the value of which is set in the output.
- array_of_objects – The value of the field is obtained from the path expression `$.phones`. Because the template specified this path within an array, the path expression is expected to return an array.
- array_of_primitives – An array of primitive values is returned by specifying the path expression `$.numbers` within array syntax.
- object – An object is replaced by the fetched value by specifying the special key value "*" in the object. If this is found, the object in the template is replaced by the object returned by the `$.address` path.

Example 2: This example demonstrates the query syntax.

To determine the ID of the service named "Upload".

The JSON sent to the node is:

```

{
  "services": [
    {
      "_id": "5f9ae9765bffe304360d10d6",
      "name": "Upload"
    },
    {
      "_id": "5f9ae9765bffe304565656b3",
      "name": "Download"
    }
  ]
}

```

The template contains a query expression (as indicated by the '?')

```
{
  "id": "@@$.services[?(@.name == \"Upload\")._id"
}
```

This query finds the object in the "services" array which has its "name" field set to "Upload". It then returns the "_id" field from that object to produce this output:

```
{"id": "5f9ae9765bffe304360d10d6"}
```

JAVA

Invokes a java class, performing user defined functionality based on the properties specified for the java class to act on the input.

The Java node presents a simplified interface to invoke a Java class as part of the flow execution. It enables to perform a custom functionality written in Java programming language and be a part of the flow definition and execution. It is similar to an exit point where user can plug-in their custom functionality as a part of the flow execution to achieve the intended objective and the purpose of the flow.

- **[Settings](#)**
Following are the Java node settings that user must specify to create a flow definition.
- **[Copying Java nodes zip file under the non-docker environment](#)**
- **[Copying Java nodes zip file under the docker environment](#)**

Settings

Following are the Java node settings that user must specify to create a flow definition.

- **[Class name](#)**
The fully qualified Java class extending the abstract class SimpleNode.
- **[Properties](#)**
Properties are name-value pairs that indicate an action to perform, or any general-purpose information that user's Java class will understand and perform an activity that serves the purpose of the node in the flow definition and execution during the runtime.

Class name

The fully qualified Java class extending the abstract class SimpleNode.

The Java node requires user to specify the Java class name to load and provide the properties recognized by the Java class to perform actions accordingly on the input received and generate output, pass on the generated output to subsequent nodes in the flow, if any present for the further processing.

Java class name specified in the node settings must implement the abstract class SimpleNode to work during the flow execution. The SimpleNode interface provides the user defined custom Java class, the input stream to process the input and output stream to pass on the output. It generates the next node in the flow, besides the standard success, error, and log terminals to disseminate the success, error, and audit log information to the nodes connected to the those terminals.

The SimpleNode interface allows the Java class to set, get, increment, and decrement a flow variable from the Java node in a flow. Flow variables are process data variables that goes with the flow execution and accessible to all nodes in the flow that includes Java nodes while a flow is being executed. Flow variables are name-value pairs, where name is a case-sensitive string that is associated with a specific value in string format.

The location of the SimpleNode interface and documentation:

```
<install_dir>/examples/dk/nodes/java/simple/interface
```

Location of the example Java classes that implement the SimpleNode interface, which are part of *com.hcl.hip.examples* package:

```
<install_dir>/examples/dk/nodes/java/simple/nodes
```

Location of an example flow that utilizes multiple Java nodes using the example Java classes (that implements the SimpleNode interface):

```
<install_dir>/examples/flowengine/simplejava
```

The readme files for the example flow and Java classes that implement the SimpleNode interface provide the additional information and instructions on creating, building user specific custom Java classes, that are used as part of Java nodes in a flow definition and invoked during the flow execution.

The jar file or jar files housing the Java classes that implement the SimpleNode abstract class must be present under the following location for the Java nodes to invoke them, when the flow is being run:

```
<install_dir>/jars/com.hcl.hip.nodes.simplejava
```

User can either copy the jar file(s) manually to the above designated location for the flow to pick up during the execution or, create a zip file with the jar file(s) that hip-rest application will copy over the designated location during the startup.

The zip file should be in the following format:

```
<nodenode>_simplejava_<version>.zip
```

Where, *<nodenode>* is any string of user's choice and *<version>* is a version number of user's choice. *_simplejava_* is case-sensitive and should be in the middle of the *<nodenode>* and *<version>* when naming the zip file.

Properties

Properties are name-value pairs that indicate an action to perform, or any general-purpose information that user's Java class will understand and perform an activity that serves the purpose of the node in the flow definition and execution during the runtime.

Name

Specifies the name of the property.

Value

Specifies the value of the property.

Copying Java nodes zip file under the non-docker environment

This section provides the procedure to copy the user defined Java node class jar file(s) assembled in a zip file to the hip-rest that runs under non-docker environment.

1. Create a folder named modules under *<install_dir>*, if it is not available.
2. Copy the zip file *<nodenode>_simplejava_<version>.zip* in the *modules* folder.
3. Start the hip-rest application.

Copying Java nodes zip file under the docker environment

This section provides the procedure to copy the user defined Java node class jar file(s) assembled in a zip file to hip-rest that runs under the docker environment.

1. Create a folder *hipmodules* under */opt*, if it is not available.
2. Copy the zip file *<nodenode>_simplejava_<version>.zip* to */opt/hipmodules*.
3. Start the hip-rest container application.

Join

The Join node gathers the individual results and appends to a single output file or terminal.

- [Settings](#)

This section lists the settings available for the Join node.

Settings

This section lists the settings available for the Join node.

- [Write To File](#)
Writes the output to a file or the output terminal (The output terminal data content is the file name).
- [File Path](#)
Specifies the path to the output file.
- [Record Delimiter](#)
Specifies the character that delimits the records.
- [Output Header](#)
Specifies whether to write a header to the output.
- [Header Flow Variable](#)
The name of a flow variable that holds the header string.
- [Header](#)
Specifies the header to write to the output.
- [Header Delimiter](#)
Specifies the characters that delimit the header.

Write To File

Writes the output to a file or the output terminal (The output terminal data content is the file name).

To avoid high memory usage while processing the big data, you must use the Write To File property.

If the Write To File is set to true, the data created in individual batches is added to the file. If the Write To File is set to false, the data created in individual batches is added to the output terminal.

File Path

Specifies the path to the output file.

Record Delimiter

Specifies the character that delimits the records.

\r specifies for the carriage return.

\n specifies for the newline.

\t specifies for the tab.

The records and the header may have record delimiters by setting the Output and Header Delimiter properties. You must not set these properties, if the original data has the delimiter.

Output Header

Specifies whether to write a header to the output.

If the Output Header is set, the Join node creates the header.

If the Output Header is set to Header defined in flow variable, the Header Flow Variable property defines the flow variable that defines the header.

If the Output Header is set to Specified Header, the Header property defines the header.

Header Flow Variable

The name of a flow variable that holds the header string.

Header

Specifies the header to write to the output.

Header Delimiter

Specifies the characters that delimit the header.

\r specifies for the carriage return.

\n specifies for the newline.

\t specifies for the tab.

Log

This node logs the raw data from the node input into the file and propagates the data from the input to the output terminal.

Flow variable substitution is supported in the log file name. In order to generate unique log file name use the Flow internal variables _FLOWINSTANCE_ or _FLOWUUID_.

Flow variable FLOWLOGNODES changes the Log node behavior.

If the variable is set to false, the log file name will not be created. If the variable is set to true, the unique log will be created. The unique log fine name is [Nodename]_%_FLOWUUID_.log.

- [Log File Name](#)

Log File Name

Specifies the log file name. If the path is a relative path, it is relative to the flow home directory.

Passthrough

The Passthrough Node propagates data from the input to the output terminal.

There are no node properties. The node could be used as a placeholder for incomplete flow during the design phase.

REST Client

The REST Client flow node provides a simple and powerful way to access REST services. It can be used to directly invoke REST APIs or can use prebuilt configurations that define the APIs of the service. The node supports:

- Passing in request data on the input terminal or building the request directly in the node.
- Returning success and error messages to the different output terminals.
- The ability to loop through an array of requests to invoke an API repeatedly.

The node is an extension of the REST adapter. In many cases, it is much simpler to configure and use the node in a flow. Especially in cases, where an API call requires to send a request and handle the responses.

- [Functionality](#)

The REST Client node operates in 3 modes:

- [Terminals](#)

The REST Client node supports the terminals as given in below table.

- [Settings](#)

This section lists the settings available for the REST Client node.

- [Authentication](#)

Provides the options to authenticate the connection. This is an optional property.

- [Input Data Request Mode](#)

Input Data Request Mode is available, when you set Configuration Mode to Configuration Packages.

- [Request Assignments](#)

Provides a quick and easy way to build request data, when the request data is not provided to the node's input terminal.

- [Response Assignments](#)

Response Assignments are used to set flow variables based on values of elements of the response. This provides a simple way to parse responses to extract elements from the responses.

- [Logging](#)

Specifies the level of logging to use for the log (trace) file produced by the node.

- [Proxy server support](#)

This documentation describes the Proxy server support.

Functionality

The REST Client node operates in 3 modes:

- General: Specifies URL, method and other properties.
- Configuration Script: References a script (JSON file) that contains the endpoint definitions.
- Configuration Package: References a package (jar file) that contains the endpoint definitions, input/output formats and optionally Java plugin code.

Terminals

The REST Client node supports the terminals as given in below table.

Table 1. Terminals

Terminal	Direction	Description
Request data	In	The data sent as HTTP request.
Successful response	Out	The HTTP response for a successful request (HTTP status is 2xx).
Error response	Out	The HTTP response for an error condition (HTTP status is 4xx or 5xx).
Success	Out	Standard success terminal.
Error	Out	Standard error terminal. This terminal is invoked depends on whether the error response terminal is connected or not. If the error response is connected, the node fails, only if a processing error occurred. If the error response is not connected, this terminal is invoked, if either the node fails, or the HTTP call returns an error status.
Log	Out	The REST Client node log file is produced, if this terminal is connected.

Settings

This section lists the settings available for the REST Client node.

Authentication

Provides the options to authenticate the connection. This is an optional property.

Authentication options are as follows:

- None: The endpoint does not require any authentication.
- Basic: The endpoint requires username and password for authentication.
- OAuth 2.0: The endpoint requires an access token to access the REST APIs securely by using OAuth 2.0 Authentication. If the access token is expired, the action to be taken can be specified through Access Token Expiry Action.
- Use Endpoint Definition: When configuration script or packages are used in REST Client node, specifying this option will use the authentication specified in the endpoint configuration and any required connection properties need to be passed through Properties table.

Input Data Request Mode

Input Data Request Mode is available, when you set Configuration Mode to Configuration Packages.

It has three options as follows:

1. Single Request: The input data is read from the input terminal and treated as a single request.
2. Multiple Requests: It sends information to the node that the data read from the input terminal is a JSON array, and it should iterate through the array and call the API for each object in the array.
3. Template: If it is set to Template, the JSON or XML request template of the specified endpoint is used as the request. The contents of the Template can be dynamically modified by Request Assignments.

Request Assignments

Provides a quick and easy way to build request data, when the request data is not provided to the node's input terminal.

If the Input Data Request Mode is set to Template, this property is enabled. To use this option, the endpoint definition in the configuration file must include a template for the request which points to a JSON file defining the actual request data, or a template for the request which can be modified via request assignments. Assignments are specified through a table with two columns: Path and Value. The path is a JSON path to identify a field in the template. This uses dot-notation to specify the path. For example, if the template contains:

```
{ "address": { "city": "Springfield" } }
```

The city field would be identified by path address.city. The value specifies the value to substitute at the specified path, which is typically set to the value of a flow variable which is specified as %flow_var%.

Response Assignments

Response Assignments are used to set flow variables based on values of elements of the response. This provides a simple way to parse responses to extract elements from the responses.

This property is enabled only for Single Request or Template input data request mode. It is provided through a table with two columns: Path and Flow variable. The path is a JSON path of a field in the response, specified using the dot-notation defined above. The value of the field will be assigned to the specified flow variable.

For example, if response data contains:

```
{ "_id": "1111", "details": { "fname": "Steve", "lname": "Smith" } }
```

The response assignment table contains:

Path	Flow variable
_id	id
details.lname	last_name

This will result in flow variable "id" being assigned "1111" and "last_name" flow variable being assigned to "Smith".

Logging

Specifies the level of logging to use for the log (trace) file produced by the node.

The default is Off. The value Information means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

When Append Log is set to true, the log messages are appended to the file. When set to false, the file is truncated and the messages are written to the empty file. If the file path is not specified, the trace is logged to the default system logger.

Proxy server support

This documentation describes the Proxy server support.

- [Proxy server support in REST Client Node](#)

The Services and REST Client Node provide the option to configure a proxy server URL. A proxy server serves as an intermediary between the client and the server. It receives REST requests from IBM Sterling Transformation Extender and acts on behalf of IBM Sterling Transformation Extender when connecting to the end server. The Proxy server is utilized when access to the destination server is restricted, and connection must be made exclusively through a proxy server.

- [Troubleshooting of proxy server](#)

Proxy server support in REST Client Node

The Services and REST Client Node provide the option to configure a proxy server URL. A proxy server serves as an intermediary between the client and the server. It receives REST requests from IBM Sterling Transformation Extender and acts on behalf of IBM Sterling Transformation Extender when connecting to the end server. The Proxy server is utilized when access to the destination server is restricted, and connection must be made exclusively through a proxy server.

- [Proxy configuration using environment variables](#)

This documentation describes proxy configuration using environment variables.

- [Proxy configuration using flow variables](#)

This documentation describes proxy configuration using flow variables.

- [Proxy configuration using properties](#)

This documentation describes proxy configuration using properties.

- [Proxy configuration using the command line](#)

This documentation describes proxy configuration using the command line.

Proxy configuration using environment variables

This documentation describes proxy configuration using environment variables.

HTTP_PROXY

To establish connections to any HTTP URLs through the REST Client Node, you can set the HTTP_PROXY environment variable on the machine where IBM Sterling Transformation Extender is installed. This configuration allows the proxy server URL provided to be utilized for establishing connections.

Example: `HTTP_PROXY=http://proxy-server-ip:port`

HTTPS_PROXY

To establish connections to HTTPS URLs through the REST Client Node, you can configure the `HTTPS_PROXY` environment variable on the machine where IBM Sterling Transformation Extender is installed. By setting this variable, the provided proxy server URL will be utilized for making connections to any HTTPS URLs.

Example: `HTTPS_PROXY=http://proxy-server-ip:port`

NO_PROXY

To bypass the proxy server for specific URLs in the machine where IBM Sterling Transformation Extender is installed, you can set the `NO_PROXY` environment variable. This variable should be configured with a comma-separated list of URLs that do not need to be passed through the proxy server URL specified in `HTTP_PROXY` or `HTTPS_PROXY`.

Example: `NO_PROXY=localhost,some-domain.com`

Note: For adding these flow variables in the docker installation, one must edit `setenv.sh` file in hip-server and hip-rest containers.

Proxy configuration using flow variables

This documentation describes proxy configuration using flow variables.

proxy_url

When deploying and running flows, you have the option to configure the "`proxy_url`" flow variable for both HTTPS and HTTP URL connections using the REST Client Node.

Proxy configuration using properties

This documentation describes proxy configuration using properties.

Proxy URL

You can configure the Proxy URL property in Service Builder and REST Client Node.

Proxy configuration using the command line

This documentation describes proxy configuration using the command line.

-PURL

In the command line mode of the REST Client Node, you can utilize the "`-PURL`" command to configure the proxy server URL.

Example: `-PURL https://proxy-server-ip:3128`

Troubleshooting of proxy server

To verify the proxy configuration checks, follow these steps:

- Check if the Proxy server URL can be accessed from the machine where IBM Sterling Transformation Extender is installed. Use the Telnet command to access the proxy server.
For example: `telnet <proxy-server-ip> <proxy-server-port>`
- If you are unable to access your port, ensure that it is enabled if you are behind a firewall.
- If your proxy server IP is not accessible, make sure to include the DNS entry of the proxy server details in the hosts file where IBM Sterling Transformation Extender is installed.
- If the REST API requests are not being passed through the proxy server, ensure that there is an entry for the end resource URLs in your host's file on the proxy server.

Route

The Route node provides a way to route data conditionally to one or more outputs of the node. The node bases decisions by evaluating a condition for a flow variable and determining whether to send the data to output 1 or 2 or both, based on the result of the condition.

Route mode operates in two conditional modes:

- In Single Condition mode, data is sent to output 1, if the condition is set to true. Data is sent to output 2, if it is set to false.
- In Multiple Condition mode, output 1 and output 2 conditions are independently evaluated. If output 1 condition is set to true, data is sent to output 1. If output 2 condition is set to true, data is sent to output 2.

See the Route example to demonstrate the usage and behavior of Route node used in a flow. The Route node example contains a readme file that contains detailed instructions about how to run the example.

- **[Settings](#)**

This section lists the settings available in the Route node.

Settings

This section lists the settings available in the Route node.

Mode

Specifies the two modes.

- In Single Condition mode, data is sent to output 1, if the condition is set to true. Data is sent to output 2, if it is set to false.
- In Multiple Condition mode, output 1 and output 2 conditions are independently evaluated. If output 1 condition is set to true, data is sent to output 1. If output 2 condition is set to true, data is sent to output 2.

Output 1 Flow Variable

Specifies the flow variable on which to route for the output 1.

Output 1 Flow Operator

Specifies the operation to use in the comparison for output 1.

Output 1 Case Sensitive

Decides whether to perform the case sensitive or insensitive comparison.

Output 1 Value

Specifies the value to compare against. If the Operator is In List or Not In List, provides a comma-separated list of values.

Output 2 Flow Variable

Specifies the flow variable on which to route for output 2.

Output 2 Flow Operator

Specifies the operation to use in the comparison for output 2.

Output 2 Case Sensitive

Decides whether to perform the case sensitive or insensitive comparison.

Output 2 Value

Specifies the value to compare against. If the Operator is In List or Not In List, provides a comma-separated list of values.

Sleep

This node suspends the execution of the flow for the specified number of milliseconds

Time in milliseconds: Use this setting to provide the specified sleep time.

Flow variable FLOWSLEEPTIME overrides this value.

SOAP Client Node

The SOAP Client Node provides a simple and powerful way to access SOAP services.

The SOAP Client Node can be used to directly invoke SOAP APIs. It can also use prebuilt configurations that define the APIs of the service. The node supports:

- Passing in request data on the input terminal or building the request directly in the node
- Returning success and error messages to the different output terminals
- The ability to loop through an array of requests to invoke an API repeatedly

The SOAP Client Node is an extension of the SOAP adapter, it internally uses REST Adapter. In many cases, it is much simpler to configure and use the node in a flow, especially in cases where an API call requires to send a request and handle the responses.

The SOAP node and the SOAP adapter only supports Service Definition mode.

The SOAP node needs to:

- Handle SOAP faults and convert fault to endpoint failure message
- Handle SOAP faults and convert fault to endpoint failure message
- **Functionality**
The SOAP Client Node operates in service definition mode.
- **Terminals**
The SOAP Client Node supports a number of terminals.
- **Settings**
This section lists the settings available for the SOAP Client node.
- **Authentication**
Endpoint definition authentication is selected by default.
- **Logging**
Specifies the level of logging to use for the log (trace) file produced by the node.

Functionality

The SOAP Client Node operates in service definition mode.

Terminals

The SOAP Client Node supports a number of terminals.

The SOAP Client Node supported terminals are listed in the following table.

Terminals

Table 1. Terminals

Terminal	Direction	Description
Request data	In	The data sent as HTTP request.
Successful response	Out	The HTTP response for a successful request (HTTP status is 2xx).
Error response	Out	The HTTP response for an error condition (HTTP status is 4xx or 5xx).
Success	Out	Standard success terminal.
Error	Out	Standard error terminal. This terminal is invoked depends on whether the error response terminal is connected or not. If the error response is connected, the node fails, only if a processing error occurred. If the error response is not connected, this terminal is invoked, if either the node fails, or the HTTP call returns an error status.
Log	Out	The SOAP Client node log file is produced if this terminal is connected.

Settings

This section lists the settings available for the SOAP Client node.

Authentication

Endpoint definition authentication is selected by default.

Logging

Specifies the level of logging to use for the log (trace) file produced by the node.

The default is Off. The value Information means log informational, the value Errors Only means log error messages only, and the value Verbose means log debug and trace level messages along with the informational and error messages.

When Append Log is set to true, the log messages are appended to the file. When set to false, the file is truncated and the messages are written to the empty file. If the file path is not specified, the trace is logged to the default system logger.

Split

A Split Node should be used when there is a need to split CSV or JSON data processing or when a map can run in a burst mode to process data in batches. This might occur when data processing becomes excessively time consuming.

Such time-consuming behavior might occur when you send big data to the flow input terminal, or it might become memory intense when complex data validation is being performed. The Split Node can be used with these, and with other data processing tasks that can be done in parallel.

The Split Node splits data records into batches. Each batch of data is processed in parallel and passed for further processing by the downstream nodes. Using the Split node can improve the performance and scalability of your flow design.

The source of data that the split node consumes can be a map or data that the split node reads directly from the input terminal or a file.

If the map provides the data, the map must run in the burst mode. This is configured using the map input card settings. The action property 'fetch as' must be set to 'burst'. 'Fetch as' property can be set to 'burst' if the adapter supports burst mode. Example adapters that support burst mode are FILE, REST and all messaging adapters like Kafka, JMS, MQ. The fetch unit controls how many records to process with one batch. If the fetch unit is not set, the default value is 0 and it means fetch all records. The fetch unit must be set to split in order to split data into multiple batches

- [Configuring a Split node](#)
- [Split example](#)

See the Split example for a demonstration of how to design, deploy, and run flows that contain Splitnode.

Configuring a Split node

- [Consuming data through an input terminal](#)

A Split node receives data through an input terminal if it is connected to an upstream node. For example, from the map node, if its input terminal is enabled as a flow terminal.

- [Consuming data from a file](#)

A Split node reads csv data from the file specified by the File Path setting. This option is supported only if it is not connected to an upstream node, or if its input terminal is not enabled as the flow terminal.

- [Defining number of Split instances](#)

A Split node splits data into batches and passes each batch to its downstream node.

- [Settings](#)

This section lists the settings available for the Split node.

Consuming data through an input terminal

A Split node receives data through an input terminal if it is connected to an upstream node. For example, from the map node, if its input terminal is enabled as a flow terminal.

Consuming data from a file

A Split node reads csv data from the file specified by the File Path setting. This option is supported only if it is not connected to an upstream node, or if its input terminal is not enabled as the flow terminal.

The data file name specified by the File Path settings can be hardcoded as a literal, or it can be parameterized using a flow variable. Enclose the flow variable name with '%' characters, for example "File Path: %my_data_file%"

Defining number of Split instances

A Split node splits data into batches and passes each batch to its downstream node.

The produced batches are processed in parallel, with the maximum number of Split node instances defined with the Maximum Instances setting.

Settings

This section lists the settings available for the Split node.

Batch Size

Specifies the number of records to include in each batch.

Maximum Instances

Specifies the maximum number of parallel instances.

Read From File

Specifies the options to read the input from a file or from the input terminal.

File Path

Specifies the path of input file.

Source

Specifies the data source. Supported options are 'map' and 'data'.

If 'map' is a source, the supported settings are:

- **Map Name:** Defines a map that will run inside the split node in the burst mode
- **Input Card Name:** Defines which input card to use in the selected map to split data. (click on 'Fetch' to get the list of input cards). Default is the 1st input card
- **Output Card Name:** Defines which output card in the selected map will produce data for the split node output terminal. (click on 'Fetch' to get the list of output cards). Default is the last output card

If 'data' is a source, the supported settings depend on the data format. Supported data formats are delimited (CSV) and JSON.

Record Delimiter

Specifies the character that delimits records. \\r for carriage return, \\n for newline and \\t for tab.

Has Header

Specifies that the header record is available in data.

Include Header

Decides whether the header record should be included in each batch sent to the output.

Output Header Split

Controls the Split node header processing, if the Has Header property is set. If the Output Header Split is enabled, the Split node processes the header in the first batch. It sets Flow Internal variable ~SPLIT~ to value HEADER when processing the header. The Split node waits for the header to process before it executes rows processing in parallel. ~SPLIT~ variable is set to the batch index when rows are processed in parallel.

If the data format is 'JSON', the supported settings are:

- **Array Path:** The path of the array in the json document
- **Output JSON Object:** If this option is turned on, when the batch size is set to 1 output a JSON object, otherwise output an JSON array
- **Output Context Before:** Controls whether the output data includes the JSON context before the selected array

Split example

See the Split example for a demonstration of how to design, deploy, and run flows that contain Splitnode.

The Split node example contains a readme file that contains detailed instructions about how to run the example.

The example is located in the following directory:

install_dir/examples/flowengine/splitter_node

Where *install_dir* indicates the directory location of the base Transformation Extender product.

Note: To install this example, as well as the other flow examples, you must install Design Studio using the Custom installation.

Status Node

A Status Node can only be used as the first node in a "status flow", as that what makes a flow a status flow. Similar to an initialization flow, a status flow may be referenced from any other main flow. A status flow has a Status node as its first node which has Success, Error and Always output terminals that provide the flow status JSON to a downstream node.

The name of the status flow can be any valid flow name. If the project has a status flow, another flow can reference it from the Flow Settings > Status Flow Option.

A status flow cannot be referenced in a flow node (sub-flow) or an initialization flow, or another status flow.

If a flow has a status flow associated with it, when the main flow completes (either successfully or in error), the associated status flow is invoked. The status is output from this node to a subsequent node based on whether the error, status or always terminal is connected. Multiple terminals can be connected to handle both success and

failure statuses in the same status flow.

- **Functionality**
This documentation describes the functionality of the Status Node.
- **Terminals**
This documentation describes about the Status Node terminals.

Functionality

This documentation describes the functionality of the Status Node.

The Status Node can be used for the following actions, as an example, but can be linked to any other nodes that are appropriate for the required action needed:

- To send an email in the event of a flow failure
- To perform a cleanup operation
- To complete a transaction, such as sending a message

Terminals

This documentation describes about the Status Node terminals.

The following terminals are supported by Status node:

- **Success:** If the main flow is successful, The Status JSON is output from this terminal
- **Error:** If the main flow fails, the Status JSON is output from this terminal
- **Always:** Whether the main flow is successful or not, the Status JSON is output from this terminal

Note: The Status Node does not have any input terminals. The output for each terminal that is linked /executed from the Status node is the flow audit of the flow that referenced it.

Terminals

- **Error and Success terminals**

An error terminal is used on a node for cases where the error can be caught with another node, preventing the flow from failing. An error terminal will only run a node if the node that has the error terminal is the initial cause of the error.

- **Log terminals**

Log terminals, like Error and Success terminals, can be enabled on any node and are output terminals only.

Error and Success terminals

An error terminal is used on a node for cases where the error can be caught with another node, preventing the flow from failing. An error terminal will only run a node if the node that has the error terminal is the initial cause of the error.

A success terminal will run a node if the terminal that has the success terminal is successful. Multiple success terminals in a flow will run multiple nodes as long as each node is successful. A node is not considered successful until all nodes that are linked to it return back to that node successfully.

A node is considered successful if a linked node fails, but that linked node has an error terminal linked to catch the error.

See the Error and Success terminals example for more information.

See the Error and Success Terminals example for a demonstration of how to use Error and Success terminals in a flow. The Error and Success example contains a readme file that contains detailed instructions about how to run the example.

- **Error and Success terminals example**

The Error and Success terminals example demonstrates usage of Error and Success terminal used in a flow.

The Error and Success example contains a readme file that contains detailed instructions about how to run the example.

The example is located in the following directory:

install_dir/examples/flowengine/error_success_terminals

Where *install_dir* indicates the directory location of the base Transformation Extender product.

Note: To install this example, as well as the other flow examples, you must install Transformation Extender Design Studio using the Custom installation.

Log terminals

Log terminals, like Error and Success terminals, can be enabled on any node and are output terminals only.

If a node has a Log Terminal that is linked, it will run the node that is linked to it after it completes, before it returns to the node that it was called from.

The data that is sent out of a Log terminal depends on the type of node. For a Map node, it contains node information as well as the map's audit log in JSON format.

Flow terminals

Scheduled flows

Listener

A Flow that has a Map node as its first node, and uses a File adapter for an input, can enable that node's input to be a Watch.

When a package is deployed with a flow that has a Watch, the Flow Engine's File Listener is started to monitor for files that match the map's input file definition.

You can use wildcards in the file adapter's filename so the File Listener will start a flow instance with each file that matches the pattern defined for the filename.

After it is deployed, the flow will run an instance when a file that matches the configured pattern of the filename appears in the trigger directory. The trigger is the directory defined for the map's input.

If a wildcard is used in the definition of the filename, the system flow variable "_WILDCARD_" will be assigned the value of the wildcard for that flow instance. The value can then be retrieved throughout the flow instance. For a complete demonstration, see the Listener example.

See the Listener example for a demonstration of how to use the Listener. The Listener example contains a readme file that contains detailed instructions about how to run the example.

- [Listener example](#)
The Listener example provides a demonstration of usage and behavior of the Listener as used in a flow.
- [Amazon SQS Listener](#)
The Amazon SQS Listener polls the selected queue from Amazon SQS and retrieves the messages.

Listener example

The Listener example provides a demonstration of usage and behavior of the Listener as used in a flow.

The Listener example contains a readme file that contains detailed instructions about how to run the example.

The example is located in the following directory:

install_dir/examples/flowengine/listener

Where *install_dir* indicates the directory location of the base Transformation Extender product.

Note: To install this example, as well as the other flow examples, you must install Transformation Extender Design Studio using the Custom installation.

Amazon SQS Listener

The Amazon SQS Listener polls the selected queue from Amazon SQS and retrieves the messages.

User should be able to use SQS Adapter as a listener in Flow Engine for existing queue to which user has access to and the listener should be able to report SQS messages as and when it arrives to the SQS queue.

Amazon SQS Listener as a source

- To receive a message

Amazon SQS Listener as a target

- To publish a message
- [Listener Properties and Commands](#)
This chapter provides a detailed description of the listener commands and properties.
- [To continuously listen to a message from a queue](#)

Listener Properties and Commands

This chapter provides a detailed description of the listener commands and properties.

Access Key

Specifies the key of AWS user for the connection. This access key is used to sign programmatic requests to AWS API calls through the adapter. The corresponding adapter command is **-AK** (or **-ACCESSKEY**).

Secret Key

Specifies the key of AWS user for the connection. Like the username and password, both the access key ID and secret access key are mandatory to authenticate SQS queue for a Get or Put request. The corresponding adapter command is **-SK** (or **-SECRETKEY**).

Region Name

Specifies the name to connect to an AWS region for the IAM user account. The corresponding adapter command is **-R** (or **-REGION**).

Queue Name

Specifies the SQS queue name to or from which messages need to be accessed. During action configuration, SQS Adapter provides options to select queue name among available queues in the provided region. The corresponding adapter command is **-Q** (or **-QUEUE**).

Create Queue

If specified, this property indicates the SQS adapter to create a queue with the name passed in the 'queue_name' property, in case it doesn't already exist. This property is optional. When the create_queue property is not specified, adapter checks if the queue already exists; if not: it throws an error. The corresponding adapter command is **-CQ** (or **-CREATEQUEUE**).

Read Mode

Specifies whether you want to delete or keep a message after reading it. Default is Keep. There are two values:

- Keep: To keep a message after reading
- Delete: To delete a message after reading

The corresponding adapter command is **-RM** (or **-READMODE**).

Attributes

Specifies if the SQS message should be accessed along with the corresponding message attributes. When the attributes flag is set to true in output card, the passed data should be in predefined JSON format, else data should be in a plain text message. The corresponding adapter command is **-A** (or **-ATTRIBUTES**).

Limit

Specifies the total number of messages to consume. The limit property is applicable and utilized only in ITX deployments. Minimum value should be 1. If no limit is specified, adapter fetches only one message at a time from the queue. The corresponding adapter command is **-QTY**.

Timeout

Specifies the time duration (in seconds) to wait for before retrieving the message from the queue. The timeout property of SQS adapter is applicable and utilized only in ITX deployments. The SQS adapter would listen to the queue for specified seconds. The corresponding adapter command is **-LSN**.

Logging

Specifies the level of logging to be used for the log (trace) file produced by the adapter. The default is off. The value info means log informational and error messages, the value error means log error messages only, and the value verbose means log debug and trace level messages along with the informational and error messages.

Append Log

Specifies the flag that indicates the action to take when the specified log file already exists. When set to true, the log messages are appended to the file. When set to false: the file is truncated, and the messages are written to the empty file. The default value is true.

Log File Name

Specifies the name of the log file, where the log messages are written. If not specified, the default log file name m4sqsltrc is used, and the file is stored to the directory in which the executed compiled map resides.

To continuously listen to a message from a queue

To continuously listen a message from one queue and send it to another queue.

1. In the Flows workspace, select Source nodes type from the Palette and drag and drop it to the canvas.
2. Right click on the Source node and select Settings.
3. Select Use Command Line option or Use Existing Connection option if you want to reuse the already created connection. If you do not want to use existing connection, make Use Existing Connection option false.
4. Specify the Action properties. Select the source queue which will read the message.
5. Select Schema Select Type field as Plaintext.
6. Click OK.
7. Select Target nodes type from the Palette and drag and drop it to the canvas.
8. Right click on the Target node and select Settings.
9. Select Use Command Line option or Use Existing Connection option if you want to reuse the already created connection. If you do not want to use existing connection, make Use Existing Connection option false.
10. Specify the Action properties. Select the target queue which will send the message.
11. Select Schema Select Type field as Plaintext.
12. Click OK.
13. Connect nodes by dragging from the output terminal of one node to the input terminal of another node.
14. Right click on the Source node and select Enable Watch.
15. Click on the Save icon.
Flow definition gets saved.
16. Deploy the flow to the server.
17. You can now send and receive messages on Amazon SQS source queue and target queue respectively.
To disable this functionality, select Disable Watch in flows.

Once you push the message from the Amazon SQS source queue the flows will run in Design Server and the message will be sent to the Amazon SQS target queue. And you can continuously listen to the messages from one queue to another queue.

Flow audits

Flow audits are a way to retrieve more verbose information about a flow instance.

There are two ways to retrieve an audit:

- From install_dir/logs
- As a response from the REST API

Method 1 – Enable the audit setting from the flow settings dialog (from an open flow, click the gear icon in the upper right). If On Error is also enabled, the audit will only be produced if an error occurs while running the flow. A log file is created in the directory with the naming convention: flow name + instance uid.

Example: flow_e9bea8c6-2f8b-4c47-b776-dcd4f571190e.log

Using this method sets the default audit behavior for whenever the flow is run.

Method 2 – From the Swagger UI, specify “log” near the bottom (look for Add Item). This will again generate the file as above, but it will also return the audit in the response unless the flow is run asynchronously.

Using this method overrides the audit settings specified when designing the flow (method 1 above).

Flow variables

Flow Variables are process data variables that go along with the flow execution, accessible to all nodes in the flow while it is being executed under flow executor/engine context.

Flow Variables are name-value pairs, where name is a case-sensitive string that is associated with a specific value in string format. Even numbers as values are maintained in character string format.

Map nodes in a flow access and manipulate through a new set of functions included in the 'flowlib' dynamic function library. This example utilizes those functions to set, get and increment the value of the flow variable defined for the flow.

Flow Variables can be set initially before the flow instance starts, or by the nodes in the flow that are propagated to the following nodes in the flow until the flow execution comes to an end.

Each flow instance gets its own set of variables, no two flow instances being executed at the same time share their flow variables with others. Flow Variables exists until the flow completes after they are defined the first time under flow executor context. In a non-flow executor context like, for example, under Command Server, exist until the top map finishes execution. The variables are shared by the top map and all its RUN maps for that specific map instance execution.

Note: Flow variables are not supported on z/OS.

See the Flow variables example for a demonstration of how to use flow variables in a flow. The Flow variables example provides a readme file that contains detailed instructions on how to run the example.

- [Flow variables example](#)

See the Flow variables example for a demonstration of how to use flow variables in a flow.

Flow variables example

See the Flow variables example for a demonstration of how to use flow variables in a flow.

The Flow variables example contains a readme file that contains detailed instructions about how to run the example.

The example is located in the following directory:

`install_dir/examples/flowengine/flow_variables`

Where `install_dir` indicates the directory location of the base Transformation Extender product.

Note: To install this example, as well as the other flow examples, you must install Design Studio using the Custom installation.

Deployment

Introduction to deployment procedures, describing configuration variables, servers and server groups and packages.

Deployment overview

A *package* bundles a map and related files for deployment. *Deployment* sends a package to a server where a runtime engine (such as Command Server) runs the maps. An administrator sets up deployment environments by defining servers and, optionally, server groups, and chooses the maps and files to include in a package.

Deploying a package to a server automatically compiles the maps in the package, if necessary, for the server platform.

Deploying a package to a web server automatically registers map endpoints in the catalog.

A *configuration variable* is an alias that represents an environment-specific or sensitive (encrypted) value. Configuration variables resolve at run time. Maps and server definitions can use configuration variables to support multiple deployment environments.

- **Server groups**

A server definition can use configuration variables to represent the server's host name, user ID, and password. A *server group* links a server definition to a specific value defined for the configuration variable. When a map deploys to the server, the server group determines how the configuration variable resolves.

- **Server definition**

An administrator identifies the physical servers and virtual machines where maps can run.

- **Packages**

When the administrator adds a map to a deployment package, the package automatically includes any files that the map references, except files referenced in map rules. The administrator must manually add files referenced in map rules to the package.

Server groups

A server definition can use configuration variables to represent the server's host name, user ID, and password. A *server group* links a server definition to a specific value defined for the configuration variable. When a map deploys to the server, the server group determines how the configuration variable resolves.

For example, an administrator who wants to deploy maps to either a test server or a production server might set up deployment as follows:

1. Define two server groups:

- TEST_GROUP
- PROD_GROUP

2. Define a configuration variable called HOSTNAME with the following values for each server group:

Server Group	HOSTNAME Values
TEST_GROUP	TEST_HOST
PROD_GROUP	PROD_HOST

3. Define the servers, specifying each server's host name as the HOSTNAME configuration variable:

Server Name	Host Name	Server Group
TEST_SERVER	%HOSTNAME%	TEST_GROUP
PROD_SERVER	%HOSTNAME%	PROD_GROUP

- When the administrator deploys a map to the server named TEST_SERVER, the server host name resolves to the value TEST_HOST.
- When the administrator deploys a map to the server named PROD_SERVER, the server host name resolves to the value PROD_HOST.

Defining a server group is optional. A server group is not required for deployment.

Server definition

An administrator identifies the physical servers and virtual machines where maps can run.

A server definition has the following attributes:

Name and description

Identifies the server among other servers in a project.

Type

Web server

Deploys a map to a web server and uses the REST API to run the map. This server type requires the URL attribute.
Execution server
Represents all other map execution environments, such as the Transformation Extender programming interface or Command Server.
Platform
Specifies the operating system, such as Linux® x64.
Transfer type
Specifies the file transfer protocol as FTP or SFTP.
Host name or IP address
Identifies the server to deploy to.
Port number
The port of the FTP or SFTP server. If not specified, the port resolves to the default port for the selected protocol.
User name and password
Identifies the user ID and password for the selected FTP or SFTP protocol.
Target directory
Deploys files to this directory on the server. Map and file paths are relative to this directory.
HIP installation directory
The location where Transformation Extender is installed on the server.
Server group name
Adds this server to the specified server group. This attribute is optional.
URL
Identifies the URL of the catalog API where the deployment function registers a map. The URL is required when the server type is web server.

Packages

When the administrator adds a map to a deployment package, the package automatically includes any files that the map references, except files referenced in map rules. The administrator must manually add files referenced in map rules to the package.

A package defines a set of maps and flows to be collectively built and deployed to a server.

- [Package definitions](#)
A detailed definition of packages.
- [Deployment](#)
Deploying a package copies it to one or more Link runtime environments. Any maps within the package are compiled during the deployment process

Package definitions

A detailed definition of packages.

A package definition is comprised of the following:

- The project that defines the maps and flows.
- A base path under which the artifacts are deployed. This can be used to ensure that similarly named artifacts are kept distinct and do not overwrite each other.
- A set of flows and/or maps to be included in the package.
- A set of additional files from the project to be included in the package.
- A default flow to be executed using the flow command server if the '--flow' command line option is not used.

For maps and flows, a URL can be specified. This defines the endpoint URL through which the map or flow can be accessed on the IBM Sterling Transformation Extender runtime server.

Building a package causes the maps listed in the package to be compiled.

Deploying a package compiles all the maps listed in the package and add all of the artifacts to a package file which gets deployed to the specified server. Dependent objects are also included in the package even if they are not explicitly selected. For example, if a flow references other flows and maps, the referenced flows and maps are included in the package.

The flow command server (flowcmdserver) has a command-line option '--flow' that specifies the flow to execute from the package (sqlite file). If the '--flow' command-line option is not specified, the flow command server will execute the default flow if one has been specified.

Deployment

Deploying a package copies it to one or more Link runtime environments. Any maps within the package are compiled during the deployment process

The package will either be copied, sent by FTP, or by a REST API call, depending on the type of server being accessed.

When a package is deployed, any maps or flows that have a URL defined will be accessible using that URL. The Swagger page of the IBM Sterling Transformation Extender runtime is updated to include details of the endpoint.

Design Server UI

This documentation describes the Design Server User Interface.

Design workspace

The Design workspace includes the following components:

- [Schema Designer](#)
This documentation describes basics about the Schema Designer.
 - [Map Designer](#)
 - [Flow Designer UI](#)
This documentation describes the Flow Designer.
-

Schema Designer

This documentation describes basics about the Schema Designer.

- [Schema Designer dictionary](#)
 - [Schema Designer structure](#)
 - [Schema Designer properties](#)
 - [Schema Designer toolbar](#)
-

Schema Designer dictionary

Map Designer toolbar

Flow Designer UI

This documentation describes the Flow Designer.

The primary components of the user interface are:

- **Palette**
The Flow Designer Palette is the left-hand pane of the Flow Designer window.
 - **Canvas**
The Flow Designer canvas is the white display area immediately to the right of the Palette.
 - **Structure pane**
The Structure pane displays the terminals for the currently selected node and allows terminals to be added, removed and configured.
 - **Information pane**
The Information pane is in the lower right-hand corner of the Flow Designer window:
 - **Toolbar**
The Flow Designer toolbar allows you to perform various tasks.
-

Palette

The Flow Designer Palette is the left-hand pane of the Flow Designer window.

The Palette contains the list of available node types which can be dragged to the canvas. Available nodes are:

- Map
 - Flow
 - Parallelizer
 - Router
-

Canvas

The Flow Designer canvas is the white display area immediately to the right of the Palette.

This is the area that you use to construct flows by dragging and linking nodes.

If the diagram exceeds the size of the screen, the canvas can be scrolled by using horizontal and vertical scroll bars. The canvas can be enlarged by double-clicking on the gray bar to the right of the canvas, which hides the Structure and Information panes.

- **Nodes**
Hovering over a node on the canvas shows an expanded view of the node, revealing all of its terminals and connections.
 - **Context menu**
If you right-click on a node, the Context menu displays.
 - **Links**
If you right click on any of the links that connect the nodes you will be given the option to delete the link.
-

Nodes

Hovering over a node on the canvas shows an expanded view of the node, revealing all of its terminals and connections.

When you click on a node, the following occur:

- The structure diagram is updated to show the terminals of the node.
 - The Information Pane is updated with the name and description of the node.
-

Context menu

If you right-click on a node, the Context menu displays.

These options are available from the Context menu:

- Settings - edits the settings of the node. Each node type has different settings.
- Delete - prompts you to confirm that you want to delete the node. If you continue, the node is removed from the canvas, and any connected links are removed. If deleting the node leaves other nodes disconnected, an error indicator is shown on these nodes and they can be connected to existing nodes to complete the flow.

Other node types have additional options in the Context menu:

- Map node: Open Map – opens the map in the Map Designer workspace
 - Flow node: Open Flow – opens the flow in another tab in the Flow Designer
-

Links

If you right click on any of the links that connect the nodes you will be given the option to delete the link.

If you want to delete the link, you will be prompted to confirm the action before the link is removed from the canvas. If deleting the link leaves other nodes disconnected, an error indicator is shown on these nodes and they can be connected to existing nodes to complete the flow.

Structure pane

The Structure pane displays the terminals for the currently selected node and allows terminals to be added, removed and configured.

The Structure diagram includes three sub-components: menu, node icon, and terminal icons.

Click the menu icon at the top of the Structure pane menu to access these functions:

- Show/Hide Log Terminal – displays, or removes, a log terminal in the structure and the expanded node. The log node provides the log for the node's execution. For example, for a map node the log node produces a map audit log.
- Show/Hide Error Terminal – displays, or removes, an error terminal in the structure and the expanded node. The error terminal is invoked if the execution of the node fails. An error status message is sent to the error node.
- Show/Hide Success Terminal – this displays, or removes, a success terminal in the structure and the expanded node. The success terminal is invoked if the execution of the node succeeds. A successful status message is sent to the success node.

Information pane

The Information pane is in the lower right-hand corner of the Flow Designer window:

The information pane displays the following information:

Node Name – the name of the node, which must be unique in the flow.

Description – a multi-line description that explains the purpose of the node.

Map or Flow Name – if the node is a map or a flow, the name of the map or flow is displayed.

Toolbar

The Flow Designer toolbar allows you to perform various tasks.

Click the associated icon to do the following:

- Save -save the current flow.
- Save As - save the current flow under a different name and/or path.
- Snapshot - create a snapshot of the current state of the flow.
- Restore Snapshot - restore a snapshot to replace the current state of the flow with the state captured in the snapshot.
- Settings - show the flow settings in a dialog.
- Analyze - perform an analysis of the flow and display the results.

Design Server Properties

The Design Server properties includes:

- **Where Used**

Where Used allows a user to select the component where the subject component is used and go directly to it in the designer.

Where Used

Where Used allows a user to select the component where the subject component is used and go directly to it in the designer.

Where Used is applicable to the artifacts level, i.e, Schemas, Maps, Flows, Connections, and Actions.

Where Used can be viewed using following methods:

- In the Schemas/Maps/Flows/Connections/Actions workspace list, right click or select the stacked dot on the component to display the context menu and select Where Used from the menu. Where Used window opens.
- Click on the Where Used icon from the Schema/Flow designer toolbar. Where Used window opens.

Dashboard

This section describes a description of IBM Sterling Transformation Extender server dashboard.

The IBM Sterling Transformation Extender Server dashboard is a graphical user interface that provides users with a centralized and visual way to monitor and manage their server environment.

- [**Server Dashboard**](#)

- [Functionality of the Server Dashboard](#)
-

Server Dashboard

The server dashboard within IBM Sterling Transformation Extender serves as a centralized control panel for managing deployed flows and viewing the outcomes of flow runs. It offers the capability to execute maps and flows, specifically those without predefined inputs. However, for running other endpoints, users are directed to the respective Swagger page.

The server dashboard shares similarities with the Swagger page and the 'Run' dialog found in the flow designer. Moreover, the server page's user interface (UI) can double as the interface for the IBM Sterling Transformation Extender Commerce dashboard. In a Commerce context, the UI provides server status updates and run information, although functionalities for adding or editing servers are not applicable.

Functionality of the Server Dashboard

The server dashboard empowers users to perform a range of tasks, including:

1. Listing existing server definitions.
2. Creating new server definitions.
3. Editing server definitions.
4. Configuring values for server group-related configuration variables.
5. Viewing historical run statistics through graphical representations like pie and bar charts for user-specified time periods.
6. Displaying a comprehensive list of deployed packages/endpoints on the server. This includes features such as column-based sorting (e.g., by package or component name), package status indication (available or stopped), endpoint-specific statistics (successes, failures, total runs), and information about scheduling.
7. Enabling users to halt or initiate packages.
8. Scheduling endpoints, inclusive of complete schedule removal.
9. Triggering on-demand runs for endpoints.
10. Facilitating input file or data submission when endpoints require inputs.
11. Retrieving output data produced by endpoints.
12. Setting flow variables and query parameters within requests.
13. Providing both manual and automatic options for refreshing the server dashboard page. The auto-refresh toggle allows data updates at fixed intervals (for example, every 5 seconds).
14. Clicking on an endpoint discloses the following options:
 - Change schedule
 - Remove schedule (only shown if the endpoint is scheduled)
 - Run now

By default, the statistical data refreshes exclusively upon clicking the 'refresh' button. The UI also supports an 'auto refresh' toggle, ensuring that the UI autonomously updates data at predefined intervals.

Using Design Server

This documentation describes Design Server tasks.

Add a user

These procedures describe how to use the Design Server to add a new user.

To add a new Design Server user, login to Design Server as an Administrator, and then follow these steps in the Design Server Welcome page:

1. Click the drop-down arrow next to the Administrator tab in the upper right corner of the Design Server Welcome window.
 2. Select the Administration option from the menu. The Users window opens.
 3. Click the plus sign icon located to the right of the Search box at the top of the page to open Add User.
 4. Complete all of the fields in Add User area with the new user's information. Be aware of the following when completing the fields:
 - The password that you assign must be at least eight characters in length and contain at least one number and one character that is neither a number or a letter.
 - In most cases the Role field will remain in its default condition and will display the Designer option.
 5. Click the Add button at the bottom of the page. You are returned to the Users page. The user that you added appears in the list of users.
-

Create a project

Create a new project using Design Server.

To create a new project using Design Server follow these steps:

1. On the Welcome page, click the Go to your Workspace button.
The Projects tab opens.
2. Click the Create New Project button on the top of the Projects tab to create a new project.
3. Enter a name for the project in the Name field. You can also enter information in the Description and Tags fields if desired.
4. Click Ok. The new project appears in the Projects list.

5. You can edit, delete, or download the project by clicking the More options icon located to the right of the project name. The following are available options:

- Click Edit to return open the Edit Project page. Make any desired changes to the project name, description, or tags.
 - Click Delete to delete the project and remove it from the Project list.
 - Click the Export icon to export the project.
 - Click the Selective Export icon to open the Selective Export page. This page lets you select specific artifacts for export.
-

Import a project

Import a project using Design Server.

To import a project using Design Server follow these steps:

1. On the Welcome page, click the Go to your Workspace button.
The Projects tab opens.
2. Click on the Import Project button. The Import Project button is located before the Create New Project button on the top of the Projects tab.
The Import Project page opens.
3. In the Import Project page, click the browse link in the Project zip file area to navigate to the file that you want to import. Alternatively, you can drag and drop the file to be imported in to the Project zip file area.
4. Enter a project name in the Project Name field. You can also enter information in the Description field.
5. Click the Import Project at the bottom of the page to import the project.
The import progress bar will appear above the Import Project button. The message, 'Project Imported successfully', will appear upon completion of a successful import.
6. An existing project can be updated using the Import file option. Supported project files include:
 - Project files created using the **Export** or **Selective Export** options of an existing project.
 - A zip file that consists only of compiled maps (mmc files).
 - Individual compiled maps (mmc files).

Export a project

You can export existing projects in the form of a zip file.

To import a project using Design Server follow these steps:

1. On the Welcome page, click the Go to your Workspace button.
The Projects tab opens.
 2. Select the existing project to export. When you select the existing project, an Export icon gets visible before the Import Project button.
 3. Click the Export icon
The export progress bar will appear above the Export icon. The message, 'Project Downloaded', will appear upon completion of a successful export.
- **Selective Export**
Use the Selective Export feature to export the selected project artifacts.

Selective Export

Use the Selective Export feature to export the selected project artifacts.

The Selective Export function creates a .zip archive file and downloads it to the local file system. By using this function, you can export the artifacts in .mtt and .mms formats which are compatible with Design Studio.

To use Selective Export function:

1. Open an existing project. The existing project opens.
2. Select Selective Export from the drop-down menu next to project name. Selective Export window opens.
3. If you need to export artifacts with .json format, click Native radio button.
4. If you need to export artifacts with .mtt or .mms format, click Classic Files radio button.
Note: Schema, Maps, Flows, Files, and connections are disabled by default.

Create a flow

Use these steps to define a flow:

1. From the Welcome page, click the Create New Project icon.
2. Type a name for the project in the Name field. Optionally, enter information in the Description and Tags fields.
3. In the Design tab, select your project.
4. In the main Design Server workspace, choose Flows. Select New New Flow dialog opens.
5. Type a flow name in the Name field, and then click OK. The Flow Designer workspace for the flow opens.
6. From the Palette, on the left side of the page, drag the Map icon onto the canvas.
7. Right click on the map node to open a list of maps.

8. Select a map from the list.
 9. Click on the map node. The structure of the map is revealed in the structure panel, and details about the node are displayed in the details panel.
 10. Change the name of the node and give it a description by clicking on the Edit icon in the Details panel.
 11. Click on the drop-down menu in the structure panel and select Edit Terminals... to change which cards of the map are displayed as terminals in the map node.
 12. Select other node types from the Palette and drag them to the canvas.
 13. Connect nodes by dragging from the output terminal of one node to the input terminal of another node.
 14. Use the toolbar in the upper right corner of the canvas and select Save to save the flow.
 15. From the toolbar select Analyze, to analyze the flow for structural errors or incomplete definitions.
 16. Click the Home icon to return to the Welcome page. From here, the flow can be added to a package and deployed to the runtime environment.
-

Define mapping between source and target

This documentation describes how to use Design Server to define mapping between source and target.

This task introduces the concepts you will use to define mapping between a source and a target. Such mapping can be accomplished in multiple ways, however, the following requirements remain constant:

- For each input, a connection to the source resource must be defined and action properties must be defined, in order to determine how the data is read from the source.
 - For each output, a connection to a target resource must be defined and action properties must be defined, in order to determine how data is written to the target.
 - For each input and output, a schema must be specified to specify the format of the data.
1. On the Design Server Welcome page, create a new project, or select an existing project to open the main Design Server workspace.
 2. Upload a file containing input data by clicking on **Files > New**.
 3. Create a schema that describes the data in the input file by clicking on **Schemas > New**
 4. Click on **Connections** to create a source action to read from the input file.
 - a. Select the File connection, and then select **New Action** from the context menu.
 - b. In the Action Type section, select **Source** as the Direction, then click **Next**.
 - c. In the Properties section, select the file that you uploaded from the File Path drop down list, then click **Next**.
 - d. In the Schema section, select the file that you created and select the root type in the Schema Type drop down list, then click **Next**.
 - e. In the Identification section, name your action. Optionally, you can provide a description, search tags and a folder.
 5. Create a schema that defines the output data.
 6. Create a target action to write to an output file. Follow the same steps as for a source, but select **Target** as the Action Type.
 7. Create a new map by clicking **Maps > New**.
 8. Add the source action to the map by navigating to **Connection > Files <source_action>**, and then selecting **Add to Map** from the context menu.
 9. Add the target action to the map by navigating to **Connection > Files <target_action>**, and then selecting **Add to Map** from the context menu.
 10. To map from a source you must add the source to the mapping area. To do this, click on the context menu for the source in the Map Structure panel, and then click on **Add**. The input is added to the mapping area..
 11. Expand the schemas for input and output in the mapping area, and define your mapping by dragging types from the source fields to the output fields. More complex mappings can be defined by clicking on the output rules, or icons, to bring up the rule editor.
 12. Click **Save** on the toolbar to save the map.
 13. Click the **Build** icon to build the map. You will receive a success message if the build is successful. If it is successful, continue with the next step.
 14. Click **Run** to run the map.
 15. After running the map, the **Results** panel appears. Click on inputs or outputs to view the data, trace or audit for the specific input and output.
-

Running flows in the Designer

When you develop a flow in the Flow Designer you can run the flow directly from the Designer either in the Design Server, or on a different runtime environment.

If you want to run in a different runtime if, for example, if its environment has been configured with client software to access a particular resource by using a Link adapter.

- [**Preparing to run a flow from the Designer**](#)
Make these preparations in order to run your flow from the Designer.
 - [**Running the flow**](#)
After you specify the server, variables and input data, using the Run properties dialog, you can run the flow.
 - [**Viewing logs**](#)
The log for an individual node can be viewed by right-clicking on the node in the canvas and selecting View Log from the menu.
 - [**Viewing flow terminal data**](#)
The input and output data of the flow can be viewed by clicking on the node containing the flow terminal and then clicking on the input or output terminal icon in the structure.
 - [**Displaying link data**](#)
The data that was sent down a link in the flow can be viewed using either of these methods:
 - [**Including Maps and Files that are Dependencies of a Flow**](#)
-

Preparing to run a flow from the Designer

Make these preparations in order to run your flow from the Designer.

1. Save the flow.
2. Click the Run icon on the toolbar located in the upper right of your display. The Run Properties dialog opens. You can use this dialog to specify Server, Variables and Input Data.

- **Server section options**
The server drop-down in the Run Properties dialog allows you to specify these options:
 - **Variables section options**
The Variables section lists in table form the flow variables that are defined in the flow.
 - **Input Data section options**
If the flow has any input terminals, then the Input Data section provides a way to provide input to the flow terminal.
-

Server section options

The server drop-down in the Run Properties dialog allows you to specify these options:

- Run on Design Server – Set this toggle to either run the flow directly on the Design Server, or to deploy it to a runtime server.
 - Server – If you are deploying the flow to a runtime server, select the server from the drop down list. The servers in this list are defined in the Deployment screen. Only servers that are defined as Local or Web type will be listed.
-

Variables section options

The Variables section lists in table form the flow variables that are defined in the flow.

The name of each variable along with its value are listed.

The values of the variables can be specified in this table. Additional variables can be added, or rows can be deleted from the table. The flow will be run with the set of variables defined in this table.

Input Data section options

If the flow has any input terminals, then the Input Data section provides a way to provide input to the flow terminal.

The data can be provided from a file or pasted directly into the dialog. The options available are:

- Select File – A file uploaded into the project can be selected as input to the API.
 - Upload a File – A file can be selected from the local machine or dragged into the panel. Once added in this way the file will then appear in the project's file list.
 - Paste Data – Input data can be entered or pasted into a text box
-

Running the flow

After you specify the server, variables and input data, using the Run properties dialog, you can run the flow.

1. Click on the Run button to run the flow.

This action prepares and packages the flow and any flows or maps that are used within the flow. If running on a remote server, the package will be deployed to the server. The flow is then run in debug mode which allows the data passed between links in the flow to be saved so that it can be viewed.

2. After the flow run is complete, indicators display on each node of the flow to indicate whether the node succeeded, failed or was not invoked.
A green tick indicator means that the node ran successfully, a red cross indicator means that the node failed (or a downstream node failed) and no indicator means that the node did not run (because no data was provided to its input). Hovering over the node status icon shows a status message for the node run.
-

Viewing logs

The log for an individual node can be viewed by right-clicking on the node in the canvas and selecting View Log from the menu.

This displays the log in a panel in the UI that shows the node status and log messages from the node. If the node is a map, the map audit is shown.

Viewing flow terminal data

The input and output data of the flow can be viewed by clicking on the node containing the flow terminal and then clicking on the input or output terminal icon in the structure.

- To view the data that was sent to a flow, click on the node that contains the flow input terminal This is always the first node in the flow, then click on the input terminal in the structure.
- To view the data that the flow produced on an output flow terminal, click on the node that contains the flow output terminal, then click on the appropriate output terminal in the structure.

The input or output data is displayed in a new browser window.

Displaying link data

The data that was sent down a link in the flow can be viewed using either of these methods:

- Right-click on the link to display the context menu, and then select View Data from the menu.
- Click on a node in the canvas, right-click on a link terminal in the structure, and then select View Data from the menu.
The link data is displayed in a new browser window.

Including Maps and Files that are Dependencies of a Flow

When executing a flow from the design server, it is possible that the flow relies on internal dependencies. These dependencies need to be explicitly defined through specially formatted statements within the flow description.

In cases where a map node executes a map using the RUN function to call other maps, you must reference these additional maps in the flow description using the following format:

```
@packagemap=[map folder]/mapname
```

Furthermore, if a map node uses a map or run map that necessitates a specific file on its input card, you can incorporate the required file into the deployment process using the following notation:

```
@packagefile=<file path>
```

Both files and maps can be grouped into a package, and then you can reference this package using:

```
@package=<package name>
```

Note: It is important to observe that all "**@package*=" statements**, when added to the flow description, must each be on a new line. These measures ensure that all essential dependencies are correctly included and referenced when executing the flow from the design server.

Introduction to Design Studio

- [Design Studio overview](#)

The Design Studio provides the means for developing event-driven application-to-application (A2A) integration, business-to-business (B2B) integration, and consumer-to-business (C2B) application integration.

- [Design Studio configuration](#)

The Design Studio components are the design-time applications that are used to define, manage, and test maps and systems in a development environment.

- [Design Studio customization](#)

The Design Studio application toolbars and shortcut keys can be customized to fit your needs. Use the configuration options in each designer application to set preferences for your working environment.

- [Map Designer](#)

Map Designer is the application in the Design Studio that is used to specify data transformation logic in the form of map rules.

- [Database Interface Designer](#)

- [Integration Flow Designer](#)

The Integration Flow Designer is the graphical process-modeling element of the Design Studio. Use the Integration Flow Designer as a modeling component for defining and managing business processes.

- [Design Studio reference](#)

There are some restrictions that apply when using the Design Studio components to design your data transformation process. Certain words and symbols have a specific meaning when used within the Design Studio applications.

Design Studio overview

The Design Studio provides the means for developing event-driven application-to-application (A2A) integration, business-to-business (B2B) integration, and consumer-to-business (C2B) application integration.

The Design Studio is the design component of IBM Transformation Extender used to model and test your e-business solutions. Use the Design Studio to:

- Define your data.
- Create maps for your data.
- Manage the systems of maps that you create.
- Develop and test maps and systems in the Microsoft Windows environment.

The Design Studio is installed on and operates on Windows platforms. The client components of the Design Studio include the Type Designer, Map Designer, Integration Flow Designer, and Database Interface Designer.

Example files are located in the *install_dir/examples/dsgnstud* directory.

Design Studio configuration

The Design Studio components are the design-time applications that are used to define, manage, and test maps and systems in a development environment.

While the Design Studio components are primarily used during the design phase of your transformation project, the Launcher and Command Server are used to execute maps and systems in a runtime environment.

- [Design Studio design tasks](#)
There are tasks that you must complete when using the Design Studio.
- [Design Studio runtime tasks](#)
At runtime, the Design Studio overwrites map and card settings.

Design Studio design tasks

There are tasks that you must complete when using the Design Studio.

Design-time tasks include:

- Creating/generating type trees.
- Modifying type properties.
- Configuring the map settings, including SourceRule settings in input cards and TargetRule settings in output cards. (These configuration settings are compiled into maps.)

Systems can be designed using the Integration Flow Designer before, during, or after the type tree and map design phase.

These design-time tasks are performed on the client components of the Design Studio. Changing these settings at the time of execution are runtime tasks.

Use a platform-specific Launcher or Command Server to execute maps and systems in a runtime environment.

Design Studio runtime tasks

At runtime, the Design Studio overwrites map and card settings.

Map settings and card settings can be overwritten in two ways:

- Modifying the execution settings of a system component in the Integration Flow Designer.
- At execution time with execution commands.

Execution commands override the map settings or card settings of the compiled map when that map is run. See the Execution Commands documentation for a complete description of the override commands.

- [Execution settings](#)

Execution settings

Execution settings in the Integration Flow Designer are either Launcher or Command Server settings that are generated for the system. Command Server settings are used when the system is to run by means of the Command Server. Launcher settings are used when the system is to run by means of the Launcher.

Choose execution settings based on the server on which the system is to run. These execution settings overwrite the map and card settings, but do not alter the map source file (.mms) or compiled map file (.mmc).

Design Studio customization

The Design Studio application toolbars and shortcut keys can be customized to fit your needs. Use the configuration options in each designer application to set preferences for your working environment.

- [Customizing Design Studio toolbars](#)
In Design Studio, you can customize the standard toolbar or create your own. You can also delete and rearrange tools within a toolbar.
- [Customizing Design Studio shortcut keys](#)

Customizing Design Studio toolbars

In Design Studio, you can customize the standard toolbar or create your own. You can also delete and rearrange tools within a toolbar.

About this task

You can customize the standard toolbar or create your own. You can also delete and rearrange tools within a toolbar.

- **Delete a tool from a toolbar.** Press the **Alt** key and drag the tool off the toolbar.
- **Rearrange tools on a toolbar.** Hold down the **Alt** key and drag any tool, placing it in the toolbar where desired.
- **Add tools to a toolbar.** Select Toolbar(s) from the **View** menu. When the **Customize** dialog box appears, click the Commands tab, drag the tools to the toolbar as desired. You can also delete and rearrange tools; however, you do not need to use the **Alt** key in the **Customize** dialog box.
- **Make a floating toolbar.** Drag a toolbar and place it inside or outside the Type Designer window.

- **Cancel all changes made to a toolbar.** In the **Customize** dialog box, click **Reset**.
- **Customize the appearance of the tools.** You can select options for showing tool tips, viewing the tools as flat (**Cool Look** check box enabled) or raised, and specifying small or large tools on the toolbar (**Large Buttons** check box enabled).

To reset a toolbar to its default configuration

Procedure

1. From the **View** menu, choose **Toolbar(s)**.
2. From the **Toolbars** tab, select the toolbar you want to reset and click **Reset**.

To create a new toolbar

Procedure

1. From the **View** menu, choose **Toolbar(s)**.
2. On the **Customize** dialog box, click **New**.
3. Enter a name for the toolbar (for example, **Editing**) and click **OK**.
4. Select the new toolbar in the **Customize** dialog box.
5. The new toolbar appears on your screen.
6. Select the **Commands** tab.
7. Drag each tool that you want into the new toolbar.
8. Click **OK** to save the toolbar when you are finished.

Results

For example, you can drag the **Cut**, **Copy**, and **Paste** tools to the new "Editing" floating toolbar.

Arrange your toolbars by dragging them into positions.

To move a toolbar

Procedure

Drag the toolbar to the new location inside or outside the Type Designer window.

Results

When positioning a toolbar inside the Type Designer window and docking is not desired, press the **Ctrl** key to prevent docking.

Customizing Design Studio shortcut keys

About this task

To customizing the trace for IBM Sterling Transformation Extender Rest execution, complete the following steps:

Procedure

1. From the **Tools** menu, choose **Short Cuts**
The Shortcut Keys dialog box is displayed.
2. In the **Select a macro list** in the **Shortcut Keys** dialog box, select a command to which you want to assign a shortcut key.
3. Click **Create Shortcut**.
A message displays that indicates whether the shortcut is currently assigned.
4. After you finish assigning shortcuts, click **OK**.

Map Designer

Map Designer is the application in the Design Studio that is used to specify data transformation logic in the form of map rules.

The Map Designer uses the definition of data objects created in the Type Designer as inputs and outputs and provides the functionality to specify rules for the transformation and routing of data.

Maps are analyzed, compiled, and tested using the Map Designer. Each map defines input and output specifications. Map rules entered in the Map Designer operate on input data objects and build output data objects.

- [Map Designer overview](#)
To use the Map Designer, you must already have created or generated the type tree(s) that define your data. The Map Designer uses the data object definitions that are stored in those type trees.
- [Map Designer Eclipse overview](#)
In IBM Transformation Extender Design Studio release 8.2 and later, the Map Designer is an Eclipse-based program. The Eclipse platform provides a common user interface for the Map Designer called a *perspective*.

- [Map deployment overview](#)

You build and run maps using the Map Designer on a Windows platform. You can also use the Map Designer to build a map to be run on another platform.

Map Designer overview

To use the Map Designer, you must already have created or generated the type tree(s) that define your data. The Map Designer uses the data object definitions that are stored in those type trees.

After defining data objects and their properties in the Type Maker, define the map in the Map Designer to specify the source of the input and the target of the output. Sources and targets are specified with map cards. Each map can have none or more input cards, and one or more output cards.

The Map Designer is used to:

- Create maps to specify the logic necessary to transform the input data to the desired output data.
- Identify the source and data objects of the input data.
- Identify the target and data objects of the output data.
- Specify and build the output data according to the map rules.
- Provide information about data validation by generating trace files.
- View the run results of the map execution.

Map Designer Eclipse overview

In IBM Transformation Extender Design Studio release 8.2 and later, the Map Designer is an Eclipse-based program. The Eclipse platform provides a common user interface for the Map Designer called a *perspective*.

For information about using the Eclipse Workbench and about keyboard navigation, see the *Workbench User Guide* in the Eclipse Help.

Map deployment overview

You build and run maps using the Map Designer on a Windows platform. You can also use the Map Designer to build a map to be run on another platform.

Each map can be built for a specific platform, and then executed on that platform to perform the transformation of the data.

Database Interface Designer

The Database Interface Designer is used to import metadata about queries, tables, and stored procedures for data stored in relational databases. Use the Database Interface Designer to identify characteristics of those objects to meet mapping and execution requirements such as update keys and database triggers.

Use the Database Interface Designer to:

- Specify the databases to use for a source or target.
- Define query statements.
- Automatically generate type trees for queries or tables.
- **Database Interface Designer unique key combinations**
There are some unique key combinations available in the Database Interface Designer in addition to the standard Microsoft Windows navigation keys.
- **Database Interface Designer configuration**
The Database Interface Designer must be configured prior to use.
- **Database Interface Designer adapters**
The IBM Transformation Extender database adapters provide the connectivity to the RDBMS for retrieving input data and routing output data. Database adapters provide the option of using a driver to connect to the platform of your choice so you can automatically create type trees for database queries and tables.

Database Interface Designer unique key combinations

There are some unique key combinations available in the Database Interface Designer in addition to the standard Microsoft Windows navigation keys.

For enhanced accessibility, the following key combinations are available in the Database Interface Designer.

Navigation description	Key combination
To navigate to each pane of the Database Differences window	Shift+down arrow
To navigate to each tab in the Database Differences window	F8
To set the focus on the first item on the left tree view in the Database Differences window	Shift+F7
To select the first selection button in the Set Table Update Key Columns window	Ctrl+A
To select the second selection button in the Set Table Update Key Columns window	Ctrl+D
To select the third selection button in the Set Table Update Key Columns window	Ctrl+B
To select the fourth selection button in the Set Table Update Key Columns window	Ctrl+L
To select the fifth selection button in the Set Table Update Key Columns window	Ctrl+E

Database Interface Designer configuration

The Database Interface Designer must be configured prior to use.

After defining database query files and database table connectivity in the Database Interface Designer, define your map in the Map Designer. In map cards, you can specify an input source as either a query or a stored procedure and an output target as either a table or a stored procedure.

The Database Interface Designer is used to support business processes that read from and write to databases under control of a Relational Database Management System (RDBMS). The Database Interface Designer provides runtime database connectivity to the Transformation Server. This connectivity is supported with database-specific adapters or open database connectivity (ODBC). ODBC is a programming interface that enables programs to access data in database management systems that use structured query language (SQL) as a data access standard.

The Database Interface Designer:

- Provides connectivity to existing resources.
- Integrates multiple resources.
- Provides transactional control when resources support transactions.
- Combines transformation capabilities and resource connectivity.

All database access is transactional for resources that support transactions.

Database Interface Designer adapters

The IBM Transformation Extender database adapters provide the connectivity to the RDBMS for retrieving input data and routing output data. Database adapters provide the option of using a driver to connect to the platform of your choice so you can automatically create type trees for database queries and tables.

The Windows-based database adapters are installed with the Database Interface Designer as part of the Design Studio. You can also install the database adapters on additional systems to provide remote database connectivity.

Note: Non-Windows database adapters do not require the Database Interface Designer if you plan to only use **mtsmaker** without a database/query file (.mdq) to generate each type tree. For information about using **mtsmaker**, see the Resource Adapters documentation.

Integration Flow Designer

The Integration Flow Designer is the graphical process-modeling element of the Design Studio. Use the Integration Flow Designer as a modeling component for defining and managing business processes.

The Integration Flow Designer manages collections of maps at design time. Other product components, such as the Command Server or Launcher, manage the execution of maps at run time.

Collections of maps are called systems. Systems can be used as a focal point for interfacing to other development components and for preparing maps for execution.

Maps are created in the Map Designer. The systems created and managed in the Integration Flow Designer can be defined with existing maps, or they can be designed with maps that have not yet been created (pseudo map components). Systems can also be designed with subsystems.

Use the Integration Flow Designer to:

- Define interactions among maps and systems of maps.
- Specify integration workflow.
- Display data flow relationships among system components.
- Validate the logical consistency of workflows.
- Prepare systems to run.
- Verify component relationships.
- Generate process control information.
- Experiment at design time.
- Coordinate multiple data sources and targets.
- Coordinate events.
- Model a variety of what-if scenarios.
- Visualize the scenario results.
- Create and manage collections of logically related maps.
- Specify system deployment servers: Use one of three predefined server definitions or create server definitions that describe the servers in your enterprise.

The graphical representation of systems in the Integration Flow Designer helps you to visualize system designs, what-if scenarios, and system execution behavior. The interface provides easy management of system definition diagrams that allow concentration on the system design. Error reduction is achieved by automation of repetitive tasks and the use of system hierarchy.

- **[Integration Flow Designer unique key combinations](#)**

There are some unique key combinations available in the Integration Flow Designer in addition to the standard Microsoft Windows navigation keys.

- **[Integration Flow Designer components](#)**

The Integration Flow Designer enables you to overwrite settings compiled into maps.

Integration Flow Designer unique key combinations

There are some unique key combinations available in the Integration Flow Designer in addition to the standard Microsoft Windows navigation keys.

For enhanced accessibility, the following key combinations are available in the Integration Flow Designer.

Navigation description	Key combination
To move the focus to the Navigator	Shift+F7
To navigate to each pane of the System File Differences window	Shift+down arrow
To navigate to each tab in the System File Differences window	F8

Tip: In the More Find/Replace window, press Alt+i twice to move the focus to the Find All button.

Integration Flow Designer components

The Integration Flow Designer enables you to overwrite settings compiled into maps.

Map components of a system provide:

- Visual indication of audit log generation.
- Identification of the source or target type: message, database, file, or application.
- Ability to override map and card settings compiled into a map.
- A method of recording your system design with linked documents.

A map component is an Integration Flow Designer object that represents an executable map and displays its relationship with other components in the same system.

Systems can contain one or more map components. To keep the system manageable, you may create smaller systems and then include them as a subsystem of a larger system. Map components and system components are executable units.

Execution settings specify how the map or subsystem executes. The execution settings for system components are maintained in the Integration Flow Designer and are eventually used on designated servers to execute the system components. Each component in a system has separate execution settings. The referenced files (maps or subsystems) are static and are not modified directly with this information.

A map component that references an executable map has a default set of sources and targets defined within the referenced map. Map settings and card settings for sources and targets are defined in the Map Designer, and may be overwritten in the Integration Flow Designer.

The sources and targets defined in the map are the interface points of the map component used within a system. The sources and targets of executable map components are displayed in the main window of the Integration Flow Designer.

In the Integration Flow Designer, the expanded view of a map component distinguishes its sources from its targets.

Design Studio reference

There are some restrictions that apply when using the Design Studio components to design your data transformation process. Certain words and symbols have a specific meaning when used within the Design Studio applications.

- [Design Studio quotation mark usage](#)
Design Studio allows you to use quotation marks.
- [Design Studio reserved words and symbols](#)
There are some words and symbols that are restricted in Design Studio.
- [Design Studio hex, decimal, and symbol values](#)
Design Studio allows you to use various hex, decimal, and symbol values.

Design Studio quotation mark usage

Design Studio allows you to use quotation marks.

Although there are platform-specific limitations regarding the usage of double and single quotation marks, when adding a text string into any map rule, component rule, or command line, use the following characters for quotation marks.

Symbol	ASCII Character	Text Reference in Documentation
'	039	Single quotation mark
"	034	Double quotation mark
''	039 and 039	Two single quotation marks (for some non-Windows environments)

Using any other characters can produce unexpected results.

Design Studio reserved words and symbols

There are some words and symbols that are restricted in Design Studio.

Reserved words and symbols have a special meaning and may be used only in the manner described in this documentation. The following is the list of reserved words and symbols, and their intended use.

Reserved Word or Symbol

Intended Use	
\$	Shorthand representation of the object name in a component rule or a map rule.
:	Used to separate components.
::	Shorthand representation of a unique component or partition path. For example, A::B refers to the unique path from the type A to the type B .
<>	Separates a partition from its partitioned type
,	Used to separate arguments of functions and maps
""	Used to enclose literal text strings.
()	Used for a component range, to enclose function or map arguments, and to block sub-expressions in a rule
@	Separates a comment from a component.
[]	Denotes an indexed member of a series.
{}	Used to enclose a list of literals.
Names of Functions	
	Names of functions are reserved words. Names of functions can be used as type names, but cannot be used as map names. For a complete list of functions, see the Functions and Expressions documentation.
Operators	
	Operators are reserved. For a complete list of operators, see the Functions and Expressions documentation.
ANY	Represents one or more types in a component name. ANY cannot be used in component rules or map rules.
COMPONENT	Refers to any component preceding the current one in the same component list. Used in the Type Designer to refer to preceding components of the same component list. This reserved word can only follow the reserved word IN. For example:
	COUNT (Record IN COMPONENT)
FALSE	Represents the logical false.
IN	Separates a component from an object that contains it. For example, LineItem IN File refers to all occurrences of the type LineItem in the type File .
LAST	Special index value that refers to the previous data object of a particular series.
NONE	Stands for the null value or non-existence of data content. Can be used in a component rule to test the presence of data. Can be used in a map rule to generate no occurrences of an output.
<space>	Separates type names. (This is an actual space.) The names of individual types in component names are separated by spaces. Component names themselves are separated by colons. For example, C:A B is the C component of the A subtype of B ; C:A B:X is the C component of the A B component of type X ; and so forth.
<symbol>	Symbol abbreviations for entering non-printable characters. For example, <CR>.
TRUE	Represents the logical true.
WHERE	Can be used in the LOOKUP or EXTRACT function in place of the comma (,) between arguments.

Design Studio hex, decimal, and symbol values

Design Studio allows you to use various hex, decimal, and symbol values.

The following table lists characters, hexadecimal values, decimal values, and symbols.

In this list, some characters in the character name are capitalized to indicate the common abbreviation for the character. For example, the <STX> abbreviation represents the **S**tart of **T**e**x**t character.

The hexadecimal values are provided as a reference. For any literal value specified in the Type Designer Properties window, hexadecimal values must be enclosed in double angle brackets. For example, <<0A>> represents the hexadecimal value for a line feed character.

The decimal values are provided as a reference. Decimal values can be used with the SYMBOL function. For any literal value specified in the Type Designer Properties window, decimal values must be enclosed in single angle brackets. For example, <10> represents the decimal value for a line feed character.

Symbols can be inserted into map rules and component rules. You can insert them from the Symbols dialog box or by typing the hexadecimal or decimal value.

Character	Hex Value	Decimal Value	Symbol
NewLine	-	-	<NL>
WhiteSpace	-	-	<WSP>

Type Designer

Getting started

The IBM Transformation Extender Design Studio is an Eclipse-based design environment that integrates Type Designer and Map Designer functionality.

The Eclipse platform provides a common user interface for the Type Designer and Map Designer called a "perspective". First-time Eclipse users must review the Workbench User Guide before using the Eclipse-based Design Studio.

The *Workbench User Guide* is located in the help.

1. Open the Design Studio.
 2. Select Help > Help Contents. The help opens for the Eclipse Platform.
 3. Under Contents, select Workbench User Guide.
- [Starting the Type Designer](#)

Starting the Type Designer

About this task

On Windows operating systems, you can start the Type Designer from the Programs menu.

Procedure

1. Select Transformation Extender > Design Studio.
 2. If you are prompted to choose a metadata directory, you can either accept the default or enter a different directory. The metadata directory is a designated workspace where your type tree files will be stored after importing them.
The first time you open the Type Designer, the Eclipse SDK Welcome page is displayed.
 3. From the Welcome page, choose Workbench (*Go to the workbench*).
The Workbench opens into the Transformation Extender Development perspective.
You must be in the Transformation Extender Development perspective before you can create a type tree.
- [Opening an existing type tree](#)
Use this procedure to open an existing type tree.

Related tasks

- [Opening or changing to the Transformation Extender Development perspective](#)

Opening an existing type tree

Use this procedure to open an existing type tree.

About this task

To open an existing type tree, either double-click the type tree .mtt file in any directory listing, or select the type tree .mtt file from the Extender Navigator view in the Design Server. Select the option under Transformation Extender preferences to change the default behavior to always open the Transformation Extender Development perspective when you double-click an existing type tree (.mtt) file outside the Design Server.

Procedure

To open an existing type tree:

1. Determine if the type tree file is in your current project.
If so, make sure the Extender Navigator view (workspace) is open and complete steps **a** and **b**.
 - a. Expand the project's subtree to show the desired file.
 - b. Double-click the file.
The type tree opens in an editor window.

When the type tree file is not in the current project, it must be imported.
2. Click File > Import.
The Import window opens.

3. Expand General.
4. Click File System and click Next.
5. Click Browse to locate the file directory.
6. Choose the directory that contains the type tree and click OK.
The source and destination directories and files appear pictorially in the Import window.
Tip: To select only specific file extensions for import, use the Filter Types option.
After you make your import selections, you must browse for a folder into which to import the type tree.
7. At the Into folder field, click Browse.
The Import into Folder window opens. This window displays the folders in the current project.
8. Select a folder and click OK.
9. Under Options, make additional selections if needed.
 - Overwrite existing resources without warning.
 - Create a complete folder structure.
 - Create selected folders only.
10. Click Finish.
The files you selected are imported into the project.

Introduction to the Type Designer

Use the Type Designer to define, modify, and view type trees. A type tree describes the syntax, structure, and semantics of your data. The syntax of data refers to its format including tags, delimiters, terminators, and other characters that separate or identify sections of data. The structure of data refers to its composition including repeating substructures and nested groupings. The semantics of data refer to the meaning of the data including rules for data values, relationships among parts of a large data object, and error detection and recovery.

- [About type trees](#)
 - [Subtypes](#)
 - [Type tree hierarchy](#)
-

About type trees

A type tree (.mtt) defines the entire contents of at least one input that you intend to map or one output you intend to map. A type tree is the mechanism for defining each element of your data. Similar to a data dictionary, a type tree contains a collection of type definitions.

Because data definitions are defined in a type tree, you should be familiar with the specifications that define your data before attempting to create one.

A data file is a simple example. The file is made up of records and each record is made up of fields. In this case, there are three kinds of data objects: a file, a record, and a field.

In a file of records, think of the data in terms of the three data objects. For example, one type defines the entire file; another type defines the entire record contained in that file. Other types in the same type tree define the data fields of the record.

A type tree has three datatype classifications: group, category, and item. The tree has a root type and other types are connected to the tree through branches of the tree. The root type is the base type from which all other types stem, representing the data objects of all types in the tree. "Root" is the default name when creating a new type tree, however, you can modify any type name.

When viewing a type tree from the Extender Navigator, you can see the different kinds of data objects, but you cannot see the layout or composition of the data. For example, by looking at the tree, you cannot tell that a record consists of fields.

Types within a type tree are listed in alphabetical order by default. To change the order of appearance for new types, modify the root type properties.

IBM Transformation Extender supports large metadata. It supports more than 65,536 types and 65,536 components in a single type tree. To reduce the number of types that maps that use large type trees must process, trim these type trees so that they contain only the required types.

Subtypes

Subtypes are created for a number of reasons like identifying distinct data object. Another reason is that specific types of an object may have different properties such as different date formats.

Think of subtypes as different "flavors". Ice cream flavors can be chocolate, strawberry, or vanilla. To create a type tree to represent ice cream as data, the different flavors of ice cream could be subtypes of the type **IceCream**.

The type **IceCream** is generic and describes any kind of ice cream. The type **Chocolate**, a subtype of **IceCream**, represents a certain kind of ice cream: chocolate.

A file of purchase order data may have two different kinds of records: header and detail. The type tree representing this data might have a **Record** type with **Detail** and **Header** as subtypes of **Record**.

Type tree hierarchy

The types in a tree are arranged in a hierarchy. If a type is subordinate to another type, it is called a *subtype*. The type on the branch stemming above a specific type is called its *supertype*.

Subtypes have more specific properties. For example, two different kinds of fields, **Name** and **Date**, may be defined as subtypes of **Field**.

The item type **Field** describes any field. The item types **Date** and **Name** are more specific kinds of fields. In a classification hierarchy such as this, the deeper the subtype is in the type tree, the more specific the data characteristics.

Example scenario

Imagine that a type tree represents your house. There is a type for the entire house (**House**). A type for each room (**Bathroom**, **Bedroom**, and so on), and types for the different furnishings in these rooms (**Bed**, **Chair**, and so on). Each type represents a complete object. A house is made up of rooms. Inside these rooms are beds, chairs, couches, and so on. You know this, but you cannot see it by looking at the classification hierarchy view of the type tree. You must open one of the types in the group view to see its components.

Type Designer basics

- [Type Designer files](#)
Type trees have the .mtt file name extension.
- [Type Designer icons](#)
This topic displays the icons used in the Type Designer and provides a description of each of them.
- [Opening or changing to the Transformation Extender Development perspective](#)
This topic describes how you open or change to the Transformation Extender Development perspective.
- [Customizing the Transformation Extender Development perspective](#)
Use the Transformation Extender preferences to configure the default settings for the Transformation Extender Development perspective.
- [Customizing the Type Designer environment](#)
Use the Type Designer preferences to configure the default type tree settings for the Transformation Extender Development perspective.
- [Search options](#)
The Design Studio supports standard search options.
- [Bookmarks and Tasks](#)
Use bookmarks and tasks to annotate type trees and map source files in the Design Server.

Type Designer files

Type trees have the .mtt file name extension.

If the **Backup on save** option is enabled in the Type Designer preferences, the backup type trees are automatically created when the type tree is saved. The backup type trees have the .bak file name extension. The backup type trees are automatically saved in the same directory as the type trees.

When a type tree is analyzed, a type tree analysis message file is automatically created in the same directory as the type tree. The Type Designer has the following file name extensions:

.mtt	Type tree file
.dbe	Type tree analysis message file
.bak	Backup type tree file

Related concepts

- [Customizing the Type Designer environment](#)

Type Designer icons

This topic displays the icons used in the Type Designer and provides a description of each of them.

Icon	Description
◆	Item type
◆	Partitioned item type
⌚	Sequence group type
⌚	Choice group type
ParallelGroup	Partitioned group
ParallelGroup	Unordered group
ParallelGroup	Category type

Opening or changing to the Transformation Extender Development perspective

This topic describes how you open or change to the Transformation Extender Development perspective.

Procedure

To open or change to the Transformation Extender Development perspective:

1. Select Window > Open Perspective > Other.
2. Select Transformation Extender Development.

The Transformation Extender Development environment opens.

The default environment (perspective) consists of the following views:

- Extender Navigator view
- Outline view
- Composition view
- Properties view

What to do next

Tip: You can also initiate this task using the Open Perspective button: 

This perspective is saved upon closing the application. The next time you open the Type Designer, you will arrive at this point—the Transformation Extender Development perspective.

The tasks described in the Type Designer documentation assume that you are beginning from the Transformation Extender Development perspective.

Customizing the Transformation Extender Development perspective

Use the Transformation Extender preferences to configure the default settings for the Transformation Extender Development perspective.

To access user preferences, click Window > Preferences > Transformation Extender.

Customize the Transformation Extender Development perspective by making your selections for the following options. After you save the selections, you must reopen the map for the Design Server to use the changed default settings.

Always open Transformation Extender perspective when opening a mtt or mms file.

Every time you open a type tree (.mtt) or map source (.mms) file, the Transformation Extender Development perspective opens.

In the Transformation Extender perspective, always save the type tree after analysis.

Every time you analyze a type tree in the Transformation Extender Development perspective, the Design Server saves it.

Show Schemas as Native Icons

Design Server displays the native icons for schema types.

Suppress Build Warnings

If warnings occur during the map build process, the process ignores the warnings and compiles the map.

In the Content Assist pane, select the components on which to enable content assistance, as well as the option to enable automatic content completion. When you enable types, maps, or functions, Design Server provides you with hover help in the Rule editor, which includes information about the components that you selected. While you are entering a map rule in the Rule editor, you can view the hover help for a type so that you can access information about those selected components in one place.

Enable Types

Enable content assistance on types.

When you hover your mouse pointer over a type in a map rule in the Rule editor, the Design Server displays the hover help, which contains information including the name of the type, the type tree (.mtt) value that is in the card, and the location of the type tree file.

Enable Maps

Enable content assistance on maps.

When you hover your mouse pointer over a map in a map rule in the Rule editor, the Design Server displays the hover help, which contains information including the name of the map, the input and output that the map in the rule uses, and details about the input and output cards.

Enable Functions

Enable content assistance on functions.

When you hover your mouse pointer over a function in a map rule in the Rule editor, the Design Server displays the hover help, which contains information including the definition and syntax of the function.

Enable AutoComplete

Enable automatic content completion.

When you are entering a map rule in the Rule editor, and you type any one of the following symbols: a single quotation mark, a double quotation mark, an opening parenthesis, or an opening bracket, Design Server automatically completes the open symbol with its corresponding closing symbol.

To display settings and dialogs that you previously selected to hide, click Clear, which is next to Clear all 'do not show again' settings and show all hidden dialogs again in the WTX Dialogs pane.

Customizing the Type Designer environment

Use the Type Designer preferences to configure the default type tree settings for the Transformation Extender Development perspective.

The Type Designer preferences include customization options for saving, comparing, entering text, and setting the default root name.

To access user preferences:

1. Select Window > Preferences > Transformation Extender > Type Tree.

Auto-Save

Specifies the time interval in minutes for automatically saving open type trees. (The default setting is 0 minutes.)

Backup on save

Creates a backup copy of the type tree using file extension .bak when a type tree file is saved. (This option is enabled by default.)

Commit changes with

Method for committing changes, such as when entering restrictions in component rules.

For example, when Enter is the chosen method, you would press Enter to enter restriction text in a component rule. As a result, the text is entered in the rule cell and the next component cell is selected.

- Enter & Tab

This is the default setting. Either Enter or Tab can be used to commit the changes.

- Enter

Use the Enter key to commit changes.

Tip: You can create a hard return in any component rule or edit area by pressing Ctrl+Enter.

- Tab

Use the Tab key to commit changes.

Tip: When Tab is the chosen method, you can create a hard return in any rule or edit area by pressing Tab.

Rule differences

- Ignore white spaces and tabs

Enable this option to ignore white spaces and tabs when comparing component rules.

Default Root

A default type name for the root type when creating new type trees in the Type Designer. (The default name is Root.)

Type tree differences

Specifies node colors when comparing type trees.

- New Node Color (The default setting is blue.)
- Different Node Color (The default setting is red.)

- [Confirmation message preferences](#)

Using the Confirmations preferences, you can enable or disable the appearance of confirmation messages. Confirmation messages are typically displayed before completing an action such as a deletion.

- [Group view preferences](#)

Use the Group View preferences to customize the appearance of the group view.

- [Font preferences](#)

Use the font preferences to change the font types that are used in the Type Designer editors and views.

Confirmation message preferences

Using the Confirmations preferences, you can enable or disable the appearance of confirmation messages. Confirmation messages are typically displayed before completing an action such as a deletion.

Confirmation messages can be displayed for the following actions:

Propagating attributes

A confirmation message is displayed prior to propagating attributes.

Changing type class

A confirmation message is displayed prior to changing the class of any type.

Deleting type(s)

A confirmation message is displayed prior to deleting a type.

Adding new type

A confirmation message is displayed prior to adding a type.

Moving type(s)

A confirmation message is displayed prior to moving a type.

Reordering type(s)

A confirmation message is displayed prior to reordering a type.

Changing Group subclass

A confirmation message is displayed prior to changing a group subclass.

Disable the option if you want the action to take place without confirmation.

Group view preferences

Use the Group View preferences to customize the appearance of the group view.

- **Show range:** When enabled, the range assigned to each component is displayed next to the component name.
- **Show component number:** When enabled, a sequential number is displayed preceding the component name.

- **Use ellipses:** Use this option to control the appearance of object names in the group view.
 - When this option is enabled, the abbreviated short object name displays in the component rule.
 - When this option is disabled, the full name of the type is displayed in the component rule.

Rule Color Specifications

You can choose specific colors for the following elements pertaining to component rules:

- Syntax
- Number
- Type Name
- Map Name
- Reserved
- Literal
- Comment
- Background

Font preferences

Use the font preferences to change the font types that are used in the Type Designer editors and views.

You can change the font type for the following areas:

- Item view
- Type tree editor
- Group view
- Analysis view
- Category view
- Properties view

Search options

The Design Studio supports standard search options.

Search and replace

- Use the search operation to search through a single map source file or type tree file, or multiple map source files or type tree files, within search scope parameters that you specify, such as workspace, working set, and so forth.
- Use the replace operation to first do the search, and then replace text in the search results.

Find and replace

- Use the find operation to search for matches on text within a single map source file or type tree file that you have open in the editor.
 - Use the replace operation to replace text in the matched find results. This option is only available for searches within a type tree file.
 - You can also do these operations using search and replace.
- **[Search and replace](#)**
This topic describes the features of search and replace.
 - **[Find and replace](#)**
This topic describes the features of find and replace.

Search and replace

This topic describes the features of search and replace.

You have the option to do a search, which does a search operation only, or a replace, which does both a search operation and a replace operation. The search option searches the entire contents of a single map source file or multiple map source files, or a single type tree file or multiple type tree files based on the criteria you selected. The replace option does the search, and replaces the values in the search string with a replacement value for the search result components that you select to be included in the replace operation.

Features of the search and replace options:

- Run through the Transformation Extender Search tab in the Search window navigated from the Search menu on the menu bar.
- Operates on an entire map source or type tree file or files. You can set the scope of the **Search** operation to do the search within the workspace, a specific working set, or a specific directory. For map source files, you can also set the scope to do the search in a current Map editor.
- Within a map source file or files, searches on:
 - All type tree names
 - All card names
 - All output objects
 - All map names
 - All card type names
 - All map rules
 - All reference files

For example, you can search through map cards within a map source file, and replace file names ending with .txt with .dat. You can replace all card types named Record Set Data with Record Data. You can find card names that include the word Test.

- Within a type tree file or files, searches on:
 - Type properties
 - Component rules
 - Restrictions
 - Type names

For example, you can search through all type trees in your workspace, and replace those type names named month with mm.

- **Search For**

Search For: is used to set the entity on which search and replace operates.

- **Limit To**

Limit To: is used to set the limitations within what is being searched by the search and replace operations.

- **Scope**

Scope: is used to set the range within which search and replace operates.

- **Using search and replace**

There are different criteria that you can set when you use search and replace in the Design Studio.

Search For

Search For: is used to set the entity on which search and replace operates.

The following list describes the search entity options you can choose:

- Property
 - Searches type properties
- Components
 - Searches components
- Restrictions
 - Searches various symbols.
- Type Name
 - Searches type names

Related tasks

- [Using search and replace](#)
-

Limit To

Limit To: is used to set the limitations within what is being searched by the search and replace operations.

The following list describes the search limitation options you can choose:

- Property
 - For type properties, you can select one of the following search limitation options:
 - Release
 - Implied default value
 - Special value(None)
 - Delimiter
 - Max Bytes
 - Special value(zero)
 - Empty
 - Min Bytes
 - Initiator
 - This is the default setting.
 - Date Time
 - Max Chars
 - Terminator
 - Pad
 - Min Chars

- Components

For components, there is one search limitation:

- Components

- Restrictions

For restrictions, there is one search limitation:

- Value

- Type Name

For type names, there is one search limitation:

- Name

Related tasks

- [Using search and replace](#)
-

Scope

Scope: is used to set the range within which search and replace operates.

The following list describes the search scope options you can choose:

Workspace

Searches for the search entity you selected, within the entire Eclipse workspace, which is where your projects are stored on your local drive

Working set:

Searches for the search entity you selected, within an entire Eclipse work set, which you create containing a subset of resources in the workspace

Directory:

Searches for the search entity you selected, within an entire folder

Current editor:

Option is only available when you select Map Source Files under Search In:

Searches for the search entity you selected, within the map source file that is open in the Map editor

Selection options:

- All Maps (default)
- Current Map
- Current and Reference Maps

Related tasks

- [Using search and replace](#)
-

Using search and replace

There are different criteria that you can set when you use search and replace in the Design Studio.

About this task

To use search and replace:

Procedure

1. Click **Search > Search** on the menu bar, or press **Ctrl+H**.
The Search window opens.
2. Click the Transformation Extender Search tab.
This is the view through which you make your search and replace selections.
3. Enter text or wildcard characters in the Search string field.
Case sensitive and Whole word are optional fields that you can select.
4. Under **Search In:**, click **Type Tree Files**.
5. Under **Search For:**, click one of the search entities.
6. Under **Limit To:**, click one of the search limitation options.
There are several search limitation options when you select **Property** under **Search For:**. There is only one search limitation option for each of the other **Search For:** options.
7. Under **Scope:**, click one of the scope entities.
8. Click **Search** to do a search operation only, or **Replace** to do both a search and a replace operation.
9. If you clicked **Replace**, the Type Designer window opens and displays the following message: Changes made using replace can not be undone. Do you want to continue with replace? Respond to the message by clicking **OK**.
10. While the operation is running, it displays the Search Query window containing the **Operation in progress** message. If it is searching through a large number of resources, the window remains open. Click **Run in Background** so that you can continue to access the Design Server graphical user interface (GUI).
You can monitor the operation's progress by opening the Progress view, and viewing the progress indicator. You can also cancel the operation in this view.
The operation completes and displays any matches in the lower pane under the **Search** tab.
11. Click a type tree file listed in the search results to see the details of the matches.

Double-click any type tree name in the list to locate it in the Type Tree editor.

12. If you clicked **Replace** to do both a search and a replace operation, do the following additional steps:

- a. Select the check box next to each type tree name in the search results details to include in the replace operation.
There are two options in the Search view that you can use if there are many search results to include (Select All), or exclude (Deselect All) from the replace operation.
 - Select All - automatically selects all of the type trees
 - Deselect All - automatically deselects all of the type trees, which were previously selected
- b. Enter the replacement text in the **With:** field.
The Replace: field contains the text you entered in the Search string field of the Search window.
- c. Click **Replace**.

The operation replaces the text in the Replace: field with the text in the With: field in every search result you selected to be included in the operation. It cannot replace text if you selected Output under the Search For: pane. When the operation completes, the Type Designer window displays a message about how many replacements were made.

d. Click OK.

Find and replace

This topic describes the features of find and replace.

You have the option to do a find, which does a find or a find next operation only, a replace, which does a replace operation, a replace/find, which does both a replace operation and a find next operation, and a replace all, which does a replace operation for all found text. The available options are dependent on the objects you are searching.

Features of the find and replace options:

- Run through the Find/Replace window navigated from the Edit menu on the menu bar, or from the Find/Replace option on the context menu of an object.
- Operates on selected objects in a map source or type tree file.
- Within a map source file, searches on:
 - Object names in a map card
 - Map rules in a card
 - Map elements in the Organizer folder, which is in the Outline view

Only the Find option is available for searches within a map source file.

- Within a type tree file, searches on:
 - Text characters associated with types
 - Text characters associated with components
 - Text characters associated with restrictions

All options are available for searches on types within a type tree file.

Only the Find and the ReplaceAll options are available for searches on components within a type tree file.

- [Using the find and replace operation](#)

There are different criteria that you can set when you use find and replace in the Design Studio.

Using the find and replace operation

There are different criteria that you can set when you use find and replace in the Design Studio.

About this task

To use find and replace:

Procedure

1. Select the area in which you want to search. For example, select the card to be searched.
2. Click **Edit > Find/Replace**.
3. In the Find field, enter the text you want to find.
4. To customize your search, select additional options in the window pertaining to direction, scope, case-sensitivity, whole words, and so forth.
5. Click Find to begin the search.
When search criteria is found, it is highlighted within the area that you selected in Step 1.
6. At this point, you can select from the following options:
 - To skip this instance and find the next, click Find.
 - To cancel the search, click Close.

Bookmarks and Tasks

Use bookmarks and tasks to annotate type trees and map source files in the Design Server.

A bookmark is a persistent marker that is visible in the Bookmarks view. A task is a persistent marker that is visible in the Tasks view. With a bookmark, you can keep track of an element of a map or type tree and return to that element quickly and easily during development. With a task, you can track the progress of your development work in type trees and maps.

- [Adding a bookmark](#)
- [Removing a bookmark](#)
- [Adding a task](#)
- [Removing a task](#)

Adding a bookmark

About this task

Use Add Bookmark to add a bookmark to an element in a map or type tree.

To add a bookmark to an element:

Procedure

1. Right-click an element in a map or type tree and click Add Bookmark.
The Add Bookmark window opens with a default value in the Enter Bookmark description field.
2. To change the default value, enter a value in the Enter Bookmark description field.
3. Click OK.

Results

The bookmark is added to the element. You can view the bookmark in the Bookmarks view. Click Window > Show view > Other, and in the Show View window, click Bookmarks under General.

Removing a bookmark

About this task

Use Remove Bookmark to remove a bookmark from an element in a map or type tree.

To remove a bookmark from an element:

Procedure

Right-click the element with the bookmark and click Remove Bookmark.

Results

The bookmark is removed.

Adding a task

About this task

Use Add Task to add a task to an element in a map or type tree.

To add a task to an element:

Procedure

1. Right-click an element in a map or type tree and click Add Task.
The Properties window opens with default values in the fields.
2. To change the default value that is in the Description field, enter a value.
3. To change the task priority, select a priority from the Priority list.
4. If you completed the task, select the Completed check box.
5. Click OK.

Results

The task is added to the element. You can view the task in the Tasks view. Click Window > Show view > Other, and in the Show View window, click Tasks under General.

Removing a task

About this task

Use Remove Task to remove a task from an element in a map or type tree.

To remove a task from an element:

Procedure

Right-click the element with the task and click Remove Task.

Results

The task is removed.

Working with type trees

- [Creating type trees](#)
- [Viewing type trees side by side](#)
- [Viewing subtypes](#)
- [Selecting subtypes](#)
- [To change the placement order of subtypes](#)
- [Defining data](#)
- [To add a component to the target tree](#)
- [To view a specific component/item restriction](#)
- [Type tree differences](#)
- [Exporting a type tree](#)

Creating type trees

The following list outlines the process for creating type trees:

- Identify the data objects in your data and define each piece of data that you intend to map.
- Create types for each data object in your data.
- Define the properties of each type.
- Create component lists.
- Define component rules, if needed.
- Define item restrictions, if needed.
- Analyze and save the tree.
- [To create a type tree](#)
- [To add types to the type tree](#)

To create a type tree

Before you begin

Remember: You must have a project created before you can create a new type tree.

About this task

Important: Be familiar with the specifications that define your data before creating a type tree.

Procedure

1. Select **File > New > Type Tree** when "type tree" is present in the shortcut menu. Otherwise, select **File > New > Other > Transformation Extender > Type Tree**.
2. Click Next.
3. In the first field, accept the default project folder or enter a different project folder name.
4. In the File name field, enter a file name and extension for the type tree. For example, *tree_1.mtt*.
5. Click Finish.
The new type tree is displayed under the project folder in the Extender Navigator. In the main window, a tab has been created for the new type tree from where you can begin adding types that define your data to the "Root" type.

To add types to the type tree

About this task

Types are always created as a subtype of the currently selected type. A new type tree has a single root type. All types are added as subtypes of the root type and then as subtypes of other types.

Procedure

1. Select the type under which you want to add a type. For example, select "Root".
 2. Choose one of the following methods to add a type:
 - Press Insert.
 - Right-click and choose Add from the context menu.The program will prompt for confirmation unless that setting has been disabled in the user preferences.
3. If prompted, click Yes to confirm that you want to add a type.
 4. Enter a name for the type.
 5. Open the properties for the type (Type > Properties).
 6. Begin defining the type properties, such as **Name**, **Class**, **Description**, and so forth.
 7. After defining the properties, save changes.

What to do next

Continue adding types that define your data.

Viewing type trees side by side

About this task

To view two type trees side by side:

Procedure

1. Open both type trees for viewing.
2. Click on the title bar of one tree.
3. Hold down the mouse button and drag down and to the left, until the gray outline of a box and a black arrow appear.
4. Release the mouse button.

Results

The two trees are visible side by side.

Viewing subtypes

About this task

To view all subtypes:

Procedure

From the type tree editor, right-click on the highest level of the type you want to expand and select Expand All Subtypes from the context menu. (For example, select the root type if you want to expand the entire tree.)
All subtypes of the selected type are displayed.

What to do next

To collapse all subtypes:

1. From the type tree editor, right-click on the highest level of the type that has subtypes to collapse and select Collapse All Subtypes from the context menu. The subtypes of the selected type are collapsed.

Selecting subtypes

About this task

To select all subtypes:

Procedure

From the type tree editor, right-click on the parent level of the type that has child types you want to select and choose Select All Subtypes from the context menu. The child subtypes of the selected parent type are selected. The grandchildren, or, types that are more than one level down from the parent, are not included in the selection.

To change the placement order of subtypes

About this task

By default, when types are added to a type tree, they are placed in alphabetical or *ascending* order. In addition to ascending order, you can change the default placement order of new types to be descending, first in the list, or last in the list. To change the placement order of types for a type tree, modify the properties of the root type.

Procedure

1. Open the properties of the root type.
 2. Go to the Order Subtypes property and make a selection from the drop-down list: Ascending, Descending, Add First, or Add Last.
 3. Save changes.
-

Defining data

For optimum data transformation, the entire contents of your data must be defined. Using the Type Designer, you can define input data so that each data object of the source data is identified. You can define the output data according to your output specifications.

How specifically you define the data is up to you. For example, if there is a large section of data that you want to process quickly, define it loosely as a chunk of text.

The Type Designer does not define data content as source data or target data. The purpose of the Type Designer is to define your data. Use the Map Designer to define input and output definitions for the data.

- [Objects, types, and classes](#)
 - [To define a literal or variable value](#)
-

Objects, types, and classes

Type trees consist of objects, types, and classes.

Objects

A data object is a complete unit that exists in your input or is built on output. A data object can be simple (such as a date) or complex (such as a purchase order).

A data object is some portion of data in a data stream that can be recognized as belonging to a specific type. When you create types, identify all of the objects that make up the data: input objects and output objects.

Types

A type defines a set of data objects that have the same characteristics. For example, the type "Date" can be defined as representing data objects in the form MM-DD-YY. The type "CustomerRecord" can be defined as representing data objects, each of which consists of a **Company**, **Address**, and **Phone** data object.

Classes

A type is classified according to whether or not it consists of other objects. Each type in a type tree must be defined in one of three classes: item, group, or category.

- **Item type**
An item type represents a simple data object that does not consist of other objects.
 - **Group type**
A group type represents a complex data object that consists of other objects. For example, "FullName" is a group type that contains the components: FirstName, MiddleInitial, and LastName.
 - **Category type**
A category type is used for inheritance and for organizing other types in a type tree. For example, you might have a category named "OrderField" to organize the different kinds of order fields in your type tree.
-

To define a literal or variable value

Procedure

1. Open the Properties for a group or category.
 2. Expand the options under Group Subclass.
 3. Expand the options under Format.
 4. In the drop-down menu next to Component Syntax, select Delimited.
 5. Expand the options under Component Syntax.
 6. In the drop-down menu next to Delimiter, select Literal or Variable.
-

To add a component to the target tree

Procedure

1. In the type tree editor, double-click the type.
The Component view opens. The Component view consists of an edit area and two columns: Component and Rule.
 2. From the type tree editor, select a component and drag it into a cell in the Component column.
The component has been added.
-

To view a specific component/item restriction

About this task

Procedure

From the type tree editor, double-click the item.
The item view opens and the item name is displayed on the tab.

Results

Restrictions are displayed in the cells (rows) of the Include column.

Related tasks

- [Using search and replace](#)
-

Type tree differences

Before you begin

The type tree differences feature allows you to compare two type tree files.

Two type trees are considered different when:

- Any of the types are different.
- Any of the types that exist in one type tree does not exist in the second type tree.
- When the order of the subtypes within a subtype is different.

A type is different when:

- Any of the properties are different.
- Any of the components are different.
- Any of the restrictions are different.

A restriction is different when:

- The restriction value is different.
- The description is different.

About this task

To compare type trees:

Procedure

1. In the Extender Navigator view or the Navigator view, press Ctrl and select two type tree (.mtt) files.
You can compare type trees with different names.
2. Right-click one of the selected type tree files, and click Compare With... > Compare Type Trees.
IBM Integration Platform opens the type trees to do the compare operation.
If the type tree files are large and do not open immediately, the Comparing Type Trees... window opens, and displays the Operation in progress... message.
The progress of the comparison continues to display until the operation completes.
3. Click Run in Background so that you can continue working while the Compare Type Trees operation runs.
You can monitor the Compare Type Trees operation by clicking the Progress tab, and viewing the progress indicator.

Results

After the Compare Type Trees operation completes, a window containing the results opens. You can resize and position the window to view all differences.

Exporting a type tree

About this task

You can export a type tree or a portion of a type tree to a type tree script file. A type tree script file (.mts) is a document file containing a script of commands in XML format. An .mts file can be used as input to the Type Tree Maker to create a type tree or portion of a type tree. See the Type Tree Maker documentation for more information.

To export a type tree or portion of a type tree:

Procedure

1. Select the type you want to export. (Select the root if you want to export the entire type tree.)
2. Right-click and choose Export from the context menu.
The Export type tree to file window opens.
3. Select a directory and enter a name for the new .mts file. (The default name is the name of the selected type followed by an .mts extension.)
4. Click Save.

Results

The subtree of the selected type is exported. If you select a type other than the root, it is assumed that you are adding to an existing tree and the document file will have a <OPENTREE> command. If you select the root type, it is assumed that you are generating a new tree and the document file has a <NEWTREE> command.

An example of a type tree of an export script and an example map that converts an exported restriction list to a cross-reference table is included with the Design Studio examples (*install_dir\examples\dsgnstud\ttmaker*).

Managing types

- [Selecting subtypes](#)
- [Drag-and-drop operations in the Type Designer](#)
- [Moving and copying objects](#)
- [Reordering objects](#)
- [Merging types](#)
- [Renaming types](#)
- [Generating a type definition report](#)
- [Testing part of a type tree](#)

You can test a type tree by generating test data for an item or a group. Type Designer creates source and compiled maps that generate and validate the test data. The test-data-generation map automatically runs and produces a text file with the sample data. After that, the test-data-validation map automatically runs on the sample data file.

Selecting subtypes

About this task

To select all subtypes:

Procedure

From the type tree editor, right-click on the parent level of the type that has child types you want to select and choose Select All Subtypes from the context menu. The child subtypes of the selected parent type are selected. The grandchildren, or, types that are more than one level down from the parent, are not included in the selection.

Drag-and-drop operations in the Type Designer

About this task

The following list is a summary of available drag-and-drop operations:

- To move an object, drag it to the destination.
- To copy an object, press **Ctrl** and drag it to the destination.
- To merge a type, press **Shift** and drag the type to the destination tree.
- To add a component name to a component rule, press **Alt** and drag the component to the component rule bar.
- To specify a type as a comment type or a variable delimiter, initiator, terminator, or release character in the Properties view, press **Alt** and drag the type from the tree to the Properties view.

Related concepts

- [Components must be in the same type tree](#)

Moving and copying objects

About this task

You can move and copy the following objects within the Type Designer by using the drag-and-drop method:

- Types (within the same tree)
When you drag a type from one tree to another, it is copied to the other tree because it is copied from one type tree file to another.
- Components (from one view to another)
- Restrictions (from one view to another)
Duplicate restrictions are not permitted.

When you move or copy a type using the drag-and-drop method, the entire subtree of the type is also moved or copied. The properties, components, component rules, and restrictions are also copied.

If a type cannot be a subtype of the type you are dragging it to, you will not be able to drag it. For example, you cannot move an item under a group.

Note: You cannot place a type under another type if it cannot be a valid subtype.

- [Moving a type](#)
- [Copying a type](#)
- [Type names](#)

Moving a type

About this task

To move a type, you can use the drag-and-drop method or use the following procedure.

To move a type:

Procedure

1. In the type tree editor, right-click the type you want to move and select Move from the context menu.
The Move dialog opens and the type name is present in the From field.
2. While the dialog is still open, return to the type tree editor and select the "destination" type. The destination type name appears in the To field of the Move dialog
3. Click Move.

Copying a type

About this task

In addition to using the drag-and-drop method, you can use the context menu to copy a type.

To copy a type:

Procedure

1. In the type tree editor, right-click on the type and select Copy from the context menu.
The Copy Type dialog opens.
2. Go back to the type tree editor and select the target type—the type under which you want to copy the given type.
The target type name appears in the To field of the Copy Type dialog.
3. In the As field, accept the default original name of the type or modify it if needed.
4. The Copy Sub-tree option is enabled by default. Disable the option if you do not want the subtree of the type copied to the target type.
5. Click Copy.
The type is copied to the target type that you selected.
6. Click Close to close the dialog.

Type names

When you move or copy a type, if that type is referenced by another type (for example, if it is used as a component), the reference is updated to reflect the new relative type name. In addition, if a type you move or copy references other types, these references are automatically updated. Referenced type names include component names, syntax item names, and comment type names.

When you move a syntax item that is referenced as a number separator, initiator, terminator, delimiter, or release character, its referenced name changes.

When you move a type that references other types, the references are automatically updated.

Reordering objects

You can reorder the following objects within the Type Designer by using the drag-and-drop method:

- Subtypes - to reorder subtypes, press **Ctrl + Shift** while dragging a subtype to the desired location. Subtypes may be reordered only when the type whose subtypes you are reordering has the **Add First** or **Add Last** setting for the **Order subtypes** property.
- Components - to reorder components, drag the component(s) to the desired location in the component list.
- Restrictions - to reorder restrictions, drag the restriction(s) to the desired location in the restriction list.
- [Reordering existing subtypes](#)

Reordering existing subtypes

About this task

If the **Order Subtypes** option is set to **Add First** or **Add Last**, you can arrange the subtypes in any order.

To reorder subtypes:

Procedure

1. Select the type.
2. Open the Properties view to confirm that the **Order subtypes** property is **Add First** or **Add Last**.
3. Right click on the type and choose **Reorder subtypes** from the context menu.
The Reorder subtypes dialog is displayed.
4. You can arrange the order by selecting a type and pressing the Up or Down buttons. You can also move a type by dragging it to a position.
5. Click Close to close the dialog.
6. Save changes.

Merging types

You can merge types from one tree to another. Merging a type copies that type and all types referenced by that type to another tree. The referenced types include any components, comment types, and any syntax items used as a number separator, initiator, terminator, release character, or delimiter. You can merge the type itself or the type with its subtree.

- [Merging a type](#)
- [Supertypes](#)
- [Existing types](#)
- [Invalid types](#)

Merging a type

Before you begin

Before using the **Merge** command, perform the following tasks:

- Analyze the type tree you are merging from.
- Analyze the type tree you are merging to.
- Ensure that the root of the type tree you are merging to has the same root name as the tree you are merging from.

About this task

To merge a type from one tree to another:

Procedure

1. Select the type you want to merge into another tree.
2. Right-click on the type and choose **Merge** from the context menu.
The Merge dialog is displayed.
3. When applicable, enable the Merge subtree check box to merge the entire subtree.
4. Open the destination type tree if it is not already open.
5. Select the destination tree.
6. Click Merge.
7. Click Close.

Supertypes

When you merge a type from one tree to another, the supertypes of that type are created. In the example above, notice that **Detail**'s supertype, **Record**, is included in the copied types.

Existing types

The **Merge** command copies a type only if it does not already exist in the destination tree. If the type already exists in the destination tree, it is not copied.

Invalid types

The **Merge** command will only merge a type if it can exist in the new tree. For example, if you try to merge an item into a tree where it would exist as a group, the type is not merged.

Types referred to by ANY in a component are not copied in a merge.

Renaming types

About this task

Remember: When you rename a type, it might move to a different position on the same level in the tree if types on that level are in alphabetical order.
To rename a type:

Procedure

1. Open the properties for a type.
2. From the Properties view, locate Property \gg Name.
3. Click in the Name field cell and enter a new name.
4. Save changes.

Related tasks

- [Using search and replace](#)

Generating a type definition report

About this task

Use the Generate Type Definition Report menu option to generate a type definition report file.

Generate a type definition report HTML file to view information about the type through a web browser, or an HTML editor. The generated type definition report file contains information, including properties, restrictions, components, and where the type is used, for the selected type, depending on the options that you select. It also includes the subtree if you select that option.

Procedure

To generate a type definition report file:

1. In the Type Tree editor of the Design Server, right-click a type in the type tree, and click Generate Type Definition Report.
The Generate Report window opens.
 2. Click Browse and specify in the Save As window, the file name, and path in which you want to generate the file.
If you choose to generate the report to an existing output file, click Yes at the prompt that gives you the option to replace the file.
 - a. To change the default current location in which to save the type definition report file, select a different location in the Save in list.
 - b. To change the default type definition report file name, enter File name.
- After you click Save, the path and file name are displayed in the Output file name field of the Generate Report window.
3. Under Type Definition Options, click the options that represent the information you want the report to include.
 4. Click Generate.
The Generate Type Definition Report window opens and displays the progress of the generate type definition report operation. The window remains open and the progress of the operation continues to display until the operation completes. There is an option available for the operation to run in the background. The reason is so that you can continue to access the Design Server graphical user interface (GUI). If the operation is long-running, you might want to select this option.
The operation writes the type definition to the output file that you specified based on the options that you selected.

Results

The type definition report file is saved in the specified location and opens in the Internal Web Browser editor that is in the Transformation Extender Development perspective. You can view the file output from within the Design Server or any external tool. You can also view the .html source file from the Design Server or numerous HTML editors.

Testing part of a type tree

You can test a type tree by generating test data for an item or a group. Type Designer creates source and compiled maps that generate and validate the test data. The test-data-generation map automatically runs and produces a text file with the sample data. After that, the test-data-validation map automatically runs on the sample data file.

For choices and partitions, Type Designer fills the first choice and first partition with data in the generation map. For sequences, Type Designer generates one index. Type Designer uses implied default-value and item-value restrictions if they are available; otherwise, it generates sample values for different data types.

- [Generating test data](#)
- [Invalid input message from test data generation](#)

The message One or more inputs was invalid displays when test data generates successfully but the validation map flags some data as not valid. This message can occur when there are data type constraints, component rules, or restrictions that the sample data does not account for. Trace the validation map and inspect the generation map rules to find the data types that are not generating correctly.

Generating test data

Procedure

1. Open the type tree and right-click on an item or group.
2. Click Generate Sample Data.
3. Change the sample data options, or accept the defaults. Optionally, you can set defaults for these options in Window > Preferences > Transformation Extender > Type Tree > Sample Data.

Create optional types

When this option is not selected, a type with the size **Min=0** and **Max=1** generates a map rule of **None**.

Fill types with data

When this option is not selected, all types generate a map rule of **None**.

Results

Type Designer generates the following files in the SampleData folder relative to the source type tree:

- A source map named *selected_type_name.mms*
- A compiled map named *selected_type_name.mmc*
- A source map named *Validation_selected_type_name.mms*
- A compiled map named *Validation_selected_type_name.mmc*
- A log file of the generation session named *SampleDataGenerator.log*
- A test data file named *selected_type_name.txt*

Invalid input message from test data generation

The message One or more inputs was invalid displays when test data generates successfully but the validation map flags some data as not valid. This message can occur when there are data type constraints, component rules, or restrictions that the sample data does not account for. Trace the validation map and inspect the generation map rules to find the data types that are not generating correctly.

Type properties

The properties of a type define the characteristics of the data objects of that type.

For *item* types, properties define whether that item is text, a number, a date and time, or a syntax value. Properties include such characteristics as size, pad characters, and justification.

For *group* types, the properties are related to the format of that group. The format of a group may be explicit or implicit. In addition, type properties include syntax objects that appear at the beginning or end of the object, as well as release characters.

- [Basic type properties](#)
- [Item properties](#)
- [Group properties](#)
- [XML properties in the type tree](#)

Defining type properties

About this task

You can define specific properties for each type. Type properties generally consist of the following:

- Definition of a type's **Class**, **Group** or **Item** properties
- Type **Initiator**, **Terminator**, and **Release** character
- A list of where a type is used in the definitions of other types

Related concepts

- [Basic type properties](#)

To access properties of a type

Procedure

Select a type and click the Properties button on the toolbar: 

The Properties view opens.

Tip: You can also access the Properties view from the Window menu. Select Window > Show View > Other > General > Properties.

Results

Now, when you select a type in the type tree editor, the corresponding type properties are displayed in the Properties view.

To define the properties of a type

Procedure

1. In the Properties view, enter all relevant information for the type. For example, the Name, Class, Description, and so forth. All information is entered in the Value column. To view a drop-down list of options (when available), you must click in the field (in the Value column) and the down arrow is displayed.
2. To define a certain property for the selected type, enter or select the property value in the **Value** column.
When needed, expand each property to view all associated values. For example, to define the type initiator as a literal value, for **Initiator**, select Literal from the drop-down list and then expand the **Initiator** property to define the literal initiator value.
3. Save changes.

Results

Continue defining additional type properties as needed.

Basic type properties

The following type properties are common to categories, groups, and items:

- [Name](#)
- [Class](#)
- [Description](#)
- [Intent](#)
- [Partitioned](#)
- [Order Subtypes](#)
- [Initiator](#)
- [Terminator](#)
- [Release Characters](#)
- [Empty](#)
- [National Language](#)
- [Document Type](#)
- [Where Used](#)

Item-specific properties are discussed in more detail in "[Item Properties](#)". Group-specific properties are discussed in more detail in "[Group Properties](#)".

- [Name](#)
- [Class](#)
- [Description](#)

- [Symmetric swapping](#)
- [Orientation](#)
- [Shaping](#)

Related concepts

- [XML properties in the type tree](#)

Related tasks

- [Defining type properties](#)

Name

The name of the type should be as descriptive as possible and reflect the information that the type represents.

A type name must conform to the following guidelines:

- A type name cannot be more than 256 characters long.
- A type name cannot be a reserved word or contain a reserved symbol. For a list of reserved words, refer to Design Studio Introduction documentation.
- A type name cannot contain only digits and/or periods.
- A type name may contain numbers and special characters.
- A type name cannot contain spaces. Use an underscore instead.
- A type name can contain the following:
 - Letters
 - Digits
 - ASCII characters 128-255
 - Special characters: #, ~, %, _, ? or \
 - Double-byte characters (Japan edition only)
- A type name cannot have the same name as another type on the same level in the same type tree.
A type name can be up to 256 characters in length, but use a short type name if possible. The full path name of each type is used in map rules in the Map Designer.

Class

The class of a type describes whether the type represents a simple data object (item), a complex data object (group), or whether it is used to organize types (category). Define the class of the selected type by selecting the class from the drop-down list in the **Value** column.

Category

Categories organize types that have common properties. Each category has a set of item properties and a set of group properties. Subtypes of the category inherit these properties.

A category does not define data objects in detail and it does not represent data to be used in a map. You never map a category type, so a category type does not have components. A category type may be a component of a partitioned group, after a component with the identifier attribute. A category cannot be a component of a non-partitioned group.

Item

The item type represents a simple data object that does not consist of any objects. An item does not have components.

Group

The group type represents a complex data object that consists of components.

To change a type's class, select the type and choose the desired class for the **Class** property in the Properties window.

If you change a type to an item, all the types in its subtree become items. If you change a type to a group, all the types in its subtree become groups. This is because the type tree has a classification hierarchy and all the nested subtypes of an item must be items. Similarly, all the nested subtypes of a group must be groups.

Description

Use this property to record a brief description of the type. The description entered is for informational purposes only. It is not used for identifying data objects at runtime.

It is good practice to add a meaningful description of the type when you are defining it.

Intent

Indicates whether the type is a general type or an XML type.

The type can only be an XML type if the type tree was created using the XML DTD Importer or the XML Schema Importer.

Refer to "[XML Properties in the Type Tree](#)" for more information about type properties created from XML.

Partitioned

If the data of this type can be divided into mutually exclusive subtypes, it can be partitioned. For information about partitioning, see "[Partitioning](#)".

- Yes
Partitioning is enabled for this type.
No
Partitioning is not enabled for this type.
-

Order subtypes

Choose the method in which the subtypes of this type will be added or viewed in the type tree.

- Ascending
Add and view subtypes of this type in alphabetic or numeric order.
Descending
Add and view subtypes of this type in reverse alphabetic or numeric order.
Add First
Add subtypes of this type to the top of the type list.
Add Last
Add subtypes to the bottom of the type list.

To manually reorder the subtypes in a type tree, the **Order Subtypes** property must be either **Add First** or **Add Last**.

Initiator

An initiator is a syntax object that appears at the beginning of a data object. Defining an initiator for a type specifies that when data of that type appears, the initiator appears at the beginning of the data object. The initiator becomes part of the data type definition.

- None
There is no initiator.
Literal
The initiator is literal. Expand the **Initiator** property to enter the literal initiator value and data language of the initiator value.
Variable
Allow for possible values. Expand the **Initiator** property to define the variable terminator **Default**, **Item**, and **Find** properties.

If each record begins with an asterisk *, define the * as a literal initiator of the record type.

The following data represents the classes in a college English department. An asterisk * is displayed at the beginning of each **ClassRecord**.

For information about other symbols used in the Value field of the Initiator property, see the Type Tree Importer documentation.

Terminator

A terminator is a syntax object that appears at the end of a data object. The terminator becomes part of the data type definition.

- None
There are no terminators.
Literal
A constant value. Expand the **Terminator** property to define the literal terminator **Value**.
Variable
Allow for possible values. Expand the **Terminator** property to define the variable terminator **Default**, **Item**, and **Find** properties.

For example, a carriage return/linefeed (CR/LF) at the end of a record is the record's terminator.

Generally, if the data ends with a given syntax object, you should define a literal terminator. For example, it is very common to define a CR/LF as a terminator of a record when you know that the record always ends with a CR/LF, regardless of where the record appears.

Release characters

A release character is a one-byte character in your data indicating that the character(s) following it should be interpreted as data, not as a syntax object. The release character is not treated as data, but the data that follows it is treated as actual data.

- [Building release characters for output data](#)
 - [Guidelines for using release characters](#)
 - [Release character example](#)
-

Building release characters for output data

If a release character is defined for a type, a release character is inserted for each occurrence of a syntax object in the data of any item contained in that type.

Guidelines for using release characters

Guidelines for using release characters include the following:

- Release characters apply to character data only, *not* binary data.
- Characters defined as pad characters are not released.
- The maximum size of an item does *not* include the release characters.

Release character example

The group type **Record** type has a literal delimiter of , and a release character of ?. The group type **Record** has three item components. Data for the record looks like the following:

Miller?, MD,Harkin Hospital,1996

The ? releases the comma after **Miller**.

In the first field, the actual data value is **Miller, MD**. Because the comma appears as part of the data, it is necessary to have the release character ?, which indicates that the , following it is data, *not* a delimiter. This data would be interpreted as the following:

Data for component #1: **Miller, MD**

Data for component #2: **Harkin Hospital**

Data for component #3: **1996**

A release character can apply to a delimiter, a terminator, or even the release character itself.

If a release character appears in the data and it is not followed by a syntax item, the release character is ignored.

Empty

The **Empty** property provides alternative type syntax for groups or items when they have no data content.

When the **Empty** property is specified for a type and there is no data content, the **Empty** syntax is displayed. For example, this can be used for XML data that contains either start and end tags or an empty tag.

You can use the **Empty** type property instead of syntax object items to potentially improve the type tree runtime processing time (during data validation).

The following options are available for the **Empty** property.

None

Default setting. Select None if you do not have an initiator, terminator, or release character.

Literal

A constant value. When **Literal** is selected, the **Value**, **Ignore Case**, **Required**, and **National language** sub-fields become available. You can use only one literal to indicate a zero-length data item.

- [Empty type property example](#)

Empty type property example

Consider an XML element called **Comment**. Presuming that this element has a simple content of an arbitrary length, it can be represented in a type tree as a text item, with the initiator value <**Comment**> and the terminator value </**Comment**>.

This item can then be used to validate the following data:

<**Comment**>Some comment...</**Comment**>

The resulting value for the item will be:

Some comment...

As another example, the following data is also successfully validated:

<**Comment**></**Comment**>

The resulting value for the item will be a zero-length string.

The problem occurs with the following data: <**Comment**/>

From the XML perspective, this data is equivalent to the <**Comment**></**Comment**> data shown above, as it represents the **Empty** element **Comment**. However, from the type tree perspective, this data is invalid because it does not start with <**Comment**> and does not end with </**Comment**> as required by the initiator and terminator item property values.

This is where the **Empty** property is useful. By defining the **Empty** property for the item to have a value of <**Comment**/>, it will be possible to validate the data <**Comment**/>.

Even if the data does not match the syntax described by the initiator and terminator properties, it will be validated because it will match the **Empty** property value. It will be treated as an *empty item*, that is, the resulting value for the item will be a zero-length string, similar to the example shown previously.

Document Type

The **Document Type** setting is a component of Document Verification. A requirement of using Document Verification is to set the **Document Type** properties of the associated type tree object.

To use the Document Verification option for XML documents, you must do the following:

- Set the **Document Type** property to **XML**.
- Set the Document Type Metadata value to **Schema** or **DTD**.
- Specify the **Location** of the DTD or Schema file.

Default

This is the default value, which indicates a non-XML document type.

XML

Indicates an XML document type. When this value is set to **XML** and the appropriate **DocumentVerification** map settings are in place, the XML document will be validated by an external program in addition to the standard data validation process.

See the Map Designer documentation for information about using the Document Verification option.

Where used

Where Used shows how and where the type is used within other types in the tree. For example, the **Where Used** property shows if the type is used as a delimiter, component, and so on.

Symmetric swapping

When the input and output objects have different symmetric swapping characteristics, the Symmetric Swapping property is considered "on" for the related mapping rule.

Examples

Original text	Resulting text
abcF (E) Dghi	abcF (E) Dghi
Input Object No swapping	
Output Object Swapping	
Original text	Resulting text
abcF (E) Dghi	abcF (E) Dghi
Input Object Swapping	
Output Object No swapping	
Original text	Resulting text
abcF (E) Dghi	abcF) E (Dghi
Input Object No swapping	
Output Object No swapping	
Original text	Resulting text
abcF (E) Dghi	abcF) E (Dghi
Input Object Swapping	
Output Object Swapping	

Orientation

Orientation is to change characters from one direction to a different direction.

Example

A simple orientation example is to define English characters "abc" as a bidirectional object with left-to-right (LTR) orientation. If you moved the object to a right-to-left (RTL) object, the output should be "cba". The following example demonstrates a string of characters that change in orientation.

Original text	Resulting text
ABC DEF Ä ÄíÄé Input left-to-right (LTR) Output right-to-left (RTL)	ÄÄíÄé FED CBA

Shaping

Text shaping is the concept of combining or separating characters where possible. The Arabic usage is with ligatures (such as the LAM, ALEF, and LAM-ALEF characters). For example, in a non-shaped word, both LAM and ALEF characters would appear separately. In a shaped word, the two characters would be replaced with a single LAM-ALEF character.

Numeric shaping is the idea that normal regular numerals (0–9) can be shaped to be Arabic-Indic

Examples

- Ü,, = LAM
- i° = ALEF
- Ü°i»» = LAM ALEF

Original text	Resulting text
abcii»»def Input Shaped Output Unshaped	abcÜ,,i°def
abcÜ,,i°def Input Unshaped Output Shaped	abci»»def

Item properties

Item types define data for a selected type. Item types are divided into the following subclasses: **Number**, **Text**, **Date & Time**, and **Syntax**. Each item subclass has a specific set of properties.

- [Item subclass](#)
- [Number item subclass properties](#)
- [Text item subclass properties](#)
- [Date & Time item subclass properties](#)
- [Syntax item subclass properties](#)

Item subclass

The subclass of an item represents the characteristics of the data. Both category and item types have the **Item Subclass** property.

To define the subclass of an item type:

1. Access the **Properties** for the selected category or item type.
2. For the **Item Subclass** property, select a value that defines the data for the type:

Number

Any number excluding active syntax objects. The interpretation can be either character or binary. See "[Number Item Subclass properties](#)".

Text

Any character excluding active syntax objects. The interpretation can be either character or binary. See "[Text Item Subclass properties](#)".

Date & Time

A valid date and time format based on the data. The interpretation can be either character or binary. See "[Date & Time Item Subclass properties](#)".

Syntax

Syntax objects are used as separators between portions of data. A restricted set of values used to define a dynamic delimiter, initiator, terminator, or release character. The interpretation is character. A syntax object cannot be longer than 120 bytes. Syntax objects, used as syntax, cannot be mapped. See "[Syntax](#)"

[Item Subclass properties](#).

For text and syntax objects, character size constraints can be in bytes or characters. Numbers are considered in digits and date-time formats are sized by the format, such as CCYYMMDD.

Number item subclass properties

Number item subclass properties can be of **Character** or **Binary** value. When you choose **Number** as the **Item Subclass** value, you must choose an **Interpret as** value: **Binary** or **Character**.

The **Interpret as** value defines how the data should be interpreted. Items with a subclass of **Number**, **Text**, and **Date & Time** can be interpreted as either character or binary. Items with a subclass of **Syntax** can be interpreted as character only.

- [Interpret as binary](#)
- [Length \(bytes\)](#)
- [Byte order](#)
- [Interpret as character](#)
- [Size \(digits\)](#)
- [Separators](#)
- [Pad](#)
- [Restrictions](#)
- [National language](#)
- [NONE and Zero](#)
- [Places](#)

Interpret as binary

Binary text items have content size and pad properties. Binary data is required to be sized or of a fixed size.

Binary number items interpret the data as a binary number or as a byte stream.

Items with an item subclass of **Text** can be interpreted as character or binary.

When **Interpret as** is set to **Binary**, the binary presentation options are Integer, Float, Packed, or BCD.

- [Binary integer presentation](#)
- [Binary float presentation](#)
- [Binary packed presentation](#)
- [Binary BCD presentation](#)

Binary integer presentation

The **Integer** value is a whole number.

Length(bytes)

Can have a length of **1**, **2**, **4**, or **8** bytes

Byte order

See "[Byte order](#)".

Sign

See "[Sign](#)".

Binary float presentation

The **Float** value is a number with decimals in a location as needed.

Length(bytes)

Can have a length of **4**, **8**, or **10** bytes

Binary packed presentation

The **Packed** value is a number that has size, decimal places, and sign properties.

The binary packed properties include Length, Implied places, and Sign.

Length

Can have a length of **1 - 16** bytes

Implied places

Can be from **0 - 31**

Sign

Can be **Trailing-** or **Trailing+**

For **Packed** numbers, the **Implied places** cannot exceed the **Length**.

Binary BCD presentation

The **BCD** value is a binary coded decimal number that has size.

Length (bytes)

Use the **Length (bytes)** property to select the number of bytes that equals the length of the item.

The **Length(bytes)** property is an option when the **Number** item subclass property is interpreted with a **Binary** value.

Byte order

Use the **Byte order** property to define the way that bytes in the data are ordered by selecting one of the following values from the Byte order drop-down list.

Value	Description
Big Endian	The most significant byte has the lowest address. (Usually systems such as IBM, HP, and Solaris.)
Little Endian	The least significant byte has the lowest address. (Usually systems such as Intel and VAX.)
Native	The order is dictated by the platform.

Byte order is an option when the **Number** item subclass is interpreted with a **Binary** value.

Interpret as character

Character number items interpret the data as symbolic data. Symbolic data has the same meaning on different computers. For example, a comma is symbolic because it has the same meaning, regardless of the computer type.

Character text items can have content size and pad properties.

When the **Interpret as** value is defined as **Character**, the **Release** property is specific to the **Character** value and is *not* available as an option for a **Binary** value. For more information, see "[Release characters](#)".

When **Interpret as** is set to **Character**, integer, decimal, and zoned presentation options are available.

- [Character integer presentation](#)
- [Character decimal presentation](#)
- [Zoned character presentation](#)
- [Places > implied](#)

Character integer presentation

The **Integer** value is a whole number.

Further information on the **Integer** value is found in "[Integer Separators](#)".

Character decimal presentation

The **Decimal** value is a number that contains decimals.

More information about the **Decimal** value is found in section "[Decimal Separators](#)".

Zoned character presentation

The **Zoned** value is a number that has a size, decimal place, pad, and sign properties.

Use the "Size (digits)" property to specify the size of the zoned number. The size of a zoned number can also be specified in terms of minimum and maximum. The minimum size must be less than or equal to the maximum size.

When the content size of a character-zoned number is used, the last digit and the sign are combined into the same digit but the content size does *not* include the initiator, terminator, release characters, or pad characters.

When the content size of a character-zoned number is important (for example, when the **SIZE** function is used on the character zoned number), the content size includes the sign but does not include the initiator, terminator, release characters, or pad characters.

Use the "[Sign](#)" property to define whether the zoned number will be signed. The default value is **No**.

The size of a zoned number is specified in terms of the minimum and maximum number of digits. If the size is specified with the **Min** and **Max** properties, the sign is *not* included.

Example

Zoned Number Not Signed	Signed Zoned Number
1230	123{
1231	123A
(Length = 4 digits)	(Length = 4 digits)

Places > implied

Numbers have implied decimal places. The number of decimal places cannot exceed the length specification. The list of available decimal places varies with the length selected. In the **Value** column, enter a total number of decimal places (not to exceed 31).

Size (digits)

Use the Size (digits) property to specify the minimum and maximum size of a number item.

Min

The minimum number of digits of the data object.
The default value is 0.

Max

The maximum number of digits of the data object.

If there is no maximum size, a **Max** value is not required.

- [Excluded from min and max size](#)
 - [Size example](#)
-

Excluded from min and max size

For character number items, there are certain objects excluded from the **Min** or **Max** count. For each **Presentation** option, the following table lists what is excluded from the minimum or maximum **Size (content)** count.

Presentation:	Integer	Decimal	Zoned
	initiators	initiators	initiators
	pad characters	pad characters	pad characters
	release characters	release characters	release characters
	separators	separators	terminators
	symbols	symbols	
	terminators	terminators	

Size example

In the following ASCII number there are a total of 12 characters:

+1234567.999

However, because the initiator (+) and separator (.) are not counted, the number would validate for a maximum size of 10 (**Max=10**).

Separators

Integer and decimal number items can have a separator for thousands and fractional places. If you opt to have a separator, choose **Yes** and sub-options will appear that enable you to choose the format and syntax.

The **Zoned** value of the **Presentation** property does not have separators.

- [Integer separators](#)
- [Separator > format](#)
- [1000's syntax > value](#)

- [1000's syntax \(literal\) > value](#)
 - [1000's syntax \(variable\) > default](#)
 - [1000's syntax \(variable\) > item](#)
 - [1000's syntax \(variable\) > find](#)
 - [Decimal separators](#)
 - [Separators > format](#)
 - [Separators > 1000's syntax](#)
 - [Separators > fraction syntax](#)
 - [Sign](#)
-

Integer separators

For integer numbers, the separator is the thousands separator.

Integer character numbers have separator properties of:

- Format
- 1000's Syntax
- Value

These properties specify the placement and value of the thousands separator.

Separator > format

Use the Separators Format property to specify the placement and value of the thousands separator.

To define the separator format, select one of the separator formats from the drop-down list in the **Value** column.

#[.]####

The thousands separator is not required on input, but if present, it must be in the proper location. The separator is not built on output.

#.####

The thousands separator is required on input in the proper location. The separator is built on output.

1000's syntax > value

Define the thousands separator as either literal or variable. Select one of the following from the drop-down list in the **Value** column:

Literal

The thousands syntax is a constant literal specified in the **1000's Syntax > Value** column.

Variable

The thousands syntax allows for variable values. Use the **1000's Syntax > Default**, **Item**, and **Find** properties to define the variable fraction separator.

1000's syntax (literal) > value

For the literal thousands separator, define the literal separator by typing the literal separator character in the **Value** column or by clicking the browse button to display the Symbols dialog box from which you can insert any non-printable value.

A separator can be from one to 120 bytes in length. A separator cannot start or end with a digit and cannot be the ? character. The ? character is a reserved character that can be used as a wildcard to represent any single valid character.

1000's syntax (variable) > default

Use the **1000's Syntax > Default** property to define the default variable separator value for the thousands place. The default literal separator value for thousands syntax is a comma.

Enter the default variable separator character or click the browse button to display the Symbols dialog box in which you can insert any non-printable value.

1000's syntax (variable) > item

For integer numbers with a variable thousands separator, the **Separator** property is **Yes**, and the **1000's Syntax** is **Variable**, you can specify an item type for the variable thousands separator.

You can select the desired syntax item from the drop-down list. Or, with the focus on the **Item** property (in the **Value** column), press **Alt** and drag the default separator type item from the type tree editor into the **Value** column.

An item type with a class of **Syntax** must exist in the type tree to be a valid **1000's Syntax Item**.

1000's syntax (variable) > find

For integer numbers with a variable thousands separator, the **Separator** property is **Yes** and the **1000's Syntax** is **Variable**. The value of the separator can be the current value or the value of the separator can be determined each time an occurrence of that type is found.

Yes

Determine the value of the separator each time an occurrence of that type is found. After the value of that separator is found, that particular value is used until it is reset either by another Find or by the occurrence of that separator as a component.

No

The system uses the value to which the separator item is currently set or, if not set, it uses the default value.

Decimal separators

For decimal numbers, the separator is the thousands separator and the fractional separator.

Decimal character numbers have separator properties of:

- Format
- 1000's Syntax
- Fraction syntax
- Value

These properties specify the placement and value of the fractional separator.

The item is assumed to have an implicit number of decimal places. To specify the number of implied decimal places, use the **Item Subclass Places** property to specify the number of implied decimal places.

Separators > format

Use the Separators Format property to specify the placement and value of the fraction separator.

To define the separator format, select one of the separator formats from the drop-down list in the **Value** column.

#####[.##]

The fractional separator is present if there are fractional digits. There is no thousands separator.

#####,##

The fractional separator is always present, even if there are no fractional digits. There is no thousands separator.

#[,###][.##]

The fractional separator is present if there are fractional digits. There is an optional thousands separator.

#[,##][,##]

The fractional separator is always present. There is an optional thousands separator.

,###,##

The fractional separator is always present. There is always a thousands separator if there are more than three whole number digits.

Separators > 1000's syntax

Use the Separators 1000's Syntax to define the thousands syntax. Select one of the following from the drop-down list in the **Value** column:

Literal

The thousands syntax is a constant literal specified in the **1000's Syntax > Value** column.

Variable

The thousands syntax allows for variable values. Use the **1000's Syntax > Default**, **Item**, and **Find** properties to define the variable fraction separator.

See the following topics for additional information:

- ["1000's Syntax \(Literal\) > Value"](#)
- ["1000's Syntax \(Variable\) > Default"](#)
- ["1000's Syntax \(Variable\) > Item"](#)
- ["1000's Syntax \(Variable\) > Find"](#)

Separtors > fraction syntax

Use the **Fraction syntax** property to define the fraction syntax as either a constant literal value or a variable value.

You can define the **Fraction syntax** as literal or variable.

Literal

A constant value.

Use the Fraction syntax > Value property to select a literal fraction separator from the **Symbols** dialog box.

Variable

Allow for variable fraction separator values. The following options are available to define the variable fraction separator:

- **Default** - Use this property to define the default variable separator value for fractions. The default literal separator value for fractions is a period. Enter the default variable separator character or click the browse button to display the Symbols dialog box in which you can insert any non-printable value.
- **Item** - For decimal numbers with a variable fractional separator, the **Separator** property is **Yes** and the **Fraction syntax** is **Variable**, you can specify an item type for the variable fraction separator.
Note: An item type with a class of **Syntax** must exist in the type tree to be a valid **Fraction syntax Item**.
- **Find** - For decimal numbers with a variable fraction syntax, the **Separator** property is **Yes** and the **Fraction Syntax** is **Variable**, the value of the separator can be either the current value or the value of the separator can be determined each time an occurrence of that type is found. Select an option:
 - Yes - Determines the value of the separator each time an occurrence of that type is found. After the value of that separator is found, that particular value is used until it is reset by another find or by the occurrence of that separator as a component.
 - No - The system uses either the value that the separator item is set to currently, or, if it is not set, uses the default value.

Sign

Use the Item Subclass Sign property to define whether the number is signed for either the **Integer** or **Decimal** value. A sign is a symbol that identifies a number as being either positive or negative. A positive sign is plus (+); a negative sign is negative (-).

Yes

The number is signed. Expand the **Sign** property to define the sign values. If the **Sign** property is **Yes**, a minimum of at least one sign value (**If number is +**, **If number is -**, or **If number is 0**) must be specified and at least one value must be required on input.

No

The number is not signed. This is the default setting.

When you select Yes, you can further define the sign values. The following sub-options are available:

Leading-

The sign precedes the number when it is negative only. For input, a sign is required for negative data, but is optional for positive data.

Trailing-

The sign follows the number when it is negative only. For input, a sign is required for negative data, but is optional for positive data.

Leading+

The sign always precedes the number. A sign is required for input and output data.

Trailing+

The sign always follows the number. A sign is required for input and output data.

Custom

Defaults to **Leading-** but can be changed.

Sign values may be specified for the following:

- **If Number is +** (positive numbers)
- **If Number is -** (negative numbers)
- **If Number is 0** (value of zero)

For each value (**If number is +**, **If number is -**, or **If number is 0**), specify the following:

Leading sign

Enter the symbol to be placed before a number.

Trailing sign

Enter the symbol to be placed after a number.

Required on input

If the number has a sign, at least one value (**If number is +**, **If number is -**, or **If number is 0**) must be required on input. Select an option from the drop-down list:

Yes

The sign is mandatory on input.

No

The sign is optional on input.

Pad

Pad implementation determines how the pad value is sized during validation and how the pad value is sized when written as output.

When the data value to be mapped to the target item is smaller than the minimum length of that item, pad characters can be used to pad the data to that minimum length. Input data can contain both content and pad characters. Output data is built according to the pad definitions of the types. Bytes are the default measurement for sizing, however, both byte and character sizing options are available.

Yes

Enables the **Pad** option. Allows the item to contain both content and pad characters.

No

All data is assumed to be content on input; no pad characters are built on output.

- [To specify a pad character](#)
- [Pad > value](#)
- [Pad > Padded to](#)
- [Padded to > length](#)
- [Padded to > SizedAs](#)
- [Padded to > CountsTowardMinContent](#)
- [Padded to > Allow Excess Trailing Pads](#)

- [Pad > justify](#)
 - [Pad > apply.pad](#)
 - [Pad > fill](#)
-

To specify a pad character

Procedure

1. Select a type and open the properties.
 2. In the Properties view, expand the options under Item Subclass.
 3. Set the Pad property to Yes.
 4. Expand the Pad properties.
 5. Click the browse button for the Pad._>.Value property to view a list of symbols.
 6. Select a symbol, and press Insert.
 7. Click OK.
- The new pad character appears in the Pad field.
-

Pad > value

Use the Pad Value property to define a 1-character pad character. The default pad value is 0.

Type the pad character symbol between angled brackets < > in the **Value** field or click the browse button to display the Symbols dialog box to insert any non-printable value.

For example, to enter a **FormFeed** value for the pad character, in the **Value** field enter <FF> or click the browse button to select the **FF (FormFeed)** symbol from the Symbols dialog box.

Pad > Padded to

Use the Pad._>.Padded to property to define whether the data item is padded to a fixed size or to the minimum content size defined for the data object.

Fixed size

The data object is padded to a fixed size (in bytes or characters) that you specify in the Length field.

For any item padded to a fixed size, the item must have a value specified for the Size (content)._>.Max property and the Padded to._>.Length value must be greater than or equal to the Size (content)._>.Max value.

Min Content

The data is padded to the value specified as the minimum size (in the Size (content)._>.Min field).

You can further specify whether to count pad characters toward the length using the CountsTowardMinContent subproperty.

Padded to > length

To pad to a fixed size, you must specify the length.

Input data can contain both content and pad characters but when an item is built for output, the item is padded to the number of bytes or characters specified in this field.

The Padded to._>.Length value must be greater than or equal to the Size._>.Max value.

You can specify the method of measurement (bytes or characters) using the SizedAs subproperty.

Padded to > SizedAs

Use the Padded to._>.SizedAs property to specify that padding is measured in either bytes or characters. The default setting is Bytes.

Trace file and audit log lengths are always reported in bytes.

Table 1. Pad implementation example (bytes compared to characters)

Scenario for empty field:	Result:
Data language is UTF-8	Two À pad characters using 4 bytes.
Pad. _{>} .Value = À (hexadecimal representation = 0xC3 0x80)	
Pad. _{>} .Padded to = Fixed Size	
Padded to. _{>} .Length = 5	
Padded to. _{>} .SizedAs = Bytes	

Scenario for empty field:	Result:
Data language is UTF-8	Five \AA pad characters totaling 10 UTF-8 bytes.
Pad > Value = \AA (hexadecimal representation = 0xC3 0x80)	
Pad > Padded to = Fixed Size	
Padded to > Length = 5	
Padded to > SizedAs = Characters	

Padded to > CountsTowardMinContent

When you select Padded to > Min Content, the **CountsTowardMinContent** field is displayed. Use this setting to specify if pad characters should count toward the length of an object when determining if it meets its minimum content length.

Yes

Pad characters are included in the count for the length of an object.

No

Pad characters are not counted toward the length of an object.

You can use the **Propagate** function here to propagate the present **CountsTowardMinContent** value to the subtypes of the present type, if present.

If you are using the trace option, there might be cases where in the trace file the content length appears to be different than the input length. A trace file lists the input length (the length used to validate an object), which includes the input length of each object plus the pad characters. In the case of numbers, signs and separators are also counted in the length.

CountsTowardMinContent > AcceptAllPads

The **AcceptAllPads** property is applicable to data objects that contain only pad characters. Use this property when you need an object that contains only pad characters (no content) to either pass or fail validation depending on whether it is a mandatory or an optional type, regardless of the minimum size requirement.

Yes

When an object contains only pad characters, the minimum size requirement is ignored and the object passes size validation. The object then passes or fails type validation depending on whether it is a mandatory or an optional type.

No

(Default setting) Pad characters do not count toward the minimum size requirement, therefore an object that contains only pad characters and that does not meet the minimum size (content) requirement fails size validation.

Example

The results of the following examples are based on these values:

Size (content)

5

Pad

Yes

Pad > Padded to

Min Content

Padded to > CountsTowardMinContent

No

Default Behavior: When **AcceptAllPads** is set to **No**, the following results occur:

Input Data (X = pad character)

Valid?

ABCDE

Yes

ABC

No

ABCXX

No

XXXXX

No

When **AcceptAllPads** is set to **Yes**, the following results occur:

Input Data (X = pad character)

Valid?

ABCDE

Yes

ABC

No

ABCXX

No

XXXXX

Yes (when type is optional)

No (when type is mandatory)

X

Yes (when type is optional)
No (when type is mandatory)

Padded to > Allow Excess Trailing Pads

When you select Padded to \geq Min Content, the Allow Excess Trailing Pads property is displayed. Use this setting to flag an element as not valid when the following conditions apply:

- The element is padded to a minimum size.
 - The number of pad characters exceeds the number that is required to achieve the minimum size.
-

Pad > justify

Use the **Justify** property to specify whether the data is padded to the left or right.

Left

The data will be on the left and will be padded (if necessary) on the right.

Right

The data will be on the right and will be padded (if necessary) on the left.

Use the **TRIMLEFT** and **TRIMRIGHT** functions to exclude pad characters from the justified side.

In the following example, xxxxxxxxxxx represent 10 spaces:

For an input of 1234567891xxxxxxxx with a right justified pad, the rule =SIZE(input) returns 20. For the same input, the rule =SIZE(TRIMRIGHT(input)) would return 10 (removing the padding on the right).

Pad > apply pad

Use the **Apply pad** property to specify when to apply the pad character. Choose a value from the drop-down list.

Fixed Group

Apply the pad characters only when the item appears in a fixed group.

Any context

Apply the pad characters when the item appears in any context.

Each item in a fixed group must be padded to a fixed size or have the same value for the minimum and maximum content size.

For example, suppose the item **Name** has a space pad character with this value:

Mary<sp><sp>

If the **Apply pad** property is **Fixed Group**, the two spaces at the end are treated as pad characters only when the item appears in a fixed group. If the **Apply pad** property is **Any context**, then the spaces are always treated as pad characters.

Each item in a fixed group must be padded to a fixed size or have the same value for the minimum and maximum content size.

Pad > fill

For padded signed numbers, this option determines placement of pad characters. Choose a value from the drop-down list.

After sign

Pad characters are placed after the sign.

Before sign

Pad characters are placed before the sign.

Restrictions

Restrictions of an item are the valid values of that item. When the **Interpret as** value is defined as **Character**, the **Restrictions** property is specific to the **Character** value and is not available as an option for a **Binary** value.

Depending on other **Item Subclass** settings, the **Restrictions** property can be set to **Value**, **Character**, or **Range**.

- [Restrictions > ignore case](#)
 - [Restrictions > rule](#)
-

Restrictions > ignore case

By default, restrictions are case-sensitive. To enable or disable the **Ignore case** property of the **Restriction**, choose from one of the following options:

Yes

Ignore case of restrictions in item type properties.

No

Do not ignore case-sensitive restrictions.

For example, if **Ignore Case = Yes** and the restriction **Value** is **ft**, the data values **ft**, **fT**, **Ft**, and **FT** are all valid.

Restrictions > rule

This setting indicates whether you are going to include or exclude the criteria (as "valid" or "invalid") specified for the restrictions.

Include

Includes the restriction values as valid data.

Exclude

Excludes the restriction values as invalid data.

National language

The National language default value is Western. For initiator, terminator, and release character **Literal** values, you can optionally specify a "[Data language](#)".

When the **Interpret as** value is defined as **Character**, the **National language** property is specific to the **Character** value and is not available as an option for a **Binary** value.

- [National language > data language](#)

National language > data language

Use the National language > Data language property to define the data language or character set of this character text item.

NONE and Zero

When the Item Subclass has a Number value and the Interpret as property has a Character value, the NONE and Zero properties are available. Expand the NONE or Zero property to specify an override data value to define the Special Value and Required on input properties.

- [**NONE > Special Value and Zero > Special Value**](#)
Enter a value in the Special Value property if the item is NONE or Zero.
 - [**NONE > Required on input and Zero > Required on input**](#)
Select a value from the Required on input property list.
-

NONE > Special Value and Zero > Special Value

Enter a value in the Special Value property if the item is NONE or Zero.

For example, if you specify * in the Special Value property for NONE, and a number object has the value *, it is interpreted as NONE.

If you enter a value in the Special Value property for NONE or Zero, enter the exact characters to be validated in the input data and built in the output data.

The maximum element length that is allowed for the Special Value property is 3000 bytes.

NONE > Required on input and Zero > Required on input

Select a value from the Required on input property list.

Yes

If the data object is NONE or Zero, the map uses the value in the Special Value property when it validates the item in the input.

No

Do not use the value in the Special Value property. No special values or input requirements are defined when data is NONE or Zero.

When the map builds the item in the output, the item might be either the value in the Special Value property or the default value for NONE or Zero. For example, if an item contains all pad characters and no actual data, the default value for NONE is used when that item is built in the output.

Places

The **Places** property allows you to specify the number of implied decimal places.

For item types defined with an **Item Subclass of Number**, a **Decimal** presentation, and a **Separator**, the **Places** property allows you to specify the minimum and maximum number of decimal places and whole number places. The minimum number of places must be less than or equal to the maximum number of places.

If the decimal number has no separator, use the **Places** property to specify the number of implied decimal places.

Text item subclass properties

Text item subclass properties can be interpreted with a **Character** or **Binary** value. Depending on the value, character or binary, the following are text item subclass properties:

- ["Interpret as Binary"](#) or ["Interpret as Character"](#)
 - ["Size \(content\)"](#)
 - ["Pad"](#)
 - ["Restrictions"](#)
 - ["National language"](#)
 - [Interpret as binary](#)
 - [Interpret as character](#)
 - [Size \(content\)](#)
 - [Pad](#)
 - [Restrictions](#)
 - [National language](#)
 - [NONE](#)
 - [Bidirectional](#)
-

Interpret as binary

Binary text items have content size and pad properties. Binary data is required to be sized or of a fixed size.

Binary number items interpret the data as a binary number or as a byte stream.

Items with an item subclass of **Text** can be interpreted as character or binary.

When **Interpret as** is set to **Binary**, the binary presentation options are Integer, Float, Packed, or BCD.

- [Binary integer presentation](#)
 - [Binary float presentation](#)
 - [Binary packed presentation](#)
 - [Binary BCD presentation](#)
-

Interpret as character

Character number items interpret the data as symbolic data. Symbolic data has the same meaning on different computers. For example, a comma is symbolic because it has the same meaning, regardless of the computer type.

Character text items can have content size and pad properties.

When the **Interpret as** value is defined as **Character**, the **Release** property is specific to the **Character** value and is *not* available as an option for a **Binary** value. For more information, see ["Release characters"](#).

When **Interpret as** is set to **Character**, integer, decimal, and zoned presentation options are available.

- [Character integer presentation](#)
- [Character decimal presentation](#)
- [Zoned character presentation](#)
- [Places > implied](#)

Size (content)

Each text or syntax object can be defined with the minimum and maximum sizes in bytes and/or characters. The product determines size for text or syntax objects according to the following rules.

- When the size of an object is in bytes only, size and validation are calculated according to the size limitations set for bytes.
- When the size of an object is in characters only, size and validation are calculated according to the size limitations set for characters.
- When an object has size values defined for both bytes and characters, the object size is determined by characters (based on any character size limitations). Bytes are used to verify that the size of the data did not exceed any byte constraints that were set.

When the content size of a text or syntax item is specified in bytes, initiators, terminators, release characters, and pad characters are excluded from the count.

Min

The minimum size of the data object. You can enter values for bytes and/or characters.
The default value is 0. The largest value allowed is 65535.

Max

The maximum size of the data object. You can enter values for bytes and/or characters.
The default value is 0. The largest value allowed is 65535.
When there is no maximum content size limitation, this value is not required.

During type tree analysis, checks are performed on byte and/or character Min and Max values according to the following methods:

- When values are present for both Min_Bytes and Min_Characters, the Min_Bytes value must be greater than or equal to MinCharacters.
- When values are present for both MaxBytes and MaxCharacters, MaxBytes must be greater than or equal to MaxCharacters.
- When no size limitations are present, no verification takes place.

Remember:

- Some character sets use two or more bytes per character.
- The trace file and audit log lengths are reported in bytes.

Pad

Pad implementation determines how the pad value is sized during validation and how the pad value is sized when written as output.

When the data value to be mapped to the target item is smaller than the minimum length of that item, pad characters can be used to pad the data to that minimum length. Input data can contain both content and pad characters. Output data is built according to the pad definitions of the types. Bytes are the default measurement for sizing, however, both byte and character sizing options are available.

Yes

Enables the **Pad** option. Allows the item to contain both content and pad characters.

No

All data is assumed to be content on input; no pad characters are built on output.

- [To specify a pad character](#)
- [Pad > value](#)
- [Pad > Padded to](#)
- [Padded to > length](#)
- [Padded to > SizedAs](#)
- [Padded to > CountsTowardMinContent](#)
- [Padded to > Allow Excess Trailing Pads](#)
- [Pad > justify](#)
- [Pad > apply.pad](#)
- [Pad > fill](#)

Restrictions

Restrictions of an item are the valid values of that item. When the **Interpret as** value is defined as **Character**, the **Restrictions** property is specific to the **Character** value and is not available as an option for a **Binary** value.

Depending on other **Item Subclass** settings, the **Restrictions** property can be set to **Value**, **Character**, or **Range**.

- [Restrictions > ignore case](#)
- [Restrictions > rule](#)

National language

The National language default value is Western. For initiator, terminator, and release character **Literal** values, you can optionally specify a "[Data language](#)".

When the **Interpret as** value is defined as **Character**, the **National language** property is specific to the **Character** value and is not available as an option for a **Binary** value.

- [National language > data language](#)
-

NONE

When the Item Subclass has a Text value and the Interpret as property has a Character or Binary value, the NONE property is available. Expand the NONE property to specify an override data value to define the Special Value and Required on input properties.

- [NONE > Special Value](#)

Enter a value in the Special Value property if the item is NONE.

- [NONE > Required on input](#)

Select a value from the Required on input property list.

NONE > Special Value

Enter a value in the Special Value property if the item is NONE.

For example, if you specify * in the Special Value property for NONE, and a text object has the value *, it is interpreted as NONE.

If you enter a value in the Special Value property for NONE, enter the exact characters to be validated in the input data and built in the output data.

The maximum element length that is allowed for the Special Value property is 3000 bytes.

NONE > Required on input

Select a value from the Required on input property list.

Yes

If the data object is NONE, the map uses the value in the Special Value property when it validates the item in the input.

No

Do not use the value in the Special Value property. No special values or input requirements are defined when data is NONE.

When the map builds the item in the output, the item might be either the value in the Special Value property, or the default value for NONE. For example, if an item contains all pad characters and no actual data, the default value for NONE is used when that item is built in the output.

Bidirectional

Use the Item subclass > Bidirectional property to define the data as bidirectional.

Certain languages that are read from right-to-left often contain numeric or other phrases that are read from left-to-right. This type of data is called "bidirectional" because it changes direction in the middle of a line.

The default setting is **No**.

To enable this setting, select **Yes**. When you enable this setting, additional options are available to further define the bidirectional data.

Text items

The Bidirectional subproperties for text item types provide options for symmetric swapping, ordering, orientation, and shaping.

Symmetric Swapping

Use this property to maintain the orientation of directional pairs of characters (such as parentheses, greater than/less than symbols, brackets, braces).

Ordering Scheme

This property pertains to the order of the data as stored in memory.

Logical, the default setting, indicates that the data is stored in memory from left-to-right, regardless of the orientation of the text. Using the **Visual** ordering scheme, the data is read and stored with the start character in the right-most position both visually and in memory.

Orientation

Orientation pertains to the direction of the text as read visually. The default direction is left-to-right (LTR), meaning the text object is read starting from the left. The direction can be right-to-left (RTL), meaning the object is read starting from the right. When you select RTL, the behavior of some text functions (such as LEFT, RIGHT, MID) can change.

Use the Contextual LTR and Contextual RTL settings when the orientation should be taken from the context of the data because the data contains "strong" characters that are either orientation left or orientation right. When no strong characters are present in the data, the orientation will be based on this setting.

For example, when you set the orientation to Contextual LTR and no strong characters are encountered (meaning the data is orientation-neutral), the data orientation will be considered left-to-right.

Text Shaping

Use this property to produce output in a different glyph (shape or bit pattern). The default setting is off, or **Unshaped**.

To enable text shaping, select **Shaped**. The output will be shaped according to the code page of the target object.

Character number items

For character number item types, you can additionally define a numeric shaping characteristic.

Numeric Shaping

Use this property to indicate whether the output of numeric values will have the shapes that are used in English (Arabic digits 0123456789) or the national numerical shapes.

The default setting is **Regular**, which means Arabic digits (0123456789). Otherwise, select **Arabic-Indic** (أ و و و و و و و و).

The Bidirectional property is not applicable to binary numbers.

Date & Time item subclass properties

The Date & Time properties provide the flexibility to define multiple combinations of date-time formats.

Date & Time items can be interpreted as either binary or character. (See sections "["Interpret as Binary"](#)" and "["Interpret as Character"](#)").

For binary **Date & Time** items, the **Presentation** property has two different values: **Packed** and **BCD**.

Packed

The **Packed** value is a number that has size, decimal places, and sign properties.

BCD

The **BCD** value is a binary coded decimal number that has size.

Other **Item Subclass** properties for **Date & Time** are displayed depending on the **Interpret as** setting (**Binary** or **Character**).

- [Date](#)
- [Time](#)
- [Format](#)
- [Time zones](#)
- [Time zone format string for XML](#)
- [Optional time segments of the time format string](#)
- [Date and time format examples](#)
- [NONE and Zero](#)

Date

For binary **Date & Time** items, use the **Date** property to define whether the date format is enabled.

Yes

Date format is enabled for this type. Expand the **Format** property to select the date format.

No

Date is not defined for this type.

- [Date > format](#)

Date > format

Select the date format that the data interpretation will be based on. For binary **Date & Time** items, the **Date > Format** property has four values.

CCYYDDD and **YYDDD** Julian date formats are supported.

- CCYYMMDD
- YYMMDD
- CCYYDDD
- YYDDD

Time

For binary **Date & Time** items, use the **Time** property to define whether the time format is enabled. Select one of the following options:

Yes

Time format is enabled for this type. Expand the **Format** property to select the time format.

No

Time is not defined for this type.

- [Time > format](#)

Time > format

Select the time format that the data interpretation will be based on. For binary **Date & Time** items, the **Time Format** property has several values. The following choices are available from the drop-down list:

- HH24MMSS
 - HH24MM
 - HH24:MM:SS
 - HH24:MM
 - Custom
-

Format

You can define a date-time format from within the type properties, except for native schema XML.

The output format for the native schema XML date/time field is always:

```
{CCYY-MM-DD}T{HH24:MM:SS.3-3+/-ZZ:ZZ}
```

To specify a different output format, use Xerces XML instead.

To define the Date & Time format:

1. Open the type properties.
2. In the Item Subclass **Format** property, click the browse button.
The Date Time dialog box is displayed.
3. Make your format selections and click OK.
You can use alphabetical characters as separators. In the example,
2001-04-02T10:32:59-0500, **T** is the separator.

Separators are limited to 60 characters.

Supported date formats:

- CCYYMMDD
- YYMMDD
- MMDDCCYY
- MMDDYY
- CCYYDDD
- YYDDD
- DDMMCCYY
- DDMMYY

Note: The DDMMCCYY and DDMMYY formats did not exist prior to version 6.5 of the Design Studio. If you had defined either one of these formats prior to 6.5 as a custom format, it will be recognized in 6.5 as the respective new format, instead of the previously defined custom format.

- [Use of format elements](#)
 - [Custom date format](#)
 - [Custom Time Format](#)
-

Use of format elements

If you select the same format element more than once for the same item, that item may not be validated separately. If you specify **MON** twice, the day of the month is not validated separately for both months. For example, if the date format element **MON** is used twice for a single item, with the following format string:

MON D-MON D

Suppose the data is this:

Feb 28-Mar 31

28 is not validated for the month of February.

Some combinations of reserved words are invalid. A separator must follow reserved words representing a variable number of digits (**D** and **M** for date) if data follows.

For example:

- D/M/CCYY is valid.
- CCYYM/D is valid.
- DMCCYY is invalid.

See the Design Studio Introduction documentation for a list of reserve words and symbols.

Custom date format

After choosing **Custom** from the date format drop-down list, click browse. The Date Format dialog box is displayed.

You can only use non-alphanumeric characters (excluding the {, } and [,] non-alphanumeric characters) as separators in the custom Date Format dialog box.

The following table provides examples of date formats.

Date Format	Description	Example
CCYY	4-digit Century + Year	1999
YY	2-digit Year (00-99)	99
MM	2-digit Month (01-12)	12
M	1- or 2-digit Month (1-12)	8
MON	3-character Month (Jan to Dec)	JAN
MONTH	Full name of Month	January
DDD	3-digit Day of year (001-366)	32
DD	2-digit Day of Month (01-31)	31
D	1- or 2-digit Day of Month (1-31)	7
DY	3-character Day of Week (Sun-Sat)	Fri
DAY	Full Name of Day of Week (Sunday-Saturday)	Friday
WW	1- or 2-digit Week of Year	13
Qn	Quarter of Year (Q1-Q4)	Q2
Custom	User defined custom date format	

After you define and save a custom format, the custom format string is displayed in the Properties window. For example, the custom date format **CCYYMMDD**, and the custom time format **HH24MMSS** display as:

{CCYYMMDD}{HH24MMSS}

Custom Time Format

After selecting **Custom** from the time format list, click browse. The Time Format window is displayed.

You can only use non-alphanumeric characters as separators, excluding the {, } and [,] non-alphanumeric characters, in the Time Format window.

The following table provides time format examples.

Time Format	Description	Example
HH24	2-digit hour in 24 hour format (00-23)	23
H24	1- or 2-digit hour in 24 hour format (0-23)	11
HH12	2-digit hour in 12 hour format (00-12)	08
H12	1- or 2-digit hour in 12 hour format (0-12)	8
MM	2-digit minute (00-59)	09
M	1- or 2-digit minute (0-59)	9
SS	2-digit second (00-59)	05
S	1- or 2-digit second (0-59)	5
AM/PM	Meridian (AM/PM)	AM
ZZZ	A time zone abbreviation. See " Time Zones " for a list of supported time zones.	EST
+/-ZZZZ	Hours and minutes before or after the Greenwich Mean Time (GMT). GMT is now referred to as Coordinated Universal Time (UTC).	+0500
+/-ZZ:ZZ	4-digit time where the format is a 2-digit hour and 2-digit minute, separated by a colon.	+05:00
+/-ZZ[;ZZ]	4-digit time where the format is a 2-digit hour and an optional 2-digit minute, separated by colon.	+05:00
+/-ZZ[ZZ]	4-digit time where the format is a 2-digit hour and an optional 2-digit minute.	+0500
TZD	4-digit time where the format is a 2-digit hour and 2-digit minute, separated by a colon. Z on output, if value is +/-00:00.	+05:00

After you define and save a custom format, the custom format string is displayed in the Properties window. For example, the custom date format CCYYMMDD, and the custom time format HH24MMSS display as:

{CCYYMMDD}{HH24MMSS}

Time zones

The following table lists the supported time zones.

Time Zone	Abbreviation	Hours before Greenwich Mean Time	Hours ahead of Greenwich Mean Time
Greenwich Mean Time (Zulu)	GMT	0	0
West African Time	WAT	-1	+23
Azores Time	AT	-2	+22
No name; Brasilia Time	###	-3	+21
Atlantic Standard Time	AST	-4	+20
Eastern Standard Time	EST	-5	+19
Central Standard Time	CST	-6	+18
Mountain Pacific Time	MST	-7	+17
Pacific Standard Time	PST	-8	+16
Yukon Standard Time	YST	-9	+15
Hawaii Standard Time	HST	-10	+14
Nome Time	NT	-11	+13
New Zealand Time	NZT	-12	+12
No name; no location	###	-13	+11

Time Zone	Abbreviation	Hours before Greenwich Mean Time	Hours ahead of Greenwich Mean Time
Guam Standard Time	GST	-14	+10
Japan Standard Time	JST	-15	+9
China Coast Time	CCT	-16	+8
West Australia Time	WAT	-17	+7
Zulu + 6 (Russia zone 6)	ZP6	-18	+6
Zulu + 5 (Russia zone 5)	ZP5	-19	+5
Zulu + 4 (Russia zone 4)	ZP4	-20	+4
Baghdad Time	BT	-21	+3
Eastern European Time	EET	-22	+2
Central European Time	CET	-23	+1

Time zone format string for XML

Note: The output format for the native schema XML date/time field is always:

{CCYY-MM-DD}T{HH24:MM:SS.3-3+/-ZZ:ZZ}

To specify a different output format, use Xerces XML.

The following time zone strings support the specification of a single character Z to indicate Coordinated Universal Time (UTC), as described by the World Wide Web Consortium (www.w3c.org) and the ISO 8601 standard:

- +/-ZZZZ
- +/-ZZ:ZZ
- TZD

When the +/-ZZ:ZZ or +/-ZZZZ format string is specified, the data validation process works in the following manner:

- Valid data that corresponds to this format string will contain either a character literal Z (representing UTC) or a zone in the appropriate format: +/-ZZ:ZZ or +/-ZZZZ, as specified.
- If a character literal Z is present, it shall be interpreted, and treated at mapping time, as UTC, which is equivalent to +00:00 or +0000.

When the TZD format string is specified, the data validation and output generation processes work in the following manner:

- Valid data that corresponds to this format string will contain either a character literal Z, representing UTC, or a zone, in the +/-ZZ:ZZ format.
- If a character literal Z is present, it shall be interpreted, and treated at mapping time, as UTC, which is equivalent to +00:00.
- If the value is +/-00:00, it generates Z in the output. Otherwise, it generates the output in +/-ZZ:ZZ format.

The following time zone strings support the omission of the minute portion of the difference from UTC:

- +/-ZZ[:ZZ]
- +/-ZZ[ZZ]

Optional time segments of the time format string

This section discusses how you can specify a portion of a time-format string to be optional. For example, you can specify that either the *time zone* portion or the *hours, minutes, seconds, fractional seconds, Meridian* portion is optional.

This flexibility is also applicable to time-format strings used in functions or in type tree scripts imported by the Type Tree Maker.

Only the time portion **or** the zone portion can be optional-not both.

To specify a portion of the time-format string as optional:

1. The following procedure assumes that the **Item Subclass** property of your type tree is **Date & Time**.
2. From within the type tree properties, navigate to Item Subclass-> Format.
3. Click the browse button to open the Date Time dialog.
4. From a Format field that is set to **Time**, go to the field directly below it and choose Custom from the drop-down menu.
5. Next to the Format field with **Custom** selected, click the browse button. The Time Format dialog is displayed.
6. Choose from the following tasks:
 - To specify the *hours, minutes, seconds, fractional seconds, and Meridian*-portion of the time format string as optional, enable the check box on the far left side of the dialog.
 - To specify the *time zone* portion of the time format string as optional, enable the check box.
 Only one segment of the time format string can be specified as optional.

Date and time format examples

The following list includes examples of popular standard date and time formats:

Format

Description

X12 EDI

Fractional seconds format: **HH24MM[SS[0-2]]**.

SWIFT

Time Zone Designator or UTC Designator format: **HH24MSS [TZD]**.

TimeStamp format: **CCYY-MM-DDTHH:MM[SS[.0-6]] [TZD]**, which is a combination of date and time.

HL7

Time format: **HH24MM[SS[.0-6]] [+/-ZZZZ]**.

TimeStamp format: **CCYYMMDDHHMM[SS[.0-6]] [+/-ZZZZ]**, which is a combination of date and time.

SAP

Time format: **HHMMSS**.

ODBC

Time format: **HH:MM:SS [.0-9]**, which is the form most commonly used in **ODBC** mapping. The fractional part is optional and not often used.

NONE and Zero

When the Item Subclass has a Date & Time value and the Interpret as property has a Character value, the NONE and Zero properties are available. Expand the NONE or Zero property to specify an override data value to define the Special Value and Required on input properties.

- [NONE > Special Value and Zero > Special Value](#)

Enter a value in the Special Value property if the item is NONE or Zero.

- [NONE > Required on input and Zero > Required on input](#)

Select a value from the Required on input property list.

NONE > Special Value and Zero > Special Value

Enter a value in the Special Value property if the item is NONE or Zero.

For example, if you specify * in the Special Value property for NONE, and a data and time object has the value *, it is interpreted as NONE.

If you enter a value in the Special Value property for NONE or Zero, enter the exact characters to be validated in the input data and built in the output data.

The maximum element length that is allowed for the Special Value property is 3000 bytes.

NONE > Required on input and Zero > Required on input

Select a value from the Required on input property list.

Yes

If the data object is NONE or Zero, the map uses the value in the Special Value property when it validates the item in the input.

No

Do not use the value in the Special Value property. No special values or input requirements are defined when data is NONE or Zero.

When the map builds the item in the output, the item might be either the value in the Special Value property or the default value for NONE or Zero. For example, if an item contains all pad characters and no actual data, the default value for NONE is used when that item is built in the output.

Syntax item subclass properties

Syntax objects are characters that precede, separate, or follow a particular data object. Item types with an **Item Subclass of Syntax** are defined and used to specify delimiters, initiators, terminators, and release characters. Syntax objects with variable values are defined as the syntax object's **Variable** property. Syntax objects appearing as actual data to be mapped as output data are defined as components of a type.

- [Syntax objects with variable values](#)
- [Example of variable syntax object as an item type](#)
- [Syntax objects as data](#)
- [Example of syntax objects as components of a type](#)
- [Delimiter > find](#)

Syntax objects with variable values

About this task

Using a syntax item to specify delimiters, initiators, terminators, and release characters is required when the value of syntax objects (delimiters, initiators, terminators, and release characters) may vary.

The restrictions of syntax items define the variable literal values.

To define a variable syntax object:

Procedure

1. Create an item type with an **Item Subclass** of **Syntax** to represent the syntax object.
2. Define the restrictions for the syntax item type.
3. For the item or group type with the variable syntax object, for the **Variable** delimiter, initiator, terminator, and release character, select the item from the **Item** drop-down list in the Properties view.
4. For the **Find** property, select Yes.
Only item types defined with an **Item Subclass** of **Syntax** appear in the drop-down list.

Related tasks

- [Defining item restrictions](#)
-

Example of variable syntax object as an item type

In this example, the group type **Header** has variable delimiter values of: , * + ~

1. Create an item type with the **Item Subclass** of **Syntax** and the name **Delimiter**. (The name can be any valid type name, but naming this item **Delimiter** is useful).
2. To define the item restrictions, double-click the **Delimiter** type. The item view is displayed.
3. Define the restrictions in the **Include** column.
4. In the Properties window, select Syntax for the **Item Subclass** property.
5. Open the properties for the delimited group type **Header**.
6. For the **Syntax** property, choose **Delimited**.
7. For the **Delimiter** property, choose **Variable**.
8. Expand the **Delimiter** property.
9. Define the Delimiter._{Default} literal value.
10. For the variable Delimiter Item property, choose the item type **Delimiter** from the drop-down list.
11. Indicate that the variable delimiter should be determined for each occurrence of the object by selecting Yes for the Delimiter._{Find} property.

Syntax objects as data

The value of a syntax object (delimiters, initiators, terminators, and release characters) may appear as actual data that can be mapped. Syntax objects that appear as actual data are defined as components of a type.

Example of syntax objects as components of a type

The following is an example of defining a syntax object as a component of a group type. The following data represents a message received from multiple departments.

Each message is made up of segments. Each department uses different segment delimiters and terminators. The message format specifies that the delimiter and terminator are the first two bytes of the message, followed by the actual data.

To define syntax objects for the delimiter and terminator:

1. Define two separate syntax objects with an **Item Subclass** of **Syntax**, one for the message delimiter and one for the message terminator. Appropriate type names might be **SegmentDelimiter** and **SegmentTerminator**.
2. Define the possible message delimiter values as restrictions of the **SegmentDelimiter** item type. Define the possible message terminator values as restrictions of the **SegmentTerminator** item type.
3. Define these item types as the first two components of the group type **Message**.
4. Expand the **Delimiter** property.
5. For the variable Delimiter._{Item} property, select SegmentDelimiter from the drop-down list.
6. For the variable Terminator._{Item} property, select SegmentTerminator from the drop-down list.

During the data validation process, the component **SegmentDelimiter** appears in the data with a value of *. The group type **Segment** has a variable delimiter specified as the item type **SegmentDelimiter**, with the value *. Therefore, it is understood that the segment has * as the delimiter.

When the value of a syntax object appears as actual data, it can be mapped as data. For example, source data may use different delimiters from several different sources. Acknowledgments of this data must be sent back to the source using the delimiter used in the original data. This data can be mapped from the input to the output if these syntax objects are defined as components within the data.

Delimiter > find

When syntax objects are **Variable**, the **Find** property must be defined. The **Find** property determines whether the value of syntax object is set on each occurrence or whether the current setting (or default value) is used.

When the **Initiator**, **Terminator**, **Release**, or **Delimiter** property value is **Variable**, select one of the following from the drop-down list in the **Value** column:

Yes

Determine the value of the syntax object each time an occurrence of that type is found. After the value of that syntax object is found, that particular value is used until it is reset by another **Find** or by the occurrence of that syntax item as a component.

INPUT: The value of the object in the input data is determined by the location in the data stream and the restrictions of the syntax item.

OUTPUT: The default value is used for building the syntax object in the output data.

No

The variable syntax object is defined as the current value or, if it is not set, as the default value.

INPUT: If the syntax object is not encountered in the data stream, the value of the syntax object is the default value.

OUTPUT: If the value of the syntax item has *not* been previously set, the default value is used.

Group properties

Group properties include the group's **Subclass** and **Format**, which describes how to distinguish one component of that group from another component of that group.

- [Group subclass](#)
- [Sequence group formats](#)
- [Explicit format](#)
- [Implicit format](#)
- [Specifying a delimiter](#)
- [Defining exclude characters](#)

During map run time, the data validation process uses the Exclude Character List group property to define a set of characters that are not allowed to exist in the data stream as data content.

Group subclass

Group types have a subclass of **Sequence**, **Choice**, or **Unordered**.

Property	Description
Sequence	A partially-ordered or sequenced group of data objects. Each component of a Sequence group is validated sequentially.
Choice	Choice groups provide the ability to define a selection from a set of components like a multiple-choice question on a test. A Choice group is valid when the data matches one of the components of the choice group. Validation of a Choice group is attempted in the order of the components until a single component is validated. If the Choice group has an initiator, the initiator is validated first.
Unordered	An unordered group has one or more components. Unordered groups can only have an Implicit format property, with the same syntax options as sequence groups: None or Delimited .

- [Properties of group subclasses](#)
- [Choice group components](#)
- [Unordered group components](#)

Properties of group subclasses

The distinction between Sequence and Choice group subclasses is that Choice groups have no **Partition** or **Format** properties.

Type syntax properties such as **Initiator**, **Terminator**, **Release**, and **Empty** can be applied to **Choice** groups. If a release character is defined, by default it applies to the **Terminator**.

Choice group components

A Choice group can have both items and groups as components. A partitioned Sequence group can only have group subtypes.

Components of a Choice group must be distinguishable from each other. The components of a Choice group cannot have a component range other than (1:1). Only one component of a Choice group built in the output data.

A Choice group data type is only one of the group components. For example, the data type **Record** is a group type with a **Group Subclass** of **Choice**. The group type **Record** has three components: **Order**, **Invoice**, and **Sales**. The data validation of **Record** will be only one of the components: **Order**, **Invoice**, or **Sales**. For this reason, the components of a Choice group must have a component range of (1:1).

Unordered group components

An unordered group has one or more components that can appear in the data stream in any order. They allow many SWIFT and FIX message types, for example, to be defined in a more natural way.

Unordered groups have no partitioned property. They have **Implicit** format properties with the same syntax options as sequence groups: **None** and **Delimited**.

When a group is defined as **Unordered**, any component can appear in the data stream. A component can be an item or a group.

Unordered group components have a range property. For example, if the unordered group, **A**, has the following component list:

B(1:S)
C

D (S)

then **A** must have one **C**, at least one **B**, and possibly some **D**s. They could appear in any order. For example, data for **A** could have the pattern: **CDBBDDD** or **BBBDDCDB**.

Component rules of an unordered group cannot reference other components of the same group. They can only reference the component to which the rule refers and the objects contained in that component.

Sequence group formats

A sequence group has either an **Explicit** or **Implicit** format.

Explicit

The explicit format relies on syntax to separate components. Each component can be identified by its position or by a delimiter in the data. Delimiters appear for missing components.

Implicit

The implicit format relies on the properties of the component types. The format is not fixed. If delimiters separate components, they do not appear for missing components.

For example, if each component of a fixed group has a fixed size, the component is distinguished from the next component by its position in the data. Or, a group may have delimiters that appear for missing components. In these cases, the format is apparent; the group has an explicit format.

If a group does not have an explicit format, it has an implicit format. An implicit format relies on the properties of the component types. In this example, the components make some pattern in the data and it is possible to distinguish between them, but the format is not fixed and if delimiters separate components, they do not appear for missing components.

When deciding what format a group has, it may help to ask first whether it is clear where one component ends and another begins. Generally, a group has an explicit format if the position of each component in the data stream is always the same or if a delimiter always marks the place for each component.

Explicit format

To specify that a group has an explicit format, choose **Explicit** for the **Format** property. Select a setting for the **Track** property, and choose the group's syntax: **Fixed** or **Delimited**.

- [Track](#)
- [Fixed syntax](#)
- [Explicit delimited syntax](#)

Track

The **Track** property indicates whether the system should track only the components that have content or all components, including those that do not have content. The settings are **Content** and **Places**.

For example, if a group **StudyGroup** has the component **Name(s)**, and Places is specified for the Track property, any empty occurrences of **Name** are tracked.

Suppose **Name** has an * initiator and a space pad character. This is the data for **StudyGroup**:

*Carolyn * *Stuart *Margaret

Notice that the second **Name** is missing.

If Places is specified for the Track property, and you want to map the third **Name**, the empty **Name** would be counted as an occurrence, so the third **Name** would be Stuart. However, if Content is specified for the Track property, the empty **Name** would not be counted as an occurrence because it does not have content and the third **Name** would be Margaret.

Fixed syntax

If a group data object is always the same size (in bytes), it has a fixed syntax. For example, a record that is always 160 bytes has a fixed syntax.

Each component of a fixed group must be fixed. If you break down a fixed group, it ultimately consists of items that are fixed. Each is padded to a fixed size or its minimum and maximum content size are equal. Do not specify the size of a fixed group. The size is automatically calculated based on the size of the group's components.

- [Guidelines for defining a fixed group](#)

Guidelines for defining a fixed group

- Each component must be a group with a fixed syntax or a fixed item. The item is padded to a fixed size or its minimum and maximum content size are equal.
- Each component must have a specified range maximum. The maximum cannot be s.
- If a component range minimum is not equal to the maximum, content is not required for optional component occurrences. For example, if a component is the item **ShippingAddress** (0:1) and **ShippingAddress** has a minimum content size of two characters, data may either contain: 1) all pad characters, or 2) if content is in the

data stream, there must be a minimum of two characters for a **ShippingAddress**. If a component is a group, no content is required for any of the items contained in an optional occurrence of that component.

Explicit delimited syntax

An explicit-format group with a delimited syntax is one whose components are separated by a delimiter and the delimiter appears as a placeholder even when a component has no content.

About delimiters and explicit-format groups:

- The only time a delimiter can be missing is when all components following the delimiter are optional and there is no data for the optional components.
- A delimiter is a character or series of characters that separates data objects.
- A delimiter cannot be longer than 500 bytes.
- The delimiter of a group appears inside the group, separating its components. When a group is delimited, that indicates something about the components of the group. The delimiter inside a group is delimiting the components.

Example

The group **Employee** has an explicit-delimited format because a comma delimiter appears between **Employee's** components, the items that make up the **Employee** object. In addition, the delimiter is displayed when a component is missing and there is data for components following it.

The components of **Employee** are the items **ID#**, **Name**, **Department**, **Address**, and **Age**.

- [Delimiter](#)

Delimiter

Use the **Delimiter** property to specify the value and location of the delimiter. For specific information on specifying the delimiter, see "[Specifying a Delimiter](#)".

In an explicit-delimited group, if the delimiter is whitespace <WSP>, the delimiter is interpreted as one byte long; each <WSP> character is interpreted as another delimiter. In the output, a <WSP> delimiter is one space.

The limit for <WSP> is 512 bytes.

Implicit format

In a group with an implicit format, the components are distinguishable not by delimiter or position, but by their pattern; something in the definition of the component types themselves. The group has no syntax property that distinguishes one component from another.

For example, the type **File** consists of **Record**(s). <CR><LF> appears at the end of each **Record**. It has been defined as the terminator of **Record**. **File**, however, has no syntax of its own. The **Record** terminator distinguishes one **Record** from another.

To specify that a group has an implicit format, choose **Implicit** for the **Format** property. Optionally, define a comment type, and choose the group's syntax: **Delimited** or **None**.

- [Floating component](#)
- [Implicit whitespace syntax](#)
- [Implicit delimited syntax](#)
- [No syntax](#)
- [Distinguishable components of an implicit group](#)

Floating component

The floating component represents an object that may appear after any component of the group.

An implicit group can have a floating component; an explicit group cannot. If the group is prefix or infix delimited, the floating component is displayed before the delimiter. If the group is postfix delimited, the floating component is displayed after the delimiter.

A floating component can be an optional component that may appear after any other component. However, it is not included in the component list because it does not appear at a specific location.

If a group has a floating component, a component must be distinguishable from a floating component. For example, components and floating component could start with different initiators.

Note: When a floating component appears in the input data, it is validated during mapping. If there are floating components in your output data, define them as actual components of the output.

A floating component can appear after the initiator (when the type has an initiator), after each component, or both. For EDI and other existing floating components, trees will be converted as "after each component".

A floating component can be specified for implicit sequence group, choice group, and unordered group definitions.

A floating component provides additional flexibility to support XML data. With the floating component property, XML element groups would have a floating component defined as an unordered group of XML comments, XML processing instructions, and/or white space.

The XML DTD Importer, for example, uses the floating component property for XML elements whose content contains other elements. For such XML element definitions, a floating component can be a choice of XML comments and/or XML processing instructions.

To define a type as a floating component:

1. In the Properties window expand the **Format** property.
2. With current focus in the Floating Component Value field, define the value for the floating component by pressing **Alt** and dragging the item from the tree into the Floating Component Value field.

Implicit whitespace syntax

Select WhiteSpace for the **Component Syntax** value when white spaces are not allowed in the data. When you select the **WhiteSpace** option, define the **Build As** and **Character Set** properties.

Note: Helpful for XML data.

- [Build as](#)
- [Character set](#)

Build as

Enter the characters that will replace white spaces.

The Build As property is only available when the Component Syntax property is defined as WhiteSpace.

Character set

Select a character set for the component from the drop-down list.

The default value is Native, where the literal values use the native character set of the computer.

[Supported character sets \(code pages\)](#)

Implicit delimited syntax

If a delimiter separates the components of a group, but the delimiter does not appear when a component is missing, the group has an implicit format with a delimited syntax.

In certain data, the delimiter may not be a placeholder.

- [Delimiter](#)

Delimiter

Use the **Delimiter** property to specify the value and location of the delimiter. For specific information on specifying the delimiter, see "[Specifying a Delimiter](#)".

In an implicit-delimited group, when the delimiter is whitespace <WSP>, all contiguous <WSP> characters are treated as one delimiter. In the output, a <WSP> delimiter is built as one space.

The limit for <WSP> is 512 bytes.

No syntax

To specify a group with an implicit format that has no syntax, choose **None** for the **Component Syntax** value.

Distinguishable components of an implicit group

Each component of an implicit group needs to be recognizable. If either of two different components appears at the same place in a data stream, there must be a distinguishable difference between one component and the other.

Sometimes components of an implicit group may be distinguished because there is something in the data that distinguishes them.

After the first item **Line** of the **Form**, the next data object could be another item **Line**. Or, it could be a **Trailer Line**. When looking at a particular **Line**, there is something in the data that identifies that **Line** either as a **Header Line**, an item **Line**, or a **Trailer Line**. The type **Line** has been partitioned to distinguish between the different kinds of **Lines**.

-

Specifying a delimiter

For the **Delimiter** property, specify whether the delimiter is a literal or a variable value.

- [Literal](#)
 - [Variable](#)
 - [Location](#)
 - [Delimiter value appears as data](#)
 - [Allow Excess Trailing Delimiters](#)
-

Literal

If the delimiter is a constant value, enter the delimiter value in the **Value** field. To enter a non-printable value, click the browse button and select a value from the Symbols dialog box.

- [National language](#)
 - [Data language](#)
-

National language

The National language default value is Western. For initiator, terminator, and release character **Literal** values, you can optionally specify a "[Data language](#)".

When the **Interpret as** value is defined as **Character**, the **National language** property is specific to the **Character** value and is not available as an option for a **Binary** value.

- [National language > data language](#)
-

Data language

Use the National language...> Data language property to define the data language or character set.

[Supported code pages](#)

Variable

Sometimes you do not know what delimiter is used in the data source, especially if you receive that data from an outside source. However, you know all of the possible values that the delimiter could be. You can create an item to represent this delimiter and specify all of the possible values as restrictions of that item. The value of the delimiter in the data is found.

To specify an item as a Variable Delimiter:

1. In the Properties view for the delimited group, click in the Delimiter...>Item value field.
 2. Press Alt and drag the item from the type tree editor into the **Item** field.
-

Location

The **Location** property specifies the location of the delimiter with respect to the components. The options are prefix (the delimiter appears before the component), postfix (the delimiter appears after the component), and infix (the delimiter appears between components).

The following table explains each option.

Property	Description	Example
----------	-------------	---------

Property	Description	Example
Prefix	Before each component. Before each member of a component in a series.	*a*a*b*c
Postfix	After each component. After each member of a component in a series.	a*a*b*c*
Infix	Between components. Between members of a component in a series.	a*a*b*c

Delimiter value appears as data

Delimiters do not appear as part of the actual data. For example, if the delimiter is specified as a comma, the comma in the following text item would be considered a delimiter, rather than part of the data itself:

Tom Smith, Jr.

If the data does contain the delimiter value, there are ways to format the data so that both the data and the delimiter are distinguishable. For example, text items can be enclosed in quotation marks. Or, a release character may be used. For information about release characters, see ["Release Characters"](#).

Allow Excess Trailing Delimiters

The type tree validation process allows data that contains excess trailing delimiters on sequence groups.

You can change the default setting for the Allow Excess Trailing Delimiters property to No so that the type tree validation process, instead, fails data that contains excess trailing delimiters.

The type tree validation process interprets a delimited sequence group that contains optional components at the end of its sequence, as having excess trailing delimiters.

For example, GROUPA contains the following components: COMPA (mandatory), COMPB (optional), COMPC (optional), and COMPD (optional). The group is infix-delimited by a tilde. The following data stream examples are valid for GROUPA:

```
A~B~C~D
A~B~C~
A~B~~
A~~~
```

For this example, you want the type tree validation process to disallow all of the data stream examples that contain unnecessary or excess trailing delimiters. To disallow the excess trailing delimiters, you can change the setting for the Allow Excess Trailing Delimiters property to No. The result is that the validation process fails all of the examples except the first one.

Defining exclude characters

During map run time, the data validation process uses the Exclude Character List group property to define a set of characters that are not allowed to exist in the data stream as data content.

The data validation process allows these excluded characters to exist in the data stream as syntax, such as delimiters, if they are not being used as data content.

The group exclude characters might be derived from previously parsed values in the data stream or might be defined as literal values.

When you define exclude characters at the group level, the data validation process handles these specified characters as if they were in-scope data syntax.

For example, you have a type tree which defines two groups, GROUPA and GROUPB. The tree defines the asterisk (*) character as a group delimiter for GROUPA. It defines the at-sign (@) character as a group delimiter for GROUPB. The tree also defines the FILE group, which contains both GROUPA records and GROUPB records.

The data stream contains content corresponding to the FILE group, which is composed of a series of both GROUPA and GROUPB records.

When a map begins to run, it parses and validates this data stream. Since the asterisk is the delimiter of GROUPA, the data content of GROUPA records is only allowed to contain asterisk characters that are escaped. If the data content contains non-escaped asterisk characters, those GROUPA records fail data validation. Similarly, since the at-sign is the delimiter of GROUPB, the data content of GROUPB records is not allowed to contain non-escaped at-sign characters. If it does, those GROUPB records fail data validation.

The type tree defines the delimiters, or markup, for the GROUPA and GROUPB records. Asterisk characters are considered to be in-scope markup while the data validation process handles GROUPA records. At-sign characters are considered to be in-scope markup while the data validation process handles GROUPB records.

Conversely, GROUPA data content is allowed to contain at-sign characters, as the GROUPB at-sign delimiter does not apply to GROUPA records. Therefore, at-sign characters are considered out-of-scope markup for GROUPA records. GROUPB data content is allowed to contain asterisk characters, as the GROUPA asterisk delimiter does not apply to GROUPB records. Therefore, asterisk characters are considered out-of-scope markup for GROUPB records.

You might require the data validation process to exclude asterisk and at-sign characters in all of the data content for both GROUPA and GROUPB records, except when those characters are used as delimiters.

If so, use the Exclude Character List property to specify the asterisk and at-sign literal values at the FILE group level. When the validation process evaluates the data, it throws an exception if there is an asterisk (*) or an at-sign (@) character in the data content within the FILE group. The asterisk and at-sign characters are still valid if they are used as group delimiters; they are invalid if they are used in data content.

Performance tip: The Exclude Character List property causes the map validation process to use more resources as it searches for each of the exclude group characters in every data element under the group on which it is defined.

Open the Exclude Character List window by clicking the Value field on the Exclude Character List property, and then clicking the button that appears at the end of the field. Specify the characters in the list as literal characters or syntax items. You can use the Add Literal, Add Syntax Item, Edit, Remove, and Remove All functions to add literal characters and syntax items to the list, edit them, and remove them from the list.

- [Adding literal](#)
- [Adding syntax type](#)
- [Escaping an excluded character in the data content](#)

Select Use release character when you configure the exclude character list to enable the release character to escape excluded characters. When enabled, a release character that precedes an excluded character in data content escapes the excluded character, and the data content passes validation. Likewise, Transformation Extender precedes an excluded character with the release character when building the output stream.

Adding literal

About this task

Use this function to add literal exclude characters to the exclude character list.

Procedure

To add literal exclude characters to the exclude character list:

1. Open the Exclude Character List window by clicking the Value field on the Exclude Character List property, and then clicking the button that appears at the end of the field.
2. In the Exclude Characters List window, click Add literal.
The Add literal window opens.
3. Supply the literal values in the following ways:
 - Type simple text directly in the Value field.
This simple text can be any text or any of the IBM Integration Platform symbols from the list of symbols.
 - Insert IBM Integration Platform symbols that you select from the list of symbols. After you select a symbol, click Insert.
Design Server inserts the literal you selected from exclude characters list into the Value field.
4. Continue to type text and insert IBM Integration Platform symbols in the Value field, as required.
Be sure to place the cursor where you need to type or have Design Server insert the symbol. You can add, insert, and replace new characters.
5. Click OK.
The Add literal window closes and the Exclude Characters List window is redisplayed.
6. Click OK.
The Exclude Characters List window closes and the Properties view is redisplayed.

Results

You can see the Literal property that you added, along with the literal value or values that you supplied, in a new row under the Exclude Character List property. Every time you use the Add Literal function, the added Literal property appears in a new row in the Exclude Character List property on the group. You can edit a Literal property in the list by using the Add Literal, Edit, and Remove functions in the Exclude Characters List window.

Adding syntax type

About this task

Use this function to add syntax type exclude characters to the exclude character list.

Procedure

To add syntax type exclude characters to the exclude character list:

1. Open the Exclude Character List window by clicking the Value field on the Exclude Character List property, and then clicking the button that appears at the end of the field.
2. In the Exclude Characters List window, click Add syntax type.
The Add syntax type window opens.
3. Select syntax type item.
4. Click OK.
The Add syntax type window closes and the Exclude Characters List window is redisplayed.
5. Click OK.
The Exclude Characters List window closes and the Properties view is redisplayed.

Results

You can see the Syntax Item property that you added, along with the syntax item value or values that you supplied, in a new row under the Exclude Character List property. Every time you use the Add syntax type function, the added Syntax Item property appears in a new row in the Exclude Character List property on the group. You can edit a Syntax Item property in the list by using the Add syntax type, Edit, and Remove functions in the Exclude Characters List window.

Escaping an excluded character in the data content

Select Use release character when you configure the exclude character list to enable the release character to escape excluded characters. When enabled, a release character that precedes an excluded character in data content escapes the excluded character, and the data content passes validation. Likewise, Transformation Extender precedes an excluded character with the release character when building the output stream.

XML properties in the type tree

When you open a type tree in the Type Designer after you imported it from a DTD or XML Schema, the XML-specific properties are displayed as read-only fields.

For each type in the resulting type tree, the Intent property is either General (indicating non-XML) or XML. All category types that are created during the import process are considered non-XML properties. All group and item types that are created during the import process are considered XML properties.

Any types that you manually add to the XML type tree are considered non-XML and have General intent. In such a case where there are both XML and non-XML types present (such as EDI data), the appropriate method of validation is determined automatically.

See the Type Tree Maker documentation for information about creating type trees by importing XML Schemas and DTDs.

See ["Utilities for XML"](#) for information about tools that can assist you with upgrading your XML type trees and maps to this version of IBM Transformation Extender.

Support for XML constructs

IBM Transformation Extender validation supports the following XML constructs.

Character Data

During validation, character data is mapped by the XML parser to IBM Transformation Extender types. This data includes both parsed character data (PCDATA) and unparsed character data (CDATA).

Comments and Processor Instructions

XML comments and processing instructions (PI) are mapped to floating components in type trees.

Namespaces

The XML Schema importer supports the specification of arbitrary prefixes for namespaces declared in the input grammar.

XSDL Hints

The xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes are collectively known as XML Schema Definition Language (XSDL) hints. These attributes specify the location of the XML Schema(s) that the XML parser uses for validation.

An XML Schema allows either or both of these attributes to display within any element tag. But the XML parser respects the location values only when the XSDL hint is specified in the root element of the schema.

The Doc group type of type trees that are created with the XML Schema or XML DTD importer contains the location of the Xerces DTD or Xerces XML Schema that is used for Xerces XML validation. The Intent->Validate As->Location property can be modified. However, use the Schema->Type->Metadata card setting in the map to change the location of the DTD or Schema if needed.

Empty Elements

Only one set of initiators and terminators for the Empty element is required for validation.

Nillable Elements

A nillable element can have one of three states: absent, present with content, or present with nil content. Both the DTD and XML Schema allow the definition of optional elements in the instance document. Additionally, the XML Schema allows nillable elements where the content can be empty when it contains an xsi:nil attribute with a value of "true", despite the fact the element's content is mandatory.

The XML Schema Importer can create the content of a nillable element within a group with a range of (0:1), which makes the element content optional.

Mixed Content

When parsing elements with a mixed content model (containing both character data and child elements), the DTD and XML Schema importers generate text items within the mixed content (instead of character sequences).

Regular Expressions

An XML Schema allows the restriction of the values of simple types that are based on regular expressions or pattern facets. During XML validation, the parser enforces the pattern facet. The XML Schema Importer fills the appropriate type properties with pattern facets encountered in the input schema, which are viewable in the Type Designer.

XML schema datatypes

This section describes the type tree constructs that correspond to XML Schema datatypes.

The following table lists some common XML Schema datatypes with their corresponding type property values in the Type Designer.

For detailed information about XML attributes and elements as type properties in the type tree, refer to the Type Tree Importer documentation.

XML Schema Datatype	Type Property	Value
simpleType	Intent > Validate As	XML_SIMPLETYPE
complexType	Intent > Validate As	XML_COMPLEXTYPE
element	Intent > Validate As	XML_ELEMENT
attribute	Intent > Validate As	XML_ATTRIBUTE
group	Intent > Validate As	XML_GROUP

- [Simple types](#)
- [Complex types](#)
- [Elements](#)
- [Attributes](#)
- [Groups and substitution groups](#)

Simple types

Elements that have assigned simple types have character data content but not child elements or attributes.

Simple type elements are represented in the Type Designer type properties with the value XML_SIMPLETYPE.

Complex types

Elements that have assigned complex types can have both child elements and attributes. The order and structure of the child elements of a complex type are known as its content model. Content models are defined using a combination of model groups, element declarations or references, and wild cards. There are three kinds of model groups: **all**, **choice** and **sequence**.

Complex type elements, including the complex types using compositor elements, are represented in the Type Designer type properties with the value XML_COMPLEXTYPE.

Elements

Element declarations are either local or global. Local elements are represented in the Type Designer type properties with the value: XML_ELEMENT.

When the schema defines several global elements, the generated type tree includes a Global choice group that contains all of the global elements. A Global choice group is represented in the Type Designer type properties with the value XML_BODY.

Attributes

Attributes are another building block of XML. The import process uses attribute declarations to name attributes and associate them to particular simple types. Attribute declarations can be either local or global.

Attributes, including both local and global, are represented in the Type Designer type properties with the value XML_ATTRIBUTE.

Groups and substitution groups

One way an XML Schema allows the creation of reusable content is by using named model groups. These global groups can be referenced throughout a schema.

Substitution groups are a flexible way to designate element declarations as substitutes for other element declarations in a content model. New element declarations can easily be designated as substitutes from other schema documents or namespaces without changing the original content model.

Groups and substitution groups are represented in the Type Designer type properties with the value XML_GROUP.

Identity constraints

The XML parser in IBM Transformation Extender enforces declared identity constraints. The XML Schema Importer sets these properties based on the XML Schema. In general, the identity constraint definition serves in one of the roles listed below:

Identity Constraint	Description
Unique	

- Enforces that a value (or combination of values) is unique within a given scope. For example, all product numbers must be unique within a catalogue.
- Key**
- Enforces uniqueness and requires that all values be present. For example, every product must have a number and it must be unique within the catalogue.
- Key References**
- Enforces that a value (or combination of values) corresponds to a value represented by a key or uniqueness constraint. For example, for every product number that is displayed as an item in a purchase order there must be a corresponding product number in the product description section.
-

Namespaces

The XML Schema Importer supports namespace and prefix properties for all elements and attributes. The importer assigns the values of these properties based on the input grammar. For each namespace in the input grammar, the importer allows you to specify the namespace prefix to be used for output documents.

During the import process, a **Location** value is specified in the type tree without a fully qualified path. In this case, a map execution process would, by default, look for the XML Schema at this location. However, if you need to change this path, you can do so.

For example, if you refer to the proper location of the schema in the XML document, then you can manually remove the path location from the type properties. When the map execution process does not find a **Location** value specified in the type tree, the process then looks to the "[XSDL Hints](#)" specified in the XML document. When XSDL hints are not present, validation fails.

The value specified in the type tree takes precedence over the XML document.

Element type declarations

The XML DTD and XML Schema importers can generate a simple type tree when encountering character content within mixed data. During the import process, when character data (CDATA/PCDATA) is encountered, the importer incorporates it into existing text items within the type tree.

Element and attribute wildcards

DTDs and XML Schemas allow the specification of wildcard elements within a grammar. The IBM Transformation Extender XML Schema and DTD importers recognize element wildcards, build the appropriate types, and set the appropriate properties for those types to represent element wildcards in the type tree.

During the import process, when a wildcard element resolves to an element that is not defined in the imported grammar, it is represented by a text item.

The value of these text items is the text string from the input buffer that runs from the start of the open tag to the end of the close tag for that element.

XML Schemas allow the specification of an attribute wildcard that matches any number of undeclared attributes within the element tag. The XML Schema Importer recognizes the attribute wildcard and creates a sequence of name and value text item pairs within the attribute list of the enclosing element. The XML validation library fills this sequence with the names and values of attributes that do not match any declared attributes in the attribute list.

Item restrictions

Item restrictions are an optional feature you can use to specify valid or invalid data objects for an item type. Item restrictions are grouped into three categories: **Value**, **Character**, and **Range**.

Restrictions of an item type are the valid or invalid values for that item. "Include" restrictions are all of the valid values for an item. "Exclude" restrictions specify all of the invalid values. For example, a unit of measure field in the data must be one of a set of values: CN, BX, PK, BR. These values should be defined as "include" restrictions of the item **UnitOfMeasure**.

Defining restrictions for an item restricts the valid data for that item. Partial lists of the valid values are not possible. For example, it is not possible to define the values for a certain item to be {A, B, C, "some other possible values"}.

While you can define restrictions for any item, most items will not have restrictions. For example, you would not want to restrict the valid values of a name field because you would probably want to accept any name as valid data for that field. However, you could assign restrictions to it if needed.

Defining item restrictions

About this task

By default, restrictions are case-sensitive. To ignore case when defining the properties of the item, choose **Yes** for the **Ignore Case** property.

In the following instructions, it is assumed that the **Enter** key is the "commit changes" key. (See [Customizing the Type Designer environment](#).)

To define restrictions:

Procedure

1. Double-click the item for which you want to define restrictions.
2. Type each restriction value in the appropriate cell and press **Enter**.
The column headings of the restriction cells will differ based on the item properties set.
3. (Optional) In the corresponding cell, enter a description for the restriction value. A description is especially helpful when the value of the restriction is not obvious.
You can add new rows for restrictions by pressing the **Insert** key or by right-clicking and choosing Insert from the context menu. The new row inserts *after* the selected row.

Related tasks

Restrictions settings

Using the Restrictions property, you can create a "restriction list" to limit an item to a particular value or set of values. Depending on the Item Subclass, you can set value, character, or range restrictions.

- [Value restrictions](#)
- [Character restrictions](#)
- [Range restrictions](#)
- [Inserting symbols](#)

Value restrictions

In the value restrictions view for an item type, there is either an Include or Exclude column, depending on the Restrictions Rule setting.

Include column

Use the Include column to specify the restrictions to use in determining if input data is valid or invalid for the item. One-to-many values are allowed. The order in which restrictions appear in the list is not relevant.

"Include" values are considered valid. An input item is considered invalid if a character other than those specified in the **Include** column appears in the data.

Exclude column

Use the Exclude column to specify the text character values to be excluded.

"Exclude" values are considered invalid. This option provides a means to specify a default set of restrictions.

To add value restrictions to an item:

1. Go to the Item Subclass Restrictions property.
2. Choose Value from the drop-down list.
3. The restriction list is case-sensitive by default. If you do not want case-sensitivity, set the Ignore case subproperty to Yes to ignore case.
4. Set the Rule subproperty to Include or Exclude the values that you will provide.
5. Double-click on the type to open the value restrictions view.
6. Enter the value restrictions Include or Exclude column.
7. (Optional) Enter corresponding descriptions in the Description column.
8. Analyze type tree.
9. Save changes.

Related tasks

- [Inserting symbols](#)

Character restrictions

In the character restrictions view for an item type, there is either an Include or Exclude column, depending on the Restrictions Rule setting.

Include character restrictions

Include First column

Use the Include First column to define the first character of a character list.

Include After column

Use the Include After column to define the character list of the characters to follow the first character (defined in the Include First column).

For example, the first character could be a letter and all characters that follow could be either letters or digits.

Exclude character restrictions

Exclude column

Use the Exclude column to specify the substrings in the input data that must be excluded and replaced with the associated reference string.

Reference String column

Use the Reference String column to define the characters that are to replace the excluded character substrings.

On output, a character text item is built by using the corresponding reference string when the content contains any of the Exclude character substrings listed. For example, you can define XML item content that excludes markup delimiters by using the corresponding reference strings (because XML character text items cannot contain the markup delimiters <, >, or & in the raw form).

To make it easier to specify a common range of characters, you can use reserved words and symbols. See the [Design Studio Introduction documentation](#) for a list of reserved words and symbols.

- [To add character restrictions to an item](#)
-

To add character restrictions to an item

Procedure

1. Go to the Item Subclass Restrictions property.
2. Choose Character from the drop-down list.
3. The restriction list is case-sensitive by default. If you do not want case-sensitivity, set the Ignore case subproperty to Yes to ignore case.
4. Set the Rule subproperty to Include or Exclude the values that you will provide.
5. Double-click on the type to open the character restrictions view.
6. Enter the character restrictions in the Include First or Exclude column.
7. Enter corresponding values in the Include After or Reference String column.
8. Analyze type tree.
9. Save changes.

Range restrictions

In the range restrictions view for an item type, there is either an Include or Exclude column, depending on the Restrictions Rule setting.

Include range restrictions

Include Minimum column

(Required) Defines the minimum value of the range.

Include Maximum column

(Required) Defines the maximum value of the range.

Description column

(Optional) Enter a brief description of the range restrictions.

Exclude range restrictions

Exclude Minimum

Defines the minimum value of the range to be excluded or considered invalid.

Exclude Maximum

Defines the maximum value of the range to be excluded or considered invalid.

Description column

(Optional) Enter a brief description of the range restrictions.

Note: Unbound restrictions are not supported.

- [Value not in range](#)
 - [To add range restrictions to an item](#)
-

Value not in range

About this task

The minimum value and the maximum values can be specified as not included in the range. For example, when a number in an Include Minimum field displayed the **Value NOT In Range** icon, it indicates that the number is not included as the minimum value. The range will therefore extend from any value that is greater than that number to the maximum value specified. Similarly, if the **Include Maximum** value is designated as "not in range", the valid range would extend up to any value this is less than the maximum value.

To specify a value as "not in range":

Procedure

1. Select the field (cell) that contains the value to be designated as "not in range".

2. Right click on the value and choose the Value NOT In Range menu item.

Inserting symbols

About this task

Symbols are used to indicate nonprintable characters. You can insert a symbol by typing it or by using the Symbols dialog.

For example, to define a carriage return/line feed as an item restriction, from the item restriction view area, right-click and select Insert Symbols from the context menu. From the list of symbols, double-click CR and double-click LF and select OK. The carriage return/line feed symbols are displayed in angle brackets in the item restriction view area: <CR><LF>

To insert a symbol:

Procedure

1. From the context menu, select Insert Symbols.
The Symbols dialog is displayed.
2. Select a symbol and click Insert or just double-click the symbol.
The symbol appears in the Value field.
3. Click OK.

Related reference

- [Value restrictions](#)
-

Ignoring restrictions

There might be instances when you do not require the data for an item to match any of its restrictions. Suppose you defined restrictions for your data, but you want to run a test on some test data, and you do not want to use the restrictions for this time only. You can ignore the restrictions for a given execution of a map.

In another example, you have a list of valid part numbers that can appear in any data circulated within your company. Suppose you receive data from some other company in the same format as your internal data. The other company may be using different part numbers, so you do not want to make their data conform to the restrictions. When you map the other company's data, you could ignore the restrictions.

For instructions on ignoring restrictions during map execution, see Map Designer and Command Server documentation.

Components

A component represents a data object that is part of another data object.

- [Components are required for group types](#)
 - [Group views](#)
-

- [Defining components](#)
 - [Required and optional data](#)
 - [Defining component rules](#)
 - [Component attributes](#)
-

Components are required for group types

Categories and groups can have components. Components of group and category types display in the group and category views. Item types do not have components.

Group types represent actual data objects, so groups must have components. The one exception is a partitioned group which is explained in "[Partitioning](#)".

By contrast, a category is used for organizing types and for type property inheritance reasons. Categories do not define actual data objects in detail. A category does not need components.

Each group must have at least one component, unless it is partitioned.

IBM Transformation Extender supports large metadata. It supports more than 65,536 types and 65,536 components in a single type tree. To reduce the number of types that maps that use large type trees must process, trim these type trees so that they contain only the required types.

- [Components must be in the same type tree](#)
- [Importance of component order](#)
- [Component range](#)

Related information

- [Type inheritance](#)
-

Components must be in the same type tree

A component must be a type in the same type tree as the type that contains the component.

You cannot define the components of a type by opening up a different type tree and dragging components from that tree. You can, however, copy types from one type tree to another.

Related information

- [Managing types](#)
-

Importance of component order

In the group view, components are listed from top to bottom in the order they appear in the data stream. The component in the first cell appears first in the data stream. The component in the second cell appears next, and so forth.

Component range

A component range can be specified for any component. A component range defines the number of consecutive occurrences of that component. The range (s) represents some or any number greater than one.

When a component is selected, the component name is displayed in the rule bar. Click in the rule bar after the component name to type the component range.

The range is displayed in parentheses immediately after the component name. The range is two numbers separated by a colon. The first number indicates the minimum number of consecutive occurrences of that component. The second number indicates the maximum number of consecutive occurrences of that component. The syntax of the component name and range is:

Component (MIN:MAX)

To enter a range after a component name, type in the rule bar or use the **Set Range** command.

The maximum component range is 2147483647.

Whenever a component has a range, each occurrence of that component may be referred to as a "member" of a series. The words "occurrence" and "member" are used interchangeably in the documentation.

- [Indefinite number](#)
- [Single occurrence](#)

Related tasks

- [Specifying a component range](#)

Indefinite number

When there is no maximum number of occurrences of a component (the maximum is indefinite) use the letter **s** to stand for "Some - you do not know how many". Therefore, a file that contains at least one record and has no maximum number of records has this component:

Record(1:s)

If the range minimum is zero, omit the **0** and only enter **s**. If a file has a minimum of zero records and no maximum number of records, it would have this as its component:

Record(s)

Remember that when you see **(s)**, the minimum of zero is implied. Therefore,

Record(0:s) is the same as Record(s)

If you enter any number alone in the parentheses, the range changes to a minimum of 0 and a maximum of that number. For example, if you enter **(5)** for a range and save and close the group view, the next time you open it, you see the range displays:

(0:5)

Single occurrence

If there is a minimum and a maximum of one consecutive occurrence of a component, its range is **(1:1)**. This is the default. If there is no range after a component name, the range **(1:1)** is implied. When you drag a type to make it a component, it is automatically created with the default component range of **(1:1)**.

Group views

When you select a group in the type tree editor, the components are listed in the Composition view.

When you double-click a group in the type tree editor, the group view opens and you can see the components of the group here as well. The contents of a selected cell are displayed in the rule bar of the group view.

- [Viewing nested components](#)

Viewing nested components

You can view nested components from the Composition view or from the group view.

As an example, open `install_dir\examples\general\deliver\deliver.mtt`. To view the components in the Composition view, select the **Collection** group type. **Record(s)** appears in the Composition view. Expand **Record(s)** to view the nested components. When you double-click the **Collection** group type, the group view opens. In the Component column, expand **Record(s)** to view the nested components.

You cannot add component rules to nested components or partitions.

Defining components

About this task

Most groups need at least one component. Categories do not have components, however, you can define components for a category for inheritance purposes.

To determine the components of a group, ask the question:

Group type _____ consists of what?

For example, "The file consists of what?" The answer might be "records". So, **Record(s)** is a component of that group or category type.

Suppose you have a data file containing order records for an office supply store. You need to define the components of the type **File**.

To define components:

Procedure

1. In the type tree, double-click the group or category type whose components you want to define.
The group or category view opens.
2. Drag each type from the type tree into the component column.
The type name is displayed in the Component column.
3. Enter component ranges where necessary.
4. Drag each component from the type tree into the group view.
5. Enter component ranges where necessary. A component range indicates the number of occurrences. The number of records in the file is indefinite, so the range is **(s)**, which represents "some." When a component is highlighted, it appears in the component rule bar.

For example, in the component rule bar, place the cursor after **Record**, type (s), and press **Enter**.
6. Close the view and click Yes if prompted to save changes.

- [Complete type name](#)

 - [Variable component names](#)
 - [Opening a component view](#)
-

Complete type name

The complete name of a group is displayed in the title bar of its window. A type's complete name is similar to a path name, beginning at the type and including all types in the path up to the root. Spaces appear between types in a complete type name.

You can have duplicate type names as long as they are not on the same level. Each type has a unique complete name, so there is no doubt as to which particular type is being referenced.

Relative type names

A component name is similar to a relative path name. Component names exclude types that the defined type and component type have in common in their complete names.

The relative type name excludes the names that appear in the complete names of both the type and the component type. For example, because **ROOT** is included in the complete type name of both **Row ROOT** and **Product Column ROOT**, it is excluded from the relative type name **Product Column**.

If more than one type in a type tree has the same relative type name as another in a group, then the full path of the type is exported instead of the relative type name. No two types that have different full type names but identical relative type names can be added to a component list.

- [Moving types with the same relative type name](#)
-

Moving types with the same relative type name

In a type tree, there could be two types with the same name that exist in different places within the tree. The relative type names could both evaluate to be the same, with respect to the component.

For example, the relative type **Group Category ROOT** might have a type named "Item" in both **ROOT** and **Category ROOT**. Both evaluate to "**Item**" with respect to the **Group** component. In this scenario, you can drag only one component named **Item** into the component list. An attempt to add a second component with the same name will be blocked.

Related concepts

- [Ambiguous type names](#)
-

Ambiguous type names

A component name can refer to more than one type. In this situation, you must change type names so that the component name is no longer ambiguous. The Type Designer does not allow components with the same relative type name to be added to component lists.

If you delete a type that is used as a component of another type, and then perform an "Undo", thus adding the type back, and the component name is ambiguous; the component name remains unresolved in the component list. In this scenario, the "Undo" operation does not result in a complete reversal of the action.

- [Manual entry of types with same relative type names](#)
-

Related concepts

- [Moving types with the same relative type name](#)
-

Manual entry of types with same relative type names

Although the drag-and-drop method is the recommended method of entering component names into the component list, it is possible to type the component list manually into the text entry area of the group view.

When you manually enter a type name in the component list that has the same relative type name as an existing component, a special icon appears. This ambiguous type name icon precedes the component name within the component column.

An *ambiguous type name* indicates that there is another type with the same relative type name in the type tree. There are two ways of eliminating the ambiguity:

- Drag one of the types from the type tree onto the type name in the component list. When you do this, the ambiguous type icon will change to a solid color to indicate that the ambiguous type name is resolved. If you attempt to drag the second type name from the type tree into the component list, you will be blocked.
- Type a path name in the group view. You must type either the full path name of the type, or if you type a partial path name it must contain enough of the path name to make the type unique.

For example, if you enter **Item Category ROOT**, or **Item Category**, the type name **Item** will be unique and the ambiguity will be removed. When you enter this unique path name, the type will be successfully entered into the component list. The ambiguity is thereby resolved.

Always drag components

Because the component rule bar allows you to add a component range, the entire component name is editable. You could enter a component name by typing it. However, this is not advisable. Always drag components into component lists. This is recommended for the following reasons:

- To avoid typographical errors
- To enter type names in the exact case in which they were created. (Type names are case-sensitive.)
- To avoid incorrectly entering a relative type name

When you drag types into a component list, the correct relative type name is automatically entered.

Viewing the component number

About this task

You can view the number of each component in a group view by changing your user preferences.

To view component numbers:

Procedure

1. From the Window menu, select Preferences > Transformation Extender > Type Tree > Group Window.
2. Enable the **Show component number** check box.
3. Click Apply and click OK.

Specifying minimum and maximum consecutive occurrences in the component list

The following table contains examples of how to specify in the component list the minimum and maximum consecutive occurrences for specific data objects:

Data Object	Min	Max	How to Specify
DateField	1	5	DateField (1:5)
DetailRecord	1	100	DetailRecord (1:100)
AddressField	2	3	AddressField (2:3)

Fixed and variable ranges

Sometimes the range of a component is described as fixed or variable. As an example, a fixed range has the same minimum and maximum, (5:5). A variable range has a different minimum and maximum, (1:10) or (s) for example.

Specifying a component range

About this task

You can specify a component range by using the Set Range functionality.

To enter a component range:

Procedure

1. Right-click on a component and select Set Range from the context menu.

2. In the Set Range dialog, enter the minimum and maximum number of occurrences.
3. Click OK.

Results

You can select multiple components and use Set Range to apply the same range to each component.

A range of (1:s) means that there will always be at least 1 occurrence, but could occur an infinite number of times. A range of (0:s) means that an occurrence is optional, but could occur an infinite number of times.

What to do next

Tip: You can view a shortcut menu for the component by clicking the down arrow located on the view toolbar: 

Related concepts

- [Component range](#)
-

Viewing the range column

About this task

To view component ranges from the Group view:

Procedure

1. From the Window menu, select Preferences > Transformation Extender > Type Tree > Group Window.
 2. Enable the **Show range column** check box.
 3. Select Apply; select OK.
-

Types that can be components

There are certain guidelines to follow when defining types. It is not necessary to memorize these guidelines because the Type Designer interface assists you when defining components. The Type Designer does not allow the dragging of invalid components.

- [Guidelines for defining components](#)
-

Guidelines for defining components

The guidelines below are numbered to allow references to each other. The numbering does not suggest a priority or a sequence to be followed in observing the guidelines.

1. Categories cannot have components.
A category is only used for organizing your type tree and for setting common properties.
 2. A partitioned group cannot have components.
A partitioned group always represents a choice among the subtypes of that group. You never map a partitioned group without its subtree, so it does not need components.

Note: A *subtree* is a branch of a type tree that includes a type and all of the subtypes that stem underneath it.
 3. If a group is not partitioned, it must have at least one component.
Nonpartitioned groups are sequences of data objects rather than choices. A sequence must contain at least one component.
 4. A type and one of its subtypes cannot be in the same component list.
 5. If a type has components, a subtype can inherit any of those components or any type in the subtree of one of those components.
 6. If a type has no components, a subtype can inherit any type that could be in that type's component list.
 7. A type that has an initiator and a terminator can have itself or one of its ancestors as a component.
 8. A type cannot have one of its subtypes as a component.
-

Variable component names

A component can refer to more than one type. To refer to all possible types whose names could appear at a certain place in the component name, use the word ANY.

The word ANY is like a wild card. It represents any type whose name could appear in that place.

The use of ANY is restricted to **Categories** and partitioned groups. For more information about using ANY in a partitioned group, see ["Partitioning"](#). For a list of reserved words and symbols, see the Design Studio Introduction documentation.

Opening a component view

About this task

Procedure

Double-click the component.

For example, if the Order window is open and it has the component **Row (s)**, when you double-click the component **Row (s)**, it opens the window of **Row**.

Required and optional data

Sometimes, a certain data object is optional; it does not have to be present in the data. For example, in purchase order data, there might be a billing address and a shipping address. If the company wants the items shipped to the billing address, the shipping address would not appear in the data. The shipping address would be optional; it might not appear in the data.

Another example is a middle name field. Some people do not have a middle name, so the middle name field might be optional.

The Type Designer needs to know what data is optional. This is evident from the component range. The range minimum tells how many occurrences of that object must be present in the data. These are the required occurrences. Optional occurrences are the ones that are not required.

For example, for the following component, the range minimum is zero. No occurrences must be present. It is optional data:

DateField (0:1)

Suppose the component looks like this:

DateField (1:5)

The range is between one and five occurrences. This means that one occurrence of **DateField** is required and the remaining four occurrences are optional.

The following table lists examples of components and explanations of their status.

Component	Status	Reason
LineItem (1:s)	1 occurrence required	Range minimum is 1
Note Field (5:5)	5 occurrences required	Range minimum is 5
RecordID	1 occurrence required	Range minimum is 1
ShipTo (0:1)	0 occurrences required (Optional)	Range minimum is 0
OrderRecord (s)	0 occurrences required (Optional)	Range minimum is 0

- [Significance of required data](#)

Significance of required data

If you define an occurrence of a component as required, you are saying that, for the data containing the component to be *valid*, this component must exist. If it does not exist, the data is *invalid*.

For example, if you define **Record** as having the component **Field (3:3)**, you are saying that there must be three **Fields** in the **Record**. If there are not three **Fields**, then either it is a **Record** in error or it is not a **Record**.

There are other factors, besides the existence of all required components that make data valid. The existence of required components is necessary, but not sufficient, for data to be valid.

Defining component rules

A component rule is an expression about one or more components. It indicates what must be true for that component to be valid. For given data, it evaluates to either "true" or "false". A component rule is similar to a test. If the data does not pass the test, it is invalid.

Component rules are used for validating data. Some important points about component rules are:

- Only components of a group can have component rules. Components of a category cannot have component rules.
- A component rule cannot be longer than 32K.
- If a component is optional and does not appear in the data, the component rule is evaluated after determining that the data is missing. In a component rule, you can specify relationships that depend on existence or nonexistence of data.

Sometimes components have relationships among each other. For example, an address field in purchase order data is preceded by a qualifier field which tells whether the address is a bill-to or a ship-to address. If the value of the qualifier field is **BT**, the address field following it is a bill-to address. If the value is **ST**, the following address is a ship-to address.

The qualifier and address fields are dependent on each other. They only make sense as a pair. If one of these fields is optional and is missing, the other field is not meaningful. If the qualifier is missing, you do not know whether the address is a bill-to or a ship-to. If the address is missing, the qualifier does not qualify anything!

You might want to define this kind of relationship and other relationships among data objects. To do this, use a component rule. For example, use a rule on the address field component to indicate that the qualifier must be present if the address is present.

The following instructions, assume that the `Enter` key has been assigned to commit changes.

To enter a component rule:

1. In the group view, select the rule cell of the component.
2. Enter the component rule in the edit area and press `Enter`.

- [Syntax errors](#)
- [Managing components](#)

Related tasks

- [Using search and replace](#)

Examples of component rules

A component rule can limit the acceptable values of a component as shown in the following example:

```
Quantity < 10000
Interest Rate > .13 & Interest Rate < .20
WHEN (PurposeCode != "PF", ShipValue = 200|ShipCode < 0)
```

The following example illustrates how a component rule can make the presence of one component mandatory, if another component is present:

```
WHEN (PRESENT (Address Field), PRESENT (Qualifier Field))
WHEN (PRESENT (PhoneNumber), PRESENT (AreaCode), ABSENT (AreaCode))
```

A component rule can compare a component to the result of an arithmetic operation as shown in the following example:

```
SUM (((QuantityOrdered:Item Record:Detail) = TotalQuantity:Summary Record:Detail
Account Balance = Credits - Debits
Extension = Quantity*Price
#Items Field = COUNT (Item Record IN Invoice))
```

Component rule syntax

A component rule is a complete expression that evaluates to either "true" or "false". It can contain functions (for example, PRESENT, COUNT, and SUM). It can also contain arithmetic operators (such as `- + * /`).

A component rule is a statement, so it does not start with an equal sign.

For more information about the syntax of expressions, see the Functions and Expressions documentation.

Entering object names in component rules

About this task

A component rule can refer to a component within a component. The syntax for a component is the component name, followed by a colon (:), followed by the object of which the component is a part. Whenever you see the colon (:) in an expression, it can be interpreted as "component of" or simply "of".

For example, the following expression means "The item number of the order record of the order":

```
Item#:OrderRecord:Order
```

All of the objects that can be used in component rules are shown in the group view. You can enter an object name into a component rule by pressing `Alt` and dragging the object into the edit area. The complete object name is automatically entered.

A component rule can refer to:

- The component it applies to and any nested components.
- Any component above the given component in the component list, and its nested components.
You can enter an object name in a component rule by typing it; however, the recommended method is to press `Alt` and drag the component into the edit area.

Shorthand notation

In a component rule, the dollar sign (\$) represents the component itself. When you enter an object name in a rule by pressing Alt and dragging the object, the dollar sign is automatically entered in the rule to represent the given component.

Component rules are context-sensitive

Component rules apply to components, not types. It applies to data in a certain context when the data is a component of a given group.

Suppose you have some order data that contains two kinds of records: a regular order record and a bulk order record. In the bulk order record, the quantity ordered must be greater than 1000. In the regular order record, the quantity can be any number. You could put a rule on the quantity ordered component of a bulk order, but not on the quantity ordered of a regular order.

Special characters in component rules

About this task

To enter the actual value of a special character in a component rule, you must enter the Hex value for one of the characters. For example, to enter the text value <WSP>, enter the Hex value for the less than sign <<3C>>, and then the rest:

```
<<3C>>WSP>
```

See the Design Studio Introduction documentation for a list of non-printable Hex and decimal values.

Inserting functions into component rules

About this task

You can use most of the functions provided with the product in component rules.

Component rules shown in the [examples](#) section use the functions COUNT, PRESENT, SUM, and WHEN. The function WHEN is similar to the function IF. However, WHEN evaluates to "true" or "false" and IF evaluates to a data object. WHEN is most often used in a component rule.

To insert a function into a component rule:

Procedure

1. In the type tree editor, double-click the type.
The Component view opens. The Component view consists of an edit area and two columns: Component and Rule.
2. In the Component column, select the component to which you want to add a function.
3. Press Ctrl+Space bar to open the list of functions.
4. From the list of functions, double-click on the function you want to insert.

Formatting a component rule

About this task

Depending on your user preference settings, you can add a new line to a component rule by pressing Ctrl and Enter (when Commit changes with is set to Enter), or by pressing Tab (when Commit changes with is set to Tab).

Comments in component rules

About this task

You can add comments to component rules. Comments do not affect how component rules are evaluated.

A comment begins with the characters /* and ends with the characters */. A comment can appear anywhere in a rule as long as it does not separate object names.

For example, the following component rule has a comment:

```
SIZE (Phone# Field:$) >=7  
/* Phone numbers must include area code */
```

Syntax errors

If you type a component rule that is syntactically incorrect and press **Enter**, the part of the rule in error is highlighted and you cannot "commit" it until the error has been corrected.

Managing components

About this task

You can easily move components around, copy them, or delete them. For information on general drag-and-drop procedures, see "[Managing types](#)".

When you move, copy, or delete a component, if it has a range and/or a component rule, the range and rule are moved, copied, or deleted with the component.

Component attributes

Three attributes can be assigned to a component in a component list:

- Identifier 
- Restart 
- Sized 

When an attribute is applied to a component, a corresponding icon is displayed with a component name in the component list.

To assign an attribute to a component:

1. In the type tree editor, double-click a component. The component view opens.
2. In the component list of the component view, right-click on the component and choose the attribute from the context menu.
To remove the attribute, repeat the procedure.

- [Identifier attribute](#)
- [Restart attribute](#)
- [Sized attribute](#)

Identifier attribute

The identifier attribute can be used on a component of a group. The identifier indicates the components that can be used to identify the type to which a data object belongs. All the components, from the first, up to and including the component with the identifier attribute, are used for type identification.

When this data is validated, it knows that, when it reaches the identifier, it has found a specific group. That group, therefore, is known to exist, even if part of the group following the identifier is missing. The Map Designer documentation discusses how data validation occurs.

The identifier attribute is also useful when identifying an object of a partitioned group. For information about using an identifier with partitioned data, see "[Partitioning](#)".

In a component list, there can be only one identifier attribute.

Restart attribute

About this task

To continue processing your input data when a data object of a component is invalid, assign the restart attribute to that component.

Do not put the restart attribute on a required component. There must be a sufficient number of valid instances to cover all required components. If you have a required component that is not valid, the restart attribute does not validate the data.

For additional information about using the **Restart** attribute, see the Map Designer documentation.

Related concepts

- [Using the Restart attribute](#)

Sized attribute

The sized attribute is used on a component in which the value specifies the size (in bytes) of the component immediately following it. The sized attribute can be used on more than one component of a group.

For example, you might have a variable length component with a number immediately preceding it that indicates the length of the component: **10Washington**. The size of the component would be 10.

Some important points about using the sized attribute are:

- The component with the sized attribute must be defined as an unsigned integer.
- If a binary byte stream item does not have a fixed size, the component preceding it must specify its size and the sized attribute must be used on that component.

The size of a component is the number of bytes from the beginning of that component, up to and including the end of the component. If a component has a series range (such as [1:3]), the size includes all of the members in the series of that component. If a delimiter separates each member of that series, the delimiters must be included in the size. Also, if release characters appear in the component, they must be included in the size.

The size does *not* include delimiters that separate one component type from the next.

- [Include self in size](#)

Include self in size

If the value of the component with the sized attribute includes the size of the component, use the **Include Self in Size** option. For example, suppose the component with the sized attribute has a length of seven bytes. The value of the component with the sized attribute would be seven. So, its data would be one byte long, to hold the character seven. If its value includes the length of itself, its value would be $7 + 1 = 8$.

For example, a sized component is 7 bytes.

+ 1 byte (the length of the character 7)

If **Include Self in Size** is selected: 8 bytes

Partitioning

By partitioning, you can define your data to distinguish the difference between data objects based on values in the data or differences in the syntax.

Partitioning is a method of subdividing objects into mutually exclusive subtypes.

A special icon in the type tree identifies a partitioned type. The partitioned type maintains the same class.

To partition a type:

1. Select the type you want to partition. (You can only partition items and groups.)
 2. From the Type menu, choose Properties.
 3. For the **Partitioned** property, choose **Yes**.
- [Determining when to partition](#)
 - [Partitioning types](#)

Related concepts

- [Distinguishable components of an implicit group](#)

Determining when to partition

There are some cases in which you will *need* to partition your data and others in which you will *want* to partition your data. You are *required* to partition for unordered data when a data object at a certain place in the data stream can be any number of types and each type has different definitions. *Choose* to partition for convenience, either to simplify mapping rules or to put additional logic into your data's definition.

- [Required partitioning](#)
- [Partitioning for convenience](#)
- [Benefits of partitioning](#)

Required partitioning

Partitioning is required when components are randomly or partially ordered. The following example represents unordered data:

BGI - 13100,REM,931104,19970424...

AXR - 10930,INV,003X114,19970422...

PVY - 19496,ORD,PO-104-1499,19970425...

BGI - 13100,ORD,PO-182-2587,19970425...

AXR - 10930,INV,003X-114,19970422...

The file would contain three different types of transactions: **Invoice**, **Order**, and **Remittance**. Each transaction has a different definition based on the type of information it represents.

Partitioning for convenience

You might decide to use partitioning in your type tree to build additional logic into the definition of your data. You may also use partitioning to simplify the rules needed in your map.

The following is an example of partitioning to simplify rules. The example compares the differences between rules needed *with* and *without* partitioning. In the rule without partitioning, you would specify a condition for each state abbreviation in each region. This could make your mapping rules long, difficult to read, and difficult to maintain. The mapping rule with partitioning is more concise, self-documenting, and easier to maintain.

Map rule without partitioning:

```
=IF(ShipToCode Field::Input=="NY" |
    ShipToCode Field::Input=="NJ" |
    ShipToCode Field::Input=="PA",
    F_MapEast (Record:Input), NONE)
```

Map rule with partitioning:

```
=F_MapEast (EXTRACT (Record:Input,
PARTITION (ShipToCode Field::Input, East)))
```

Benefits of partitioning

Using the [previous example](#), explore the benefits of partitioning.

- The rule is shorter than the rule without partitioning. The knowledge of which states belong to each region is maintained in the type tree rather than the map rule.
- It is easy to read this map rule and understand the mapping function being performed. For example, if the state belongs to the list of states in the eastern region, execute the **MapEast** functional map.
- The partitioning method is easier to maintain. If a value for **State** is added or moves from one region to another, it can be easily changed in the type tree and automatically reflected in any mapping rules that reference the partitioned object.
- Partitioning using a restriction list used with the **Ignore Case** setting eliminates the need for PROPER, LOWERCASE, or UPPERCASE functions to compare each state with a literal.

Partitioning types

When data objects of different types appear in the same place in the data, the types must be distinguishable. This means that the data needs to be distinguishable by their definitions in the type tree.

When the data object at any given point in the data may belong to any of a number of different types, there must be some way to tell the difference between them. To do this, you create a type and define a mutually exclusive subtype for each data object that may appear in the same place in the data. Once the subtypes are created, the subtypes also need to be distinguishable. Subtypes are distinguishable based on a value in the data or in the syntax of the different types.

Partitioning items

Use one of the following three methods to partition items in type trees:

- Initiators
- Restrictions
- Format

Partitioning an item type using initiators

To partition by initiator, each subtype must have an initiator and the value of the initiator must be unique for each subtype.

Partitioning by initiator is the most efficient method of partitioning.

Related concepts

- [Partitioning a group type using initiators](#)
-

Partitioning an item type using restrictions

If an item has restrictions, you can partition that type, create mutually exclusive subtypes, and divide the restrictions between subtypes. A restriction cannot appear in more than one subtype of that item.

- [Example of using restrictions](#)
-

Example of using restrictions

You have new data that needs to be entered into the Type Designer. Each new record contains the name of the employee and his or her department.

The **Employee List** type tree illustrates components of **Record**.

The following is the new data containing the name of the employee and the department.

Steven Barlow,Doc

Heather Proust,Qa

Mary Whiting,Doc

Genie Elks,Sup

Francine Maxwell,Dev

Mark Brown,Sup

Daryl Schwartz,Acc

Harry O'Brian,Sal

Ellen Randolph,Dev

Paula Keller,Qa

Define the values of **Department** as a character text item.

Define the example data as valid restrictions (enter in the **Include** column) of **Department**:

If the departments are located in different offices, you can divide the data into separate files; one file per office. To do this, map the data from the main office to one file, the data from the development office to one file, and the data from the support office to another file. Then create subtypes of **Department: MainOffice**, **DevelopmentOffice**, and **SupportOffice** and partition **Department**. When you partition **Department** and create subtypes, you are saying that a given department data object belongs to only one of the subtypes based on its value.

The subtypes of **Department** inherit the restrictions of **Department**. Now allocate restrictions among subtypes. To do this, delete the restrictions from the subtype that do not apply to that particular office. For example, the **MainOffice** item has only the departments in that office, **DevelopmentOffice** item has only the departments in that office, and the **SupportOffice** item has only the departments in that office.

Partitioning an item type by format

Subtypes that differ by their format are distinguishable from each other.

Partitioning groups

Use one of the following three methods to partition groups in type trees:

- Initiators
 - Identifiers
 - Component rules
- [Partitioning a group type using initiators](#)
 - [Partitioning a group type using identifiers](#)
 - [Partitioning a group type using component rules](#)
-

Partitioning a group type using initiators

To partition by initiator, each subtype must have an initiator and the value of the initiator must be unique for each subtype.

The method of partitioning by initiators for group types is similar to item types.

Related concepts

- [Partitioning an item type using initiators](#)
-

Partitioning a group type using identifiers

About this task

In a component list, only one component can have the identifier attribute.

The identifier attribute distinguishes the components that can be used to identify the type to which a data object belongs. Typically, use this technique to distinguish group partitions when components following the identifier are different for each partition, or, if you have a multilevel partitioned subtree. In the latter case, using an identifier accelerates data validation.

A partition is valid when each component up to and including the identifier is validated. If the set of components is valid, the partition exists.

If the identifier set of components is not valid, the partition is determined not to exist. Either validation occurs for the next partition at the same level (if there is one) or it is determined that the partitioned group does not exist.

If the partition exists, what occurs next depends on the position of the partition type in the subtree.

- If the partition is partitioned (that is, it has subtypes), the rest of the components are skipped and the process begins to validate subtypes until a subtype is valid, exists and is in error, or does not exist.
- If the partition has no subtypes, the remaining components are validated. If all remaining components are valid, the partition not only exists, but also is valid. If one or more components are found to be in error, the partition exists, but its type is in error. If the partition exists, but its type is in error, the error is propagated back up the partitioned subtree until the group being validated is reached. When a partition is found to exist, the system will not continue to search for partitions.

To specify a component as the identifier:

Procedure

1. From the type tree editor, double-click a component.
The Component view opens.
2. In the Component column, right-click on the component and choose Identifier from the context menu.

Results

The identifier symbol appears in the component column next to the component name.

Partitioning a group type using component rules

Component rules are used to partition data when a value or range of values can be used to distinguish one partition from another.

Type inheritance

Properties, components, and restrictions of a type can be inherited by the types created as subtypes under it. Some properties of a type can also be propagated to already existing subtypes.

When you create a type, it becomes a subtype of whatever type is selected at the time. Everything that defines a type gets passed down: properties (with the exception of the Partitioned property), components, and restrictions. After a type is created, you can then modify any aspect of its definition.

When a group is created within a category, the item properties do not apply, so they are not inherited. When an item is created under a category, the group properties are not inherited.

- [Inheritance of item properties and restrictions](#)
- [Inheritance of category properties and components](#)
- [Propagation of type properties](#)

Creation time is not the only time type properties can be passed from a type to its subtypes. You can use propagation to pass along certain type properties.

Related concepts

- [Components are required for group types](#)
-

Inheritance of item properties and restrictions

Properties and restrictions of items are inherited when a new item is created.

For example, an item named **Department** is defined as a character text item that has a content size minimum of 2 and maximum of 3. Department has a list of "include" restrictions that consists of valid departments: ACC (Accounting), SLS (Sales), and MKT (Marketing).

The type **MainOffice** is created as a subtype of **Department**. **MainOffice** inherits the properties and restrictions of **Department**.

You can delete any restrictions that are not applicable to **MainOffice**.

Inheritance of category properties and components

Categories can be used for organizing types and for inheritance reasons. Generally, you would use categories when you want to put items, groups, and possibly other categories under it as subtypes.

- [Organizing types under a category](#)
- [Using categories for inheritance](#)
- [When not to use categories](#)

Organizing types under a category

If you have two tables defined in one type tree, you could divide the types of the two tables into different categories. A benefit of using a category type is that you can have any class of subtype: groups, items, and other categories.

Using categories for inheritance

The properties of a category include group and item properties. Assign properties to a category that you want types beneath the category to inherit.

Any group created under a category inherits the property of the category. Any item created under a category inherits the category's item properties. A category created under a category inherits both the group and item properties. Each type created under a category inherits the other properties of the category, such as initiator and terminator.

As an example, if most groups in your **LabInfo** data are infix delimited with ~ and most items in your **LabInfo** data are unsigned integers, you can define these as the properties of the category **LabInfo**. Any types you create under **LabInfo** inherit its properties.

You can change the properties of the root type, which is a category. Categories can have components, so you can also use them for inheriting components.

When not to use categories

It is best not to use a category type when the subtypes will specifically be item types or specifically be group types.

For example, you have a type named **Field** for which the only subtypes will be items. If you make **Field** a category type, each time you create a subtype, the new type will also be a category type by default. You will have to change the **Class** property from **Category** to **Item** for each subtype that you create. Instead, make **Field** an item type so that the **Class** property for any subtypes you create will automatically be defined as item types.

Propagation of type properties

Creation time is not the only time type properties can be passed from a type to its subtypes. You can use propagation to pass along certain type properties.

Propagation passes the setting of a particular type property from the given type to all of the types in the subtree as applicable and defined by their context. When you select a type property for propagation that does not apply to a given subtype, it is not propagated.

- [Propagation of type properties common to all types](#)
You can propagate some type properties that are common to all types such as Item Subclass, Description and Type Syntax, to each of its subtypes, without the process checking additional criteria to determine if the type property can be propagated.
- [Propagation of type properties for specific types](#)
You can propagate some other type properties such as Separators and Restrictions, to each of its subtypes for specific types, with the process checking additional criteria to determine if the type property can be propagated.
- [Propagating type properties](#)
These are the instructions for propagating type properties in type trees.

Propagation of type properties common to all types

You can propagate some type properties that are common to all types such as Item Subclass, Description and Type Syntax, to each of its subtypes, without the process checking additional criteria to determine if the type property can be propagated.

The type properties that fall into this category are the properties in the root of the tree, or are children properties that apply to all types to which their parent property is set, and are global in that these properties apply to all items.

The propagation process checks that the settings for some type properties such as the Item Subclass property, the Interpret as property, and if applicable, the Presentation property in a type, match the settings for these same properties in its subtypes, and if they match, the selected property is propagated. But, the propagation process does not check the settings of other properties to determine if the selected property exists in the item, because the selected property in this case, applies to all item types.

Examples of propagating a type property that has no children properties

A given category type that is in the root of the tree has the following type property setting: Description._>An example. The Description type property has no children properties. When you select the Description type property setting of An example to be propagated, the process propagates the Description setting of An example to all types in the tree. The Description property is a type property that is common to all types.

A given category type has the following type property settings: Item Subclass._>Text and for its child property, Interpret as._>Character. When you select the child Interpret as type property to be propagated, the process propagates the Interpret as setting of Character to each subtype of that category that also has the same Text type property setting. The Interpret as property is a type property that is common to all types except syntax types.

Examples of propagating a type property that has children properties

A given category type has the following type property settings: Item Subclass._>Number, and for its children properties, Interpret as._>Binary, and Presentation._>Integer. When you select the parent Item Subclass type property to be propagated, the process propagates the Item Subclass setting of Number, as well as the settings for its children properties, Interpret as setting of Binary, and the Presentation setting of Integer, to each subtype of that category. The Item Subclass property is a type property that is common to all types.

A given category type has the following type property settings: Item Subclass._>Text and for its child property, Interpret as._>Character. When you select the parent Item Subclass type property to be propagated, the process propagates the Item Subclass setting of Text, as well as the setting for its child property, Interpret as setting of Character, to each subtype of that category. The Item Subclass property is a type property that is common to all types.

Related tasks

- [Propagating type properties](#)

Propagation of type properties for specific types

You can propagate some other type properties such as Separators and Restrictions, to each of its subtypes for specific types, with the process checking additional criteria to determine if the type property can be propagated.

The type properties that fall into this category are children properties that do not apply to all types to which their parent property is set, and are specific to a type, in that these properties do not apply to all item types.

The propagation process checks that the settings for some type properties such as the Item Subclass property, the Interpret as property, and if applicable, the Presentation property in a type, match the settings for these same properties in its subtypes, and if they match, the selected property is propagated. But, depending on the property being propagated and the context, the process also checks other property settings. If you are propagating a child property, depending on the context, the process also checks the settings of the parent property, because the selected property might only apply to specific item types.

Examples of propagating a type property that applies to a specific type

A given category type has the following type property settings: Item Subclass._>Number, and for its children properties, Interpret as._>Character, and Presentation._>Decimal. When you propagate the Separators child property, the process affects only types in the type tree that also have those same Number, Character, Decimal type property settings. The Separators property is a type property that applies to the specific Presentation types, Decimal and Integer. For those types that have the Presentation type property setting of Zoned, the Separators property does not apply; it is not an available type property.

A given category type has the following type property settings: Restrictions._>Value and for its child property, Ignore case._>No. The Ignore case type property has no children properties. When you select the child Ignore case type property setting of No to be propagated, the process propagates the Ignore case setting of No to all types in the category whose parent Restrictions property setting is Value. The Ignore case property is a type property that applies to a specific Restrictions type, Value. For those types that have the Restrictions type property setting of Range, the Ignore case property does not apply; it is not an available type property.

Related tasks

- [Propagating type properties](#)

Propagating type properties

These are the instructions for propagating type properties in type trees.

About this task

Use Propagate to pass a type property setting from a type to its subtypes.

Procedure

To propagate a type property:

1. Open the Properties view for a type.
2. Right-click the property you want to propagate, such as Item Subclass > Restrictions, and select Propagate from the context menu.
3. When a confirmation message is displayed, select Yes.
Upon completion of the propagation, a message is displayed that confirms the number of types that the propagation process has changed.
4. Click OK to close the message box.

Results

The setting of the specified type property from the selected type is propagated to all of the appropriate subtypes in the type tree.

Error detection and recovery

- [Error detection](#)
 - [Error recovery](#)
-

Error detection

During map execution, the input data is compared to the data definition in the type tree. If the data does not match the definition, it is invalid or "in error".

To validate a data object as belonging to a certain type, the data must be matched to its type definition. For data to be valid, the following must be true:

- The data must have the properties that were defined for the type.
- If the type is an item that has restrictions, the data object must match one of the restrictions.
- If the type is a group, the components of the data object must match those defined in the group view, and each component rule must evaluate to "true" at map execution time.

Ultimately, all data objects, no matter how complex, consist of items because items represent the smallest unit of data. When all of the items that collectively comprise a component are found, the component has been "found."

When executing a map, invalid data is recorded in the trace file. You can decide what you want the system to do when errors are encountered: you can map the errors to an output and also have the system ignore invalid data. For methods on ignoring invalid data, see ["Restart attribute"](#).

- [How error detection works](#)
 - [Existence indicators](#)
 - [Existence versus presence of components](#)
-

How error detection works

When data is validated, the system may encounter data that does not match its type definition. A combination of how that type is defined and what data shows up determines what happens next. As data is validated, the system tracks valid data objects, data objects that exist but are in error, and data that cannot be recognized as belonging to any type.

If a data object is valid, the information is recorded, as needed, and validation continues.

If the system is looking for a data object of a particular type, and something in the data does not exactly match the type definition, the system bases the determination on whether to continue validation on whether that data object is known to exist.

If a data object contains enough information to determine its existence, errors associated with that data object are recorded and validation continues.

If a data object exists but contains errors, it is marked as an error. If a restart point is specified for the component of the type in error, these errors are ignored and validation continues.

If a data object does not contain enough information to determine its existence, the following occurs:

- If no validation recovery mechanism is specified, validation is stopped because it will get lost if it continues. Validation recovery mechanisms are discussed in the section ["Error Recovery"](#).
- If recovery mechanisms are specified, the system returns to the nearest restart point and resets what it is looking for. It proceeds by examining the data byte-by-byte until it either recognizes something or reaches the end of the data stream. All rejected bytes (from the first byte not associated with a type to the last unrecognizable byte) are collectively marked as an unidentified foreign object (UFO). A UFO is data in error with no valid data contained within it.

In summary, the data object of an input card could be valid, yet contain errors. If the data object of any input card is invalid, output data is not built. If all input card data objects are valid, the input is mapped to the output based on the map rules. Operators, most functions, and map references operate on valid data. To map invalid data, use the **REJECT** function.

Existence indicators

When the source or destination of a data object exists, the system knows that the entire data object of that source or destination exists. For example, if a source specified to contain a transaction is a file, and that file exists, the transaction exists. On the other hand, if you get a `Source not available` message, the data object of that source does not exist because the source itself does not exist.

When the data object of a source or destination exists, specific information about errors will appear in the data. For example, you might have any of the following:

- The data object is valid because it conforms to its type definition.
- The type of the data object exists, but has no content.
- The data object is in error because it does not conform to its type definition.
- The data object is valid but contains errors. You indicated that you wanted to ignore certain errors.

In addition to these conditions, the system can also tell if there is any unknown data remaining after the card object has been recognized. This can occur if there really is "junk" at the end. It may also be that enough data was identified to determine the status of the entire object and the data at the end could not, for some reason, be determined to have anything to do with the data object.

When a data object exists, the status of that object is determined by validating its type properties. If an entire data object is an item, it is easy to determine what the status is: whether it is valid or whether it does not match its item format, whether its value is not one of the specified restrictions, or whether it is missing an initiator or terminator. If the source or destination exists and the entire data object is an item, there is nothing else it could possibly be.

If the type of the entire data object is a group, the status of each component must be determined. The system uses existence indicators to determine whether a group component exists. If a component exists, the system can also tell you its status. If a component is required in another component that exists, the system will notify you if that required component is missing.

Existence versus presence of components

A component exists if the data object in which it is contained exists and if the component takes up space (if there is at least one byte in the data stream representing that component).

For example:

- If a delimiter appears as a placeholder for that component.
- If the type of that component has an initiator that distinguishes that component from any other component that may appear at that position in a data stream, the component exists if the initiator is there.
- If the type of that component is a group with an identifier and all components up to and including that identifier have been found to be valid.
- If the type of the component is an item with a restriction list and one of its restrictions appear in the data.
- If the type of the component is an item with a **Padded To** length specified and the item contains at least the number of bytes in the **Pad To** length.
- If the type of an optional component is valid, but the component rule evaluates to FALSE, the component only exists if there is a syntactic placeholder.

Data might exist, but might not be present. The presence of data is determined by whether the data has content. The following definitions are used in other parts of the documentation:

EXISTS

Something in the data represents that data object.

CONTENT

The data contains at least one byte other than a syntactical placeholder, such as a pad character or delimiter.

PRESENT

The data object exists and has content.

ABSENT

The data object does not exist or it exists and has no content.

Required components must exist. They do not necessarily have to be present. For example, a required item with no minimum content size can exist, be absent, and still be valid. However, if some minimum content size is specified, a required component is not valid if there is no minimum content.

The existence of optional components depends on the context in which they are used. For example:

- In a delimited group, an optional component must exist if data follows.
- In a fixed group, an optional component must exist if trailing white space is required. If no trailing white space is required, an optional component must exist if data follows.
- In an implicit group, an optional component is not required.

Unlike a required component, when an optional component exists, it might not have content - even when the minimum content specification is greater than zero bytes. The following table explains the conditions that must be met for required and optional components.

	EXISTS	CONTENT	PRESENT	ABSENT
Required Component	Must exist in any context	Must conform to content specification	Must be present if minimum content specification is greater than zero bytes.	Can be absent only if minimum content specification is zero.
Optional Component	Depends on context	Need not have content	Not necessary	Can be absent

Error recovery

It is good practice to map invalid data when it is encountered. For example, you have a file of records and some records are invalid. If your structure is designed to map invalid data when it is encountered, processing can continue without interruption.

To map invalid data of a particular object, you can assign the **Restart** attribute. The **Restart** attribute allows the processing of input data to continue when a data object of a component is invalid. Errors are ignored for invalid data object during validation. Using error-handling functions, you can map the invalid data.

- [Using the **Restart** attribute](#)

- [How the Restart attribute works](#)
- [Mapping invalid data](#)

Using the Restart attribute

The Restart attribute provides instructions for handling errors encountered in a data stream. The Restart attribute gets assigned to a component and takes effect during data validation.

During data validation, the Restart attribute identifies a "start over" point when an unidentified foreign object (UFO) is encountered in the data. All unrecognized data is considered an error of the type with the Restart attribute assigned.

If you are mapping data of a component with a Restart attribute in place, only the valid occurrences of that component are mapped. For example, suppose your input is a file of records, and the **Record** component of **File** has the Restart attribute. Suppose some of the records are invalid. When you map the **Record** objects, only the valid records are mapped. To map the invalid records (for example, to an error file) use an error-handling function, such as REJECT, in the map rule.

For information about error-handling functions, see the Functions and Expressions documentation.

Typically, you would assign the Restart attribute to a component that has a series range. For example, (1:20) or (s), and the objects in the series are independent of one another. If each record in your file is independent from the others, it makes sense to ignore an error if it encounters an invalid one. A bad record does not make the next record meaningless. But suppose the records are related. Maybe they are records related to one purchase order; if any record is bad, you want to stop after validation because it is important to have all records. Losing any records would make the overall data incomplete.

For additional information about using the **Restart** attribute, see the Map Designer documentation.

To assign the Restart attribute to a component

Tip: To capture all errors of the component using Restart, place the Restart attribute at the highest level possible in the type tree.

1. From the type tree editor, double-click the component. The component view opens.
2. Right-click the component and select Restart from the context menu. You can remove the Restart attribute by performing the same action again.

JSON native schema restart

JSON schema fields with `_V` following the name and fields starting with `oneOf`, `allOf` and `anyOf` are the virtual fields.

Virtual JSON fields do not appear in the data and have no syntax. Syntax is controlled by real fields above these virtual fields.

Real fields are fields that appear in the JSON data. It is impossible to restart to a data location that does not appear in the data.

Selecting a virtual field for restart may fail. Use a real field either above or below the virtual fields for restart.

Related tasks

- [Restart attribute](#)

How the Restart attribute works

The Restart attribute can do the following tasks:

- Identify valid data objects that contain objects in error.
- Tell the system where to start over when a unidentified foreign object (UFO) is encountered in the data during the validation process.
All unrecognized data is considered to be an error of the type with Restart assigned to it.
- Identify the UFOs and existing data objects in error that are ignored when mapping input to output.

When an invalid data object is a component that does not have the Restart attribute assigned, that component is marked in error. If components from the beginning of the data are marked in error because no Restart attribute is assigned, the following results occur. Processing stops after validation, and input data is not mapped to output.

Do not put the Restart attribute on a required component. There must be a number of valid instances that is enough to cover all of the required components. If you have a required component that is not valid, the Restart attribute does not validate the data.

When the Restart attribute is added to components that have only one mandatory element, it is ignored. Adding Restart to the parent level works only when there are no children that have one mandatory value. In this scenario, the ISERRORS and REJECT functions would report the first error. But if there are other errors, they are not captured because Restart stopped and restarted at the next parent level.

The Restart attribute is supported on components of Xerces type trees.

For more information about using the **Restart** attribute, see the Map Designer documentation.

Mapping invalid data

You can map the invalid or rejected data which you can use to determine what is wrong with the data. To do this, you use the restart attribute, in conjunction with the **REJECT**, **CONTAINSERRORS**, and **ISERROR** functions in map rules. For information on using these functions, see the Functions and Expressions documentation.

Type Tree Analyzer

Use the type tree analyzer to analyze your type definitions.

The type tree analyzer analyzes type definitions and ensures internal consistency. For example, if you defined a group as fixed, but accidentally defined one of its items with no **Padded To** length, errors occur during analysis.

The analyzer checks your data definitions for logical consistency. It does not compare your definitions to your actual data. The resulting analyzer messages indicate whether your type tree definitions are acceptable; not whether they match your data.

- [Mapping effects](#)
- [Internal consistency](#)
- [When to Analyze Structure or Logic](#)
- [To analyze a type tree](#)
- [Error and warning messages](#)

Related information

- [Distinguishable objects](#)

Mapping effects

The analyzer helps you define your data by locating objects in your input data and creating the objects in your output data. The analysis indicates whether there is something in your definition that may prevent a correct mapping of your data.

If you do not analyze a tree before you map the data or you analyze a tree and do not resolve the errors, you will be warned that you may receive unpredictable results when you map.

Internal consistency

The analyzer checks the logic of your data definitions. For example, suppose you defined a group **PO** as fixed and consists of **Line(s)**. For the **PO** to be fixed, it cannot have an indefinite number of **Lines**. An analysis error would occur, indicating that you defined **PO** as fixed but it has a variable number of components.

When to Analyze Structure or Logic

You can choose to analyze the structure or the logic of your type definitions, or both.

- [Logical analysis](#)
Logical analysis addresses the integrity of the relationships that you define.
- [Structural analysis](#)
Structural analysis addresses the integrity of the underlying database.

Related tasks

- [To analyze a type tree](#)

Logical analysis

Logical analysis addresses the integrity of the relationships that you define.

Logical analysis detects, for example, undefined components, components that are not distinguishable from one another, item restrictions that do not match the properties of that item, and circular type definitions. The analyzer also checks delimiter relationships to each other and to components, undefined inherited relationships, and logic errors contained in component rules.

Structural analysis

Structural analysis addresses the integrity of the underlying database.

Generally, you should not encounter structural analysis errors. Structural analysis might be able to detect and possibly correct defects caused by system environment failures.

To analyze a type tree

About this task

Follow this procedure to analyze a type tree.

Procedure

To analyze a type tree:

1. Select a type and open the properties.
2. In the type tree editor, right-click the root type.
3. From the context menu, choose Analyze...
 - Logic and Structure,
 - Logic Only, or
 - Structure Only.

The Analysis Results view opens.

The Analysis Results view displays the name of the type tree, the type of analysis, and the status of the process. When the analysis process completes, the number of errors and warnings are displayed.

Select the option under Transformation Extender preferences to change the default behavior to automatically save the type tree after analysis.

Error scenario

After analysis, the Analysis Results dialog displays error L201.

The error concerns the type **File**. **File**'s first component, **Record(s)** is a series. The way the data is defined does not allow one **Record** to be distinguishable from the next **Record** in the series.

There are a number of reasons why the records might not be distinguishable. To see how you can define **Record** to solve the problem, you can look at the list of things that make objects of a component distinguishable in ["Distinguishable Objects"](#).

A good way to figure out how to resolve an error is to look at the data. When you look at the data, it is clear where a record ends. Ask the question: *How can I tell the difference between one record and the next?* Perhaps each record ends with a carriage return/linefeed.

In this case, perhaps you forgot to define CR/LF as the terminator of **Record**.

To resolve the problem, open the Properties for the **Record** type and define the terminator. After you define a terminator and analyze the tree again, no errors should occur.

Related reference

- [Customizing the Transformation Extender Development perspective](#)

Related information

- [When to Analyze Structure or Logic](#)

Error and warning messages

Analysis results might contain error and warning messages.

Warnings are relatively insignificant. They indicate an inconsistency that occurred when you changed something in the tree that was resolved. For example, if you change a group to an item, the analyzer removes the components of that type because items do not have components. To remind you of this change, the analyzer issues a warning.

Errors are important. An error is a problem in your type definitions that you should correct. An error may result in unpredictable results in your mapping.

Occasionally there are errors that prevent the analysis of the rest of your definitions (for example, when a component type cannot be found in the tree). **Analysis halted before completion** is displayed. This error might be due to one of the following:

- Undefined COMPONENTs found: ending analysis.
- Circular reference found in COMPONENT list: ending analysis.

When this occurs, click Results, correct the errors, and analyze the tree again.

Objects in a data stream

A data stream is a byte-by-byte flow of data. Objects in a data stream include both data objects and syntax objects. Syntax objects indicate where a data object begins or ends. They include separators, initiators, terminators, delimiters, release characters, and pad characters. Sometimes, data values are used to identify where another data object begins or ends.

It might be necessary to distinguish between data objects in a component series, data objects of different types, or even syntax objects.

Type tree analyzer and distinguishable objects

The type tree analyzer indicates whether your data definitions are sufficient to distinguish the objects in your data stream. The following discussion explains how you can define your data so that the objects that need to be distinguishable are distinguishable. Chances are, if you analyzed your tree and received a message that involves distinguishable objects, you need to define the types differently or more specifically.

Bound types

A type is bound if its definition makes it clear where an instance of that type ends. If a type is bound, different objects of that type can be distinguished in a data stream. A bound type is easier to distinguish between an object of that type and an object of another type. The following tables describe how types may be bound.

An object of this type:

Is bound if any of the following is true:

Item

It is padded to a fixed size or its minimum and maximum content size are equal.
It has a terminator.

It has an include restriction list.

Partitioned item

Each non-partitioned item in the subtree is bound.

Sequence Group

It has an explicit fixed format.
It has a terminator.

Its last component is bound.

It is postfix delimited and its last component has a fixed range. For example, **Comment Field (3:3)** has a fixed range of **(3:3)**.

Partitioned Group

Each non-partitioned group in its subtree is bound.

Choice Group

It has a terminator.
The type of each selection component is bound.

Unordered Group

It has a terminator.

Bound components

A component is bound if it is possible to tell if a data object belongs to that component without comparing it to a component that follows it.

- [Component of a fixed group](#)
 - [Component of an explicit delimited group](#)
 - [Component of an implicit group](#)
 - [Component of a choice group](#)
 - [Component of an unordered group](#)
-

Component of a fixed group

Condition

Example

A range maximum is specified (it is not "s"), and its type is either a fixed group or an item whose length is fixed.

The component **InventorySection (0:3)** is bound because it is assumed there will be spaces in the data stream for 3 **InventorySections**.

Component of an explicit delimited group

Condition

Example

A range maximum is specified (it is not "s") if a component of the same group follows.

In the component list, **Security Sequence (0:10) Trailer** is bound in an explicit delimited group. It is assumed there will be a delimiter for all 10 **Security Sequences** in the data stream because **Trailer** is required.

The component is the last one and the explicit group has a terminator.

In the component list, **Security Sequence (s)** is bound in an explicit delimited group with a terminator. The system assumes the terminator will appear to indicate that there are no more **Security Sequences**.

Component of an implicit group

Condition

Example

Its range is fixed and its type is bound.

The component **Inventory Record (3:3)** is bound, if the type **Inventory Record** is bound according to any of the conditions listed under "[Bound Types](#)".

It has a component rule that binds it.

The component **PO Record (s)** is bound, if it has the following component rule which binds it:

PO# Field:PO Record = PO# Field:PO Record[LAST]

The type tree analysis checks only that the component has a rule that refers to the component itself. The analysis does not check that the rule binds the component. You must ensure that the rule is one that binds the component.

It is sized (using the Sized attribute) by the component that precedes it.

The component **Name Field (0:2)** is bound, if the previous component in the group has the Sized attribute.

Component of a choice group

Condition

Example

A component is bound if the type of a component is bound.

The component **Customer Record** is bound if the type **Customer Record** is bound.

Component of an unordered group

Condition

Example

A component is bound if its range is fixed and its type is bound.

The component **Address Field** is bound if its range is fixed, for example **(3:3)**, and the type **Address Field** is bound.

Group starting set

Data objects in a data stream need to be distinguishable when they could belong to two different groups. Specifically, the difference between the data that can come first in one group and the data that can come first in the other group. All of the possible types of data that may appear first in a group are referred to as the group's starting set.

The following describes the starting set of a group based on its group format:

Group Format	Starting Component Set
--------------	------------------------

Group Format	Starting Component Set
Explicit <ul style="list-style-type: none"> • Delimited • Fixed 	Includes the type of its first component.
Implicit <ul style="list-style-type: none"> • Sequence • Unordered 	<ul style="list-style-type: none"> • Includes the type of all components up to and including the first component that has a minimum range of at least one. • Includes the type of each component.
Choice	Includes the type of each component.

Group unbound set

Based on the nature of a bound group, the end of a bound group is determined without analyzing the data that follows it. However, if a group is not bound, the data that belongs to that group must be distinguishable from data that belongs to another type that might follow it in the data stream.

The unbound set of a choice or unordered group consists of the type of each component. The unbound set of a partitioned group consists of the unbound set of each unbound partition.

- [Unbound set of a sequence group](#)

Unbound set of a sequence group

The unbound set does not include a type that could come last, if that type is a required occurrence. For example, if the type **Comment Record** could appear last and the component is specified as **Comment Record (2:2)**, it is not in the unbound set, because the two occurrences of **Comment Record** are required. However, if **Comment Record** could appear last and the component is specified as **Comment Record (1:2)**, then **Comment Record** is in the unbound set, since its second occurrence is optional.

To determine the unbound set of a group, start with the last component of the group and proceed backward up the component list. If a component is unbound or has a minimum range of zero, continue up the list. Stop at the first component that is bound or that is unbound but has a minimum range greater than zero. Essentially, a group's unbound set is everything that is not clearly defined at the end of the group.

Initiator-distinguishable types

Initiator-distinguishable types are used during validation to determine existence of a type object based on the existence of its initiator.

- [Determining if a component is initiator-distinguishable from its following set](#)
- [Determining if a partition is initiator-distinguishable from its following set](#)
- [Determining if two types are initiator-distinguishable](#)

Determining if a component is initiator-distinguishable from its following set

A component is initiator-distinguishable from its following set if:

- The component is not a member of the identifier set and
- The type of the component has an initiator and
- The following set is empty or
- The type of the component is initiator-distinguishable from each type in its following set.

Type trees are analyzed to determine if components are initiator-distinguishable. Each implicit sequence group, choice group, and unordered group is analyzed to determine if their components are initiator-distinguishable. A component is marked as initiator-distinguishable when that component is initiator-distinguishable from its following set. The basis for this determination is found in ["Determining If Two Types are Initiator-Distinguishable"](#).

Determining if a partition is initiator-distinguishable from its following set

In a partitioned type, a partition is initiator-distinguishable from its following set if:

- The type of a partition has an initiator and
- The following set is empty or
- The type of the partition is initiator-distinguishable from each partition in its following set and the following set of a partition is the type of each partition that may follow.

Type trees are analyzed to determine if partitions are initiator-distinguishable. Each partitioned type is analyzed to determine if its partitions are initiator-distinguishable.

Determining if two types are initiator-distinguishable

The following table lists ways two types may be initiator-distinguishable. This is helpful if data validation errors indicate a type does not exist.

Type1	Type2	How to define them as initiator-distinguishable
item	item	If Type1 and Type2 have an initiator, and the initiators are different.
item	sequence group	<p>Either:</p> <ul style="list-style-type: none"> Type1 and Type2 both have an initiator and the initiators are different. <p>or</p> <ul style="list-style-type: none"> Type1 has an initiator, Type2 does not, Type2 has no delimiter, and Type1 is initiator distinguishable from type of each component in the starting component set of Type2.
item	choice group or unordered group	<p>Either:</p> <ul style="list-style-type: none"> The Type1 and Type2 both have an initiator and the initiators are different. <p>or</p> <ul style="list-style-type: none"> Type1 has an initiator, Type2 does not, Type2 has no delimiter, and Type1 is initiator distinguishable from type of each component of Type2.
item	partitioned item or partitioned group	Type1 has an initiator and is initiator distinguishable from each partition of Type2.
partitioned item	item or sequence group	Type1 has an initiator and each partition is initiator distinguishable from Type2.
partitioned item	partitioned item or partitioned group	Type1 has an initiator and each partition is initiator distinguishable from each partition of Type2.
sequence group	item	Type1 has no identifier, Type1 and Type2 both have initiators, and the initiators are different.
sequence group	sequence group	<p>Type1 has no identifier and</p> <ul style="list-style-type: none"> Type1 and Type2 both have initiators and the initiators are different <p>or</p> <ul style="list-style-type: none"> Type1 has an initiator, Type2 does not have an initiator, Type2 has no delimiter, and Type1 is initiator distinguishable from the starting component set of Type2.
sequence group	choice group or unordered group	<p>Type1 has no identifier and</p> <ul style="list-style-type: none"> Type1 and Type2 both have initiators and the initiators are different. <p>or</p> <ul style="list-style-type: none"> Type1 has an initiator, Type2 does not have an initiator, Type2 has no delimiter, and Type1 is initiator distinguishable from the type of each component of the Type2.
sequence group	partitioned item	Type1 has no identifier and Type1 must be initiator distinguishable from each partition of Type2.
sequence group	partitioned group	Type1 has no identifier and the Type1 must be initiator distinguishable from each partition of Type2.
partitioned group	partitioned item	Type1 has no identifier and each partition Type1 must be initiator distinguishable from Type2.
partitioned group	sequence group	Type1 has no identifier and each partition of the Type1 must be initiator distinguishable from Type2.
partitioned group	partitioned item	Type1 has no identifier and each partition of Type1 must be initiator distinguishable from each partition of Type2.
partitioned group	partitioned group	Type1 has no identifier and each partition of Type1 must be initiator distinguishable from each partition of Type2.
choice group or unordered group	item	Type1 and Type2 both have an initiator and the initiators are different.
choice group or unordered group	partitioned item	Type1 is initiator-distinguishable from each partition of Type2.
choice group or unordered group	choice group or unordered group	<p>Either:</p> <ul style="list-style-type: none"> Type1 and Type2 both have an initiator and the initiators are different. <p>or</p> <ul style="list-style-type: none"> Type1 has an initiator and Type2 does not, Type2 has no delimiter, and Type1 is initiator-distinguishable from the type of each component of Type2.
choice group or unordered group	sequence group	<p>Either:</p> <ul style="list-style-type: none"> Type1 and Type2 both have an initiator and they are different. <p>or</p> <ul style="list-style-type: none"> Type1 has an initiator and Type2 has no initiator and no delimiter, and Type1 is initiator-distinguishable from the type of each component in the starting component set of Type2.
choice group or unordered group	partitioned group	Type1 is initiator distinguishable from each partition of the Type2.

Distinguishable objects of the same component

When a component has a series range, for example, (1:10) or (s), one occurrence of that component must be distinguishable from the next occurrence of that same component.

Different data objects of a component are distinguishable if any of the following is true:

- The component type is bound.
- The component type is a non-partitioned group with an unbound set that is content-distinguishable from the component type as a whole.
- The component type is a partitioned group and the unbound set of each non-partitioned group in its subtree is content-distinguishable from the component type as a whole.

Content-distinguishable components

A component is distinguishable from its following set when the component is:

- Initiator-distinguishable from its following set.

or

- Content-distinguishable from its following set.

A component is content-distinguishable from its following set when:

- The following set is empty.

or

- The type of the component is content-distinguishable from each component in its following set.

Content-distinguishable types

The following table lists the ways in which two types may be content-distinguishable. The table is helpful particularly if you analyzed your tree and received an error indicating that two types are not distinguishable. Look up the combination of types in the first two columns and read the list of ways to define them that would make them distinguishable.

For example, if you get an error indicating that **X** is not distinguishable from **Y**, where **X** is an item, and **Y** is a partitioned group, you would find the row in the table where **Type1** is an item and **Type2** is a partitioned group.

Remember that the order in which you compare two types matters. When you ask the question "Is type A content-distinguishable from type B?", this is not the same question as "Is type B content-distinguishable from type A?"

If you are trying to determine whether two types are distinguishable and you follow the guidelines in the following tables, you may encounter a situation in which you are comparing a type to itself. A type is never distinguishable from itself.

Another thing to keep in mind is that the context in which a type is used matters. When you ask the question, "Is type A, as a component of type C, content-distinguishable from type B?" this is not the same question as, "Is type A, as a component of type D, content-distinguishable from type B?"

The following table shows how to define types as content-distinguishable.

Type 1	Type 2	How to define them as content-distinguishable
item	item	<p>The first component or partition is either:</p> <ul style="list-style-type: none">• An item and marked as initiator distinguishable and <p>Both items are different partitions of the same partitioned subtree, or The second type has an initiator and those initiators are mutually exclusive, or Both types have the same initiator and the value of the first item is distinguishable from the value of the second item, or The second type has no initiator and the initiator of the first type is distinguishable from the value of the second type.</p> <ul style="list-style-type: none">• An item and not marked as initiator distinguishable and <p>Both items are different partitions of the same partitioned subtree, or The first item has an initiator, second has an initiator and initiator value of first is distinguishable from initiator value of the second. Both types have initiators and they are the same, or both types have no initiator and the value of the first item is distinguishable from the value of the second item. The first item has an initiator, second does not, and value of initiator distinguishable from the value of second item. The first item has no initiator, second does, and the first item's value is distinguishable from the value of the second item's initiator.</p>
item	sequence group, choice group, or unordered group	<p>The first component or partition is either:</p> <ul style="list-style-type: none">• An item marked as initiator distinguishable and <p>The second type has an initiator and those initiators are mutually exclusive, or The second type has no initiator and the item is initiator-distinguishable from each type in the starting component set of the group.</p> <ul style="list-style-type: none">• An item not marked as initiator distinguishable and <p>The item and group both have an initiator and the initiator of the item is distinguishable from the initiator of the group, or The item has no initiator, the group has an initiator, and the item's value is distinguishable from the value of group's initiator, or Both types have initiators and they are the same or both types have no initiator, and the item's value is distinguishable from the type of each component in the starting component set of the group, or The item has an initiator, the group has no initiator, and the item is content-distinguishable from the type of each component in the starting component set of the group, or The item has no initiator, the group has an initiator, and the item's value is distinguishable from each type in the starting component set of the group.</p>

Type 1	Type 2	How to define them as content-distinguishable
item	partitioned item or partitioned group	The first component or partition is content-distinguishable from each partition of the second type.
partitioned item	item	Each partition of the first type is content-distinguishable from the second type.
partitioned item	sequence group	Each partition of the first type is content-distinguishable from the second type.
partitioned item	choice group	Each partition of the first type is content-distinguishable from second type.
partitioned item	unordered group	Each partition of the first type is content-distinguishable from second type.
partitioned item	item	Each partition of the first type is content-distinguishable from second type.
partitioned item	partitioned group	Each partition of the first type is content-distinguishable from second type.
group	item	Each partition of the partitioned group is content-distinguishable from the item.
partitioned group	partitioned item	Each partition of the partitioned group is content-distinguishable from each partition of the item.
partitioned group	sequence group	Each partition of the partitioned group is content-distinguishable from the second group.
partitioned group	partitioned group	Each partition of the first partitioned group is content-distinguishable from each partition of the second partitioned group.
partitioned group	choice group	Each partition of the partitioned group is content-distinguishable from the choice group.
partitioned group	unordered group	Each partition of the partitioned group is content-distinguishable from the unordered group.
sequence group	item	<p>The first component is either:</p> <ul style="list-style-type: none"> • A group marked as initiator distinguishable and <p>The item has an initiator and the initiator value of the group is distinguishable from the initiator value of the item, or The second type has no initiator and the initiator value of the first type is distinguishable from the value of the second type.</p> <ul style="list-style-type: none"> • A group not marked as initiator distinguishable and <p>The group has an initiator, the item has an initiator and the initiator value of the group is distinguishable from initiator value of the item, or The group has an initiator, the item does not, and value of the initiator is distinguishable from value of the item, or Both types have initiators and they are the same, or both types have no initiator and each type in the starting component set of the group is content-distinguishable from the value of the second item.</p>

Ending-distinguishable types

Ending-distinguishability is used to determine if the end of a data object is distinguishable from the start of any other data object that could be next in the data.

The following table describes how two types may be ending-distinguishable. This is helpful if you are validating data and you receive a message that says a type exists, but it belongs to the wrong component.

Type1	Type2	How to define them as ending-distinguishable
item	item or sequence group or choice group or unordered group	Type1 is bound or the value of Type1 is content-distinguishable from Type2.
item	partitioned item or partitioned group	Type1 is bound or the value of Type1 is content-distinguishable from each partition of Type2.

Type1	Type2	How to define them as ending-distinguishable
sequence group	item or sequence group or choice group or unordered group	<p>Either:</p> <ul style="list-style-type: none"> • Type1 is bound. <p>or</p> <p>For each component in the unbound set of Type1</p> <ul style="list-style-type: none"> • If the component has a fixed range it must be ending-distinguishable from Type2. • If the component range is variable, it must be content-distinguishable from Type2 and ending-distinguishable from Type2.
sequence group	partitioned item or partitioned group	<p>Either:</p> <ul style="list-style-type: none"> • Type1 is bound. <p>or</p> <p>For each component in the unbound set of Type1</p> <ul style="list-style-type: none"> • If the component has a fixed range it must be ending-distinguishable from each partition of Type2. • If the component range is variable, it must be content-distinguishable from each partition of Type2 and ending-distinguishable from each partition of Type2.
choice group or unordered group	item or sequence group or choice group or unordered group	<p>Either:</p> <ul style="list-style-type: none"> • Type1 is bound. <p>or</p> <ul style="list-style-type: none"> • For each component of Type1, <p>The type of that component is bound, or The type of that component is unbound, and that type must be ending-distinguishable from Type2.</p>
choice group or unordered group	partitioned item or partitioned group	<p>Either:</p> <ul style="list-style-type: none"> • Type1 is bound. <p>or</p> <ul style="list-style-type: none"> • For each component of Type1, <p>The type of that component is bound, or The type of that component is unbound, and that type must be ending-distinguishable from each partition of Type2.</p>
partitioned item or partitioned group	item, sequence group, choice group, or unordered group	<p>For each partition of Type1, either:</p> <ul style="list-style-type: none"> • The partition is a partitioned type and ending-distinguishable from the second type, or • The partition of the first type is bound, or • The partition of the first type is unbound and ending-distinguishable from the second type.
partitioned item or partitioned group	partitioned item or partitioned group	<p>For each partition of the first type, either:</p> <ul style="list-style-type: none"> • The partition is a partitioned type and ending-distinguishable from the second type, or • The partition of the first type is bound, or • The partition of the first type is unbound and ending-distinguishable from the second type.

Distinguishable data objects of an implicit group

When a data object belongs to an implicit sequence, determining the component a data object belongs to depends on the format of the sequence, the type definition of a component, and the component properties.

- [Guidelines for defining an implicit delimited sequence](#)
- [Guidelines for defining an implicit sequence that has no delimiter](#)
- [Guidelines for defining an implicit unordered group that is delimited](#)
- [Guidelines for defining an implicit unordered group that has no delimiter](#)

Guidelines for defining an implicit delimited sequence

- If the type of a component has a terminator, that terminator must be different from the delimiter of the explicit group. If the delimiter and terminator are both defined as literal values, a type analysis confirms both have different values.
- The type of a component cannot be a binary item whose length is not fixed or sized.
- If the type of a component or a contained component is not bound, the type of the component cannot have a delimiter that is the same as the delimiter of the implicit sequence.
- If the range of a component is not bound, the type of that component must be content-distinguishable from the type of each component in the following set of that component.

- If the type of a component has both an initiator and terminator, the nested delimiters do not have restrictions. If this is not the case, all contained delimiters must be different.

Related concepts

- [Content-distinguishable types](#)

Guidelines for defining an implicit sequence that has no delimiter

- The type of a component cannot be a binary item whose length is not fixed or sized.
- If the range of a component is bound, but the type of the component is unbound, the type must be ending-distinguishable from each type in the component's following set.
- If the range of a component is not bound, all the following rules apply:
 - The type of the component must be content-distinguishable from each type in the component's following set.
 - If the maximum range for that component is greater than one, and the type is unbound, the type must be ending-distinguishable from itself.
 - If the type of the component is unbound, the type must be end-distinguishable from each type in the component's following set.

Guidelines for defining an implicit unordered group that is delimited

- The type of a component cannot be a binary item whose length is not fixed.
- The type of a component must be content-distinguishable from the type of each other component.
- If the type of a component has both an initiator and terminator, the nested delimiters do not have restrictions. If this is not the case, all contained delimiters must be different.

Guidelines for defining an implicit unordered group that has no delimiter

- The type of a component cannot be a binary item whose length is not fixed.
- The type of a component must be content-distinguishable from the type of each other component.
- If the type of a component is unbound, the type must be ending-distinguishable from the type of each other component.
- If the maximum range is greater than one and the type is unbound, the type must be ending-distinguishable from itself.

Distinguishable data objects of an explicit group

When a data object belongs to an unordered group, distinguishing one data object from another depends on the format of the unordered group and the type definition of each component.

- [Guidelines for defining an explicit fixed group](#)
- [Guidelines for defining an explicit delimited group](#)
- [Objects of a choice group](#)
- [Objects of a partitioned type](#)

Guidelines for defining an explicit fixed group

- In a fixed group, each component must be either an item of fixed size, an item padded to a fixed length, or an explicit fixed group.
- The range maximum for each component must have a specific value; it cannot be **s**. A fixed amount of space is assumed in the data stream for each series member of a component in a fixed group.

Guidelines for defining an explicit delimited group

A component of an explicit delimited group can be a group or item, with the following restrictions:

- If the type of a component has a terminator, that terminator must be different from the delimiter of the explicit group. If the delimiter and terminator are both defined as a literal, analysis confirms if both have different values.
- If a component of an explicit delimited group is a binary item whose length is not fixed, that component must be sized by the component that precedes it.
- If the type of a component, or a contained component, does not have a terminator and the type of the component has a delimiter that is the same as the delimiter of the explicit group, the type of the component *must* be an explicit sequence. In this case, the delimiter appears as a placeholder for every data object if data of the same delimiter follows it.
- If an explicit group has a delimiter, the range maximum of any component other than the last one must have a specific value; it cannot be **s**. A delimiter is assumed in the data stream for each series member of a component of an explicit group with a delimiter.

Objects of a choice group

When a data object belongs to a choice group, which component the data object belongs to is based on the order the components appear in the type definition.

In a choice group, if a component is unbound it must be content-distinguishable from the type of each component that follows it in the component list.

Objects of a partitioned type

When data objects of different types appear in the same place in the data, the types must be distinguishable. The data must be distinguishable in the type definition. When a partition is part of a partitioned object, the process of cycling through the partitioned subtree begins to make the determination of which partition the data object belongs to.

In a partitioned type, each partition must be content-distinguishable from the type of each partition that follows it.

Related concepts

- [Partitioning types](#)

Distinguishable syntax objects

The system must be able to distinguish between different syntax objects contained within a group. To ensure that the syntax objects are distinguishable, use the following guidelines:

- If a component is unbound, make sure its delimiter and any delimiter contained in it is distinguishable from the delimiter of the group. If you get an analysis error, look for missing placeholders or components with a range maximum of **s**.
In a component or a contained component with the same delimiter as the type delimiter, the system assumes that the delimiter appears as a placeholder for every data object if data with the same delimiter follows it.
- If the delimited group has a terminator, make sure that the delimiter and any contained delimiter is distinguishable from the terminator.
The type tree analysis verifies if the above requirement is met in a non-partitioned group.

Utilities for XML

There are XML utilities provided with the Type Designer.

- Use the XML Type Tree/Schema Synchronization Utility to synchronize a type tree with an XML schema or DTD.
- Use the XML Type Tree Compatibility Utility to add non-XML types that were added to the type tree after it was originally created, to the target type tree. The XML Type Tree Compatibility Utility is also available from the command line (dsxmlconv).
- Use Any-2-XML to create a map that can transform any input data into XML output. Any-2-XML is also available from the command line (dtxany2xml)

There is also a Map Migration Utility (dsmapconv) that updates map source files and the associated XML type trees to the current XML format that is available from the command line.

See the Utility Commands documentation for information about all command line utilities.

- [XML Type Tree/Schema Synchronization utility](#)
- [XML type tree compatibility utility](#)
- [Modifying the target type tree](#)
- [Any-2-XML](#)

The Any-2-XML utility is an extension of the type tree Export as Schema functionality that you can use to create a map that can transform any input data into XML output, based on a type tree structure that you select.

XML Type Tree/Schema Synchronization utility

About this task

Use this utility to synchronize a type tree with an XML schema or DTD.

You can use this utility only to update type trees that are generated from a DTD or schema when you use the XML DTD or XML Schema importers.

To synchronize a type tree with an XML DTD or schema:

Procedure

1. Right-click on the root type and select Synchronize from the menu.
The XML Type Tree/Schema Synchronization Utility opens.
2. From the drop-down list, select the importer that was originally used to create the type tree: XML, which is the default setting, or DTD.

3. Click the browse button and choose a type tree.
 4. In the next field, click the browse button and select the modified DTD or schema file to which you want to synchronize the type tree.
The Create backup file option is enabled by default and the location for the backup file is automatically displayed (based on the type tree you selected). You can change the location and file name extension if wanted.
 5. If applicable, select the national language of the original type tree.
 6. Click Next to begin synchronization.
- The following list includes the possible results:
- If no modifications were made to the original type tree created from the DTD or schema, the synchronization process completes successfully.
 - If modifications were made to the original type tree created from the DTD or schema, they are displayed in the left pane of the utility in red text. You can incorporate any differences into the new (target) type tree.
- For example, you can take an attribute that was added to the original type tree and add it to the target type tree (see "Modifying the Target Type Tree").
7. Change as needed and click Next.
- When you see that the type tree was synchronized successfully, click Finish to close the utility.

XML type tree compatibility utility

About this task

If you have type trees that are generated with the XML Schema or DTD importers of IBM Transformation Extender 6.7 or 7.5 or earlier, and you are now using this version, you must update your type trees to use the current XML validation. To update your type trees, you can use the XML Type Tree Compatibility Utility. This utility is also available from the command line (`dsxmlconv`).

When you use the XML Type Tree Compatibility Utility, there are two important requirements. One is that you must specify the correct version of the IBM Transformation Extender XML Schema or DTD importer that was used to create the original type tree. The other is that you must have the original DTD or Schema.

To make a type tree compatible with this version of IBM Transformation Extender XML validation:

Note: The original DTD/schema file is required when you use the XML Type Tree Compatibility Utility.

Procedure

1. Right-click the root type and select Convert from the menu.
The XML Type Tree Compatibility Utility opens.
 2. From the drop-down list, select the importer that was originally used to create the type tree: XML Schema, which is the default setting, or DTD.
 3. Click the browse button and choose a type tree.
 4. From the drop-down list, choose the version of the IBM Transformation Extender importer that is used to create the type tree.
Note: You must specify the correct version of the IBM Transformation Extender importer that was used to create the original type tree. If you use an incorrect version number, the conversion process can complete successfully, however, the type tree would be invalid.
 5. In the Select the XML grammar location field, accept the default value for the original XML DTD or Schema used to create the type tree if it is accurate. Otherwise, enter the correct location of the XML grammar.
 6. Enable or disable the Create backup file option. By default, the option is enabled and the location for the backup file is automatically displayed in the subsequent field, which is based on the type tree that you selected. You can change the location and file name extension if necessary.
 7. If applicable, select the national language of the original type tree.
 8. Click Next to begin the update process.
- The following list includes the possible results:
- If no modifications were made to the original type tree created from the DTD or schema, the process completes successfully.
 - If modifications were made to the original type tree, they are displayed in the right pane of the utility in red text. You can incorporate any differences into the new (target) type tree (see "Modifying the Target Type Tree").
- For example, the non-XML types that were added to the original type tree can be added to the new (target) type tree.
9. When you see that the type tree was synchronized successfully, click Finish to close the utility.

Modifying the target type tree

About this task

When the XML utility encounters any non-XML types that have been added to the type tree after it was first created from a schema or DTD, the unrecognized types are displayed in red text.

The instructions below describe how to add the types back into your target tree, however, you have the ability from within this utility to make any necessary modifications to the target type tree in the same manner as you would from the type tree editor (using add, delete, copy, and paste operations).

The following procedures can be used for both XML utilities: XML Type Tree Compatibility Utility and XML Type Tree/Schema Synchronization Utility.

To add a type to the target tree

Procedure

1. In the left pane of the XML utility, right-click on the type and select `Edit > Copy`.
2. In the right pane (which displays the target type tree), right-click on the corresponding (parent) type and select `Edit > Paste`.
The type appears in the target tree.
3. After making all changes, click Next to continue.

To add a component to the target tree

Procedure

1. In the right pane (which displays the target type tree), select the type to add the component to.
 2. At the bottom of the pane, select the Components tab.
 3. Press **Alt** and then select-and-drag the type to the **Component** column of the Components tab.
 4. After adding all components, click Next to continue.
-

Any-2-XML

The Any-2-XML utility is an extension of the type tree Export as Schema functionality that you can use to create a map that can transform any input data into XML output, based on a type tree structure that you select.

How it works

Choose a type within a type tree that models the XML output you want to produce. The utility converts the type into an XML Schema from which it creates a new XML type tree. A new map source file is created containing the new map. The input card of the new map references the original type tree and input and the output card references the new XML type tree and the new output file name. The result of running the new map is XML output.

- [Using Any-2-XML](#)
-

Using Any-2-XML

Procedure

1. Open a type tree that models the XML output structure you want to produce.
 2. In the type tree editor, select a type that represents the portion of the input file that you want to export.
This must be a group or item.
 3. Right-click the type and click Export as Schema.
The Export as Schema dialog opens.
 4. Optional: You can specify the schema name and path if you do not want to use the default values. Click the button at the end of the Schema field, and in the Select window, specify the schema name and path.
 5. Select the Create a map that transforms the input data described by the type tree into XML output check box.
 6. Click the button at the end of the Input file name field, and in the Select window, select the input file that corresponds to the type tree.
 7. In the Output file name field, enter a filename and path for the XML output file that is generated as a result of running the new map. You can also click the button at the end of the field, and make your selections in the Select window.
 8. In the Map file name field, enter a name for the new map source file.
 9. Click OK to start the utility.
The following files are created:
 - XML Schema (*orig_type_tree_name_plus_exported_type_name.xsd*, which is the default, or *name_you Optionally_specified.xsd*)
 - Type tree (*orig_type_tree_name_plus_exported_type_name.mtt*)
 - Map source file (.mms)A log file (*map_name.log*) is created only when an error occurs.
 10. Open the new map.
 11. Build and run the map.
An XML output file is created.

 - [Type tree analysis logic error messages](#)
 - [Logic error and warning messages](#)
 - [Type tree analysis structure error messages](#)
 - [Type tree analysis structure warning messages](#)
-

Type Tree Analyzer errors and warnings

The Type Tree Analyzer checks the logic and internal consistency of your data definitions. Type tree analyzer error and warnings messages are issued on the type of analysis that is performed: logic and structural.

- Logical analysis addresses the integrity of the relationships that you define in the type tree.
- Structural analysis addresses the integrity of the underlying database.

Warnings indicate a successful analysis and are relatively insignificant. Warning messages provide information about inconsistencies that occurred, when the type tree was changed, and were automatically resolved.

Errors are important. Error messages provide information about errors in your type definitions that you should correct. An error may result in unpredictable results in your mapping.

Words in italics represent information that varies, indicating information specific to the type for which the message is generated.

Type tree analysis logic error messages

The following table lists the logic error messages that result from a logical analysis of a type tree:

Return Code	Message
L100	COMPONENT neither inherited nor local: ' <i>type name</i> ' of TYPE: ' <i>type name</i> ' Hint: Look at the super-type's component list. The component is a valid type, but the supertype has a component list that restricts you from using this type as a component. You may have added subtype components before adding supertype components. Either remove all supertype components or add the components in error to the component list of the supertype.
L101	This GROUP must have at least one component - TYPE: ' <i>type name</i> ' Hint: If you want to map this group, add components. If you do not want to map it, make it a category.
L102	Circular reference found in COMPONENT # (' <i>type name</i> ') - TYPE: ' <i>type name</i> ' Hint: Look at the type of the component in error. It is probably missing an initiator or terminator.
L103	Circular reference found in Floating Component type - TYPE: ' <i>type name</i> ' Hint: Look at the floating component type in error. It is probably missing an initiator or terminator.
L104	DELIMITER for TYPE - ' <i>type name</i> ' must have a value Hint: All delimited groups need a delimiter. Edit delimited group properties to insert the missing delimiter.
L105	DELIMITER type neither inherited nor local - TYPE: ' <i>type name</i> ' Hint: The delimiter name has been entered incorrectly. It should be the name of a local type, or the name of an inherited delimiter, or the name of a type in the sub-tree of the inherited delimiter.
L106	Default DELIMITER not specified - TYPE: ' <i>type name</i> ' Hint: This Type was specified with a FIND option for its delimiter. Please add a default value to define what to use for building outputs.
L107	Default DELIMITER not in restriction list - TYPE: ' <i>type name</i> ' Hint: This delimiter was specified as a syntax item. Add the default value to the restriction list for that syntax item.
L108	DELIMITER type is not a SYNTAX ITEM - TYPE: ' <i>type name</i> ' Hint: Delimiters specified as an item must be specified to be interpreted as SYNTAX to set the value of the delimiter if it appears as a component in a data stream.
L109	DELIMITER type has no restriction list - TYPE: ' <i>type name</i> ' Hint: All syntax items need a restriction list.
L110	RELEASE CHARACTER neither inherited nor local - TYPE: ' <i>type name</i> ' Hint: The release character name has been entered incorrectly. It should be either the name of a local type, the name of an inherited release character, or the name of a type in the sub-tree of the inherited release character.
L111	Default RELEASE CHARACTER not specified - TYPE: ' <i>type name</i> ' Hint: This Type was specified with a syntax item for its release character. Please add a default value to define a value for the release character that has not been encountered in the data.
L112	Default RELEASE CHARACTER not in restriction list - TYPE: ' <i>type name</i> ' Hint: This Type was specified with a syntax item for its release character. Please add the default value to the restriction list of that syntax item.
L113	RELEASE CHARACTER type is not a SYNTAX ITEM - TYPE: ' <i>type name</i> ' Hint: Release characters specified as an item must be specified to be interpreted as SYNTAX to set the value of the release character if it appears as a component in a data stream.
L114	RELEASE CHARACTER type has no restriction list - TYPE: ' <i>type name</i> ' Hint: All syntax items need a restriction list.
L115	Floating Component TYPE neither inherited nor local - TYPE: ' <i>type name</i> ' Hint: The floating component name has been entered incorrectly. It should be either the name of a local type, the name of an inherited floating component, or the name of a type in the sub-tree of the inherited floating component.

- L116 INITIATOR type neither inherited nor local - TYPE: '*type name*'
 Hint: The initiator name has been entered incorrectly. It should be either the name of a local type, the name of an inherited initiator, or the name of a type in the sub-tree of the inherited initiator.
- L117 Default INITIATOR not specified - TYPE: '*type name*'
 Hint: This Type was specified with a syntax item for its initiator. Add a default value to define a value for that initiator has not been encountered in the data.
- L118 Default INITIATOR not in restriction list - TYPE: '*type name*'
 Hint: This Type was specified with a syntax item for its initiator. Add the default value to the restriction list of that syntax item.
- L119 INITIATOR type is not a SYNTAX ITEM - TYPE: '*type name*'
 Hint: Initiators specified as an item must be specified to be interpreted as SYNTAX to set the value of the initiator if it appears as a component in a data stream.
- L120 INITIATOR type has no restriction list - TYPE: '*type name*'
 Hint: All syntax items need a restriction list.
- L121 TERMINATOR type neither inherited nor local - TYPE: '*type name*'
 Hint: The terminator name has been entered incorrectly. It should be either the name of a local type, the name of an inherited terminator, or the name of a type in the sub-tree of the inherited terminator.
- L122 Default TERMINATOR not specified - TYPE: '*type name*'
 Hint: This Type was specified with a syntax item for its terminator. Add a default value to define a value for that terminator has not been encountered in the data.
- L123 Default TERMINATOR not in restriction list - TYPE: '*type name*'
 Hint: This Type was specified with a syntax item for its terminator. Please add the default value to the restriction list of that syntax item.
- L124 TERMINATOR type is not a SYNTAX ITEM - TYPE: '*type name*'
 Hint: Terminators specified as an item must be specified to be interpreted as SYNTAX to set the value of the terminator if it appears as a component in a data stream.
- L125 TERMINATOR type has no restriction list - TYPE: '*type name*'
 Hint: All syntax items need a restriction list.
- L126 COMPONENT range minimum (#) greater than range maximum (#) - COMPONENT '*type name*' - TYPE: '*type name*'
 Hint: The minimum range must be less than or equal to the maximum range.
- L127 COMPONENT range minimum (#) less than inherited range minimum(#)- COMPONENT '*type name*' - TYPE: '*type name*'
 Hint: The component in error has been inherited. Look at the range of the component with the same name in the super-type's component list.
- L128 COMPONENT range maximum (#) greater than inherited range maximum(#)- COMPONENT '*type name*' - TYPE: '*type name*'
 Hint: The component in error has been inherited. Look at the range of the component with the same name in the super-type's component list.
- L129 COMPONENT RULE references a COMPONENT later in the component list - '*type name*' - TYPE: '*type name*'
 Hint: Move the component rule to the component later in the list.
- L130 COMPONENT RULE references undefined type - COMPONENT # of TYPE: '*type name*'
 Hint: Verify the spelling of the data object name. The rule should reference a data object name of the component or a data object name of a component earlier in the component list.
- L131 COMPONENT RULE references components of a partitioned group - COMPONENT # of TYPE *type name*
- L132 Invalid partitioning: TYPE has no SUBTYPES - TYPE: '*type name*'
 Hint: Remove the partitioned option from the class window or add sub-types to the Type in error.
- L133 Type of COMPONENT exists, but its relative name is not valid: '*type name*' in TYPE: '*type name*'
 Hint: To get the correct relative name, drag the type you want to use as a component and drop it in the component list of the Type. (Remember to delete the invalid component!)
- L134 Reference to 'ANY' not allowed: COMPONENT number # of TYPE: '*type name*'
 Hint: In this case, the Type in error is a group and it is not the root of a partitioned tree. ANY cannot be used if that component needs to be validated. So, if that group is partitioned, you cannot use ANY for a component up to and including the identifier (if there is one). If that group is not partitioned, you cannot use ANY at all.
- L135 COMPONENT number # cannot reference a CATEGORY in TYPE: '*type name*' (because group is not partitioned)

Hint: In this case, the Type in error is a group and it's not the root of a partitioned tree. A category cannot be used if the component must be validated. So, if that group is partitioned, you cannot use a category for a component up to and including the identifier (if there is one). If that group is not partitioned, you cannot use a category as a component at all.

L136

COMPONENT '*type name*' occurs more than once in list - TYPE: '*type name*'

Hint: Each component in the same component list must have a unique type name. Try to make sub-types of the type name in error and replace each non-unique component with one of the new sub-types.

L137

COMPONENT '*type name*' and its super-type cannot be in same COMPONENT LIST (in TYPE: '*type name*')

Hint: Try making another sub-type of the super-type and replace the super-type reference with the new sub-type.

L138

COMPONENT '*type name*' is same type as delimiter - TYPE: '*type name*'

Hint: A component and a delimiter cannot have the same name. You may need to add sub-types to the type name used in error to resolve this one.

L139

COMPONENT '*type name*' is sub-type of delimiter - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify a delimiter. You can add another sub-type to the syntax item and replace the delimiter name with the new sub-type name.

L140

COMPONENT '*type name*' is super-type of delimiter - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify a delimiter. You can add another sub-type to the syntax item and replace the component name with the new sub-type name.

L141

COMPONENT '*type name*' is same type as initiator - TYPE: '*type name*'

Hint: A component and an initiator cannot have the same name. You can add sub-types to the type name used in error and replace both the component name and the initiator name.

L142

COMPONENT '*type name*' is sub-type of initiator - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify an initiator. You can add another sub-type to the syntax item and replace the initiator name with the new sub-type name.

L143

COMPONENT '*type name*' is super-type of initiator - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify an initiator. You can add another sub-type to the syntax item and replace the component name with the new sub-type name.

L144

COMPONENT '*type name*' is same type as terminator - TYPE: '*type name*'

Hint: A component and a terminator cannot have the same name. Try adding sub-types to the type name used in error and replace both the component name and the terminator name with one of the new sub-types.

L145

COMPONENT '*type name*' is sub-type of terminator - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify a terminator. You can add another sub-type to the syntax item and replace the terminator name with the new sub-type name.

L146

COMPONENT '*type name*' is super-type of terminator - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify a terminator. You can add another sub-type to the syntax item and replace the component name with the new sub-type name.

L147

COMPONENT '*type name*' is same type as Floating Component - TYPE: '*type name*'

Hint: Make both the floating component name and the component name sub-types of the floating component.

L148

COMPONENT '*type name*' is sub-type of Floating Component - TYPE: '*type name*'

Hint: Make both the floating component name and the component name sub-types of the floating component.

L149

COMPONENT '*type name*' is super-type of Floating Component - TYPE: '*type name*'

Hint: Make both the floating component name and the component name sub-types of the floating component.

L150

COMPONENT '*type name*' is same type as release character - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify a release character. You can add sub-types to the syntax item and replace both the component name and the release character name with the new sub-type names.

L151

COMPONENT '*type name*' is sub-type of release character - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify a release character. You can add another sub-type to the syntax item and replace the release character name with the new sub-type name.

L152

COMPONENT '*type name*' is super-type of release character - TYPE: '*type name*'

Hint: This occurs when a syntax item is used to specify a release character. You can add sub-types to the syntax item and replace the component name with the new sub-type name.

- L153
DELIMITER '*type name*' is same type as initiator - TYPE: '*type name*'
 Hint: A delimiter and an initiator cannot have the same name. You may need to add sub-types to the type name used in error and replace both the delimiter and initiator names to refer to the new sub-types.
- L154
DELIMITER '*type name*' is sub-type of initiator - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both an initiator and a delimiter. You can add another sub-type to the syntax item and replace the initiator name with the new sub-type name.
- L155
DELIMITER '*type name*' is super-type of initiator - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both an initiator and a delimiter. You can add another sub-type to the syntax item and replace the delimiter name with the new sub-type name.
- L156
DELIMITER '*type name*' is same type as terminator - TYPE: '*type name*'
 Hint: A delimiter and a terminator cannot have the same name. You may need to add sub-types to the type name used in error and replace both the delimiter and terminator names to refer to the new sub-types.
- L157
DELIMITER '*type name*' is sub-type of terminator - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both a delimiter and a terminator. You can add another sub-type to the syntax item and replace the terminator name with the new sub-type name.
- L158
DELIMITER '*type name*' is super-type of terminator - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both a delimiter and a terminator. You can add another sub-type to the syntax item and replace the delimiter name with the new sub-type name.
- L159
DELIMITER '*type name*' is same type as release character - TYPE: '*type name*'
 Hint: A delimiter and a release character cannot have the same name. You may need to add sub-types to the type name used in error and replace both the delimiter and release character names to refer to the new sub-types.
- L160
DELIMITER '*type name*' is sub-type of release character - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both a delimiter and a release character. You can add another sub-type to the syntax item and replace the release character name with the new sub-type name.
- L161
DELIMITER '*type name*' is super-type of release character - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both a delimiter and a release character. You can add another sub-type to the syntax item and replace the delimiter name with the new sub-type name.
- L162
DELIMITER '*type name*' is same type as Floating Component - TYPE: '*type name*'
 Hint: A delimiter and a floating component cannot have the same name. Try adding sub-types to the type name used in error and replace both the delimiter and floating component names to refer to the new sub-types.
- L163
DELIMITER '*type name*' is sub-type of Floating Component - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both a delimiter and a floating component. You can add another sub-type to the syntax item and replace the floating component name with the new sub-type name.
- L164
DELIMITER '*type name*' is super-type of Floating Component - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both a delimiter and a floating component. You can add another sub-type to the syntax item and replace the delimiter name with the new sub-type name.
- L165
INITIATOR '*type name*' is same type as terminator - TYPE: '*type name*'
 Hint: An initiator and a terminator cannot have the same name. You may need to add sub-types to the type name used in error and replace both the initiator and terminator names to refer to the new sub-types.
- L166
INITIATOR '*type name*' is sub-type of terminator - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both an initiator and a terminator. You can add another sub-type to the syntax item and replace the terminator name with the new sub-type name.
- L167
INITIATOR '*type name*' is super-type of terminator - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both an initiator and a terminator. You can add another sub-type to the syntax item and replace the initiator name with the new sub-type name.
- L168
INITIATOR '*type name*' is same type as release character - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both an initiator and a release character. You can add sub-types to the syntax item and replace both the initiator name and the release character name with a new sub-type name.
- L169
INITIATOR '*type name*' is sub-type of release character - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both an initiator and a release character. You can add another sub-type to the syntax item and replace the release character name with the new sub-type name.

- L170 INITIATOR '*type name*' is super-type of release character - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both an initiator and a release character. You can add another sub-type to the syntax item and replace the initiator name with the new sub-type name.
- L171 INITIATOR '*type name*' is same type as Floating Component - TYPE: '*type name*'
 Hint: An initiator and a floating component cannot have the same name. Try adding sub-types to the type name used in error and replace both the initiator and floating component names with the new sub-types.
- L172 INITIATOR '*type name*' is sub-type of Floating Component - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both an initiator and a floating component. You can add another sub-type to the syntax item and replace the floating component name with the new sub-type name.
- L173 INITIATOR '*type name*' is super-type of Floating Component - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both an initiator and a floating component. You can add another sub-type to the syntax item and replace the initiator name with the new sub-type name.
- L174 TERMINATOR '*type name*' is same type as release character - TYPE: '*type name*'
 Hint: A terminator and a release character cannot have the same name. You may need to add sub-types to the type name used in error and replace both the terminator and release character names with the new sub-types.
- L175 TERMINATOR '*type name*' is sub-type of release character - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both a terminator and a release character. You can add another sub-type to the syntax item and replace the release character name with the new sub-type name.
- L176 TERMINATOR '*type name*' is super-type of release character - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both a terminator and a release character. You can add another sub-type to the syntax item and replace the terminator name with the new sub-type name.
- L177 TERMINATOR '*type name*' is same type as Floating Component - TYPE: '*type name*'
 Hint: A terminator and a floating component cannot have the same name. You may need to add sub-types to the type name used in error and replace both the terminator and floating component names with the new sub-types.
- L178 TERMINATOR '*type name*' is sub-type of Floating Component - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both a terminator and a floating component. You can add another sub-type to the syntax item and replace the floating component name with the new sub-type name.
- L179 TERMINATOR '*type name*' is super-type of Floating Component - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both a terminator and a floating component. You can add another sub-type to the syntax item and replace the terminator name with the new sub-type name.
- L180 RELEASE CHARACTER '*type name*' is same type as Floating Component - TYPE: '*type name*'
 Hint: A release character and a floating component cannot have the same name. You may need to add sub-types to the type name used in error and replace both the release character and floating component names to refer to the new sub-types.
- L181 RELEASE CHARACTER '*type name*' is sub-type of Floating Component - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both a release character and a floating component. You can add another sub-type to the syntax item and replace the floating component name with the new sub-type name.
- L182 RELEASE CHARACTER '*type name*' is super-type of Floating Component - TYPE: '*type name*'
 Hint: This occurs when a syntax item is used to specify both a release character and a floating component. You can add another sub-type to the syntax item and replace the release character name with the new sub-type name.
- L183 COMPONENT NAME ambiguous: '*type name*' in TYPE: '*type name*'
 Hint: This type has a component whose relative name can be associated with more than one type in the type tree. Rename the conflicting types.
- L184 RESTRICTION longer than max TYPE size - RESTRICTION # of TYPE: '*type name*'
 Hint: The Type in error is an item. Either change the maximum size of the item or remove the restriction.
- L185 RESTRICTION used in an earlier partition - RESTRICTION # of TYPE: '*type name*'
 Hint: Item Partitions must have mutually exclusive restrictions. Remove the restriction from one of the partition restriction lists.
- L186 Type of COMPONENT does not exist - '*type name*' in TYPE: '*type name*'
 Hint: You probably entered an incorrect type name. Try the drag and drop approach to get the correct one.
- L187 TYPE must be partitioned (since in a partitioned tree and has sub-types) - TYPE: '*type name*'
 Hint: All types in a partitioned sub-type must have mutually exclusive data objects. Set the partitioned property for the type in error.

- L188
TYPE is FIXED, COMPONENT # must have a maximum range value - TYPE *type name*
- L189
TYPE is FIXED, but COMPONENT # is not fixed - TYPE: `*type name*'
Hint: If the component is not intended to be fixed in size, change the group format for the Type to implicit. If the group format is intended to be fixed, check the component: if that component is an item, make sure it has a Padded To length; if that component is a group, change its type to be of fixed syntax.
- L190
BINARY text ITEM used as COMPONENT neither FIXED nor SIZED - COMPONENT # of TYPE: `*type name*'
Hint: The size of a binary text item must either have a Padded To length or it must be sized by the previous component.
- L191
COMPONENT with SIZED attribute is not an UNSIGNED INTEGER ITEM TYPE - COMPONENT # of TYPE: `*type name*'
Hint: A component used to size the component that follows it must be defined as an unsigned integer item type.
- L192
The last COMPONENT in the COMPONENT LIST may not have a SIZED attribute: TYPE: `*type name*'
Hint: Specify a component to follow the one with the sized attribute.
- L193
Range of COMPONENT # must have a maximum value to indicate how many placeholders are needed for its series in TYPE: `*type name*'.
Hint: Change the range maximum to a specific value (not "s") if you may re-define the data this way.
- L194
Cannot distinguish delimiter from terminator in TYPE: `*type name*'.
Hint: Make the range of the last component in the type fixed or make the delimiter of the type different from its terminator.
- L195
Cannot distinguish delimiter contained in COMPONENT # from terminator of TYPE: `*type name*'.
Hint: Make that component bound or make that contained delimiter different from the type terminator.
- L196
Cannot distinguish delimiter of COMPONENT # from delimiter of TYPE: *type name* because COMPONENT # has no placeholder.
Hint: Make that component bound or make that component's delimiter different from the type delimiter.
- L197
Cannot distinguish delimiter of COMPONENT # from delimiter of TYPE: *type name* because COMPONENT # has no range maximum.
Hint: Make that component bound, or make that component's delimiter different from the type delimiter, or specify a range maximum that has a specific value (not "s") for the last component of COMPONENT #.
- L198
Cannot distinguish delimiter contained in COMPONENT # from delimiter of TYPE: `*type name*'.
Hint: Make that contained component bound or make that contained component's delimiter different from the type delimiter.
- L200
Cannot distinguish delimiter contained in COMPONENT # from delimiter of TYPE: `*type name*'.
Hint: Either make that contained component bound, make that contained component's delimiter different from the type delimiter, or specify a range maximum that has a specific value (not "s") for the last component of the contained component.

Logic error and warning messages

The tables in this section list the logic warning messages that result from a logic analysis of a type tree.

The following table lists the warnings than can result when a map is compiled.

Warnings should be resolved because they may produce unpredictable results at mapping time.

Return Code

Message

- L199
COMPONENT # is not distinguishable from COMPONENT # that may follow in TYPE: `*type name*'.
Hint: Make the first COMPONENT bound, or look at the tables in "[Distinguishable objects](#)" to see how you can define the two component types as distinguishable.
- L201
Different data objects of COMPONENT # are not distinguishable in TYPE: `*type name*'.
Hint: See "[Distinguishable objects](#)" for more information about distinguishable objects.
- L202
RESTRICTION list deleted: TYPE is not an ITEM - TYPE: `*type name*'
Hint: Type class was changed from an item to a group or category, so the restriction list was deleted. If this was not your intent, change it back to the way it was.
- L203
COMPONENT list deleted: TYPE is an ITEM - TYPE: `*type name*'
Hint: Type class was changed from a group to a item or category, so the program deleted its component list. If this was not your intent, change it back to the way it was.
- L204
DELIMITER deleted: TYPE is not a DELIMITED GROUP - TYPE: `*type name*'
Hint: Group format was changed from delimited to something else, so the program deleted its delimiter. If this was not your intent, change it back to the way it was.
- L205

COMPONENT RULE deleted: TYPE is a CATEGORY - TYPE: 'type name' (warning)
Hint: Type class was changed from a group to a category, so its component rule was deleted. If this was not your intent, change it back to the way it was.

L206

DELIMITER cannot be found (because first component is not required) - TYPE: 'type name' (warning)
Hint: If the delimiter is missing, a previously set initiator value or the default value is used.

L251

COMPONENT NAME could apply to more than one type:'type name' in TYPE: 'type name' (warning).

Type tree analysis structure error messages

The following table lists the structure error messages that result from a structural analysis of a type tree:

Return Code	Message
S100	Invalid TYPE Name: SubTYPE # of TYPE: 'type name'
S101	Invalid TYPE chain: SubTYPE # of TYPE: 'type name'
S118	Invalid TYPE NAME WhereUsed chain - TYPE NAME: 'type name' (error).
S133	Referenced COMPONENT not 'InUse' - COMPONENT # of TYPE: 'type name' (error).
S134	COMPONENT previously referenced - COMPONENT # (COMP #) of TYPE: 'type name' (error).
S149	Bad Parent COMPONENT Index - COMPONENT 'type name' - TYPE: 'type name' (error)

Type tree analysis structure warning messages

The following table lists the structure warning messages that result from a structural analysis of a type tree:

Return Code	Message
S102	Unused DELIMITER deleted: 'type name' (at index #)
S103	Invalid DELIMITER pointer deleted - TYPE: 'type name'
S104	Invalid default DELIMITER pointer deleted - TYPE: 'type name'
S105	Invalid RELEASE Char pointer deleted - TYPE: 'type name'
S106	Invalid default RELEASE Char pointer deleted - TYPE: 'type name'
S107	Invalid INITIATOR pointer deleted - TYPE: 'type name'
S108	Invalid default INITIATOR pointer deleted - TYPE: 'type name'
S109	Invalid TERMINATOR pointer deleted - TYPE: 'type name'
S110	Invalid default TERMINATOR pointer deleted - TYPE: 'type name'
S111	Resetting DELIMITER Use Count (was # now #) - DELIMITER: 'type name'
S112	Unused DESCRIPTION deleted: 'type name' (at index #)
S113	Invalid DESCRIPTION pointer deleted - TYPE: 'type name'
S114	Resetting DESCRIPTION Use Count (was # now #) - DESCRIPTION: 'type name'
S115	Invalid Floating Component TYPE pointer deleted - TYPE: 'type name'
S116	Invalid TYPE UsedInComp chain repaired - TYPE: 'type name'
S117	Unused TYPE NAME deleted - TYPE NAME: 'type name' (at index #)
S119	Resetting TYPE NAME use count (was # now #) - TYPE NAME: 'type name'
S120	Repaired empty TYPE NAME WhereUsed chain - TYPE NAME: 'type name'
S121	Unused RESTRICTION NAME deleted: 'type name' (at index #)
S122	Invalid RESTRICTION NAME deleted no DESCRIPTION was available - TYPE: 'type name' .

```

S123    Invalid RESTRICTION NAME deleted DESCRIPTION was `type name' - TYPE: `type name'
S124    Resetting RESTRICTION NAME Use Count (was # now #) - RESTRICTIONS: `type name'
S125    Unused RESTRICTION DESCRIPTION deleted: `type name' (at index #)
S126    Invalid RESTRICTION DESCRIPTION deleted - TYPE: `type name'
S127    Resetting RESTRICTION DESCRIPTION Use Count (was # now #) - RESTRICTIONS: `type name'
S128    Unused RULE deleted: `type name' (at index #)
S129    Invalid RULE pointer deleted - COMPONENT # of TYPE: `type name'
S130    Resetting RULE Use Count (was # now #) - RULE: `type name'
S131    Invalid COMPONENT TYPE Description pointer - COMPONENT #
S132    COMPONENT marked `InUse' found in Free Chain- COMPONENT #
S135    COMPONENT in Free Chain referenced by a TYPE - COMPONENT #
S136    COMPONENT recovered and added to Free Chain - COMPONENT #
S137    TYPE in Free Chain referenced by another TYPE - TYPE #
S138    TYPE recovered and added to Free Chain - TYPE X'%04X'
S139    TYPE marked `InUse' but not referenced - TYPE #
S140    Referenced TYPE not marked `InUse' - TYPE #
S141    TYPE Free Chain not in order: sorting
S142    COMPONENT Free Chain not in order: sorting
S143    Overlap found in LIST Free Chain
S144    Free Chain extends into unallocated region
S145    Overlap found in COMPONENT LIST SPACE: list cleared COMPONENTS will be deleted
S146    Invalid COMPONENT LIST pointer: all COMPONENTS DELETED - TYPE: `type name'
S147    Resetting COUNT in COMPONENT LIST: some COMPONENTS may be lost
S148    RULE truncated (due to internal error): `type name' (at index #)
S150    CATEGORY `type name' was missing GROUP and/or ITEM attributes
S151    GROUP `type name' was missing GROUP attributes
S152    ITEM `type name' was missing ITEM attributes

```

Type Tree Importer

Introduction to the Importer Wizard

Use the Importer Wizard to convert metadata into type tree script (.mts) files. The Importer Wizard can import various data formats to create type trees (.mtt).

The Importer Wizard uses a series of maps to convert metadata into a type tree script file (.mts). The Type Tree Maker then processes this type tree script and generates a type tree that contains all the supported types that are defined in the imported metadata.

Many of the type trees that are generated by the Importer Wizard can be immediately used for map development. However, depending on the contents of the interface-specific metadata file, it might be necessary for the generated type tree to be modified using the Type Designer.

You cannot simultaneously have a type tree open in the Type Designer while importing a type tree with the same name.

- [Accessing the Importer Wizard](#)
- [CORBA IDL Importer](#)
- [Java Class Importer](#)
- [Java Message Service \(JMS\) Importer](#)

- [Text File Importer](#)
 - [Type Library Importer](#)
 - [Type Tree Maker Importer](#)
-

List of importers

The following is a list of importers available in the Importer Wizard:

- COBOL Copybook (deprecated)
- COBOL Copybook
- CORBA IDL
- Java Class
- Java Message Service (JMS)
- JavaScript Object Notation (JSON)
- PL/I
- Text File
- Type Library
- Type Tree Maker
- WSDL
- XML DTD
- XML Schema

Note: Some importers, such as application-specific importers, are add-on components.

Application-specific importers

Additional application-specific importers are available.

For information about using an application-specific importer, see the documentation installed with the particular application pack for IBM Sterling Transformation Extender.

Configuring JVM options from the dtx.ini file

About this task

Importers convert metadata from external sources into the type trees at design time. Most importers have an associated Wizard in the Type Designer.

Importers with the Java native interfaces use the JVM options specified in the **dtx.ini** file to create Java virtual machine (JVM). You can use the JVM options to tune the importer's behavior, such as setting up big initial or maximum heap size.

The following have Java native interfaces:

- CORBA IDL Importer
- Java Class Importer
- JMS Importer
- PL/I Importer
- WSDL Importer
- XML DTD Importer
- XML Schema Importer

The following JVM options can be modified in the **dtx.ini** file to fit your specifications:

- JVM Options
 - JNI Layer Trace
 - [JVM options](#)
 - [JNI layer trace](#)
 - [Configuring JVM options example](#)
-

JVM options

Lists additional options passed to the JVM at initialization time. The syntax of the individual entry is:

Option

Description

optionN

=<single JVM option with its arguments>

Where **N** is an integer number between 1 and 128. If the same entry appears more than once the first occurrence is taken.

JNI layer trace

The Java Native Interface (JNI) layer trace provides trace and debugging information about how IBM Sterling Transformation Extender interacts with the Java Virtual Machine (JVM). Use the JNI layer trace to collect details about a Java adapter problem that are not recorded in the Java-based adapter trace file. For example, if an exception is not recorded by a IBM Sterling Transformation Extender Java-based adapter or command (such as JMS, Java Class, SOAP, JExit), the JNI trace file records the error. If the Java adapter does not load at all, the JNI layer trace file records details about the failure.

When IBM Sterling Transformation Extender creates the JVM with the -verbose option (specified in the **[JVM Options]** section of the dtx.ini file), the JNI layer trace file includes the details about the JVM garbage collection, class loading, and JNI invocation calls.

The JNI layer trace can produce a large amount of information and impact performance. Avoid using the JNI layer trace in a production system, unless you enable it for a limited time and then disable it.

You can define the following options:

Option	Description														
Switch	Master switch. Valid values are on and off. If off, the rest of the options are ignored.														
File	Specifies the full path of the file that receives the tracing information. IBM Sterling Transformation Extender automatically appends the process ID (<i>PID</i>) of the Launcher system or IBM Sterling Transformation ExtenderIBM Integration Bus execution group to the end of the file name. This behavior is the default. As an example, you want IBM Sterling Transformation Extender to write the trace information to the jni.log file in the /apps/wtx84/logs path location. You specify the File option as file=/apps/wtx84/logs/jni.log . IBM Sterling Transformation Extender automatically appends the <i>PID</i> to the end of the file name and writes the trace information to /apps/wtx84/logs/jni.log_pid .														
pid	Turns off the functionality that automatically appends the process ID (<i>PID</i>) to the end of the file name. Add the following entry: pid=off . See the description for the File option.														
Level	Controls the amount of information recorded by the JNI trace. A higher trace level includes the trace information of all the numerically lower levels. For example, trace level 100 includes the information of all trace levels lower than 100. <table border="1"><thead><tr><th>Level</th><th>Description</th></tr></thead><tbody><tr><td>10</td><td>Critical information that tracks execution details of the IBM Sterling Transformation Extender JNI layer</td></tr><tr><td>20</td><td>Errors that surface from the JNI layer as a result of IBM Sterling Transformation Extender JNI calls</td></tr><tr><td>30</td><td>Warning information about the timing and sequence of IBM Sterling Transformation Extender JNI calls. Configuring JVM options example

The following is an example from the **dtx.ini** file:

```
...
[External Jar File]
jar1=c:\MyApp\libs\myapp.jar
jar2=c:\MyApp\classes
[JVM Options]
option1=-Xms200m
option2=-Xmx300m
[JNI Layer Trace]
switch=on
file=c:\dtxjpi.log
...
```

Accessing the Importer Wizard

About this task

The following procedure describes how to access the Importer Wizard.

To access the Importer Wizard:

Procedure

1. Open the Design Studio application.
2. Navigate to the Importer Wizard through either one of the following ways:
Click **File > Import**.
In the Extender Navigator view or Navigator view, right-click the location in a project in which you want to create the new type tree, and select **Import > Import**. The Import window opens.

3. Expand the Transformation Extender folder, select one of the available importers from the import source list, and click Next. Follow the Importer Wizard instructions.

CORBA IDL Importer

The CORBA Interface Definition Language (IDL) Importer is used to generate a type tree representation of an IDL file.

See the *CORBA Adapter* documentation for information about the CORBA IDL Importer.

Java Class Importer

The Java Class Importer allows the user to create a type tree that can be used to manipulate Java objects from within a map using the Java Class Adapter.

See the *Java Class Adapter* documentation for information about the Java Class Importer.

Java Message Service (JMS) Importer

The JMS Importer creates type trees that represent the public fields and constructors of Java classes that are sent as objects using JMS messages.

See the *Java Message Service Adapter* documentation for information about the JMS Importer.

Text File Importer

The Text File Importer automatically generates type trees that describe the format of the data in text files.

See the *Resource Adapters Introduction* for information about the Text File Importer.

Type Library Importer

The Type Library Importer reads the format of COM Components and Methods to automatically generate type trees for use with the COM Automation Adapter.

See the *COM Automation Adapter* documentation for information about the Type Library Importer.

Type Tree Maker Importer

The Type Tree Maker Importer is a facility for automatically generating type trees from a script containing Type Tree Maker commands (.mts file extension).

See the *Type Tree Maker* documentation for detailed information about the Type Tree Maker.

COBOL Copybook (Deprecated) Importer

The COBOL Copybook Importer imports the definition of one or more COBOL copybooks in a file and generates a type tree that contains the corresponding type definitions. The copybook file might contain more than one COBOL copybook. If your file contains multiple COBOL Copybook definitions, all definitions are contained in a single type tree.

The importer uses a series of maps to convert the copybook format into a type tree script file (.mts). The Type Tree Maker then does the following actions: processes this type tree script and generates a type tree that contains all of the supported types that are defined in the copybook.

Running the COBOL Copybook (Deprecated) Importer

About this task

Use the COBOL Copybook (Deprecated) Importer to automatically generate COBOL Copybook type trees.

The metadata for the type trees is in the form of COBOL copybooks.

If you are running the COBOL Copybook (Deprecated) Importer to generate a type tree that is used with the CICS Adapter, you must select the [Customer Information Control System \(CICS\) option](#). The option is in the window where you select byte and character sets.

The following procedure describes how to use the COBOL Copybook (Deprecated) Importer Wizard to generate a type tree from COBOL copybooks.

There is an example of a COBOL Copybook file in the *install_dir\examples\general\copybook* folder.

To run the COBOL Copybook (Deprecated) Importer:

Procedure

1. Access the Importer Wizard in the Design Studio application.
2. In the Import window, expand the Transformation Extender folder, select COBOL Copybook (Deprecated) from the import source list, and click Next. The COBOL Copybook Importer window opens.
3. Enter or select the name of the metadata source file that you want to import, following the Importer Wizard instructions, and then click Next. The metadata source files have a default file extension of .cpy.
4. If you are importing metadata to generate a COBOL Copybook type tree, select a character set from the Character set for execution-time data list, and a byte order that is set from the Byte order for execution-time data list. The Generate tree for Customer Information Control System check box is disabled.
5. To generate a type tree that is used with the CICS Adapter, select the Generate tree for Customer Information Control System check box. The Character set for execution-time data list and the Byte order for execution-time data list are disabled.

The importer operation generates the type tree with the following parameters:

- Character data set is **EBCDIC**
 - Byte order is **Big Endian**
 - Standard header information is added to the type tree
6. Click Next.
 7. Enter or select the parent folder of the generated type tree.
 8. For File name, do one of the following choices:
 - To create a type tree file, enter a new name.
 - To overwrite an existing type tree file, enter its name if it does not already display in the field.The default name for the type tree is the COBOL Copybook file name with the .mtt extension.

9. To generate the type tree, click Next.

If you selected a file name for an existing type tree file, you are prompted to continue or stop the import operation in the Overwrite Warning window.

After the import operation runs, it displays the run results in the COBOL Copybook Importer window. If errors or warnings, or both, occur, they display in that same window. The errors and warnings are also saved to error and log files in the product installation directory. The file names are Cpybkimp.err and cobol.log. You can open these files and analyze them in a text editor after the import operation completes. The import operation deletes and regenerates these log files every time a new COBOL Copybook is imported. If errors occur, the import operation cannot generate the type tree until you resolve the problem. If only warnings occur, the import operation can still generate the type tree. However, to ensure that the reported warnings do not interfere with the requirements necessary for a valid instance document, inspect the generated type tree.

10. After the type tree generation process is complete, click Finish.

If the type tree was generated, you are given the option to open the type tree in the Type Tree editor. The Properties view for the generated type tree contains the imported data format for the generated type tree. You can also click the type tree in the Extender Navigator view or the Navigator view to view the date and time that the import operation generated the type tree, under the Info property in the Properties view.

Wrapped and unwrapped copybook format

The COBOL Copybook Importer automatically processes copybook files in wrapped and unwrapped formats.

There is an example of a COBOL Copybook file in the *install_dir\examples\general\copybook* folder.

- [Wrapped format](#)
 - [Unwrapped format](#)
-

Wrapped format

A wrapped copybook file has COBOL source records that are terminated by either a carriage return/line feed (Hex 0D 0A) or line feed (Hex 0A). Each source record can be fixed or variable length. The important distinguishing characteristic of a wrapped copybook file format is the terminator (newline or carriage return/linefeed) at the end of each source record.

Ensure that the last statement ends with a carriage return/line feed or line feed as appropriate.

Unwrapped format

An unwrapped copybook file has fixed 80-byte source records with no line feed or carriage return/line feed at the end of each source record.

Copybook specifications

The COBOL Copybook Importer uses as input a copybook file (.cpy) containing data description entries, as defined by the ANSI X3.23 specification with the following exception and additions:

- Each entry must have either a data-name or the reserved FILLER clause. (This is an exception to the ANSI X3.23 specification.)
- The COBOL Copybook Importer also supports these USAGE clauses:
 - COMPUTATIONAL-3
 - COMPUTATIONAL-4
 - COMPUTATIONAL-5
 - COMPUTATIONAL-X
 - COMP-3
 - COMP-4
 - COMP-5
 - COMP-X

Trees that are generated by the COBOL Copybook Importer can be used immediately for map development. However, depending on the contents of the copybook file, it might be necessary for the generated type tree to be modified using the Type Designer.

Troubleshooting

This section discusses modifications that you can make before processing a copybook file to accomplish successful type tree generation by the Importer Wizard. It also provides information about the restrictions and limitations under which the Importer Wizard for COBOL Copybook metadata files generates type trees so that, after processing, you can accurately modify the generated type tree.

Modifying a copybook file

If the copybook file does not conform to what the COBOL Copybook Importer Wizard expects, a type tree is not successfully generated. Before importing the copybook file, you might want to:

- Check that the level number statements (for example, 01, 05, 10) in your copybook do not start before Column 8.
- Check for statements not supported by the COBOL Copybook Importer. The importer does not expand any embedded COPY clauses. Add the data included in the embedded COPY clauses before you run the COBOL Copybook Importer.

Note: If you do not modify the copybook file before running the COBOL Copybook Importer wizard, use the Type Designer to manually modify the generated type tree. See the section "[COBOL Features Not Supported](#)" for information.

Modifying a generated type tree

The COBOL Copybook Importer automatically generates type trees from COBOL copybooks that describe the format of data. However, a copybook might contain certain statements or have insufficient information that result in type trees being generated that require some manual modification. Use the Type Designer to modify any type tree that is generated by the COBOL Copybook Importer so that the types contained in the tree accurately represent your data. The situations that might require type tree modifications are:

- The copybook contains REDEFINES clause(s).
- The copybook contains VALUES THROUGH or VALUES THRU clause(s).
- The copybook contains statements that are not supported by the wizard.
- The Byte-Storage Mode is used.

REDEFINES clause

If a copybook contains a REDEFINES clause, the COBOL Copybook Importer adds a group subtype for the REDEFINES object. However, a copybook does not contain sufficient information for the COBOL Copybook Importer to determine how the redefined type is used.

For example, REDEFINES might be used to overlay different **Record** subtypes. In this case, you might want to:

- Copy the **Record** subtype as another subtype.
- Modify the new subtype to use the appropriate **REDEFINES** objects.
- Partition **Record** and specify the component rule that distinguished **Record** subtypes.
- Add a **File** type and specify the pattern of **Record** subtypes as components of **File**.

COBOL Occurs Depending On

COBOL provides support for a variable-length table data structure whose length is determined by the Occurs Depending On (ODO) clause and the data element that it identifies. A variable-length table provides support for a table structure that contains a number of rows that are not defined at design time; for example, an account table, which contains a varying number of accounts.

- [COBOL Occurs Depending On component rules](#)

COBOL Occurs Depending On component rules

When you use the COBOL Copybook Importer to import a COBOL copybook that includes an ODO clause, the ODO restriction is not automatically imported into the type tree. If you need to impose the rules necessary to enforce the ODO in the type tree, you need to make changes to the type tree after it has been imported.

The ODO restrictions are most commonly implemented in a IBM Sterling Transformation Extender type tree as component rules. To implement an ODO restriction as a component rule, put the component rule on the component that is identified with the ODO clause, used to determine the length of the variable-length table. The component rule references the previously defined component, identified by the ODO clause, which limits the number of occurrences of the current component.

- [When component is numeric](#)
- [When component is not numeric](#)

When component is numeric

If the component that is limiting the number of occurrences is numeric, create a component rule on the component that is identified with the ODO clause as described in this topic.

The following example represents two lines from a COBOL copybook:

```
05 ORDREV_OUT_NUM_ACCTS PIC 9(04).
05 ORDREV_OUT_ACCOUNT_INFO OCCURS 0 TO 1000 TIMES
  DEPENDING ON ORDREV_OUT_NUM_ACCTS.
```

Add the following type tree component rule to the construct representing `ORDREV_OUT_ACCOUNT_INFO`:

```
ORDREV_OUT_ACCOUNT_INFO
RULE: COUNT($) <= ORDREV_OUT_NUM_ACCTS Field
```

When IBM Sterling Transformation Extender parses the data at run time, the `ORDREV_OUT_NUM_ACCTS` data field contains a numeric value. For this example, assume that at run time, the value of `ORDREV_OUT_NUM_ACCTS` is 50. That value will be used in the component rule: `COUNT($) <= ORDREV_OUT_NUM_ACCTS Field`, so `COUNT($) <= 50`.

When this rule is run, the first 50 occurrences of `ORDREV_OUT_ACCOUNT_INFO` are processed. IBM Sterling Transformation Extender determines any data that follows the data consumed as the 50 occurrences, to be the successive construct in the copybook.

When component is not numeric

If the component that is limiting the number of occurrences, such as `ORDREV_OUT_NUM_ACCTS` in the previous example, is not numeric, then you might need to specify some additional component rule functions.

The following example specifies `ORDREV_OUT_NUM_ACCTS` as text, not numeric.

```
05 ORDREV_OUT_NUM_ACCTS PIC X(04).
05 ORDREV_OUT_ACCOUNT_INFO OCCURS 0 TO 1000 TIMES
  DEPENDING ON ORDREV_OUT_NUM_ACCTS.
```

You need to specify a rule that converts the text item to a number as in the following example:

```
ORDREV_OUT_ACCOUNT_INFO
RULE: COUNT($) <=
  TEXTT tonumber(ORDREV_OUT_NUM_ACCTS Field)
```

COBOL features not supported

The COBOL Copybook Importer does not handle certain COBOL features that might be in the definition file. If an unsupported statement is encountered, a warning message appears. Types for the following COBOL statements must be added manually to the type tree that is generated by the Importer.

- The COBOL Copybook Importer does not support the THROUGH option in the VALUES clause. The range of values must be added manually to the restriction list for the level 88 item or items that use the THROUGH clause. Alternatively, a component rule could be placed on the item where it is used. For example, the following item defined in the copybook could have a component rule specified as: \$ >= "A" & \$ <= "F":

```
15 CODE-ID PIC X(1).  
     88 OTM-TRD-GSP VALUE `A' THROUGH `F'.  

```

If you are not concerned with validating codes or values, or both, in your input data that conforms to the copybook definition for a particular item, delete the entire restriction list generated by the COBOL Copybook Importer.

- The COBOL Copybook Importer does not expand any embedded COPY clauses. The data included in the embedded COPY clauses must be manually added to the type tree or added to the copybook before you run the wizard.
- The COBOL Copybook Importer does not support the SYNCHRONIZED clause.

Bytes assigned for COMP data

The COBOL Copybook Importer calculates COMP's item space using the Word-Storage Mode. Therefore, if you use the Byte-Storage Mode, you will have to manually change the type tree definitions in the type tree that is generated.

For example, if your data is **PIC 9(5)**, the item in the generated type tree is assigned four bytes.

The following table shows how many bytes are required for each mode:

Digits (9s) Signed	Digits (9s) Unsigned	Bytes Assigned by Importer (Required for Word-Storage Mode)	Bytes Required for Byte-Storage Mode
1-2	1-2	2	1
3-4	3-4	2	2
5-6	5-7	4	3
7-9	8-9	4	4
10-11	10-12	8	5
12-14	13-14	8	6
15-16	15-16	8	7
17-18	17-18	8	8

Bytes assigned for COMP-3 data

If your COBOL data is a PIC clause that is COMP-3, the number of bytes the COBOL Copybook Importer assigns to the item created in the type tree is shown in the following table:

Number of Digits in PIC (With or Without a Sign)	Number of Bytes Assigned to Item
1	1
2-3	2
4-5	3
6-7	4
8-9	5
10-11	6
12-13	7
14-15	8
16-17	9
18	10

For example, if your COBOL data is PIC S999 COMP-3, the Importer Wizard creates an item that is a 2-byte byte stream. If it is PIC S99V9, the item created in the type tree is also a 2-byte Byte Stream. If it is S99V999, the item created in the tree is a 3-byte Byte Stream.

COBOL Copybook Importer

The COBOL Copybook Importer imports the definition of one or more COBOL copybooks in a file and generates a type tree that contains the corresponding type definitions. The copybook file might contain more than one COBOL copybook definition. If your file contains multiple COBOL Copybook definitions, you can import the definitions into a single type tree in the following ways:

- Import a selected subset of the definitions.
- Import all of the definitions.
- Import definitions from different COBOL Copybook files.

- [Running the COBOL Copybook Importer](#)
Use the COBOL Copybook Importer to automatically generate COBOL Copybook type trees.

 - [COBOL and type tree mapping](#)
-

Running the COBOL Copybook Importer

Use the COBOL Copybook Importer to automatically generate COBOL Copybook type trees.

About this task

The metadata for the type trees is in the form of COBOL copybooks.

If you are running the COBOL Copybook Importer to generate a type tree that is used with the CICS Adapter, you must select the Customer Information Control System (CICS) option. The option is in the Output File Location window.

The following procedure describes how to use the COBOL Copybook Importer Wizard to generate a type tree from COBOL copybooks. You specify the data in the COBOL Copybook Sources page, and the options and data structures in the Importer Options and Structure Selection page.

There is an example of a COBOL Copybook file in the *install_dir\examples\general\copybook* folder.

To run the COBOL Copybook Importer:

Procedure

1. Access the Importer Wizard in the Design Studio application.
2. In the Import window, expand the Transformation Extender folder, select COBOL Copybook from the import source list, and click Next. The Type Tree Importer window opens.
3. If you are importing a single COBOL structure to generate a type tree, do the following steps:
 - a. In the COBOL Copybook Sources page, make sure that the Choose mapping field is set to Single COBOL Copybook to type tree. This selection is the default setting. If it is not selected, you can select Single COBOL Copybook to type tree from the Choose mapping list.
 - b. Enter or select the name of the COBOL program or COBOL Copybook metadata source file that you want to import, in the COBOL file field.
The COBOL Copybook Importer supports COBOL files with the following extensions: .cbl, .ccp, .cob, and .cpy. You can configure the type of support for each COBOL file extension, under Window > Preferences > Importer > COBOL > More COBOL options > File Extension Support. You can select to import the COBOL Copybook from a full program or from a data structure only. The metadata source files have a default file extension of .cpy.
 - c. Click Next. The Importer Options and Structure Selection page opens.
 - d. Follow the Importer Wizard instructions to select a communication data structure.
4. If you are importing multiple COBOL structures to generate a single type tree, do the following steps:
 - a. In the COBOL Copybook Sources page, select Multiple COBOL Copybooks to type tree from the Choose mapping list.
 - b. Click Add, and then enter or select the name of the COBOL Copybook metadata source file that you want to import, in the COBOL file field.
 - c. Click Next. The Importer Options and Structure Selection page opens.
 - d. Follow the Importer Wizard instructions to select a communication data structure and then click Finish. The selected data structure displays in the Multiple possible output list.
 - e. Repeat these steps as required. All of the selected data structures display in the Multiple possible output list.
5. Click Next. The Output File Location page opens.
6. Enter or select the Project, Folder, and File name.
7. To generate a type tree that is used with the CICS Adapter, select the Generate type tree for Customer Information Control System check box.
8. Click Finish.

If the type tree was generated, you are given the option to open the type tree in the Type Tree editor. The Properties view for the generated type tree contains the imported data format for the generated type tree. You can also click the type tree in the Extender Navigator view or the Navigator view to view the date and time that the import operation generated the type tree, under the Info property in the Properties view.

Related tasks

- [Accessing the Importer Wizard](#)
-

Selecting communication data structures

Communication data structures are used by the COBOL Copybook Importer to import metadata to generate the type tree structure.

After the importer wizard starts, you can make selections for the following items:

- Runtime options (Character set, Byte order)
- Compiler options (Quote, Trunc, Nsymbol)
- Source structures

The runtime options, Character set and Byte order, describe the runtime data. The character set code represents a standard collection of letters, numbers, and symbols. The byte order set code represents a convention a machine processor uses to position its lowest byte within a word. The processor positions the lowest byte beginning either from the leftmost or the rightmost position. The default setting for these properties is Native, which you can override. To override the default setting for character set, click Select and in the Select Value window, select a valid character set code from the Character set list. To override the default setting for byte order, select a valid byte order set code from the Byte order list.

Under Compiler options, Quote, Trunc, and Nsymbol describe the COBOL compiler options that affect how your COBOL program is processed to create data structures for import. You can define compiler options by configuring the options under the COBOL Preferences page before you run the COBOL Copybook Importer. After the importer wizard starts, you can override some of these compiler options under Compiler options. The default values for the Quote, Trunc, and Nsymbol compiler options are set in the following ways. Quote is set to **DOUBLE**. Trunc is set to **STD**. Nsymbol is set to **DBCS**. To override the default settings, select the values from the Quote, Trunc, and Nsymbol lists.

Under Source structures, are the structures that are found in the selected COBOL Copybook file. Select the top-level source data structures that you want to import into the type tree. If you chose to map a single COBOL copybook to a type tree, select one data structure. If you chose to map multiple COBOL copybooks to a type tree, you can select more than one data structure. After you made your selections, click **Apply**.

If you selected a file name for an existing type tree file, you are prompted to continue or stop the import operation in the Overwrite Warning window. If errors occur, the import operation cannot generate the type tree until you resolve the problem.

If the type tree was generated, you have the option to open the type tree in the Type Tree editor. The Properties view for the generated type tree contains the imported data format for the generated type tree. You can also click the type tree in the Extender Navigator view or the Navigator view to view the date and time that the import operation generated the type tree, under the Info property in the Properties view.

COBOL Copybook Importer compiler preferences

You can set the COBOL compiler preferences for an individual file import through the importer wizard. You can also change the default compiler options in the COBOL Preferences page.

To set the default COBOL compiler preferences, go to **Window > Preferences**. Expand the Importer option and select COBOL. Set the COBOL compiler preferences under the various tabs.

If you are importing COBOL copybooks that contain data types G for graphic, or N for national, be sure to set the locale correctly.

When you are importing data from these different file types, you can also select the correct file extension support option for each of the file types. These settings control how the importer operation processes the copybook and generates the type tree. Therefore, the settings must correctly reflect the contents of the copybook that is being imported.

Troubleshooting

When the COBOL Copybook Importer is unsuccessful in importing a COBOL copybook file, the wizard displays an error message with the details about the import operation.

Before you run the COBOL Copybook Importer, make sure that the COBOL copybook is syntactically correct. The COBOL Copybook Importer does a preprocessing compiling step before it begins the type tree generation step. This preprocessing step checks that the copybook is set up using correct COBOL syntax. If the COBOL copybook is not syntactically correct, the import operation stops running and displays an error message.

Make sure that the file extension support option is correctly selected in the COBOL Preferences page for the file type. The option must correctly reflect the contents of the copybook file. As an example, the default file extension support option in the COBOL Preferences page for the .cob file extension is Full program. A COBOL copybook file with the .cob extension must contain a complete COBOL program for the importer operation to successfully process it and generate the type tree.

If the data type is G for graphic, or N for national, be sure to set the locale correctly in the COBOL Preferences page. Otherwise, the import operation cannot generate the type tree and returns an error message.

Correct the problems in the COBOL copybook file that the importer detects, and reimport the file.

- [COBOL Copybook Importer error message types](#)
- [COBOL Copybook Importer log and trace files](#)

COBOL Copybook Importer error message types

The COBOL Copybook Importer produces various types of error messages when it is unsuccessful in importing a COBOL Copybook file into your project.

If the COBOL Copybook files are stored locally in part of the Eclipse workspace, the syntax error messages are listed in the Problems view. To view the source of the error in your code, double-click the error message line that is in the Problems view. To see the error markers, open the COBOL Copybook file that is in the workspace, with the workbench Text Editor. Errors are logged in a generic log file, which is located under the metadata directory in the workspace that you selected when you opened the Design Studio: [workspace]\.metadata\.

If the COBOL Copybook files are not stored locally in part of the workspace, the syntax error messages are logged in the log file.

COBOL Copybook Importer log and trace files

When the COBOL Copybook Importer runs, it writes information to log and trace files.

The log and trace files are created under the metadata directory in the workspace that you selected when you opened the Design Studio: [workspace]\.metadata\log. Use the logging and tracing information for debugging and troubleshooting purposes.

COBOL and type tree mapping

The COBOL Copybook Importer operation maps data names to type tree names.

The COBOL Copybook data names are converted to type tree names according to the following rules:

- Characters that are not valid in type tree element names are replaced with the underscore (_) character. For example, the invalid \$ character in monthly\$total is replaced with the underscore (_) character. Therefore, monthly\$total becomes monthly_total.
- Duplicate names are made unique by appending one or more numeric digits to the names. For example, there are two instances of year. You can make one of the instances year1 and leave the other instance as year.

The COBOL Copybook Importer maps COBOL Copybook data types to type tree elements according to the following table. The importer operation maps FILLER items by appending a number incrementally to the end of the name. Examples are FILLER1, FILLER2, FILLER3, and so on. COBOL Copybook types that are not shown in the table are not supported by the importer.

The following table lists COBOL Copybook data types and the corresponding properties in the resulting type tree.

COBOL Copybook data type	Type tree properties
String, length n Examples of PICTURE clauses for alphanumeric data: PIC X(n) PIC A(n)	<ul style="list-style-type: none"> Item Subclass \geq Text Interpret as \geq Character Size (content) \geq Max \geq Bytes = n Pad \geq Yes Padded to \geq Fixed Size Length = n Sized As \geq Bytes
External decimal, length n , virtual places m Example of a PICTURE clause for external decimal data: PIC 9(11)V99	<ul style="list-style-type: none"> Item Subclass \geq Number Interpret as \geq Character Presentation \geq Zoned Size (digits) \geq Max \geq Bytes = $n + m$ Sign \geq Yes or No Pad \geq Yes Padded to \geq Fixed Size Length = $n + m$ Places \geq Implied = $n + m$
Packed decimal, length n , virtual places m Examples of the USAGE clause for packed-decimal data: <ul style="list-style-type: none"> USAGE COMP-3 USAGE PACKED DECIMAL 	<ul style="list-style-type: none"> Item Subclass \geq Number Interpret as \geq Binary Presentation \geq Packed Length = n Implied = m Sign \geq Yes or No
Integer, length n For the actual sizes of binary and floating point decimals, see the <i>COBOL Language</i> reference on the IBM website, http://www.ibm.com . Note: The COBOL Copybook Importer is not supported on Linux®.

OpenAPI importer

The OpenAPI importer creates an IBM Sterling Transformation Extender type tree from an Open API JavaScript Object Notation (JSON) document. The importer also can generate a sample map or sample Launcher system that hosts the Open API endpoints.

OpenAPI is a standard, language-agnostic interface to REST APIs, which allows you to import an OpenAPI JSON document into a type tree. OpenAPI also allows you to host REST API as endpoints in an IBM Sterling Transformation Extender map for both input (GET) and output (PUT). OpenAPI supports the following actions:

- GET (retrieve one or more tree definitions)
- POST (create a new tree or edit tree fields)
- DELETE (delete the results of a tree or the tree definition)
- PUT (replace tree fields)

There are two ways to use the OpenAPI importer:

- Use an IBM Sterling Transformation Extender map to the REST API (for more information see [Mapping to a REST API with the OpenAPI importer](#))
- Use IBM Sterling Transformation Extender Launcher to host the REST API (for more information see [Hosting a REST API with the OpenAPI importer via the Launcher](#))
- **Mapping to a REST API with the OpenAPI importer**
The OpenAPI importer creates a type tree from an OpenAPI JSON document. Optionally, you can generate a sample map or sample Launcher system that hosts the API.
- **Hosting a REST API with the OpenAPI importer via the Launcher**
The OpenAPI importer creates a type tree from an OpenAPI JSON document. You can use the IBM Transformation Extender Launcher to host the API.

Mapping to a REST API with the OpenAPI importer

The OpenAPI importer creates a type tree from an OpenAPI JSON document. Optionally, you can generate a sample map or sample Launcher system that hosts the API.

Procedure

1. [Access](#) the Importer Wizard in Design Studio
2. In the Import window, expand the Transformation Extender folder, select OpenAPI from the import source list, and click Next.
3. Enter or select the name of the JSON file that you want to import, and click Next.
4. Choose a path from the list to display the operations that are included in the path.
5. Select the operation that you want to import to generate a type tree and adapter command line properties, and click Next.
6. Select Use a Transformation Extender map to call the REST API, and click Next.
7. Configure the API connection information and click Next.

Scheme

Select the security transfer protocol to use for the API connection

Host

Specify the hostname and port of the HTTP listener in the format *hostname:port*.

Base path

Type the base path on which the API is served, which is relative to the host. If it is not included, the API is served directly under the host. The base path value must start with a leading forward slash (/).

Produces

Select the MIME types that the API can produce. This selection is global to all API calls but can be overridden on specific API calls.

8. Specify the artifact that is generated.

Folder name

Specify the folder in which the artifact will be saved, or create a new folder.

Type tree name

Type a brief descriptive name for the tree. The format is *filename-operationId.mtt*.

Note: If you do not specify an *operationId*, the HTTP operation is used.

HTTP adapter command
Type the name of the file that contains the HTTP adapter command to run. The format is *filename-operationIdHttpCommand.txt*.
Note: If you do not specify an *operationId*, the HTTP operation is used.

Generate sample map source
Click to enable the generation of a sample source map. The default is clear, which indicates that a sample map is not generated.

Map source file
If you enabled Generate sample map source, type the name of the sample map file that is generated. The format is *filename-operationIdSampleMap.mms*.
Note: If you do not specify an *operationId*, the HTTP operation is used.
Tip: The sample map allows you view everything that was generated. You can edit this map so it suits your purposes. The sample map contains three cards:

- httpRequest**
The first card includes that data you want to send to the REST API.
- execute**
The second card invokes the HTTP adapter by using the HTTP command generated by the importer, and using the information on the httpRequest card as the payload.
- httpResponse**
The third card parses the HTTP response to produce output that you can validate against the type tree that you created..

Hosting a REST API with the OpenAPI importer via the Launcher

The OpenAPI importer creates a type tree from an OpenAPI JSON document. You can use the IBM Transformation Extender Launcher to host the API.

About this task

The type tree structure that is generated is very similar to the type tree that is created when you use a map to call the REST API. The difference is that for this type tree structure, there is no definition category to describe the JSON data. Instead, the JSON is expressed as a blob by using the *httpPayload* item.

Procedure

1. [Access](#) the Importer Wizard in Design Studio.
 2. In the Import window, expand the Transformation Extender folder, select OpenAPI from the import source list, and click Next.
 3. Enter or select the name of the JSON file that you want to import, and click Next.
 4. Choose a path from the list to display the operations that are included in the path.
 5. Select the operation that you want to import to generate a type tree and adapter command line properties, and click Next.
 6. Select Use Transformation Extender Launcher to host the REST API, and click Next.
 7. Configure the API connection information and click Next.
- Scheme**
Select the security transfer protocol to use for the API connection.
- Host**
Specify the hostname and port of the HTTP listener in the format *hostname:port*.
- Base path**
Type the base path on which the API is served, which is relative to the host. If it is not included, the API is served directly under the host. The base path value must start with a leading forward slash (/).
- Produces**
Select the MIME types that the API can produce. This selection is global to all API calls but can be overridden on specific API calls.
8. Specify the artifact that is generated.
- Folder name**
Specify the folder in which the artifact will be saved, or create a new folder.
- HTTP message type tree name**
Type a brief descriptive name for the message type tree. The format is *filename-operationId.mtt*.
Note: If you do not specify an *operationId*, the HTTP operation is used.
- Data definitions type tree name**
Type a brief descriptive name for the data definitions type tree. The format is *filename-operationId.mtt*.
Note: If you do not specify an *operationId*, the HTTP operation is used.
- HTTP adapter command**
Type the name of the file that contains the HTTP adapter command to run. The format is *filename-operationIdHttpCommand.txt*.
Note: If you do not specify an *operationId*, the HTTP operation is used.
- Generate sample map source**
Click to enable the generation of a sample source map. The default is clear, which indicates that a sample map is not generated.
- Map source file**
If you enabled Generate sample map source, type the name of the sample map file that is generated. The format is *filename-operationIdSampleMap.mms*.
Note: If you do not specify an *operationId*, the HTTP operation is used. Tip: The sample map allows you view everything that was generated. You can edit this map so it suits your purposes. The sample map contains three cards:
- httpRequest**
The first card includes that data you want to send to the REST API.
 - execute**
The second card invokes the HTTP adapter by using the HTTP command generated by the importer, and using the information on the httpRequest card as the payload.
 - httpResponse**
The third card parses the HTTP response to produce output that you can validate against the type tree that you created..
- Generate sample integration flow designer library (XML format)**

Click to enable the generation of a sample integration flow designer library in XML format. The default is not selected, which indicates that a sample integration flow designer library is not generated.

XML library file

If you enabled Generate sample integration flow designer library (XML format), type the name of the sample designer flow library that is generated. The format is *filename-operationIdSampleSystem.xml*.

Note: If you do not specify an *operationId*, the HTTP operation is used.

Tip: The XML library file is a metadata object that allows for more fine-tuned XML model definitions.

9. Click Finish to generate the type tree and, if you chose to generate a sample map, generate the map.

JavaScript Object Notation (JSON) parser

You can use JavaScript Object Notation (JSON) parsing with IBM Sterling Transformation Extender Design Studio to accept a JSON document as a type tree.

Design Studio accepts a JSON document as type tree input, and creates an MTX file from the JSON document that shows all the fields in the structure that is contained in the JSON document. Depending on the data in the JSON document, two field types are supported (text and numeric). Boolean field types are displayed as text field types with `true` or `false` as the data. Any field that contains a null value is considered a text field.

Additionally, JSON documents include two JSON group types, JSON arrays and JSON objects. The default attribute for both group types is unordered (which is the default), but you can also select a sequenced attribute. Choosing the sequenced attribute causes IBM Sterling Transformation Extender to process the document in sequence order, which ameliorates any confusion that can occur with unordered processing. To change an attribute from unordered to sequenced, select the Set Default Group Class as sequenced option on the Native JSON Customization page and click Finish.

Important: Native JSON converts invalid type tree characters such as `:` and `.` to `~`. Additionally, reserved words such as `any`, `component`, `false`, `in`, `last`, `none`, `true`, and `where` are prefixed by a number sign (`#`). If a field cannot be found in the type tree at the level of the data during parsing, and no any type field is found, the parse fails with the message `Could not find type to assign JSON data`. All escaped characters except `\u` four-hex-digits are converted into actual values on input and then converted to escape characters on output. However, hex digits are not converted because they cannot be converted back on output. The validation that is performed by the JSON parser is minimal because only numeric fields need to be validated. All numeric fields have an optional leading sign and an optional decimal point. Exponential numeric fields are not supported in the core engine and fail validation. Trace and audit functions are almost identical to the IBM Sterling Transformation Extender native core engine parse, except when the JSON Parser is parsing and outputting JSON data. When JSON data fails parsing or validation, you receive a detailed message of what error occurred and where the erroneous data is in the structure. Entries in the trace file appear for all data points and groups. You can also add an AnyType group field to any level of the JSON document. The anytype group field contains two fields, a name fields and a data text field, which allows the JSON tree to handle data that was not in the original document. When you use the AnyType field, any type of data is mapped to the field. To add AnyType group fields to the JSON document, select the Add AnyType fields to every level option on the Native JSON Customization page and click Finish.

Important: Your sample JSON document must include all the fields that might occur.

Guidelines for the JSON prototype object schema file

You must follow these guidelines when you create the JSON prototype object schema file:

- The JSON file that you use for IBM Sterling Transformation Extender native JSON processing must be a prototype object that best represents the data you plan to use.
- Ensure that all fields are defined in the JSON file.
- When you use arrays, ensure that all fields that are to be used in that array are defined in the first iteration of that array.
- When you use native JSON to define the main input or output card, always select the main Type as the first JSON type.
Note: The main input or output card is the card that has the file or other source that defines how to parse or create the document.
- The encoding field on input always returns the value `NONE`. On output, this field can be set to any valid JSON encoding and the JSON document is produced that uses that encoding. If you do not configure the encoding, the default encoding used is `UTF-8`.

JSON importer

The JSON Importer is a utility for creating type trees from JavaScript Object Notation (JSON) data definitions.

The JSON Importer creates type trees that parse JSON data. You can use the type trees in your maps to validate and transform complex data.

- [Running the JSON Importer](#)

Running the JSON Importer

About this task

Use the JSON Importer to automatically generate type trees.

The metadata for the type tree is in the form of JSON data definitions.

The following procedure describes how to use the JSON Importer Wizard to generate a type tree from JSON data definitions. You specify the data import configuration properties in the Data Import page, and the communication data structure in the Importer page.

Procedure

To run the JSON Importer:

1. [Access](#) the Importer Wizard in the Design Studio application.

2. In the Import window, expand the Transformation Extender folder, select JSON from the import source list, and click Next.
3. Enter or select the name of the JSON file that you want to import.
4. Click Next.
5. Enter or select the parent folder for the type tree file that the import process creates.
6. Enter the name of the type tree file that the import process creates.
7. Click Next. The import process runs.
If the type tree was generated successfully, the Type Tree Created Successfully message displays.
8. Click Finish.
If the type tree was generated, you are given the option to open the type tree in the Type Tree editor. The Properties view for the generated type tree contains the imported data format for the generated type tree. You can also click the type tree in the Extender Navigator view or the Navigator view to view the date and time that the import operation generated the type tree, under the Info property in the Properties view.

PL/I Importer

The PL/I Importer is a utility for creating type trees from PL/I data definitions.

The importer works with the PL/I compiler in a Windows environment. First it creates data structures from a PL/I source file or an include file. The importer decides the file type by file extension. If the extension is "pli", the importer regards the file as "Full program". If the extension is "inc" or "mac", the importer regards the file as "Data Structure Only". The importer does not support another file extension. The importer then presents the PL/I data structures for the user to generate the type tree from the selected one. The importer will report any syntax errors in PL/I files.

- [Running the PL/I Importer](#)

Use the PL/I Importer to automatically generate PL/I type trees.

- [PL/I Importer preferences](#)

- [PL/I Language Support](#)

- [Troubleshooting](#)

- [PL/I and type tree mapping](#)

Running the PL/I Importer

Use the PL/I Importer to automatically generate PL/I type trees.

About this task

The metadata for the type tree is in the form of PL/I data structures.

If you are running the PL/I Importer to generate a type tree that is used with the CICS Adapter, you must select the CICS option.

The following procedure describes how to use the PL/I Importer Wizard to generate a type tree from PL/I files.

Procedure

To run the PL/I Importer:

1. [Access](#) the Importer Wizard in the Design Studio application.
2. In the Import window, expand the Transformation Extender folder, select PL/I Include from the import source list, and click Next.
The Type Tree Importer window opens, and you can specify the data import configuration properties.
3. If you are importing multiple PL/I structures to generate a type tree, do the following steps:
 - a. Select Multiple PL/I structures to type tree (default) from the mapping list.
 - b. Follow the Importer Wizard instructions to select the names of the metadata source files that you want to import, and to select a communication data structure.
The files display in the Multiple possible output list.
4. If you are importing a single PL/I structure to generate a type tree, do the following steps:
 - a. Select PL/I to type tree from the mapping list.
 - b. Enter or select the name of the metadata source file that you want to import, following the Importer Wizard instructions, and select a communication data structure.
The file displays in the PLI file field.
5. Click Next.
The metadata source files have a default file extension of .pli. The metadata source files have a default file extension of .pli. If a file has the .pli extension, it is assumed to be a complete PL/I program. A file is assumed to be an include file if it has the .inc or .mac extension. If the file is an include member, then it must consist of only one or more data structures. For a PL/I file to be successfully imported into your project, it must be a complete PL/I program or include file. The importer operation can process only those files with the correct file extensions; files with incorrect extensions cause an importer error.
6. Enter or select the parent folder of the generated type tree.
7. For File name, do one of the following choices:
 - To create a type tree file, enter a new name.
 - To overwrite an existing type tree file, enter its name if it does not already display in the field.
- The default name for the type tree is the PL/I file name with the .mtt extension.
8. To generate the type tree, click Next.
If you selected a file name for an existing type tree file, you are prompted to continue or stop the import operation in the Overwrite Warning window.

After the import operation runs, it displays the run results in the PL/I Importer window. If errors or warnings, or both, occur, they display in that same window. The errors and warnings are also saved to error and log files in the product installation directory. The file names are PLIimp.err and PLI.log. You can open these files and analyze them in a text editor after the import operation completes. The import operation deletes and regenerates these log files every time a new PL/I file is imported. If errors occur, the import operation cannot generate the type tree until you resolve the problem. If only warnings occur, the import operation can still generate the type tree. However, to ensure that the reported warnings do not interfere with the requirements necessary for a valid instance document, inspect the generated type tree.

9. After the type tree generation process is complete, click Finish.

If the type tree was generated, you are given the option to open the type tree in the Type Tree editor. The Properties view for the generated type tree contains the imported data format for the generated type tree. You can also click the type tree in the Extender Navigator view or the Navigator view to view the date and time that the import operation generated the type tree, under the Info property in the Properties view.

Related tasks

- [Accessing the Importer Wizard](#)

PL/I Importer preferences

You can set the PL/I compiler preferences for an individual file import through the importer wizard. You can also change the default compiler options in the PL/I Preference page.

To set the default PL/I compiler preferences, go to Window>Preferences . Expand the Importer option and select PL/I.

Under the General tab, you can modify the following parameters:

Parameter	Options	Description
Platform	<ul style="list-style-type: none"> Win32 z/OS Not Specified 	The platform on which the PL/I program runs. Selecting a platform sets the other platform Information attributes to default values that are appropriate for that platform.
Code page		The code page of the runtime data on the target platform.
Enable IMS Support	<ul style="list-style-type: none"> Select Enable IMS Support check box. Clear Enable IMS Support check box. 	The length field is recognized by the following rule: <ul style="list-style-type: none"> The name of the field is LL. The attribute of the field is a 4-byte integer, declared as FIXED BIN(31). The first field of the IMS message structure.
CICS option	<ul style="list-style-type: none"> None CICS Transaction Server for z/OS v3.1 CICS Transaction Server for z/OS v3.2 	The version of the CICS Transaction Server for z/OS if the importer is generating CICS type trees. This specification is for the runtime data on the target platform.
Floating point format	<ul style="list-style-type: none"> IEEE Binary IBM 390 Hexadecimal IEE Decimal 	The floating point format of the runtime data on the target platform.
Endian	<ul style="list-style-type: none"> Little endian Big endian 	The selection for the data character set of runtime data, which defines the way that bytes in the data are ordered.
DBCS option	<ul style="list-style-type: none"> NODBCS DBCS 	<ul style="list-style-type: none"> The NODBCS option causes the listing to show all DBCS shift-code as ":" The DBCS option ensures that the listing is sensitive to possible presence of DBCS.

Parameter	Options	Description
GRAPHIC option	<ul style="list-style-type: none"> • NOGRAPHIC • HIC • GRAPHIC 	<ul style="list-style-type: none"> The NOGRAPHIC option specifies that the source program does not contain double-byte characters. The GRAPHIC option specifies that the source program can contain double-byte characters. The hexadecimal code 0E is treated as the shift-out control code. The hexadecimal code 0F is treated as the shift-in control code. These hexadecimal codes are treated in these ways wherever they are in the source program, including occurrences in comments and string constants.
File extension support		Using this table, you can change the default extension behavior. As an example, you can assign an extension to contain a full program or data structures only.

Under the More PL/I options tab, you can modify the following parameters to change the advanced PL/I compiler preferences:

Parameter	Options	Description
Error message language	Default: US English	The language of error messages of PL/I compiler.
LIMITS	<ul style="list-style-type: none"> • NAME • EXTNAM E • FIXEDBI N • FIXEDDE C 	<ul style="list-style-type: none"> The NAME option specifies the maximum length of variable names in your program. The EXTNAM E option specifies the maximum length for EXTERNAL name. The FIXEDBIN option specifies the maximum precision for SIGNED FIXED BINARY to be either 31 or 63. The FIXEDDEC option specifies the maximum precision for FIXED DECIMAL.
MARGINS	<ul style="list-style-type: none"> • Left • Right 	<ul style="list-style-type: none"> The Left option is the column number of the leftmost character that is processed by the compiler. The Right option is the column number of the rightmost character that is processed by the compiler.
Macro preprocessor	<ul style="list-style-type: none"> • NOMACRO • MACRO • SYSPARM 	<ul style="list-style-type: none"> The NOMACRO option does not start the macro preprocessor. The MACRO option starts the macro preprocessor. The SYSPARM option is used to specify the value of the string that is returned by the macro facility built-in function SYSPARM.
Character Conversion	<ul style="list-style-type: none"> • BLANK • CURRENCY • NOT • OR 	<ul style="list-style-type: none"> The BLANK option specifies up to 10 alternative symbols for the blank character. The CURRENCY option is used to specify an alternative character to be used in picture strings instead of the dollar sign. The NOT option specifies up to seven alternative symbols that can be used as the logical NOT operator. The OR option specifies up to 7 alternative symbols as the logical OR operator. These symbols are also used as the concatenation operator, which is defined as two consecutive logical OR symbols.
NAMES		The NAMES option specifies the extralingual characters that are allowed in identifiers. Extralingual characters are those characters other than the 26 alphabetic characters, 10-digit characters, and special characters that are defined in PL/I Language Reference.

- [Enable IMS Support](#)

Enable IMS Support

If the PL/I source file that you use in your application is for an IMS application, you need to select Enable IMS Support in the PL/I importer preferences.

Once you select Enable IMS Support, the PL/I importer converts 4 bytes LL field to 2 bytes. The conversion is necessary for the following reason: An IMS PL/I application using the PLITDLI interface defines the length field as 4 bytes. IMS requires any input message coming from the client to have a field length of 2 bytes. Therefore, when a message is passed to IMS Transaction Manager to invoke the IMS PL/I application, IMS Transaction Manager edits the message and changes the 2 bytes length field to 4 bytes before passing it to the PL/I application. Therefore, when the application generates a type tree from the imported PL/I source, the original 4 bytes LL field must be converted to 2 bytes to pass the message to IMS. The PL/I importer recognizes the length field for conversion if the name of the field is LL, the field is declared as FIXED BIN(31), and it is the first field of the IMS message structure.

PL/I Language Support

Some limitations exist for the PL/I language support. Only simple REFERs are supported by the PL/I importer. The REFER usage is simple if there is only one structure element using REFER, and that element has no later siblings and no parents with siblings, and that element is:

- Either a scalar string or AREA
- A one-dimensional array of char with constant lbound
- Or an array of elements of constant size and with only the upper bound in the first dimension being non-constant

The following are examples of simple PL/I structures:

```
dcl
 1 nc1      based,
 2 ne       bin fixed(15),
 2 nx1      char( nc refer(ne) );
dcl
 1 nc2      based,
 2 ne       bin fixed(15),
 2 nf       bin fixed(15),
 2 nx2( nc refer(ne) ) char( nd refer(nf) );
dcl
 1 nc3      based,
 2 ne       bin fixed(15),
 2 nx3( nc refer (ne) , 2 ),
```

```
3 nb1      char(4),
3 nb2      char(6);
```

If the source file contains a COMPLEX REFER (which is not a SIMPLE REFER), the data structure that has the complex refer will not appear. You can see the following error message in the Problems View: Message ID: IBM2627I W Message Text: 2627 : No metadata will be generated for the structure [structure name] since its use of REFER is too complex. Note: Translation: The message is not translated, so if you are using the product in a language other than English, the message will appear as follows: Message ID: IBM2627I W.

Troubleshooting

When your application is unsuccessful in importing a PL/I file into your project, your application will display an error message. You might then correct the problem and re-import the file.

- [Error message types](#)

Error message types

The types of PL/I error messages that you might encounter are:

- PL/I files that are part of your workspace (local) that you selected when you opened the Design Studio: When your application is unsuccessful in importing a local PL/I file, which is part of the workspace, into your project, syntax error messages are displayed in the Problems view. To view the source of the error in your code, click the error message line in the Problems view. Errors are also logged in a generic log file, which is located under the metadata directory in the workspace that you selected when you opened the Design Studio: [workspace]\.metadata\CommonBaseEvents.log
- PL/I files that are not part of your workspace: If the file is not part of the workspace the syntax error messages, if any, are logged in the log file.
- Additional Error Feedback:
 - PL/I Exception.getMessageNote()**: returns the following message if the PL/I source has syntax errors: For the PL/I source which is expected to be a full program because of its file extension Possible reasons for failure: Syntax errors were found in the source. Check the problems task list for the list of errors.
 - PL/I Exception.getErrorMessageVector()**: returns a vector that consists of an ErrorMessageInfo object or objects. The purpose of ErrorMessageInfo is to give the information about a syntax error in the PL/I source. Syntax errors include: Error Message, Severity Code, Line Number, and File Location information. You get an ErrorMessageInfo object for each syntax error.
 - PL/I Exception.getMessage()**: The import of the PL/I source has failed: Check the problems task list for the list of errors.
- Data name mangling: Duplicate names are made unique by the addition of two numeric digits. For example, two instances of year become year01 and year02.

PL/I and type tree mapping

PL/I names are converted to type tree names according to the following rules:

- Characters that are not valid in type tree element names are replaced with 'x'. For example, monthly\$total becomes monthlyxtotal.
- Duplicate names are made unique by the addition of one or more numeric digits. For example, two instances of year become year and year1.

PL/I importer maps PL/I data types to type tree elements according to the following table. PL/I types that are not shown in the table are not supported by the importer. The following restrictions also apply:

- Data items with the COMPLEX, FLOAT, VARYING, and VARYINGZ attributes are not supported.
- Data items with the FLOAT attribute are supported. PL/I FLOAT IEEE is not supported.
- VARYING and VARYINGZ pure DBCS strings are supported.
- Data items that are specified as DECIMAL(p,q) are supported only when p > q.
- Data items that are specified as BINARY(p,q) are supported only when q = 0.
- If the PRECISION attribute is specified for a data item, it is ignored.
- PICTURE strings are not supported.
- ORDINAL data items are treated as FIXED BINARY(7) data types.

The following table lists PL/I data types and the corresponding properties and property values in the resulting type tree.

PL/I	Type Tree properties and property values
FIXED BINARY (n) where n = 7	<ul style="list-style-type: none"> Class._>.Item Item Subclass._>.Number Sign._>.Yes Presentation._>.Integer Interpret as._>.Binary Length(bytes)._>.1
FIXED BINARY (n) where 8 = n = 15	<ul style="list-style-type: none"> Class._>.Item Item Subclass._>.Number Sign._>.Yes Presentation._>.Integer Interpret as._>.Binary Length(bytes)._>.2

PL/I	Type Tree properties and property values

Note: The PL/I importer is not supported on Linux®.

XML Schema and DTD Importers

You can create type trees by importing XML Schemas and DTDs.

Tuning Importer Behavior

The XML Schema and DTD Importers have a Java native interface and use the JVM options specified in the dtx.ini file to create a Java virtual machine (JVM). For information about configuring JVM options to tune the importer's behavior, see [Configuring JVM Options from the dtx.ini File](#).

- [XML Schema Importer](#)
- [XML DTD Importer](#)

XML Schema Importer

Use the XML Schema Importer wizard to generate a type tree from an XML Schema.

Supported Schemas

The XML Schema Importer only supports schemas that conform to the 2001 XML Schema specification defined by the Worldwide Web Consortium (W3C). Other schema options, such as BizTalk or XDR, are not supported. However, some providers such as BizTalk provide tools that can convert a proprietary schema to the latest W3C XML Schema specification.

Limitations

There is a limitation regarding the "union" XML Schema datatype. During the import process, the union datatype is converted to a text item in the type tree. As a result, you cannot create rules for mapping the member subtypes.

Running the XML Schema Importer

Use the XML Schema Importer to automatically generate XML Schema type trees.

About this task

The following procedure describes how to use the XML Schema Importer Wizard to generate a type tree from an XML Schema.

To run the XML Schema Importer:

Procedure

1. [Access](#) the Importer Wizard in the Design Studio application.
2. In the Import window, expand the Transformation Extender folder, select XML Schema from the import source list, and click Next.
The XML Schema Importer window opens.
3. Enter or select the name of the XML Schema file that you want to import, following the Importer Wizard instructions, and then click Next.
4. If applicable, select the national language that describes execution-time data. The default value is Western.
5. Under Validation, select one of the following validation types:
 - Xerces to create a version 8.0 type tree that is validated by using the Xerces parser.
By default, the importer generates all of the global elements. You can also select a subset of the global elements to generate in the type tree. For more information about this option to select a subset of global elements, see the related topic.

By default, the importer does not enable the support xsi:type attributes for derived types. You can select the option that enables the support of xsi:type attributes. For details about xsi:type attributes and derived types, see the related topics.
 - Classic to create a version 7.5.1 type tree that is validated by using classic validation.
6. When XSDL Hints are required in the resulting type tree, to specify the location for the placeholders for them, select the location in the XSDL Hints Location list. The XSDL Hints Location options are None (default), All Elements, Global Elements, and Root Elements.
7. Click Next
8. Enter or select the parent folder of the generated type tree.
9. For File name, do one of the following choices:
 - To create a type tree file, enter a new name.
 - To overwrite an existing type tree file, enter its name if it does not already display in the field.
The default name for the type tree is the XML Schema file name with the .mtt extension.
10. To generate the type tree, click Next.
If you selected a file name for an existing type tree file, you are prompted to continue or stop the import operation in the Overwrite Warning window.

After the import operation runs, it displays the run results in the XML Schema Importer window. If errors or warnings, or both, occur, they display in that same window. The errors and warnings are also saved to a log file in the product installation directory. The file name is either xmlsimp.log or ttmaker.log, depending on where in the process the errors and warnings occur. You can open this file and analyze it in a text editor after the import operation completes. The import operation deletes and regenerates these log files every time a new XML Schema is imported. If errors occur, the import operation cannot generate the type tree until you resolve the problem. If only warnings occur, the import operation can still generate the type tree. However, to ensure that the reported warnings do not interfere with the requirements necessary for a valid instance document, inspect the generated type tree.
11. After the type tree generation process is complete, click Finish.
If the type tree was generated, you are given the option to open the type tree in the Type Tree editor. The Properties view for the generated type tree contains the imported data format for the generated type tree. You can also click the type tree in the Extender Navigator view or the Navigator view to view the date and time that the import operation generated the type tree, under the Info property in the Properties view.

About classic validation

For information about "Classic" validation, see the documentation provided with IBM Sterling Transformation Extender version 7.5.1.

The following changes to the type tree structure are not included in the version 7.5.1 documentation:

- If a group representing a compositor (xs:sequence, xs:choice, xs:all) has a single component with a range (1:1), the group is removed.
- If a type tree contains a structure like the following structure:

```
- choice (1:1)
- Seq1
- element (0:s)
- Seq2
- element (0:s)
```

It is transformed into the following structure:

```
- choice (0:1)
- Seq1
- element (1:s)
```

```
- Seq2
  - element (1:s)
```

XML type tree description

Using Xerces validation, the root of an imported type tree is named XSD.

- [Misc category](#)
 - [Prolog category](#)
 - [Attr category](#)
 - [Type category](#)
 - [Element category](#)
 - [Doc group](#)
 - [Global](#)
-

Misc category

The **Misc** category represents generic types that can be contained in XML instance documents.

The **Comment** text item represents an XML comment. The **PI** text item represents an XML processing instruction. **Name** and **value** represent global attributes that will be added in the placeholder group created for wildcard schema elements anyAttribute or anyType (see "Element and Attribute Wildcards" in the Type Designer documentation for information about wildcards). **PCDATA** represents a PCDATA section in the instance document.

Prolog category

The **Prolog** category contains the type tree constructs used to describe the XML prolog in the instance document.

Version, **encoding**, and **standalone** items represent attributes in the XML prolog.

The **Decl** unordered group holds the **version**, **encoding** and **standalone** items. **Version** is mandatory, while **encoding** and **standalone** are optional within the **Decl** group.

Attr category

The **Attr** category contains type tree constructs generated from a Schema document that represents attributes from the XML Schema Instance namespace, such as **nil**, **noNamespaceSchemaLocation**, **schemaLocation**, and **type**.

Related concepts

- [XML Schema Importer](#)
-

Type category

The **Type** category contains constructs that represent the global types in the schema.

The complex type **Address** contains a sequence of elements. The components of the sequence are organized in the **Comp** category. The sequence in the **Address** type has three elements that are represented by these item types in the type tree: **city**, **name**, **street**. The **TypeDef** group from the **Address** category contains the text items that have been defined in its **Comp** category.

The complex type **USAddress** is an extension of the **Address** type that adds two more elements: **state** and **zip**.

- The item **zip** is a numeric item. Its type in the schema is "positiveInteger".
- The item **state** has the **USState** type in the schema. **USState** is defined as a text item, but it has a set of allowed values. To see these values, double-click on the **USState** item.

The complex type **UKAddress** is also an extension of the **Address** type in the schema, but it adds the element **UKPostcode** and the attribute **exportCode**. It is represented in type tree by the **UKAddress** category, that besides the **Comp** category, contains the **Attr** category and the **AttrList** group. The **AttrList** group contains the items that have been defined in the **Attr** category-in this case the **exportCode** numeric item.

Element category

The **Element** category contains constructs that represent the global elements defined in the schema.

This example has only one global element (**Person**) which is why the **Element** category has only one child node (the **Person** category).

Doc group

The **Doc** group represents the whole XML instance document.

This includes the **Prolog** of the document and the top-level element of the instance document - **ElementDecl** group of the **Person** element.

In preceding image, the example has only one global element declared in the schema (**Person**). For that reason it is directly included in the **Doc** group.

If more than one global element was declared in the schema, a choice group named **Global** would be defined as a choice selection for the elements because the XML instance document must have only one root element. In that case, this **Global** group would be included in the **Doc** group along with **Prolog**.

Global

The Global group is present in the imported type tree when the input XML Schema contains more than one global element.

Based on the preceding example, if a second global element named "address" is added, the imported type tree would contain the choice group Global.

```
<element name="address" type="ipo:Address"/>
```

The components of the Global group are all globally defined XML Schema elements.

XML schema elements and attributes

This section lists type properties in the resulting type tree that are created from the imported XML Schema elements and attributes.

XML schema elements

The following table lists XML Schema elements with corresponding types created in the resulting type tree.

XML Schema Element	Type Tree Type Class
all	Unordered group named TypeDef
annotation	(The comments in the XML Schema are ignored during the import process.)
any	Text item named anyElem
anyAttribute	Sequence group named anyAttr containing name and value text items
appinfo	(Application information is ignored during the import process.)
attribute	Text item
attributeGroup	Category containing a Comp category and a AttrGroupDecl group
choice	Category containing a Comp category and a TypeDef choice group
complexContent	Sequence Group named TypeDef
complexType	Category containing at a minimum a Comp category and a TypeDef sequence group
documentation	(Text comments are ignored during the import process.)
element	This is a group when the element definition contains a reference to a global type, otherwise, it is a category
extension	Sequence froup named TypeDef
field	Property named Field Path in the Intent > Validate As > Derivation > ID Constraints property group.
group	Category containing a Comp category and a GroupDecl group
import	(Not represented)

```

include

Primitive datatypes

The following table lists primitive XML Schema datatypes and the corresponding properties in the resulting type tree.

XML Schema Type	Item Subclass, Interpret as, Presentation	Description
anyURI	Text, Character	
base64Binary	Text, Character	
boolean	Text, Character	Restricted to the values: "0", "1", "true" or "false"
date	Date & Time, Character	Custom date format: {CCYY-MM-DD}
dateTime	Date & Time, Character	Custom date/time format: {CCYY-MM-DD}T{HH24:MM:SS[.0-6]}
decimal	Number, Character, Decimal	Custom separator format: #####[.##]
double	Number, Character, Decimal	Custom separator format: #####[.##]
duration	Text, Character	
float	Number, Character, Decimal	Custom separator format: #####[.##]
gDay	Text, Character	
gMonth	Text, Character	
gMonthDay	Text, Character	
gYear	Date & Time, Character	Custom date format: {CCYY}
gYearMonth	Date & Time, Character	Custom date format: {CCYY-MM}
hexBinary	Text, Character	
NOTATION	Text, Character	
QName	Text, Character	
string	Text, Character	
time	Date & Time, Character	Custom time format: {HH24:MM:SS[.0-6]}

Derived datatypes

The following table lists derived XML Schema datatypes and corresponding properties in the resulting type tree.

XML Schema Type	Item Subclass, Interpret as, Presentation	Restrictions
byte	Number, Character, Integer	Size: <ul style="list-style-type: none"> • Min: 1 • Max: 3 Restriction: Range; Rule: Include <ul style="list-style-type: none"> • Min: -128 • Max: 127

xsi:type support for abstract and concrete data types

IBM Sterling Transformation Extender supports the `xsi:type` attribute.

You can use the `xsi:type` attribute for substitution groups, elements that are defined as either abstract or concrete, or elements that are defined by either abstract or concrete types. The support for `xsi:type` creates choices for these types that can receive the `xsi:type` attribute at run time.

For example:

- When a type is defined as abstract, the corresponding imported type tree type is created as a choice of all the types that extend the abstract type.
- When a type is defined as concrete, the corresponding imported type tree type is created as a choice of the concrete type and all the types that extend the concrete type.

In the following Schema fragment, the type `Address` is defined as abstract and the types `US-address` and `UK-address` are simple extensions of the abstract type. An `address` element in an instance document must contain an `xsi:type` attribute to specify a concrete type. The validation library uses the `xsi:type` attribute to determine the real type that is specified and validate the type correctly.

```
<!-- abstract type -->
<x:complexType name="Address" abstract="true">
  <x:sequence>
    <x:element name="street" type="xs:string" />
    <x:element name="city" type="xs:string" />
  </x:sequence>
</x:complexType>
<!-- concrete types -->
<x:complexType name="US-address">
  <x:complexContent>
    <x:extension base="Address">
      <x:sequence>
        <x:element name="zip" type="xs:integer" />
      </x:sequence>
    </x:extension>
  </x:complexContent>
</x:complexType>
<x:complexType name="UK-address">
  <x:complexContent>
    <x:extension base="Address">
      <x:sequence>
        <x:element name="postalCode" type="xs:string" />
      </x:sequence>
    </x:extension>
  </x:complexContent>
</x:complexType>
<!-- abstract type -->
<x:element name="address" type="Address">
```

Related tasks

When XSDL hints are required in output

During the XML Schema import process, when you do not accept the default **XSDL Hints Location** setting (**None**), the following choices are listed:

- **All Elements**: Creates XSDL hints placeholders for all types described by the XML Schema.
- **Global Element**: Creates XSDL hints placeholders for all global elements.
- **Root Element**: Do not use.

When the actual value of the XSDL hint is required in the output, you must follow specific instructions.

For example, during the import process you select Global Element for the **XSDL Hints Location** value. In the generated type tree, all global types (represented in the type tree as components of the **XSD Element** category) contain in their **AttrList** group at least two optional text items: **xsi-noNamespaceSchemaLocation** and **xsi-schemaLocation**.

For either of these items, you can create a map rule that sends the XSDL hint to the output. For example, when a map rules sends the **schemaLocation** XSDL hint to the output, the output looks similar to:

```
<ipo-out:purchaseOrders
  xmlns:ipo-out="http://www.example.com/IPO"
  xsi:schemaLocation="http://www.example.com/IPO ipo.xsd">
```

When the <http://www.w3.org/2001/XMLSchema-instance> namespace is not declared in the input XML Schema, you must manually add the definition in the output card.

To add a namespace to the output card:

1. Open the output card.
2. Expand the **Type** setting.
3. Under Schema Type > Name Spaces is a list of the namespaces identified in the input Schema.
4. Right-click the **Name Spaces** setting and choose **Add** from the context menu.
5. On the new line, enter <http://www.w3.org/2001/XMLSchema-instance> in the Setting column and **xsi** in the Value column and click OK.
6. Save, build, and run the map.

The resulting XML document has a header that looks similar to the following text:

```
<?xml version="1.0"?>
<ipo-out:purchaseOrders
  xmlns:ipo-out="http://www.example.com/IPO"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:SchemaLocation="http://www.example.com/IPO ipo.xsd">
```

See the Map Designer documentation for information about how to add XSDL hints to an output card when you are using native XML schema validation instead of type trees and Xerces validation.

Related tasks

- [Running the XML Schema Importer](#)
-

Example using XSDL hints

During the XML Schema import process, when you select a value other than "None" for the **XSDL Hints Location**, extra steps are required if the actual value of the XSDL Hints are required in the output.

1. From the Type Designer Startup window, select Import a type tree and click OK.
The Importer Wizard is displayed.
2. Select XML Schema and click Next.
3. Select the following example file and click Next:
install_dir\examples\xml\ipo.xsd
4. At the prompt to specify a national language, accept the default (Western) and click Next.
5. In the Filename field, enter a filename and path for the type tree (.mtt) you are about to create. For example, enter:
install_dir\examples\xml\ipo_global_elements.mtt
6. Under Validation, select Xerces.
7. For the XSDL Hints Location, select Global Elements.
8. Click Next.
9. When type tree generation is complete, click Finish and open the type tree.

All global types contain at least two optional text items in their **AttrList** group (to which values can be assigned in a map as map rules):
xsi~noNamespaceSchemaLocation and xsi~schemaLocation.

10. Using the Map Designer, open the following example map:
`install_dir\examples\xml\ipo.mms`

11. Update the input and output cards of validationMap with the ipo_global_elements.mtt type tree.

12. In the output card, delete the existing rule: **Output = Input**.

13. Enter new map rules in the output card. The **xsi~schemaLocation** attribute should be equal to <http://www.example.com/IPO ipo.xsd>.

This rule causes the output document to contain the schemaLocation XSDL hint (<http://www.example.com/IPO ipo.xsd>).

```
<ipo-out:purchaseOrders  
    xmlns:ipo-out="http://www.example.com/IPO"  
    xsi:schemaLocation="http://www.example.com/IPO ipo.xsd">
```

See the Map Designer documentation for information about how to add XSDL hints to an output card when you are using native XML schema validation instead of type trees and Xerces validation.

When a namespace is not declared in an input schema, you must manually define it in the output card. See "[To add a namespace to the output card](#)" for instructions.

XML DTD Importer

Use the XML DTD Importer to create type trees that describe the format of XML data.

Many of the type trees that are generated by the Importer Wizard can be immediately used for map development. However, depending on the contents of the interface-specific metadata file, it might be necessary for the generated type tree to be modified using the Type Designer.

You cannot simultaneously have a type tree open in the Type Designer while importing a type tree with the same name.

Running the XML DTD Importer

Use the XML DTD Importer to automatically generate XML DTD type trees.

About this task

The following procedure describes how to use the XML DTD Importer Wizard to generate a type tree from an XML DTD.

To run the XML DTD Importer:

Procedure

1. [Access](#) the Importer Wizard in the Design Studio application.
2. In the Import window, expand the Transformation Extender folder, select XML DTD from the import source list, and click Next.
The XML DTD Importer window opens.
3. Enter or select the name of the XML DTD file that you want to import, following the Importer Wizard instructions, and then click Next.
4. If applicable, select the national language that describes execution-time data. The default value is Western.
5. Under Validation, select one of the following validation types:
 - Xerces to create a version 8.0 type tree that is validated with the Xerces parser.
 - Classic to create a version 7.5.1 type tree that is validated with classic validation.
6. To create a placeholder for the document type (DOCTYPE) declaration in the resulting type tree, select the Generate DOCTYPE option.
7. Click Next.
8. Enter or select the parent folder of the generated type tree.
9. For File name, do one of the following choices:
 - To create a type tree file, enter a new name.
 - To overwrite an existing type tree file, enter its name if it does not already display in the field.
The default name for the type tree is the XML DTD file name with the .mtt extension.
10. To generate the type tree, click Next.
If you selected a file name for an existing type tree file, you are prompted to continue or stop the import operation in the Overwrite Warning window.
- After the import operation runs, it displays the run results in the XML DTD Importer window. If errors or warnings, or both, occur, they display in that same window. The errors and warnings are also saved to a log file in the product installation directory. The file name is either dtd.log or ttmaker.log, depending on where in the process the errors and warnings occur. You can open this file and analyze it in a text editor after the import operation completes. The import operation deletes and regenerates these log files every time a new XML DTD is imported. If errors occur, the import operation cannot generate the type tree until you resolve the problem. If only warnings occur, the import operation can still generate the type tree. However, to ensure that the reported warnings do not interfere with the requirements necessary for a valid instance document, inspect the generated type tree.
11. After the type tree generation process is complete, click Finish.
If the type tree was generated, you are given the option to open the type tree in the Type Tree editor. The Properties view for the generated type tree contains the imported data format for the generated type tree. You can also click the type tree in the Extender Navigator view or the Navigator view to view the date and time that the import operation generated the type tree, under the Info property in the Properties view.

DTD elements and attributes in the type tree

In the following image you can see a pattern of how DTD elements and attributes transform into types in the type tree for both Xerces and classic 7.5.1 validation. In this image you can also see some structural differences in the construction of a classic and Xerces type tree.

WSDL Importer

The Web Services Description Language (WSDL) Importer is a utility for generating type trees from message definitions contained within WSDL documents.

Tuning Importer behavior

The WSDL Importer has a Java™ native interface and uses the JVM options specified in the dtx.ini file to create a Java virtual machine (JVM). For information about configuring JVM options to tune the importer's behavior, see ["Configuring JVM options from the dtx.ini file"](#).

Import options

The WSDL import process can create a classic type tree or a native XML schema (.xsd) file from the WSDL document. You select the type of output in the WSDL Importer wizard.

- When the WSDL document structure requires support for derived types (such as through the xsi:type attribute), create a native XML schema.
- When the WSDL document structure does not require support for derived types, create a classic XML type tree. Classic type trees are smaller than native XML schemas.

Classic type tree processing

The importer reads a WSDL document and assembles lists of port types, operations, services, messages, and bindings. When the parsing is complete, the importer creates a map for each web service operation and adds it to the resulting XML map source file. During this process, the XML Schema Importer is used to create the types defined in the input WSDL document.

After the WSDL Importer imports the WSDL document, it creates a WSDL type tree (.mtt) file and an XML (*_map.xml) file. Use File > Import > Map from XML in the Design Studio to import the XML file to create a map. The import process creates a map (*WSDLname.map.mms*) that uses the new WSDL type tree in the output cards.

Native XML schema processing

When you select native XML schema validation in the wizard, the WSDL Importer imports the WSDL document and creates two XML schemas:

WSDLname.xsd
Contains the XSD and WSDL-based schema types.

WSDLname_soap.xsd
Contains the SOAP envelope, header, and body types.

Use the *WSDLname_soap.xsd* as the card's native type tree.

- [Support for SOAP arrays](#)
- [WSDL document elements](#)
- [WSDL document types](#)
- [Running the WSDL Importer](#)
Use the WSDL Importer to automatically generate type trees or XML schemas.
- [Special symbols](#)
- [Character restrictions](#)
- [WSDL example](#)

Support for SOAP arrays

The WSDL Importer can process SOAP arrays and produce relevant type trees when the type of the array's elements is known. When a SOAP array derived type is found, the value of the arrayType attribute (if present) is used to create a reference to the defined type.

Type tree representation	Type definition
- ElemDecl + AttrList - Wrapper - Group (0:1) - Seq (0:1) valueOf(arrayType) (s)	<x:element name="arrayOfThings"> <x:complexType> <x:complexContent> <x:restriction base="tns:Array"> <x:sequence> <x:element name=="int" maxOccurs="unbounded"/> </x:sequence> <x:attribute ref="tns:arrayType" wsdl:arrayType="xs:int[]"/> </x:restriction> </x:complexContent> </x:complexType> </x:element>

WSDL document elements

A WSDL document typically contains the elements listed in the following table.

Element	Description
message	Message definitions
types	Type definitions. Normally XML Schema.
portType	List of operations available for the port.
binding	Definitions of how operations are bound to transports.
service	Defines the ports offered by the service.

WSDL document types

There are two different types of WSDL documents:

- WSDL Service Interface documents
- WSDL Service Implementation documents.

WSDL Service Interface documents contain **type**, **portType**, and **binding** elements.

The WSDL Service Implementation contains import and service elements, as well as a description of a service that implements a service interface. The **import** element imports a WSDL Service Interface definition.

The WSDL Importer gets its information from the import service interface and not from the service implementations. Both document types can be combined into a single document. If both document types are not combined into a single document, the Service Implementation document will include an import statement to import the Service Interface document. If a Service Implementation document is processed by the importer, the importer must be able to import the Service Interface document to obtain the message definitions.

Running the WSDL Importer

Use the WSDL Importer to automatically generate type trees or XML schemas.

Procedure

To run the WSDL Importer:

1. [Access](#) the Importer Wizard in the Design Studio application.
2. In the Import window, expand the Transformation Extender folder, select WSDL from the import source list, and click Next.
The WSDL Importer window opens.
3. Enter the Uniform Resource Identifier (URI) of the WSDL document that you want to import or select a WSDL document, following the Importer Wizard instructions, and then click Next. When you are importing a WSDL document that references a URI on another machine, access to that other machine might be required. For example, if the WSDL document imports type definitions with a reference to an HTTP-based URL, network access to that referenced URL is required.
4. If applicable, select the national language that describes execution-time data. The default value is Western.
5. Choose to generate either a classic type tree or a native XML schema.
6. Click Next.
7. Select one or more operations that are defined for the specific class to be run in the map, and click Next.
8. Enter or select the parent folder of the generated type tree or XML schema.
9. Accept the default file name or enter a new name.
 - For classic type tree generation, the default file name is *WSDLname.mtt*.
 - For XML schema generation, the default file name is *WSDLname.xsd*.
10. To generate the type tree, click Next.
After the import operation runs, it displays the run results in the WSDL Importer window. If errors or warnings, or both, occur, they display in that same window. The errors and warnings are also saved to a log file in the product installation directory. The file name is *wsdlimp.log*. You can open this file and analyze it in a text editor after the import operation completes. The import operation deletes and regenerates this log file every time a new WSDL is imported. If errors occur, the import operation cannot generate the type tree or XML schema until you resolve the problem. If only warnings occur, the import operation can still generate the type tree or XML schema. However, to ensure that the reported warnings do not interfere with the requirements necessary for a valid instance document, inspect the generated type tree or XML schema.
11. After the generation process is complete, click Finish.
You can open the type tree to display the imported data format in the Properties view. Click the type tree in the Extender Navigator view or the Navigator view to display the time stamp of the import operation and other details in the Properties view.

Related tasks

- [Accessing the Importer Wizard](#)

Special symbols

After importing a **.wsdl** file, you might see the <IGNORE>, <QUOTE>, and <ANYQUOTE> symbols as initiators or terminators in the resulting type tree.

- [ANYQUOTE and QUOTE](#)
- [IGNORE](#)

ANYQUOTE and QUOTE

<ANYQUOTE> and <QUOTE> symbols are used to allow for pairs of double quotes or pairs of single quotes.

This mechanism is needed, for example, to allow for both double-quote pairs and single-quote pairs for the attributes in XML data.

During the data validation process, the <ANYQUOTE> symbol can match both double and single quote characters, and <QUOTE> must match the same quote character (single or double) that was recognized by the last <ANYQUOTE> symbol.

This logic is used to allow for pairs of matching double or single quotes and to prevent the pairs with mixed double and single quotes.

- [ANYQUOTE and QUOTE examples](#)

ANYQUOTE and QUOTE examples

When a text item is defined with initiator <ANYQUOTE> and terminator <QUOTE>, the following data validates successfully.

"John"

The following data also validates successfully:

'John'

However, the following data fails validation:

"John'

In the failed result, the initial double quote is validated by <ANYQUOTE> and the value John validates successfully as the value of the text item. However, the last single quote fails validation because it is represented in the type tree by the <QUOTE> symbol and the previous <ANYQUOTE> symbol validated a double quote character.

If <QUOTE> is encountered during data validation, and no <ANYQUOTE> symbol was encountered before that, both double quote and single quote characters in data will be accepted as valid.

IGNORE

The <IGNORE> symbol is used by the validation engine to ignore a portion of the input data. The syntax is:

<IGNOREcPar1cPar2cPar3>

Option	Description
c	A character used as a separator for Par1, Par2 and Par3 values.
Par1	A string that is expected to appear at the beginning of the data that is to be ignored.
Par2	A string that is mapped on output as a result of the <IGNORE> symbol.
Par3	A string that is expected to appear at the end of ignored data. If it is omitted, the ignored data ends when what follows the <IGNORE> symbol in the type tree is recognized in the data on input.

- [IGNORE examples](#)

IGNORE examples

In the following examples, a comma (,) is used as the separator among Par1, Par2, and Par3 <IGNORE> values (this is the c character in the <IGNORE> syntax).

Example 1

A text item is defined with this initiator: <IGNORE, ab, cdef, gh>John

The following data validates successfully:

abghJohnSmith

The following data is built on output:

cdefJohnSmith

Example 2

A text item is defined with this initiator: <IGNORE,,xsd:,,:>Bill

The following data validates successfully:

```
xs:BillSmith
```

The following data is built on output:

```
xsd:BillSimth
```

Example 3

A text item is defined with initiator <<IGNORE,,,,:>Color> and terminator </Color>.

The following data validates successfully:

```
<ab:Color>Blue</Color>
```

The following data is built on output:

```
<Color>Blue</Color>
```

Example 4

A text item is defined with initiator <<IGNORE,,,,:>Color> and terminator </Color>.

The following data validates successfully:

```
<Color>Blue</Color>
```

Although the colon (:) does not appear anywhere in the input data, the validation process recognizes that no data should be ignored because the **Color** value in the data matches the **Color** value in the initiator, so in that case, the <IGNORE> symbol in the initiator will not ignore any data on input.

On output, the data is the same as on input:

```
<Color>Blue</Color>
```

This is because the second parameter (Par2) in the <IGNORE> symbol was specified as "empty".

Character restrictions

You can customize a character restrictions configuration file that is utilized by the WSDL Importer.

- [Using a configuration file for character restrictions](#)
 - [XML configuration file and schema](#)
 - [Using character restrictions](#)
 - [Understanding character restriction ordering](#)
 - [Multiple character restriction sets](#)
-

Using a configuration file for character restrictions

The WSDL Importer uses a configuration file during type tree generation that you can customize to include specific Exclude character restrictions.

Character restriction lists often contain entity references, such as & (ampersand) or ' (apostrophe) that are special characters in XML. If you use the same character restrictions across multiple type trees, using a configuration file to specify these character restrictions eliminates the need to create an individual restriction list for each type tree.

XML configuration file and schema

The XML-based configuration file (xmlsimp.xml) and XML Schema (xmlsimp.xsd) are installed with the Design Studio. These files work together to specify Exclude character restrictions for items in a type tree that represent values for simple elements and attributes in XML documents.

- [XML schema](#)
 - [XML configuration file](#)
 - [Customizing the configuration file](#)
-

XML schema

The xmlsimp.xsd schema file defines a valid structure for the xmlsimp.xml configuration file. This schema file, located in the Design Studio installation directory, must not be modified or moved because it is used by the importers to validate the xmlsimp.xml configuration file during the import process. The absence of this schema file will cause the import process to fail; modifying the file can cause unexpected results, such as the creation of an invalid type tree.

XML configuration file

The `xmlsimp.xml` configuration file, which specifies character restrictions for item types in a type tree, is also located in the Design Studio installation directory and must not be moved. This file can be encoded using any encoding scheme supported by the IBM alphaWorks XML4J 3.2.1. (For a full list of supported encodings, consult XML4J documentation.)

The default content of the `xmlsimp.xml` configuration file specifies the five entity references supported by XML (apostrophe, quotation mark, greater-than, less-than, ampersand) as Exclude characters, as shown:

```
<!-- The default character restrictions -->
<character_restrictions name="default_cs">
  <elements>
    <character_restriction exclude="&apos;" reference_string="&#39;"/>
    <character_restriction exclude="&apos;" reference_string="&#39;"/>
    <character_restriction exclude="&quot;" reference_string="&#34;"/>
    <character_restriction exclude="&quot;" reference_string="&#34;"/>
    <character_restriction exclude="&gt;" reference_string="&gt;"/>
    <character_restriction exclude="&gt;" reference_string="&#62;"/>
    <character_restriction exclude="&lt;" reference_string="&lt;"/>
    <character_restriction exclude="&lt;" reference_string="&#60;"/>
    <character_restriction exclude="&amp;" reference_string="&amp;#amp;"/>
    <character_restriction exclude="&amp;" reference_string="&#38;"/>
    <character_restriction exclude="&apos;" reference_string="&apos;"/>
    <character_restriction exclude="&quot;" reference_string="&quot;"/>
  </elements>
  <attributes>
    <character_restriction exclude="&apos;" reference_string="&#39;"/>
    <character_restriction exclude="&apos;" reference_string="&#39;"/>
    <character_restriction exclude="&quot;" reference_string="&#34;"/>
    <character_restriction exclude="&quot;" reference_string="&#34;"/>
    <character_restriction exclude="&gt;" reference_string="&gt;"/>
    <character_restriction exclude="&gt;" reference_string="&#62;"/>
    <character_restriction exclude="&lt;" reference_string="&lt;"/>
    <character_restriction exclude="&lt;" reference_string="&#60;"/>
    <character_restriction exclude="&amp;" reference_string="&amp;#amp;"/>
    <character_restriction exclude="&amp;" reference_string="&#38;"/>
  </attributes>
</character_restrictions>
```

Customizing the configuration file

You can edit the `xmlsimp.xml` configuration file to suit your requirements. For example, if you process Latin-1 characters, you might add the eacute (é) character to your Exclude list as shown:

```
<character_restrictions name="latin1">
  <elements>
    <character_restriction exclude="&apos;" reference_string="&#39;"/>
    <character_restriction exclude="&apos;" reference_string="&#39;"/>
    <character_restriction exclude="&quot;" reference_string="&#34;"/>
    <character_restriction exclude="&quot;" reference_string="&#34;"/>
    <character_restriction exclude="&gt;" reference_string="&gt;"/>
    <character_restriction exclude="&gt;" reference_string="&#62;"/>
    <character_restriction exclude="&lt;" reference_string="&lt;"/>
    <character_restriction exclude="&lt;" reference_string="&#60;"/>
    <character_restriction exclude="é" reference_string="&#eacute;"/>
    <character_restriction exclude="é" reference_string="&#233;"/>
    <character_restriction exclude="é" reference_string="&#xE9;"/>
    <character_restriction exclude="é" reference_string="é'"/>
    <character_restriction exclude="&amp;" reference_string="&amp;#amp;"/>
    <character_restriction exclude="&amp;" reference_string="&#38;"/>
    <character_restriction exclude="&apos;" reference_string="&apos;"/>
    <character_restriction exclude="&quot;" reference_string="&quot;"/>
    <character_restriction exclude="&gt;" reference_string="&gt;"/>
  </elements>
  <attributes>
    <character_restriction exclude="&apos;" reference_string="&#39;"/>
    <character_restriction exclude="&apos;" reference_string="&#39;"/>
    <character_restriction exclude="&quot;" reference_string="&#34;"/>
    <character_restriction exclude="&quot;" reference_string="&#34;"/>
    <character_restriction exclude="&gt;" reference_string="&gt;"/>
    <character_restriction exclude="&gt;" reference_string="&#62;"/>
    <character_restriction exclude="&lt;" reference_string="&lt;"/>
    <character_restriction exclude="&lt;" reference_string="&#60;"/>
    <character_restriction exclude="&amp;" reference_string="&amp;#amp;"/>
    <character_restriction exclude="&amp;" reference_string="&#38;"/>
  </attributes>
</character_restrictions>
```

You must specify the proper encoding in the XML prolog in the configuration file. For example, if the character é is encoded in the configuration file as Latin-1 (ISO-8859-1) byte value 0xE9, the XML prolog of the configuration file must specify that the ISO-8859-1 encoding is used, instead of the default UTF-8.

Using character restrictions

Importers that utilize the configuration file build Exclude character restrictions for item types in a type tree in the same order as the configuration file. When the configuration file is processed by an importer, duplicate entries are eliminated, but the remaining entries are NOT reordered by the importer in any way.

For this reason it is important to understand how the ordering of character restrictions in the configuration file affects data processing at map execution time.

Understanding character restriction ordering

When input data is assigned to an item (A) that has Exclude character restrictions defined and item A is mapped to an item (B) on output, where item B also has Exclude character restrictions defined, the following process occurs:

- The input data is first validated for item A according to the rules specified in "[Validation of Input Data](#)", and the *internal* data is constructed.
- The internal data is passed to item B on output and the process described in "[Construction of Output Data](#)" takes place, producing the final output data.
- [Validation of input data](#)
- [Construction of output data](#)
- [Summary of the ordering process](#)

Validation of input data

When a text item within a type tree has Exclude character restrictions specified, a particular process takes place during input validation. For each character in the input data (starting from the first character), the program checks the **Reference String** column for reference strings that begin with the same character-checking the longest reference strings first. When a reference string is found, its occurrence in the input data is replaced with the paired Exclude value.

Construction of output data

When output data is being built from the output card for an item in a type tree that has Exclude character restrictions specified, the program looks for each character of data (starting from the first character) assigned to the item in the **Exclude** column. The program searches the **Exclude** column in the order that the restrictions are specified. When an Exclude character is found, it is replaced with the associated reference string, which is then moved to output.

Summary of the ordering process

- During input validation, the program looks in the **Reference String** column for the longest reference string beginning with the selected character.
- On output, the program looks for the first available match in the **Exclude** column.

Multiple character restriction sets

It is possible to specify multiple character restriction sets in a single configuration file. Each character restriction set is represented by a **<character_restrictions>** element in the configuration file. This element has the **name** attribute which identifies each character restriction set.

Another XML element in the configuration file, **<use_character_restrictions>**, specifies which character restriction set to use during the subsequent import. The value of this element should match the name of the character restriction set that you want the importer to use for the generated type trees.

If multiple **<character_restrictions>** elements are given the same **name** attribute value, and if that **name** is specified as the value for the **<use_character_restrictions>** element, the **<character_restrictions>** element which was specified first in the configuration file will be used.

If the **<use_character_restrictions>** element has a value that does not match the **name** attribute value of any **<character_restrictions>** element, the result of the import process will be the same as when an empty **<character_restrictions>** element is used.

WSDL example

If you installed the examples, you can find WSDL example files in the following directory: *install_dir\examples\web_services*.

Return codes and error messages

- [COBOL Copybook return codes and messages](#)
- [XML parsing error messages](#)

COBOL Copybook return codes and messages

If the COBOL copybook input file specified to the Importer Wizard contains incorrect or invalid COBOL copybook statements, the Importer Wizard maps will attempt to skip the erroneous statements and continue on with the next valid statement. Invalid statements are reported in the COBOL Copybook importer error and warning report.

Trying to import a file that contains a large number of errors or is not a valid COBOL copybook definition might result in the failure of the Importer Wizard to create a type tree. When this situation occurs, the maps executed by the Importer Wizard might report warning and error messages when you run the COBOL Copybook importer wizard.

The following is a list of return codes and messages along with hints or instructions for trying to resolve the problem:

Return Code	Message
N/A	Unable to rename ... An attempt might have been made to write to a read-only directory, an output file directory might be missing, or there might not be sufficient disk space on the output drive.
1	User aborted map If you cancel execution before the map completes, this message is displayed.
2	Not enough memory to execute map Close other running applications and re-try.
3	Could not open map One of the map executable files (.mmc) cannot be found. Check that the following four files are present in the install directory: UnBlock.mmc , NormalizeCopyBook.mmc , TranslatFile.mmc , BuildTTMakerScript.mmc
4	Could not read map
5	Could not read inputs
6	Invalid map handle
7	Invalid card number was specified Your map might be corrupt.
8	One or more inputs was invalid Check to make sure a proper copybook input file was specified.
9	Target not available This might be a security/authorization problem. Verify that you have authorization for read access for the input copybook file and write access for the specified output directory and the product installation directory.
10	Internal error
11	Could not build one or more outputs An attempt might have been made to write to a read-only directory, an output file directory might be missing, or there might not be sufficient disk space on the output drive.
12	Source not available An incorrect file name or path for the copybook input file might have been specified.
13	Could not open work files There might not be sufficient disk space on the drive where the install directory exists to create necessary importer work files.
15	Map must be recompiled You might have an outdated version of the importer maps versus the installed version of the Command Server. Re-install the correct version of the importer.
16	Disk write error An attempt might have been made to write to a read-only directory or file. Also, check the amount of available disk space.
17	Disk read error An attempt might have been made to access a file on a shared resource that is not accessible. Also, check the amount of available disk space.
18	Page usage count error An internal paging problem exists.
19	Internal calling error
20	Reopen file failed A map did not run correctly.
21	Input valid but unknown data found The input specified is likely not a valid copybook. Check to make sure a proper copybook input file was specified.
22	Page size too small

28	<p>Input type contains errors Invalid copybook statement(s) were found in the specified input. The COBOL Copybook Importer error report file should contain details on the problem statement(s).</p>
50	<p>Type exists and is not overwritten A duplicate definition was found in the .mts file. The COBOL Copybook Importer uses the first definition found for a given field or group name and ignores or warns about any duplicate names.</p>

XML parsing error messages

The following error messages pertain to the XML parsing that takes place when using the XML Schema Importer or XML DTD Importer.

Value	Message
-1	Input XML data is invalid.
-2	Error allocating memory.
-3	Invalid input parameters.
-4	Error initializing XML4C library.
-5	Error instantiating SAX2Parser.
-6	Error instantiating MemBufInputSource.
-7	DTD metadata location not in 'root_element DTD_URI' format.
-8	Unexpected parser error.
-9	Could not find type to assign XML data.
-10	Could not find type to assign attribute XML data.
-11	URL of the DTD against which the input instance is validated, is malformed

Type Tree Maker

Introduction

The Type Tree Maker is an application that is installed with the Design Studio. The Type Tree Maker reads-in an XML document file (.mts file extension) containing type tree commands and uses these commands to create or update a type tree.

- Example files
- Command files
- Accessing the Importer Wizard
- [Creating document files](#)
- [Example files](#)
- [Command files](#)
- [Accessing the Importer Wizard](#)

Creating document files

About this task

About this task

The document file that the Type Tree Maker uses may be produced in one of the following ways:

- Using the Type Designer to export all or part of a type tree. For more information on exporting a type tree or a portion of a type tree, see the Type Designer documentation.
- Executing an importer map (using the importer wizard) that generates a Type Tree Maker document file. For information about the importer wizard, see [Type Tree Maker Importer](#).
- Creating a map that generates a document (script) file. The document (script) file must conform to the file structure and syntax explained in the [Type Tree Maker Document File documentation](#).

Example files

The default directory `install_dir\examples\dsgnstud\ttmaker` contains example files including a type tree that contains definitions of a document file and a map that converts a data dictionary definition to a document file. These examples are explained in the [Examples](#) documentation.

Command files

The Type Tree Maker creates command files (`.mts`). A Type Tree Maker command file is represented by an acorn icon.

Accessing the Importer Wizard

About this task

The following procedure describes how to access the Importer Wizard.

To access the Importer Wizard:

Procedure

1. Open the Design Studio application.
2. Navigate to the Importer Wizard through either one of the following ways:
 - Click File > Import .
 - In the Extender Navigator view or Navigator view, right-click the location in a project in which you want to create the new type tree, and select Import. The Import window opens.
3. Expand the Transformation Extender folder, select Type Tree Maker from the import source list, and click Next.
4. Follow the Importer Wizard instructions.

Using the Type Tree Maker

- [Creating an XML document file](#)
- [Creating a Type Tree](#)
- [Type Tree Maker Importer](#)
- [Starting the Type Tree Maker from a command line](#)

Creating an XML document file

About this task

The Type Tree Maker uses document files in an XML format (.mts file extension) to create type trees. The following steps describe how to use the Type Designer to export an example type tree (xreftbl.mtt) to an XML document file (.mts).

To create an XML document file (.mts) using the Type Designer:

Procedure

1. Open a project in the Design Studio.
2. If not already imported into your work area, import the file system for the Export Type Tree Maker Example. The files are located at `install_dir\examples\dsgnstud\ttmaker\export`.
3. Open the xreftbl.mtt type tree. In the type tree editor, right-click on the root type Data and select Export from the context menu. The Export tree to file dialog opens.
4. Enter a new or accept the default file name and path and click Save. The exported .mts file is saved as Data.mts.

Results

After the export, when you execute the .mts file, the Type Tree Maker converts it into a type tree.

Creating a Type Tree

About this task

Use the Type Tree Maker to create the type tree.

To create a type tree using the Type Tree Maker:

Procedure

1. From the Start menu, click Programs > Transformation Extender > Design Studio > Type Tree Maker . The Open Type Tree Maker Command File window opens.
2. Navigate to the *install_dir\examples\dsgnstud\ttmaker\export* folder to select Xreftbl.mts. You created this file in the earlier section.
3. Click Open.
The IBM Transformation Extender Type Tree Maker generates a type tree and presents it in the Type Tree Maker window.
4. Click Close to exit the Type Tree Maker application.
The Type Tree Maker has created a type tree or modified an existing type tree, based on the information in the selected command file. The name of the type tree file is the name specified in the NEWTREE or OPENTREE command in the command file. View the type tree by opening it in the Type Designer.

Results

[Examples](#) describes the examples that are installed with the Type Tree Maker. These examples are for two uses of the Type Tree Maker and show command files and the types of commands they might contain.

Type Tree Maker Importer

The Type Tree Maker Importer is a facility that automatically generates type trees from a script (.mts file extension) that contains Type Tree Maker commands.

- [Running the Type Tree Maker Importer](#)
-

Running the Type Tree Maker Importer

About this task

This example uses the acme_tables.mtt file installed in *install_dir\examples\dsgnstud\ttmaker\import* directory. The acme_tables.mtt file was exported in the Design Studio to create the acme_tables.mts file. See [Creating an XML Document File](#) for details about creating .mts files.

To run the Type Tree Maker Importer:

Procedure

1. [Access the Importer Wizard](#) in the Design Studio application.
2. In the Import window, select Type Tree Maker from the import source list, and click Next. The Type Tree Maker Importer window opens.
3. Enter or select the name of the Type Tree Maker (.mts) file that you want to import, in the File name field, following the Importer Wizard instructions.
4. To generate the type tree, click Next. If the destination type tree file exists, you are prompted to continue or stop the import operation in the Overwrite Warning window.
After the import operation runs, it displays the run results in the Type Tree Maker Importer window. If errors or warnings, or both, occur, they appear in that same window. The errors and warnings are also saved to a log file in the product installation directory. The file name is ttmaker.log. You can open this file and analyze it in a text editor after the import operation has completed. The import operation deletes and regenerates this log file every time a new Type Tree Maker (.mts) file is imported. If errors occur, the import operation cannot generate the type tree until you resolve the problem. If only warnings occur, the import operation can still generate the type tree; however, you should inspect it to ensure that the reported warnings do not interfere with the requirements necessary for a valid instance document.
5. After the type tree generation process is complete, click Finish.
A BR tag was used here in the original source. If the type tree was generated, you are given the option to open the type tree in the Type Tree editor. The Properties view for the generated type tree contains the imported data format for the generated type tree. You can also click the type tree in the Extender Navigator view or the Navigator view to view the date and time that the import operation generated the type tree, under the Info property in the Properties view.

Starting the Type Tree Maker from a command line

When you start the Type Tree Maker from a command line, use the options listed in the following table.

The following is the syntax of **ttmakr64**:

ttmakr64 <full_path_of_.mts_file> [-A] [-B] [-H] [-N]

Command Line Option

Use

- | | |
|----|---|
| -A | Automatically analyze trees that are created or modified. Related to the ANALYZE processing instruction described in Processing instructions . |
| -B | Batch mode. Automatically closes the Type Tree Maker window when finished. Related to the AUTOCLOSE processing instruction described in Processing instructions . |
| -H | Hide the tree window. Displays a partial Type Tree Maker window for faster command file processing. Related to the HIDETREE processing instruction described in Processing instructions . |
| -N | Display no Type Tree Maker window. |

Type Tree Maker document file

The document file used by the Type Tree Maker to create a type tree is an XML-based document with a specific structure. This script file, which has the file extension **.mts**, contains commands and command elements that must be specified in a particular way and in a specific sequence.

The following file (**ttmaker60.mts**) is provided with the product, located in the **examples\dsgnstud\ttmaker** directory.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE TTMAKER SYSTEM "ttmaker60.dtd">
<?ANALYZE?><TTMAKER Version="n.n">
<NEWTREE Filename="install_dir\examples\dsgnstud\ttmaker\export\element.mtt">
<ROOT SimpleTypeName="Element" SetUpProperties="DEFAULT" SetUpComponents=
"DELETE" OrderSubtypes="ASCENDING"><Sequence partition="NO"><Implicit/>
</Sequence>
<CharTextWestern><Size Min="0" Max="S"/>
<Western CharSet="NATIVE"/>
<ValueRestrictions IgnoreCase="NO" Rule="INCLUDE"></ValueRestrictions>
</CharTextWestern>
</ROOT>
<ITEM SimpleTypeName="Acc't#Qual'rCd" CategoryOrItemParent="Element"
Description="Acct No. Qualifier Code
(896 V3050)" partition="NO" OrderSubtypes="ASCENDING"><CharTextWestern>
<Size Min="0" Max="2"/>
<PadText Justify="LEFT" ApplyPad="ANYCONTEXT"><PadValue>&lt;SP&gt;</PadValue>
<PaddedToFixedSize Length="2"/>
</PadText>
<Western CharSet="NATIVE"/>
<ValueRestrictions IgnoreCase="NO" Rule="INCLUDE"><Value Description=
"Time Deposit">01</Value>
<Value Description="Stock">05</Value>
<Value Description="Bond">06</Value>
<Value Description="Life Insurance Face Value">07</Value>
<Value Description="Retirement Acct - Vested Interest">08</Value>
<Value Description="Demand Deposit">DA</Value>
<Value Description="Return Items on Demand Deposit Acct">RD</Value>
<Value Description="Return Items on Savings Acct">RS</Value>
<Value Description="Savings">SG</Value>
<Value Description="Mutually Defined">ZZ</Value>
</ValueRestrictions>
</CharTextWestern>
</ITEM>
</NEWTREE>
</TTMAKER>
```

When you use the Type Designer to import and create a type tree from **ttmaker60.mts**, you can see in the type tree how the structure of the document file is represented.

- [File structure](#)
- [Composition of the .mts file](#)

File structure

A Type Tree Maker document (script) file begins with an XML prolog and is followed by a **TTMAKER** element.

The **Prolog** identifies the XML version and the Document Type Definition (DTD) of the document file.

The **TTMAKER** element contains a series of lines where each line in the **TTMAKER** element must be either a command or comment.

- [Commands and comments](#)
- [Prolog](#)
- [TTMAKER element](#)
- [XML tag notation](#)

Commands and comments

Commands and comments begin in the first character position of a line.

- A command line begins with a command initiator.
 - Command initiators are XML start-tags.
- A command line ends with a command terminator
 - A command terminator consists of the appropriate XML end-tag, followed by a carriage return/linefeed <NL>.
- Comments begin with the symbols <!-- and end with the symbols --><NL>.

Characters used as markup delimiters by XML may occur within elements contained in **TTMAKER**.

Prolog

The **Prolog** consists of an XML declaration, followed by a DTD declaration, followed by a series of processing instructions.

The XML declaration is either

```
<?<SP>XML<SP>version="1.0"<SP>encoding="UTF-8"?>  
or  
<?<SP>XML<SP>version="1.0"<SP>encoding="Shift_JIS"?>  
The DTD declaration is  
<!DOCTYPE TTMAKER<SP>SYSTEM<SP>"ttmaker60.dtd">  
• Processing instructions
```

Processing instructions

Processing instructions act on a tree or the Type Tree Maker window. One or more of the following processing instructions can be used:

Processing Instruction

Effect on Type Tree or Window

```
<?AUTOCLOSE?>  
Automatically closes the Type Tree Maker window after the document file has been processed. The command line option is -B.  
<?ANALYZE?>  
Performs a logic analysis on type trees referenced in the document file before saving the type tree. The command line option is -A.  
<?HIDETREE?>  
Hides the type tree while processing the document file. Very large trees can be created or modified faster if the HIDETREE instruction is used. The command line option is -H.  
<?REPLACE?>  
Replaces an existing type when a new type command is issued and the type tree already has an existing type with the same name. If not used, the existing type is not replaced and an error message is issued.
```

The processing instructions listed provide similar results to using the command line options.

TTMAKER element

The **TTMAKER** element has a start tag `<TTMAKER Version="6.0">` and end tag `</TTMAKER>`. For example:

```
<TTMAKER Version="6.0">... </TTMAKER>
```

The **TTMAKER Element** consists of one or more **NEWTREE** and **OPENTREE** elements.

The **NEWTREE** element begins with a start tag `<NEWTREE Filename="install_dir\examples\dsgnstud\ttmaker\export\ttmaker60.mtt">` and end tag `</NEWTREE>`. For example:

```
<NEWTREE Filename="install_dir\examples\dsgnstud\ttmaker\export\ttmaker60.mtt"></NEWTREE>
```

The **TTMAKER Choice Expression** consists of a choice of the **NEWTREE** and **OPENTREE** commands:

The **NEWTREE** and **OPENTREE** elements instruct the Type Tree Maker to create a new tree or open an existing one. A **Choice** expression determines the sequence of actions to be performed at a particular location in the type tree. Each **Choice** is a sequence of commands that acts on a particular type. The class of the active type determines the valid command sequence.

For example, if the active type is a group, you can add components and new **GROUP** types. If the active type is an item, you can add restrictions and new **ITEM** types.

A **Choice** expression identifies a sequence of commands. It is not an XML element, so it has no start or end tag.

XML tag notation

Each element in the document file has a start tag and an end tag. **NEWTREE** and **OPENTREE** elements contain other elements. Elements are organized as follows:

Element	Description
Command elements	Actions that initialize type trees, types, and operate on active types
Choice elements	Elements within a command that specify a choice of other elements
Sequence elements	Elements within a command that specify a sequence of other elements
Text elements	Character or integer text items

Each type of element has a start tag and an end tag. Command elements are followed by a `<NL>`. Choice, sequence, and text elements are components of a command. They are not followed by a `<NL>`.

A start tag is the name of the element enclosed in angle brackets. For example: `<CATEGORY>` is the start tag for the **CATEGORY** command.

An end tag uses the same element name and includes a slash (/) inside the left angle bracket. For example, `</CATEGORY>` is the end tag for the **CATEGORY** command.

Some elements have attributes. An attribute list, when defined, appears after the name of the element between the angle brackets of the start tag. For example:

```
<delimited location="INFIX">
```

Composition of the .mts file

This section contains descriptions for Type Tree Maker commands and command elements that make up the Type Tree Maker document (script) file (.mts).

In a Type Tree Maker document (script) file (.mts), command components must be on the same line as the command in which they are contained. In the following examples, components may appear on separate lines for documentation purposes only.

- [Commands](#)
- [Command elements](#)

Commands

Commands in the context of the .mts file are referring to those tags within level one that serve as a command. For example, **NEWTREE** is a command that tells the Type Tree Maker to create a new type tree. Each command and related component is described in this documentation.

- [AddComponent](#)
- [AddRestriction](#)
- [ASCTYPE_XML](#)
- [BinaryDatetime](#)
- [BinaryNumber](#)
- [BinaryText](#)
- [CATEGORY](#)
- [CharDateTime](#)
- [CharNumber](#)
- [CharRestrictions](#)
- [CharTextJapanese](#)
- [CharTextWestern](#)
- [Choice](#)
- [ChoiceComponent](#)
- [GROUP](#)
- [ITEM](#)
- [NEWTREE](#)
- [PROPAGATE](#)
- [Range](#)
- [Range command](#)
- [Range command element](#)
- [RangeRestrictions](#)
- [Sequence](#)
- [SequenceComponent](#)
- [SyntaxItem](#)
- [Unordered](#)
- [UnorderedComponent](#)
- [Value](#)
- [ValueRestrictions](#)

AddComponent

The **AddComponent** command adds a component to the group specified as the active type.

The component is added as the last component in the component list of the active type. If the active type is an item, the **AddComponent** command is ignored and an error message is written to the error file.

See the Type Designer documentation for information on specifying component rules.

Components of AddComponent

A group view displays the components of the **AddComponent** command.

The **AddComponent** element has as an attribute the complete type name of the type to which the component is to be added. It then has either a "[SequenceComponent](#)", "[ChoiceComponent](#)", or "[UnorderedComponent](#)" command element.

Example

```
<AddComponent CompleteTypeName="ACMEREC Table ACME">
<SequenceComponent>
<RelativeTypeName>ACMEREC Row</RelativeTypeName>
<Range Min="0" Max="S"/>
</SequenceComponent>
</AddComponent>
```

AddRestriction

The **AddRestriction** command adds a restriction to the item type specified as the active type.

Components of AddRestriction

A group view displays the components of the **AddRestriction** command.

The **AddRestriction** element has as an attribute the complete type name of the type to which the restriction is to be added. The **AddRestriction** command then has a "[ValueRestrictions](#)", "[RangeRestrictions](#)", or "[CharRestrictions](#)" command.

Example

```
<AddRestrictions CompleteTypeName="Acc't#Qual'rCd Element Data">
<ValueRestrictions>
<Value Description="Life Insurance">07</Value>
<Value Description="Retirement Acct">08</Value>
</ValueRestrictions>
</AddRestrictions>
```

ASCTYPE_XML

The **ASCTYPE_XML** command specifies that an element has XML specific attributes.

Example

```
<xs:element name="ASCTYPE_XML">
<xs:complexType>
<xs:choice>
<xs:element ref="XML_DOCUMENT"/>
<xs:element ref="XML_COMMENT"/>
<xs:element ref="XML_PI"/>
<xs:element ref="XML_PCDATA"/>
<xs:element ref="XML_ELEMENT"/>
<xs:element ref="XML_ANYELEMENT"/>
<xs:element ref="XML_ATTRIBUTE"/>
<xs:element ref="XML_ATTRIBUTELIST"/>
<xs:element ref="XML_CONTENT"/>
<!--
NOTE: The following five XML types are present in the type
tree but they never appear in the mapping. They are only
used to represent the corresponding XML Schema constructs.
They never appear in the type tree generated from a DTD
document, only from XML Schema document.
-->
<xs:element ref="XML_SIMPLETYPE"/>
<xs:element ref="XML_COMPLEXTYPE"/>
<xs:element ref="XML_ATTRIBUTEGROUP"/>
<xs:element ref="XML_GROUP"/>
<xs:element ref="XML_GLOBAL"/>
</xs:choice>
</xs:complexType>
</xs:element>
```

Each of the above declared elements corresponds with their XML Schema counterparts, providing the same level of information.

BinaryDatetime

The **BinaryDatetime** command defines a binary date-time item.

Components of BinaryDatetime

A group view displays the components of the **BinaryDatetime** command.

In addition to its Presentation attribute (**PACKED** or **BCD**) and its **BinaryDateTimeFormatString** element, the **BinaryDatetime** command can have either "[ValueRestrictions](#)" or "[RangeRestrictions](#)" command.

Example

```
<BinaryDatetime Presentation="PACKED">
<BinaryDateTimeFormatString>YYMMDD</BinaryDateTimeFormatString>
</BinaryDatetime>
```

BinaryNumber

The **BinaryNumber** command defines a binary numeric item.

Components of BinaryNumber

A group view displays the components of the **BinaryNumber** command.

The **BinaryNumber** command must have either a BCD, BinFloat, BinInt, or Packed element and either a "[ValueRestrictions](#)" or "[RangeRestrictions](#)" command.

Example

```
<BinaryNumber>
<BinInt Length="4" Sign="YES" ByteOrder="NATIVE"/>
</BinaryNumber>
```

BinaryText

The **BinaryText** command defines a binary text item.

Components of BinaryText

A group view displays the components of the **BinaryText** command.

The **BinaryText** command can have a Size, **ForNONE**, or "[ValueRestrictions](#)" element.

Example

```
<BinaryText>
<Size Min="1" Max="4"/>
<NONE RequiredOnInput="YES"><NULL></NONE>
</BinaryText>
```

CATEGORY

The **CATEGORY** command adds or replaces a category type as a subtype of the active type.

If the active type is a group or item, the **CATEGORY** command is ignored and an error message is written to the error file.

Components of CATEGORY

The following group view displays the components of the **CATEGORY** command.

The **CATEGORY** command must have at least one TypeSyntax, a Sequence, Choice, or Unordered group subclass command, and one of the item subclass command elements.

Example

```
<CATEGORY SimpleTypeName="Field" CategoryParent="Data">
<Sequence partition="NO">
<Implicit/>
</Sequence>
<CharTextWestern>
<Size Min="0" Max="S"/>
<Western CharSet="NATIVE"/>
<ValueRestrictions IgnoreCase="NO" Rule="INCLUDE"/>
</CharTextWestern>
</CATEGORY>
```

CharDateTime

The **CharDateTime** command defines a character date & time item.

Components of CharDateTime

A group view displays the components of the **CharDateTime** command.

In addition to its required CharDateTimeFormatString command element, the **CharDateTime** command can have PadText, Zero and **ForNONE** command elements, as well as either a "[ValueRestrictions](#)" or "[RangeRestrictions](#)" command.

Example

```
<CharDatetime>
<CharDateTimeFormatString>{YYMMDD}{HH24MM}</CharDateTimeFormatString>
<Western CharSet="NATIVE"/>
<NONE>*****</NONE>
<RangeRestrictions Rule="INCLUDE"/>
</CharDatetime>
```

CharNumber

The **CharNumber** command defines a character number item.

Components of CharNumber

A group view displays the components of the **CharNumber** command.

The **CharNumber** command has a required **CharNumber_1 Choice Expression**, which is either a CharInt, Decimal, or Zoned command element and can have Western, Zero, and **ForNONE** command elements and either a "[ValueRestrictions](#)" or "[RangeRestrictions](#)" command.

Example

```
<CharNumber>
<CharInt>
<TotalDigits Min="0" Max="6"/>
<IntegerFormatString>{#';'####}</IntegerFormatString>
</CharInt>
<Western CharSet="ASCII"/>
<Zero>*****</Zero>
</CharNumber>
```

CharRestrictions

The **CharRestrictions** command adds a character restriction to an item.

Components of CharRestrictions

A group view displays the components of the **CharRestrictions** command.

The **CharRestrictions** command has attributes for indicating whether or not the case of restrictions should be ignored and for specifying a syntax item for a release character and can have either a "[IncludeChar](#)" or "[ExcludeChar](#)" command element.

Example

```
<CharRestrictions IgnoreCase="NO">
<ExcludeChar>
<ExcludeValue>$</ExcludeValue>
<RefString>%DOLLAR%</RefString>
</ExcludeChar>
<ExcludeChar>
<ExcludeValue>&#amp;</ExcludeValue>
<RefString>%AMPERSAND%</RefString>
</ExcludeChar>
</CharRestrictions>
```

CharTextJapanese

The **CharTextJapanese** command defines a character text item.

Components of CharTextJapanese

A group view displays the components of the **CharTextJapanese** command.

The **CharTextJapanese** command can have "[Size](#)", "[PadText](#)", **ForNONE**, and "[Japanese](#)" command elements and a "[ValueRestrictions](#)" command.

Example

```
<CharTextJapanese>
<Size Min="0" Max="15"/>
<Japanese CharSet="NATIVE"/>
</CharTextJapanese>
```

CharTextWestern

The **CharTextWestern** command defines a character text item.

Components of CharTextWestern

A group view displays the components of the **CharTextWestern** command.

The **CharTextWestern** command can have "[Size](#)", "[PadText](#)", **ForNONE**, and "[Western](#)" command elements, as well as a "[ValueRestrictions](#)", "[RangeRestrictions](#)" or "[CharRestrictions](#)" command.

Example

```
<CharTextWestern>
<Size Min="0" Max="15"/>
```

```
<Western CharSet="NATIVE"/>
<ValueRestrictions IgnoreCase="NO" Rule="INCLUDE"/>
</CharTextWestern>
```

Choice

The **Choice** command defines a character text item.

Components of choice

A group view displays the components of the **Choice** command.

The **Choice** command can have a [WhiteSpace](#), [FloatingComponent](#) and [ChoiceComponent](#) command.

ChoiceComponent

The **ChoiceComponent** command defines a character text item.

Components of ChoiceComponent

A group view displays the components of the **ChoiceComponent** command.

The **ChoiceComponent** command can have **RelativeTypeName** and **Rule** command elements.

Component Description

RelativeTypeName: Specifies the relative type name of the syntax item used as the separator. A relative type name is a series of simple type names separated by spaces.

Rule: Specifies the component rule (optional) associated with the component. A rule can be up to 32K bytes.

GROUP

The **GROUP** command adds a new group as a subtype of the active type.

If the active type is an item, this command is ignored and an error message is written to the error file.

Components of GROUP

A group view displays the components of the command.

The **GROUP** command can have "[TypeSyntax](#)", a "[Sequence](#)", "[Choice](#)", or "[Unordered](#)" group subclass command.

Example

```
<GROUP>
<SimpleTypeName>MyGroup</SimpleTypeName>
<setUpProperties>INHERIT </setUpProperties>
<terminator>
<WLiteral><NL></WLiteral>
</terminator>
</GROUP>
```

ITEM

The **ITEM** command adds a new item to the active type.

If the active type is a group, this command is ignored and an error message is written to the error file.

Components of ITEM

A group view displays the components of the **ITEM** command.

The **ITEM** command can have "[CharTextWestern](#)", "[CharTextJapanese](#)", "[CharNumber](#)", "[CharDateTime](#)", "[BinaryText](#)", "[BinaryDatetime](#)", "[BinaryNumber](#)", and "[SyntaxItem](#)" commands.

Example

```
<ITEM>
<SimpleTypeName>MyItem</SimpleTypeName>
<iprop_char_text>
<size>0</Min><Max>S</Max></size>
</iprop_char_text>
</ITEM>
```

NEWTREE

The **NEWTREE** command creates a new type tree.

Components of NEWTREE

A group view displays the components of the **NEWTREE** command.

The **NEWTREE** command can have a **ROOT** command element and an **OPENTREE** command.

Example

```
<NEWTREE>
<FileName>install_dir\mytree.mtt</FileName>
<ROOT>
<SimpleTypeName>Sales</SimpleTypeName>
<Description>Tree for Sales</Description>
</ROOT>
</NEWTREE>
```

PROPAGATE

The **PROPAGATE** command allows propagation and deletion of subtypes of the active type.

Keyword Description

INITIATOR: Propagates all initiator properties of the active type to all types in the sub-tree of the active type.

TERMINATOR: Propagates all terminator properties of the active type to all types in the sub-tree of the active type.

RELEASE: Propagates all release properties of the active type to all types in the sub-tree of the active type.

PARTITION: Propagates the partition property of the active type to all group or item types in the sub-tree of the active type.

DESCRIPTION: Propagates the description property of the active type to all types in the sub-tree of the active type.

GROUPFORMAT: Propagates all group properties of the active type to all group and/or category types in the sub-tree of the active type. This keyword is ignored for items.

ITEMFORMAT: Propagates all item properties of the active type to all item and/or category types in the sub-tree of the active type. This keyword is ignored for groups.

DELETESUBTYPES: Deletes subtypes of the active type.

Example:

```
<PROPAGATE>TERMINATOR</PROPAGATE>
```

Range

Range can be a command and a command element.

Range command

The **Range** command defines a range restriction for an item. For example, <Range>x, y

Range command element

The **Range** command element defines a range for a component. For example, [<Range>x, y]

Components of Range

A group view displays the components of the **Range** command/command element.

Component Description

Min: Specifies the integer value of the minimum range.

Max: Specifies the value of the maximum range: either an integer or the value (**S**) for an unspecified maximum range.

Example

```
<Range>
<Min>2</Min>
```

```
<Max>S</Max>
</Range>
```

RangeRestrictions

The **RangeRestrictions** command specifies that an item will have range restrictions.

Components of RangeRestrictions

A group view displays the components of the **RangeRestrictions** command.

The **RangeRestrictions** command can have "[ValueRestrictions](#)" and "[Range](#)" commands.

Sequence

The **Sequence** command defines a group as a sequence group.

Components of Sequence

A group view displays the components of the **Sequence** command.

The **Sequence** command can have an Implicit or Explicit command element and a **SequenceComponent** command.

SequenceComponent

The **SequenceComponent** command defines a component as a sequence group.

Components of SequenceComponent

A group view displays the components of the **SequenceComponent** command.

The **SequenceComponent** command can have a **RelativeTypeName**, Range, or **Rule** command.

Component Description

RelativeTypeName: Specifies the relative type name of the syntax item used as the separator. A relative type name is a series of simple type names separated by spaces.

Rule: Specifies the component rule (optional) associated with the component. A rule can be up to 32K bytes.

SyntaxItem

The **SyntaxItem** command defines a syntax item.

Components of SyntaxItem

A group view displays the components of the **SyntaxItem** command.

The **SyntaxItem** command can have a Size, Western, or Japanese command element and a **ValueRestriction** command.

Unordered

The **Unordered** command specifies a value restriction for an item.

Components of Unordered

A group view displays the components of the **Unordered** command.

The **Unordered** command can have a "[Delimited](#)" or "[WhiteSpace](#)" command elements and either a **FloatingComponent** or "UnorderedComponent" command.

UnorderedComponent

The **UnorderedComponent** command defines a component for an unordered group.

Components of UnorderedComponent

A group view displays the components of the **UnorderedComponent** command.

The **UnorderedComponent** command can have a **RelativeTypeName**, Range, or Rule command.

Component Description

RelativeTypeName: Specifies the relative type name of the syntax item used as the separator. A relative type name is a series of simple type names separated by spaces.

Rule: Specifies the component rule (optional) associated with the component. A rule can be up to 32K bytes.

Value

The **Value** command specifies a value restriction for an item.

Components of Value

A group view displays the components of the **Value** command.

ValueRestrictions

The **ValueRestrictions** command specifies that an item will have value restrictions.

Components of ValueRestrictions

A group view displays the components of the **ValueRestrictions** command.

The **ValueRestrictions** command can have an **IgnoreCase** or **Rule** attribute and a **Value** command.

IgnoreCase

Yes: Not case sensitive

No: Case sensitive

Rule: Specifies the component rule (optional) associated with the component. A rule can be up to 32K bytes.

S

Command elements

This documentation contains descriptions of command elements. Command elements consist of other elements and expressions. Elements have XML start and end tags. Expressions are implied groups within a command that are not enclosed in XML tags.

-

BCD

The **BCD** command element specifies BCD properties for an item type.

Components of BCD

A group view displays the components of the **BCD** command element.

The **BCD** command element can have a **Size** command element.

Example:

```
<BCD>
<size>
<Min></Min>
<Max>10</Max>
</size>
</BCD>
```

BinFloat

The **BinFloat** command element specifies binary float properties for a item type.

Components of BinFloat

A group view displays the components of the **BinFloat** command element.

The **BinFloat** command element can have a **Length** attribute.

Component Name	Attributes	Description
Length	1, 2, 4	Specifies a length restricted to 1, 2, or 4 bytes.

Example

```
<BinFloat>
<Length>10</Length>
</BinFloat>
```

BinInt

The **BinInt** command element specifies binary integer properties for an item type.

Components of BinInt

A group view displays the components of the **BinInt** command element.

The **BinInt** command element can have a **Length**, **Sign**, or **ByteOrder** attribute.

Component Name	Attributes	Description
Length	1, 2, 4	Specifies a length restricted to 1, 2, or 4 bytes.
Sign	Yes	Default setting. Specifies the sign attribute value of the number.
	No	Specifies the sign attribute value of the number.
ByteOrder	<ul style="list-style-type: none"> BIGENDIAN LITTLEENDIAN NATIVE 	Specifies the byte order attribute value of the number.

Example

```
<BinInt>
<Length>10</Length>
<ByteOrder>BIGENDIAN</ByteOrder>
</BinInt>
```

CharInt

The **CharInt** command element specifies character integer number properties.

Components of CharInt

A group view displays the components of the **CharInt** command element.

The **CharInt** command element can have "[TotalDigits](#)" , "[PadNumber](#)" , **IntegerFormatString** and "[ThousandsItem](#)" command elements.

IntegerFormatString: Specifies the syntax of the character integer item.

Integer format strings

The form of an integer format string is similar to that for decimals, except that the Fraction sub-string is not included:

```
"{" + Leading-sign(1) + Whole# + Trailing-sign(1) + "}"
```

Example

```
{L+}
{L-`(`###T-`)}'
```

Decimal

The **Decimal** command element specifies character decimal number properties.

Components of Decimal

A group view displays the components of the **Decimal** command element.

The **Decimal** command element can have **TotalDigits**, **PadNumber**, **DecimalFormatString**, **ThousandsItem**, and **FractionItem** command elements.

DecimalFormatString: Specifies the syntax of the character decimal item.

Decimal format Strings

A decimal format string is enclosed in braces { }. It has an optional "[Leading-Sign](#)" , a required Whole#, a required Fraction, and an optional Trailing-Sign. The following is an example of a decimal format string:

```
{" + Leading-Sign(1) +Whole# + Fraction + Trailing-Sign(1) + "}"
```

Leading-Sign

The following table describes the optional **Leading-Sign** format string.

Sub-string Values Description:

"L" + Positive + Negative + Zero(1)

A leading sign is required for positive numbers and negative numbers.

"L"+ "[" + Positive + "]" + Negative + Zero(1)

A leading sign is optional for positive numbers and required for negative numbers.

"L" + Positive + "[" + Negative + "]" + Zero(1)

A leading sign is required for positive numbers and optional for negative numbers.

"L" + Positive + Zero(1)

A leading sign is required for positive numbers and there is no leading sign for negative numbers.

"L" + Negative + Zero(1)

A leading sign is required for negative numbers and there is no leading sign for positive numbers.

Example

```
{L+}
```

Whole#

The following table describes the required **Whole#** format string.

Sub-string Values	Description
min-digits(1) + "#" + value(1) + "###" + max-digits(1) -or- min-digits(1) + "#" + "[" + value(1) + "]" + "###" + max-digits(1)	Specifies the thousands separator and the range of whole number digits. If min-digits is not used, the default is zero. If max-digits is not used, the default is S . If a ThousandsItem is specified, a Value must be present as the default for the syntax item.
"V" + implied-places	Specifies the decimal to be implicit and implied places specifies where the intended decimal separator is to be placed.
value + min-digits(1) + "##" + max-digits(1)	Specifies the value of the decimal separator to be required and the range of fraction digits. If min-digits is not used, default is zero. If max-digits is not used, default is S .
"[" + value + min-digits(1) + "##" + max-digits(1) + "]"	Specifies the value of the decimal separator to be optional if there is no fractional portion of the number. It also specifies the range of fraction digits. If min-digits is not used, default is zero. If max-digits is not used, default is S .

Examples

####[`.'##] is interpreted as:

- There is no thousands separator.
- The decimal separator has the value of a period (.) .
- The decimal separator and fraction are optional.
- There are no restrictions on the whole number digits, or on fractional digits.

Value Description:

L-#####V2

An implicit decimal, implied to two places, with a required leading minus sign for negative numbers.

L-#####[`.##]

ANSI decimal.

L-1####[,1##]

EDIFACT decimal.

L-'N'####'##

SWIFT decimal.

Fraction

The following table describes the required **Fraction** format string.

Sub-string Values Description

"V" + implied-places

Specifies the decimal to be implicit and implied places specifies where the intended decimal separator is to be placed.

value + min-digits(1) + "##" + max-digits(1)

Specifies the value of the decimal separator to be required and the range of fraction digits. If min-digits is not used, default is zero. If max-digits is not used, default is **S**.

"[" + value + min-digits(1) + "##" + max-digits(1) + "]"

Specifies the value of the decimal separator to be optional if there is no fractional portion of the number. It also specifies the range of fraction digits. If min-digits is not used, default is zero. If max-digits is not used, default is **S**.

Trailing-Sign

The following table describes the optional **Trailing-Sign** format string.

Sub-string Values Description

"T" + Positive + Negative + Zero(1)

A trailing sign is required for positive numbers and negative numbers.

"T" + "[" + Positive + "]" + Negative + Zero(1)

A trailing sign is optional for positive numbers and required for negative numbers.

"T" + Positive + "[" + Negative + "]" + Zero(1)

A trailing sign is required for positive numbers and optional for negative numbers.

"T" + Positive + Zero(1)

A trailing sign is required for positive numbers and there is no trailing sign for negative numbers.

"T" + Negative + Zero(1)

A trailing sign is required for negative numbers and there is no trailing sign for positive numbers.

Sign Sub-string formats

The following table describes the sub-strings:

Sub-string name	Sub-string Values	Meaning
Positive	"+" + value(1)	
Negative	"-" + value(1)	
Value	A text-string enclosed in single-quotes. Value has a release character of "/" if the text uses a single-quote or "/" in the format string.	The sign value of the previous sign-indicator. If Value is not used, the default is "+" for positive numbers and "-" for negative numbers.
Zero	"Z" + value	Specifies the required leading sign value if the number is zero. If Zero is not used, there is no sign associated with a zero.
	"[" + "Z" + value + "]"	Specifies the optional leading sign value if the number is zero. If Zero is not used, there is no sign associated with a zero.

Delimited

The **Delimited** command element is a sequence element that specifies delimited properties of a group type.

Delimited consists of a location attribute and a **Delimiter Choice**.

Components of delimited

A group view displays the components of the Delimited command element.

The **Delimited** command element can have a **location** attribute, and "[DelimiterLiteral](#)" and "[Variable](#)" command elements.

Location attribute value:

PREFIX: Specifies before each component.

INFIX: Default setting. Specifies between each component.

POSTFIX: Specifies after each component.

Examples

```
<delimited location="PREFIX">
<Variable>
<RelativeTypeName>Record Separator</RelativeTypeName>
<DefaultSyntaxValue><CR></DefaultSyntaxValue>
</Variable>
<delimited>
<delimited>
<WLiteral WesternCharSet="ASCII">
<WesternLiteral>#</ WesternLiteral >
</WLliteral >
</delimited>
```

DelimiterLiteral

The **DelimiterLiteral** command element specifies the properties of a western literal.

Components of DelimiterLiteral

A group view displays the components of the DelimiterLiteral command element.

The **DelimiterLiteral** command element can have Western and Japanese and command elements.

empty

A group view displays the components of the **empty** command element.

The **empty** command element can have **IgnoreCase** or **Required** attributes, Western or Japanese commands and a **LiteralValue** command.

IgnoreCase

Yes: Not case sensitive.

No: Case sensitive.

Required

OnInput: Only required on input.

OnOutput: Only required on output.

Always: Always required.

Never: Never required.

ExcludeChar

A group window displays the components of the **ExcludeChar** command element.

The **ExcludeChar** command element can have an **ExcludeValue** or **RefString** command element.

ExcludeRange

The **ExcludeRange** command element defines the range restriction to be excluded for an item.

Components of ExcludeRange

A group view displays the components of the **ExcludeRange** command element.

The **ExcludeRange** command element can have a **Min** or **Max** command elements.

ExcludeValue

The **ExcludeValue** command element defines the values to be excluded for an item.

Components of ExcludeValue

A group view displays the components of the **ExcludeValue** command element.

The **ExcludeValue** command element can have a **Description** attribute. Enter the values to be excluded from the restriction list in the item view.

Explicit

The **Explicit** command element specifies the attributes and syntax for an explicit group.

Components of Explicit

A group view displays the components of the command element.

The **Explicit** command element can have a **Track** attribute and a Delimited command.

Track

Content
 Track only content.

Places
 Track existing components even if they have only a placeholder.

Example

```
<Explicit>
<delimited>
<WLiteral WesternCharSet="ASCII">
<WesternLiteral>#</ WesternLiteral >
</WLliteral >
</delimited>
</Explicit>
```

FractionItem

A group window displays the components of the **FractionItem** command element.

The **FractionItem** command element can have a **Find** attribute and **RelativeTypeName** command element.

Find

- **Yes:** Specifies to find the item separator.
- **No:** Default setting. Specifies not to find the item separator.

RelativeTypeName: Specifies the relative type name of the syntax item used as the separator. A relative type name is a series of simple type names separated by spaces.

Example

```
<FractionItem find="YES">
<RelativeTypeName>My Tag</RelativeTypeName>
</FractionItem>
```

Implicit

The **Implicit** command element specifies the attributes and syntax for an implicit group.

Components of Implicit

A group view displays the components of the **Implicit** command element.

The **Implicit** command element can have a **Delimited** or **WhiteSpace** command and a **FloatingComponent** command.

IncludeChar

A group window displays the components of the **IncludeChar** command element.

The **IncludeChar** command element can have an **IncludeFirst** or **IncludeAfter** command element.

INITIATOR

The **INITIATOR** command element properties of the initiator of a type.

Components of INITIATOR

A group view displays the components of the **INITIATOR** command element.

The **INITIATOR** command element can have a **Literal** or **Variable** command element.

Example

```
<initiator>
<WLiteral>
<WesternLiteral>:35B</WesternLiteral>:
</WLliteral>
</initiator>
```

Japanese

The **Japanese** command element specifies the Japanese character set.

Components of Japanese

A group view displays the components of the **Japanese** command element.

The following data languages can be defined in the **Japanese** component.

Literal

A group view displays the components of the **Literal** command element.

The **Literal** command element can have an **IgnoreCase** attribute, a Western or Japanese command element, and a **LiteralValue** command.

IgnoreCase

- **Yes:** Not case-sensitive.
- **No:** Case-sensitive.

Modify

A group view displays the components of the **Modify** command element.

The **Modify** command element can have a **PROPAGATE**, **AddComponent**, or **AddRestriction** command.

OneByteLiteral

A group window displays the components of the **OneByteLiteral** command element.

The **OneByteLiteral** command element can have a **LiteralValue** or **Western** command element.

Packed

The **Packed** command element specifies binary packed properties for an item type.

Components of Packed

A group view displays the components of the **Packed** command element.

The **Packed** command element can have a **Length**, **ImplicitDecimalPlaces**, or **TrailingSign** attribute.

Length: Specifies the length of the packed number.

ImplicitDecimalPlaces: Specifies the implicit decimal places of the packed number.

TrailingSign

- **Yes:** Specifies the presence of a Components sign.
- **No:** Specifies the absence of a Components sign.

Example

```
<Packed>
<Length>10</Length>
<ImplicitDecimalPlaces>2</ImplicitDecimalPlaces>
</Packed>
```

PaddedToFixedSize

A group view displays the components of the **PaddedToFixedSize** command element.

PadNumber

The **PadNumber** command element specifies the one-byte pad character for number text items.

Components of PadNumber

A group view displays the components of the **PadNumber** command element.

The **PadNumber** command element can have **Justify**, **ApplyPad**, or **Fill** attributes, and either a **PadValue** or "**PaddedToFixedSize**" command.

Justify:

- **LEFT:** Default setting. Specifies left justification.
- **RIGHT:** Specifies right justification.

ApplyPad:

- **ANYCONTEXT:** Specifies to pad the number text in any context.
- **FIXEDGROUP:** Default setting. Specifies to pad the number text only in a fixed context.

Fill:

- **BEFORE:** Specifies to pad the number before the sign.
- **AFTER:** Default setting. Specifies to pad the number after the sign.

PadValue: Specifies the value of the one-byte pad character.

Example

```
<PadNumber fill="AFTER">
<PadValue><></PadValue>
<PaddedToFixedSize Length="50"/>
</PadNumber>
```

PadText

The **PadText** command element specifies the one-byte pad character for character text items.

Components of PadText

A group view displays the components of the **PadText** command element.

The **PadText** command element can have a **Justify** or **ApplyPad** attributes and a **PadValue** or "[PaddedToFixedSize](#)" command element.

Justify:

- **LEFT**: Default setting. Specifies left justification.
- **RIGHT**: Specifies right justification.

ApplyPad:

- **ANYCONTEXT**: Specifies to pad the text in any context.
- **FIXEDGROUP**: Default setting. Specifies to pad the text only in a fixed context.

PadValue: Specifies the value of the one-byte pad character.

Example

```
<PadText>
<PadValue><SP></PadValue>
<PaddedToMinContent/>
</PadText>
```

RELEASE

The **RELEASE** command element specifies the release character for the active type.

Components of RELEASE

A group view displays the components of the **RELEASE** command element.

The **RELEASE** command element can have a "[OneByteLiteral](#)" or "[Variable](#)" command element.

Example

```
<Release>
<ReleaseLiteral>
<OneByte>?</OneByte>
</ReleaseLiteral>
</Release>
```

ROOT

The **ROOT** command element specifies the properties for the root of the type tree.

Components of ROOT

A group view displays the components of the **ROOT** command element.

The **ROOT** command element can have a **SimpleTypeName**, **Description**, **SetUpProperties**, **SetUpComponents**, or **OrderSubtypes** attributes. The **ROOT** command element can also have a Sequence, Choice, or Unordered group subclass command and one of the item subclass command elements.

Component	Description
SimpleTypeName	Specifies the simple type name of the category added or replaced.
Description	Describes the category added or replaced.
SetUpProperties	INHERIT : If a property is not used, property is inherited. DEFAULT : Default setting. If a property is not used, properties that apply to the root of a newly created type tree are used.
SetUpComponents	INHERIT : Inherit all components. DEFAULT : Default setting. Do not inherit components.
OrderSubTypes	ASCENDING : Default setting. Specifies that subtypes of the category replaced or added in ascending order. DESCENDING : Specifies that subtypes of the category replaced or added in descending order. ADDFIRST : Specifies that subtypes of the category replaced or added to the beginning of the list. ADDLAST : Specifies that subtypes of the category replaced or added to the end of the list.

Example

```
<Root>
<Description>Sales Automation </ Description>
</Root>
```

Size

The **Size** command element specifies the size properties of an item.

Components of Size

A group view displays the components of the **Size** command element.

The **Size** command element can have a **Min** or **Max** attributes.

Component Description:

- **Min**: Specifies the integer value of the minimum size.
- **Max**: Specifies the value of the maximum size: either an integer or the value (**S**) for an unspecified maximum size.

Example

```
<size>
<Min>2</Min>
<Max>S</Max>
</size>
```

TERMINATOR

The **TERMINATOR** command element specifies the terminator of the active type.

Components of TERMINATOR

A group view displays the components of the **TERMINATOR** command element.

The **TERMINATOR** command element can have a Literal or Variable command elements.

Example

```
<terminator>
<Literal>
<WesternLiteral><NL></WesternLiteral>:
</Literal>
</terminator>
```

ThousandsItem

The **ThousandsItem** command element specifies the thousands separator of a character decimal number or a character integer as an item.

Components of ThousandsItem

A group view displays the components of the **ThousandsItem** command element.

The **ThousandsItem** command element can have a **Find** attribute and a **RelativeTypeName** command element.

Component Name	Description
Find	Yes : Specifies to find the item separator. No : Default setting. Specifies not to find the item separator.
RelativeTypeName	Specifies the relative type name of the syntax item used as the separator. A relative type name is a series of simple type names separated by spaces.

Example

```
<ThousandsItem>
<RelativeTypeName>My Decimal</RelativeTypeName>
</ThousandsItem>
```

TotalDigits

The **TotalDigits** command element specifies the digits properties for a character number.

Components of TotalDigits

A group view displays the components of the **TotalDigits** command element.

The **TotalDigits** command element can have a **Min** or **Max** attributes.

Component Name	Attributes	Description
TotalDigits	Min Max	Specifies the minimum and maximum digits of the character decimal number. If not used, the default is a minimum of 0, maximum of unspecified (S).

Example

```
<TotalDigits>
<Min>2</Min>
<Max>15</Max>
</TotalDigits>
```

TTMAKER

A group view displays the components of the **TTMAKER** command element.

The **TTMAKER** command element can have a **Version** attribute and a [NEWTREE](#) or [OPENTREE](#) commands.

TypeSyntax

A group view displays the components of the command element.

The **TypeSyntax** command element can have an [INITIATOR](#), [TERMINATOR](#), [RELEASE](#), or [empty](#) command elements.

Variable

The **Variable** command element specifies properties of a variable syntax object.

Components of Variable

A group view displays the components of the **Variable** command element.

The **Variable** command element can have a **Find** attribute and a **RelativeTypeName** or **DefaultSyntaxValue** command elements.

Component	Description
Find	YES: Specifies to find the value of the variable delimiter. NO: Default setting. Specifies not to find the item delimiter. Use the last value found or the default value of the variable delimiter.
RelativeTypeName	Specifies the relative type name of the syntax item used as the separator. A relative type name is a series of simple type names separated by spaces.
DefaultSyntaxValue	Specifies the literal used as a default whenever a value for the syntax item has not been set in the data. If unprintable, enter as symbolic values. If entering a symbolic value in a map rule to be interpreted by the Type Tree Maker, separate the first character from the rest. For example, "<" + "CR>" or "<CR>"

Example

```
<Variable find="YES">
<RelativeTypeName>My Tag</RelativeTypeName>
<DefaultSyntaxValue>:35B</DefaultSyntaxValue>
</Variable>
```

Western

The **Western** command element specifies western character set properties.

Components of western

A group view displays the components of the **Western** command element.

The following data languages can be defined as a character set of a **Western** literal:

WhiteSpace

A group view displays the components of the **WhiteSpace** command element.

The **WhiteSpace** command element can have a **BuildAs** attribute and a Western command element.

Component Description:

BuildAs: Enter the characters that will replace white spaces.

Zero

The **Zero** command element specifies a special value for zero.

Components of Zero

A group view displays the components of the **Zero** command element.

The **Zero** command element can have a **RequiredOnInput** attribute.

Attribute Description

RequiredOnInput: The special value is required on input.

Zoned

The **Zoned** command element specifies character zoned number properties.

Components of zoned

A group view displays the components of the **Zoned** command element.

The **Zoned** command element can have an **ImplicitDecimalPlaces** or **Sign** attribute and either a **TotalDigits** or **PadText** command element.

Component	Description
ImplicitDecimalPlaces	Specifies the number of implied decimal places.
Sign	Yes: Indicates the zoned number has a sign. No: Indicates the zoned number does not have a sign.

Example

```
<zoned>
<ImplicitDecimalPlaces>0</ImplicitDecimalPlaces>
</zoned>
```

Type Tree Maker examples

Type Tree Maker examples are provided with the Design Studio. These examples show how to use the Type Tree Maker and Type Tree Maker document files.

When you install the Design Studio, two example folders are created. One example folder is created at: *install_dir \examples\dsgnstud\ttmaker*.

The ttmaker directory contains the following folders:

Folder Description:

export: Exporting item restrictions to create a cross-reference file.

import: Importing metadata to create a type tree.

The second examples folder is created at: *install_dir \ttmaker*.

The ttmaker directory at this location contains the following folder:

dtd: The document type definition (DTD) defining the structure of the Type Tree Maker document file.

- [Export example](#)
- [Import example](#)
- [DTD example](#)

Export example

The export folder contains files that can be used to export an item's restriction list and then process the resulting document file to create a cross-reference file. [Generating a Cross-Reference Table from a Restriction List](#) describes this procedure in detail. The following briefly describes the procedure:

- In the Type Designer, select the type and use the Export command to create an **.mts** file for that type.
 - A map to create a cross-reference table uses the **.mts** file exported from the Type Designer. Each row in the resulting output contains two items from the restriction list: the restriction and its description.
 - The file can be used as a lookup file for some other mapping task.
 - [Installed export example files](#)
 - [Files created](#)
 - [Generating a cross-reference table from a restriction list](#)
-

Installed export example files

The following files are installed in the export folder:

Table 1.

File	Use
export.mms	Map file that uses the .mts file as input to create the xref.txt file.
element.mtt	Type tree that contains the item with the restriction list.
xreftbl.mtt	Type tree that defines the cross-reference table to be produced.
readme.txt	Readme file that briefly describes the Export example.
ttmaker60.mtt	Type tree that contains the types that define the structure and syntax of the Type Tree Maker document file.

Files created

When you work through this example, the following files are created:

Table 1.

File	How the File is Created
element.mts	Type Tree Maker command file created by exporting the sub-tree from the Element type tree.
xref.txt	The cross-reference table created by running the map.

Generating a cross-reference table from a restriction list

About this task

The following section explains how a Type Tree Maker document file containing a restriction list is mapped to a cross-reference table.

To generate a cross-reference table from a restriction list:

1. Open a project in the Extender Studio.
2. If not already imported into your work area, import the file system for the Export Type Tree Maker Example. The files are located at *install_dir\examples\dsgnstud\ttmaker\export*.
3. Open the **element.mtt** type tree.
4. Double-click the item type **Acc't#Qual'rCd**.
5. The item view opens. The restriction list appears in the **Include** column.
6. Close the item view when you finish looking at the restrictions.
7. To export the subtree with this restriction list, right-click **Acc't#Qual'rCd** and select Export from the context menu. The Export tree to file dialog opens.
8. Enter a new or accept the default file name and path and click Save. The exported **.mts** file is saved. This file contains commands with information that will be used to create the cross-reference file.
9. Open the example map source **export.mms**.
This map source file contains two maps: an executable map **exprstrc** and a functional map **It'sARow**.
10. Build and run the **exprstrc** map.
11. View run results.

Results

The cross-reference file now contains the necessary information from the item restriction list.

Import example

The import folder is installed in the *install_dir\examples\dsgnstud\ttmaker* folder. It contains files that can be used to create a Type Tree Maker document file from a file that contains metadata. Metadata is data about data; it defines the syntax, structure, and semantic rules of data. A type tree is a graphical representation of metadata. The document file that is used by the Type Tree Maker is metadata in a textual form.

The type tree that defines the document file is a schema. It defines data about metadata. The type tree that defines the input metadata is a schema too; it defines the metadata used to generate the document file.

A map whose purpose is to update rows in a database table with data from another data file might then use the resulting type tree.

Briefly, this procedure consists of the following:

- Define the map that generates a Type Tree Maker document file from the input metadata.
 - The Type Tree Maker generates a type tree from the document file. The type tree defines several tables, their data fields and rows.
 - This type tree could then be used by another map (which is not supplied as part of this example). The map could read or update rows in database tables with the contents of some other input.
- [Installed import example files](#)
 - [Files created](#)
 - [MyImport.mtt type tree](#)
 - [Mapping from metadata to a TTMAKER document](#)

Installed import example files

The following files are installed in the import folder:

Table 1.

File	Use
createtable.mms	Map file that contains the executable map TableImport, which generates the output file acmetbls.mts . This .mts file is the input to the Type Tree Maker. This is described in the section, " Files Created ".
acmemeta.mtt	Type tree that defines the schema for the table, row, and field types to be created. This tree contains the type MetaFile, which defines the input to the map.
myimport.mtt	Type tree that contains the definition of the Type Tree Maker document file to be created.
acmedef.txt	Data for the MetaFile input.
readme.txt	Readme file that briefly describes the Import example.

Files created

The following files are created when working through this example:

Table 1.

Files Created	How the File is Created
acme_tables.mts	Type Tree Maker document file created by running the map.
acme_tables.mtt	Type tree generated by the Type Tree Maker from the acme_tables.mts file.

MyImport.mtt type tree

The **myImport.mtt** is a customized version of **ttmaker60.mtt**. The **ttmaker60.mtt** type tree is generic; it can be used for any Type Tree Maker document file. A customized version helps to visualize the solution to a specific problem. In **ttmaker60.mtt**, a type tree consists of either a NEWTREE or OPENTREE element, which in turn consists of a series of **OPENTREE Choice Expression(s)**.

The **myImport.mtt** type tree replaces the generic **OPENTREE Choice Expression** with specific components for constructing a specific type tree. The **ttmaker60.mtt** type tree was made more specific for this example, as follows:

ttmaker60.mtt was saved as **myImport.mtt**. The layout of the type tree to be created was designed.

Specific types were added as subtypes of the ITEM, GROUP, and CATEGORY Element types under the root **XML**.

Each specific type was modeled after its parent type. For example, the FieldType ITEM Element is identical to the generic ITEM Element.

After all the subtypes were made, the components of NEWTREE were changed to incorporate the specific types for this example.

Now, you are ready to make the map using the modified MyImport type tree.

Mapping from metadata to a TTMAKER document

In the **createtable.mms** source file, **tblimp** is the executable map. It takes as its input the **Acme** metadata file and produces a type tree command file that will create a new type tree file defining this data. The TableImport map generates the **.mts** file.

The input card for the map uses the definitions of the metadata contained in the **Acmemeta.mtt** type tree file and uses the actual metadata contained in **ACMEDEF.TXT**:

The **acmemeta.mtt** type tree describes the **Acme** metadata:

The type of the output card for the map is Document XML from the myimport.mtt type tree.

The **TableImport** executable map contains rules that create the **.mts** file from the input metadata.

After you build and run the map, view the Run Results.

When you run the Type Tree Maker with the **acme_tables.mts** file as input, the Type Tree Maker window shows the type tree being built. When the Type Tree Maker completes, the Type Tree Maker window and a completion message is displayed.

The **acme_tables.mtt** type tree contains types for all the fields, rows, and tables defined in **acmedef.txt**.

This type tree can then be used to describe the input or output data for some other map.

DTD example

The following **.dtd** file is installed in the *install_dir\ttmaker\dtd* folder:

Table 1.

File	Use
ttmaker60.dtd	The document type definition (DTD) defining the structure for the Type Tree Maker document file.

Return codes and error messages

When the Type Tree Maker finds a problem with a command, it returns either an error message or a warning message, depending on the severity of the problem. These error and warning messages, viewable from the Type Tree Maker, are also stored in the *install_dir\ttmaker.log* file.

The **ttmaker.log** file record contains the line number of the command that caused the error or warning message, followed by a message. An example of a warning message is Warning 34 at line 3: Overwrote existing type (and possible subtree).

- [Type Tree generation error messages](#)
- [Type tree generation logic warning messages](#)
- [Errors and warnings](#)

Type Tree generation error messages

The error and warning messages are listed in the following tables. The hints show some likely causes for the error message.

A general hint is to always check the spelling and syntax of the commands.

Table 1.

Message	Description
Command line too long	Correct the command line. The maximum size of a command line is 4096 bytes.
Invalid syntax in command line	Correct the command.
Cannot create type tree	A directory may not exist. All directory names in the path must conform to 8.3 rules: a maximum of eight characters for file name and a three-character extension.
Cannot set root type	The definition of the root type is incorrect.
Cannot set description	The type was not created properly.
Cannot set current type (Type does not exist.)	The type was not created properly.
Cannot create type (already exists?)	The type cannot fit under the active type (for example: a group cannot be placed under an item), the active type name is too long, or the number of types exceeds the maximum number of types allowed in a type tree.
Invalid reserved word	Check the command line and correct.
Memory failure	Close applications and run Type Tree Maker again.
[] mismatch	Check the command line syntax and correct.
Cannot open type tree	The type tree file does not exist.
Cannot set type information	The type was not created properly.
Cannot set character attributes	The active type is not a character item.
Cannot set binary attributes	The active type is not a binary item.
Cannot set delimited format	The active type is not a delimited group.
Cannot set implied format	The active type is not an implied group.
Cannot add component	The active type is an item that cannot have a component list.
User aborted	The user pressed Cancel.
Cannot set initiator	The type was not created properly.
Cannot set terminator	The type was not created properly.
Cannot set release character	The type was not created properly.
Cannot delete restriction list	The active type is not an item.
Cannot delete component list	The active type is an item that cannot have a component list.
Cannot add restriction	The active type is not an item. Only items can have restrictions.
Cannot propagate	The type was not created properly.
Cannot get type information	The type was not created properly.
Cannot get initiator	The type was not created properly.
Cannot get terminator	The type was not created properly.
Cannot get release character	The type was not created properly.
Cannot get delimited format	The active type is not a delimited group.
Cannot get implied format	The active type is not an implied group.
Cannot get character attributes	The active type is not a character item.

Message	Description
Cannot get binary attributes	The active type is not a binary item.
Cannot replace type - class of type is incorrect	The active type does not match the class.
Cannot get type name	The type was not created properly or the path name was specified incorrectly.
Cannot get type information to replace type	The type was not created properly.
Hex value is not valid	The valid Hex characters are 0-9 and A-F.
Cannot save type tree specified in last NEWTREE= command	The path name is invalid.
Component rule is invalid	Check the syntax of the component rule.
Cannot delete subtype	The type does not exist.
Analysis errors occurred	The tree did not analyze correctly.
Invalid file name specified	Check for invalid characters or the size of the file name.
Invalid type name	Check the type name for reserved characters or reserved words.
Overwrote existing type (and possible subtree)	The type already existed in the tree and was overwritten.
Separator option has Find set but no default	For the Separator option, you must specify Default when you specify Find .
Analysis warnings occurred	The Type Tree Analyzer produced warnings.

Type tree generation logic warning messages

The following messages are generated if you use the Type Tree Maker to create a type tree.

Table 1.

Return Code	Message
L202	RESTRICTION list deleted: TYPE is not an ITEM - TYPE: 'type name' Hint: Type class was changed from an item to a group or category, so the restriction list was deleted. If this was not your intent, change it back to the way it was.
L207	Root of TYPE Tree is not a CATEGORY - TYPE: 'type name'
L208	DELIMITER location not specified - TYPE: 'type name'
L209	SYNTAX ERROR in COMPONENT RULE - COMPONENT # of TYPE: 'type name'
L210	TYPE created from an ITEM or a GROUP is a CATEGORY - TYPE: 'type name'
L211	TYPE created from an ITEM is a GROUP - TYPE: 'type name'
L212	TYPE created from a GROUP is an ITEM - TYPE: 'type name'
L213	Floating Component TYPE deleted because TYPE has an Explicit format - TYPE: 'type name' (warning)
L214	Invalid ITEM presentation. Presentation set to defaults - TYPE: 'type name' (warning)
L215	DELIMITER length greater than maximum allowed in TYPE: 'type name' Hint: Delimiters, initiators, and terminators are limited to 120 bytes.
L216	The Padded To length for item - 'type name' was less than the maximum content size.
L217	Fixed TYPE - 'type name' must include white space or have a terminator.
L218	RELEASE CHARACTER for TYPE - 'type name' must have a value.
L219	INITIATOR for TYPE - 'type name' must have a value.
L220	TERMINATOR for TYPE - 'type name' must have a value.
L221	Name for TYPE - 'type name' contains reserved characters. Please rename.
L222	DELIMITER for TYPE - 'type name' had no value. The group format has been set to Implicit with No syntax. (warning)
L223	No syntax item specified as DELIMITER for TYPE 'type name'
L224	No syntax item specified as RELEASE CHARACTER for TYPE 'type name'
L225	No syntax item specified as INITIATOR for TYPE 'type name'
L226	No syntax item specified as TERMINATOR for TYPE 'type name'
L227	No syntax item specified as 1000's separator for TYPE 'type name'
L228	No syntax item specified as decimal separator for TYPE 'type name'
L229	1000's separator for TYPE 'type name' has no value
L230	Decimal separator for TYPE 'type name' has no value
L231	1000's separator type neither inherited nor local TYPE 'type name'
L232	Default 1000's separators not specified TYPE 'type name'
L233	Default 1000's separator not in restriction list TYPE 'type name'
L234	1000's separator type is not a SYNTAX ITEM TYPE 'type name'
L235	1000's separator type has no restriction list TYPE 'type name'
L236	Decimal separator type neither inherited nor local TYPE 'type name'
L237	Default decimal separator not specified - TYPE 'type name'
L238	Default decimal separator not in restriction list TYPE 'type name'
L239	Decimal separator type is not a SYNTAX ITEM TYPE 'type name'
L240	Decimal separator type has no restriction list TYPE 'type name'

Errors and warnings

When the Type Tree Maker finds a problem with a command, it creates either an error message or a warning message, depending on the severity of the problem. These error and warning messages that can be viewed from the Type Tree Maker window are also stored in the file **ttmaker.log** in your product installation directory. When the Type Tree Maker finishes running, view the errors and warnings in the **ttmaker.log** file.

The **ttmaker.log** file record contains the line number of the command that caused the error or warning message, followed by a message. An example of a warning message is:

```
Warning 34 at line 3: Overwrote existing type (and possible subtree)
```

See [Return Codes and Error Messages](#) for a list of error and warning messages.

A general hint is to always check the spelling and syntax of the commands.

Integration Flow Designer

Integration Flow Designer overview

The Integration Flow Designer is a component of the Design Studio that provides a graphical facility to combine collections of maps and run them as a single unit.

The Integration Flow Designer has an easy-to-use graphical interface. You can create system diagrams, what-if scenarios, generate process control information, and see how the systems will behave at execution time. Additionally, the automation of the Integration Flow Designer helps reduce the number of errors that often result from manual operations.

The term for a collection of maps is system. Using the Integration Flow Designer, you create a system file by combining map components and then saving them as a single file known as a system definition file (.msd).

The Integration Flow Designer provides both local and client functionality. Use the Command Server or Launcher to execute a system's process control information on both Windows and UNIX operating systems.

- [When to Use the Integration Flow Designer](#)

When to Use the Integration Flow Designer

Use the Integration Flow Designer when you have multiple maps to manage within your enterprise. Just one click can build or port as many maps as you have defined in any system.

Note: You must use the Integration Flow Designer to generate systems if you plan to use the Launcher. The Integration Flow Designer is the client definition facility for the Launcher.

You do not need the Integration Flow Designer if you are using a Command Server. However, you will find it to be very useful as a client facility for managing maps that will be run by a Command Server. The Integration Flow Designer generates process control information for Command Servers in the form of command files. Generating these command files manually is tedious and error-prone. Using the Integration Flow Designer eliminates possible manual errors.

Using the Integration Flow Designer

When you use the Integration Flow Designer to create systems from collections of maps, you will typically have maps already created and ready to use. However, using the Integration Flow Designer, you can create placeholder maps called pseudo maps. You can add input and output cards to these pseudo maps and create source maps as you move forward with your design.

For each system, you can select a server and choose the execution mode: **Launcher** or **Command**. If you are using the Launcher, you must generate a Launcher system file (.msl). The .msl file is the only file that the Launcher recognizes. If you are using the Command Server, you can generate text command files.

When you select a server for the system, the system is called an executable system. For each executable system, you can create and run deploy scripts that automate the process of generating and deploying a system to a different server.

After you generate an .msl file, you are ready to run the system using the Launcher.

Stages of using the Integration Flow Designer

The three main stages of using the Integration Flow Designer are discussed.

- [Stage 1: defining systems](#)
- [Stage 2: verifying component relationships](#)
- [Stage 3: preparing systems to run](#)

Stage 1: defining systems

Use the Integration Flow Designer at design time to model what-if scenarios and visualize the results.

In the first stage, you use the Integration Flow Designer to construct system definition files. A system definition file is a model of a system of maps that you want to execute. System definition files are maintained in various system windows that you open and view. The diagrams include map and subsystem components and their execution properties. Data flow relationships are automatically derived and displayed. The system definitions are stored in system definition files (.msd) based on how you decide to organize them. The Navigator helps you to graphically interact with system definition files and the various systems that they contain.

The Integration Flow Designer includes a Doc Links feature that helps you document your design. You can link any text or Windows-registered document type to both map and system components. Then you can view and edit this document by referencing it through the system component to which it is linked. For example, you can link a Microsoft Word document to a map component that specifies design information for this map. You can link a document from a preferred project management tool to a map or a system to assist in managing the project plan. In addition to Doc Links, the Integration Flow Designer enables you to enter free-form text directly to the system definition file.

While you are defining systems, you can use the Integration Flow Designer to open the Map Designer and/or the Database Interface Designer using a map you select in a system. You can also open the Type Designer using a type tree associated with a map input or output card that you select.

Stage 2: verifying component relationships

The Integration Flow Designer displays a system graphically, which allows you to visualize your designs and verify that relationships between components are configured properly.

You can view the contents of maps and subsystems by double-clicking the icons in the system window. This allows you to view the details associated with a component's sources or targets. Visual cues, such as tool tips for specific sources and targets, help you to see key pieces of setup information. Displaying information graphically reduces the need to hunt for information buried within a system definition; however, a find-and-replace operation can also be used.

Stage 3: preparing systems to run

After you design your systems and verify component relationships, you use the Integration Flow Designer to prepare them to run. The Integration Flow Designer assists you in this process by building maps and porting them to designated servers. You can easily build and port entire systems, or specific groups of maps or individual maps.

The Integration Flow Designer also generates process control information based on the execution mode you specify for a system and the execution settings you have specified for the various components within the system. The Integration Flow Designer produces command files for systems that will be run by a Command Server and Launcher system files (.msl) for systems that will be run by a Launcher.

The Integration Flow Designer includes an Analyzer that checks your system definitions for logical consistency to ensure they can be executed. The Analyzer detects any inconsistencies you may have introduced in the definition while experimenting with system models.

Systems that will be run by a Launcher can be designed to run independently on one or more servers or as a distributed system across multiple servers. Event coordination among multiple servers is analyzed at design time before deployment. During execution, data from one system component to another can flow seamlessly without the need for a global controller.

Integration Flow Designer basics

- [Filename extensions](#)
- [Starting the Integration Flow Designer](#)
- [Converting files from previous versions](#)

Filename extensions

The Integration Flow Designer views a map as an indivisible unit recognizing both source and compiled maps. For design purposes, it also enables you to define placeholders for maps that have not yet been implemented (pseudo maps). The Integration Flow Designer generates or uses the following files:

Filename Extension	Description
.msd	System definition file generated by the Integration Flow Designer
.msl	Launcher system file, a system definition file generated for the Launcher
.mmc	Compiled map generated by the Map Designer
.mtt	Type tree file generated by the Type Designer

Note: Pseudo maps and external systems do not have filename extensions.

Starting the Integration Flow Designer

About this task

This procedure assumes that you have installed the Design Studio.

To start the IFD

Procedure

Select Integration Flow Designer from the Design Studio program menu. The Startup window is displayed with the following options:
The Startup window is displayed with the following options:

- Open an existing system definition file
Select this option to browse for a specific .msd file.
- Create a new system definition file
Select this option to create a new .msd file.
- Open a recently used system definition file
Select this option to choose one or more .msd files from the displayed file list. You can also double-click on a file from this list to open it.

To disable the Startup window

Procedure

To disable the Startup window, enable the Do not show this at startup check box. You can always access this dialog from the Help menu by choosing Startup Window.

Converting files from previous versions

When upgrading your version of the Design Studio, some file conversions must take place. Always create backups of your files before converting to a new version.

Integration Flow Designer user interface

The Integration Flow Designer interface includes a navigation pane (Navigator), floating toolbox, and main window for each open system. The menu bar and toolbar are customizable.

- [Navigator](#)
- [Toolbox](#)
- [Menu Commands](#)
- [Customizing your work environment](#)

Navigator

About this task

The Navigator is the navigation pane for the Integration Flow Designer. The Navigator displays a list of open system definition files (.msd) and the systems they contain.

To view and position the Navigator:

Procedure

1. From the View menu, choose Navigator.
The Navigator is displayed.
2. To reposition the Navigator, do one of the following:
 - a. Double-click the border of the Navigator (gripper) to dock or float the navigation pane.
 - b. Right-click on the gripper to view a context menu for positioning the Navigator.

Results

There are two tabs that represent the List view and the Composition view.

- [Navigator icons](#)
- [Navigator: List view](#)
- [Navigator: Composition view](#)
- [Using the Navigator](#)
- [Displaying components from the navigator](#)
- [Dragging components](#)

- [System windows](#)

Navigator icons

In addition to the alphabetical and compositional structure showing the contents of each system file, information about entries in the Navigator is conveyed visually with icons.

The following table lists and briefly describes some of the icons that appear in the Navigator.

Icon	Description
	system definition file (.msd)
	system or subsystem (relative to positioning)
	system component
	log file
	document link
	deployment definition

Navigator: List view

The List view displays open system definition files. This hierarchy includes:

- Defined Servers
- Systems
- Subsystems
- Components within a system
- Cards within a map component
- Doc Links (within a map component)
- Log Files (within a map component)
- Deploy Scripts

A subsystem is displayed under the system that contains it, a map component is displayed under the system that contains it, and so forth. Components at the same level are listed alphabetically.

Click any item to display its components in the system window. Right-click on any icon to view a context menu for that component.

Navigator: Composition view

The Composition view presents open system definition files sorted alphabetically. Each system definition file can be expanded to present all executable systems that it contains. An *executable system* is one that has an assigned server. Systems that do not have an assigned server do not appear in Composition view.

Click any system to display its components in the system window. Right-click on any icon to view a context menu for that component.

Using the Navigator

Use the Navigator to open and interact with one or more system definition files. To view the systems in the Navigator, expand or compress the node using + or -.

Once a system definition file is selected, you can use File menu commands, toolbar tools, or a context menu to close, save or copy the file.

- [Drag-and-drop functionality](#)
- [Clipboard functionality in the Integration Flow Designer](#)
- [System and subsystem components](#)
- [Focus options](#)
- [Resizing/moving options](#)

Drag-and-drop functionality

The following drag-and-drop operations are available in the Integration Flow Designer.

- Servers can be copied/moved across system files or can be copied within the same system file.
- Components can be copied/moved across system files or copied within the same system file.
- Systems can be copied/moved across system files or copied within the same system.
- Doc Links can be copied/moved across system files or within the same system file.

Clipboard functionality in the Integration Flow Designer

- Servers can be copied into the clipboard and/or pasted across system files and within system files.
- Components (systems or maps) can be copied and/or pasted across system files and within the same system file.
- Doc Links can be copied and/or pasted across system files and within the same system file.

System and subsystem components

- The symbols next to the component names in the Navigator indicate the type of component. Even though both systems and subsystems have the same symbol, it is their position in the Navigator that determines the reference. For example, system symbols always appear directly under a system definition file symbol. A subsystem symbol can appear anywhere below a system symbol. Right-clicking on these symbols yields a different context menu depending on where the symbol is located.
- A question mark is displayed on the subsystem component icon when unresolved references exist. An unresolved reference is when the subsystem references a system that does not exist.

Focus options

The following focus options are available when using the Integration Flow Designer.

- When you double-click a component in the Navigator, it selects the component, opens the system window containing that component (if it is not already open), and refocuses the system window on the selected component.
- Place the cursor on a system, subsystem, or map component symbol in the Navigator and double-click or press `Enter` to synchronize the focus of the Navigator and the active system window.

Resizing/moving options

- Use the Navigator gripper to dock or float the Navigator.
- Right-click on a non-client area in the Navigator to view a context menu that enables options to undock, float, or hide the Navigator window.
- To re-dock the Navigator, drag-and-drop the Navigator to the left or right edge of the main window of the Integration Flow Designer.
- The Navigator can be sized horizontally when docked, or it can be sized as a normal window when undocked.

Displaying components from the navigator

About this task

From the Navigator you can display a specific system, subsystem component or map component. When you double-click a component in the Navigator, the corresponding system window opens and becomes the active window.

Dragging components

In the Integration Flow Designer, you can perform drag-and-drop operations on servers, components, and document links within the Navigator. To move items, simply click-and-hold and drag the item to the desired location. To copy an item, you must also press `CTRL` while dragging the item.

You can only move or copy items to items of similar nodes.

System windows

The Integration Flow Designer main window displays any open system windows. Each system window is composed of a work area, a title bar, drop-down lists to specify the system server and execution mode, and a platform indicator displaying the type of platform associated with the assigned server. Specify the server and type of platform in the Add Server or Edit Server dialog by selecting New or Edit from the Server menu.

Multiple system windows can be open at the same time so you can view and work on several system definition files. The size and position of each system window is saved in its system definition file; when reopened, each system window is presented in its last state.

System Window Element Description

Title bar

The title bar of each window, as shown in the preceding image, displays the system name and the path of the containing system definition file (.msd).

Because you can have multiple system definition files open concurrently, a system window's title bar helps you to identify which system is being viewed. The same system name can be used throughout the various system definition files that you have open. The combination of the system name and the system definition file that contains the system is unique.

Work area

The work area is the main viewing area of the system window and is where you construct the system definition file, which is the graphical representation of the components that compose the system. It can also show links that represent data flow between the components. Components can be source maps, compiled maps, pseudo maps, or other systems (also known as subsystems).

Property Bar

The property bar is displayed below the title bar to show the assigned **Server**, the **Execution Mode**, and the **Platform** of the assigned server.

Server

From the Server field, you can select a server on which the system will run from drop-down list. This drop-down list contains the list of default servers as well as each server that is defined within the currently selected system definition file

Execution Mode

Assign the execution mode to define the type of Command or Launcher that will run the system. The Execution Mode drop-down list includes Command and Launcher . Selecting Command specifies that this system will be run using a Command Server. Selecting Launcher specifies that this system will be run using a Launcher.

Platform

This field shows the platform type associated with the assigned server. Specify the platform type in the Add Server or Edit Server dialogs which appear by selecting New or Edit from the Server menu.

Toolbox

When enabled from the View menu, the toolbox is displayed automatically when a system window is opened. It provides the tools needed to create or modify a system definition file.

The toolbox location is saved when the Integration Flow Designer is closed. The next time you open the Integration Flow Designer, the toolbox is displayed at the previously saved location.

To use each tool, you must click the button and then click in the system window. Each tool button is described in the following table.

Tool Name	Use This Tool To...
Select	Draw a box around one or more components in the system definition file to select them. You can then perform operations on the selected group.
Add Text	Add a text block to your system definition diagram.
Override	Override sources and targets. The source or target of the first card selected will override the source or target of the second card selected.
Add Pseudo Link	Draw links between system components. Pseudo links serve a documentation purpose and are represented by a red dotted line.
Add Source Map	Add source map components.
Add Compiled Map	Add compiled map components.
Add Pseudo Map	Add pseudo map components.
Add Subsystem	Add subsystem components.
Add External System	Add an external system placeholder.

Menu Commands

You can perform actions in the IFD through menu commands, tools, and shortcut keys. Not all menu commands have tool icons and not all tool icons are represented in the command menus. When working with systems, you can activate commands several ways:

- Select functionality from the menu bar
- Click the tools on the toolbar
- Right-click an icon in the Navigator
- Double-click objects in the Navigator
- Right-click in the system window or component in the system window
- Click the execution settings button on any map icon in the system window

Note: IFD commands are available as listed above; however, most procedural information in this guide uses the menu access as a default method. Please use the access method most convenient for you.

- [Menu Bar](#)
- [File menu](#)
- [Edit menu](#)
- [View Menu \(Alt+V\)](#)
- [System menu](#)
- [Tools menu](#)
- [Window Menu \(Alt+W\)](#)
- [Help menu](#)

Menu Bar

The IFD menu bar provides the common menu structure for commands generally used with Windows programs as well as commands specific to the IFD.

File menu

The File menu provides the options that are generally available in Windows applications.

Using the keyboard, press **Alt F** to view the File menu.

Command	Key stroke	Description
New	Alt+F, N or Ctrl+N	Creates a new system definition file and opens a system window
Open	Alt+F, O or Ctrl+O	Displays the Open dialog for opening an existing system definition file
Close	Alt+F, C	Closes the active system definition file
Save	Alt+F, S or Ctrl+S	Saves the active system definition file
Save As	Alt+F, A	Saves the active system definition file with a new file name
Source Control	Alt+F, L	Displays a submenu with Source Control options
System Definition File Differences	Alt+F, D	Begins the compare system definition file operation
Print	Alt+F, P or Ctrl+P	Prints a copy of the system definition diagram shown in the active system window
Print Preview	Alt+F, V	Displays the active system window in preview mode
Print Setup	Alt+F, R	Changes the printer and printing options
Recently Used File List	Alt+F, 1 Alt+F, 2 ...	Presents up to eight of the most recently used system definition files
Exit	Alt+F, X	Quits the application; prompts to save system files

Edit menu

The Edit menu provides the editing commands that are generally available in Windows' applications. It also contains the **Find** and **Replace** commands, which are useful for adapting systems to new server environments.

Using the keyboard, press **Alt E** to view the Edit menu.

Command	Key Stroke	Description
Undo	Alt+E, U or Ctrl+Z	Reverses the last action, such as cut, copy, paste, and delete operations and the visual positioning of a component within the system window
Delete	Alt+E, D or Del	Deletes the selected component or components
Cut	Alt+E, T or Ctrl+X	Cuts the selection and places a copy on the clipboard
Copy	Alt+E, C or Ctrl+C	Copies the selection to the clipboard
Paste	Alt+E, P or Ctrl+V	Inserts the contents of the clipboard into the active system window
Select All	Alt+E, A or Ctrl+A	Selects all components in the active system window
Find	Alt+E, F or Ctrl+F	Displays the Find dialog for locating system component names in the Navigator
Replace	Alt+E, R or Ctrl+R	Displays the Replace dialog for replacing system component names in the Navigator
More Find/Replace	Alt+E, M	Displays the More Find/Replace dialog for locating and editing system component names and paths in an entire system definition file

View Menu (Alt+V)

The View menu offers you choices of viewing specific items.

Using the keyboard, press **Alt V** to view the View menu.

Command	Key	Description
Toolbars	Alt+V, T	Displays the Customize dialog for toolbars
Status Bar	Alt+V, S	Shows or hides the status bar in the system window
Navigator	Alt+V, N	Shows or hides the Navigator
Toolbox	Alt+V, X	Shows or hides the toolbox
Grid	Alt+V, G	Toggles the display of the grid in the active system definition diagram
Build Results	Alt+V, B	Presents the latest build results
Deploy Results	Alt+V, D	Presents the latest deploy results

System menu

The System menu contains commands that initiate actions for a selected system.

Using the keyboard, press **Alt S** to view the System menu.

Command	Key	Description
New	Alt+S, N	Creates a new system and displays its window
Delete	Alt+S, D	Deletes the active system.
Copy	Alt+S, C	Displays the Copy System dialog to copy the active system as a new system in the same or a different system definition file (.msd)

Command	Key	Description
Rename	Alt+S, R	Displays the Rename System dialog to rename the active system
Build Maps	Alt+S, B	Builds all maps that are referenced by source map components and subsystem components contained in the active system window
Analyze	Alt+S, A	Analyzes the active system.
Generate	Alt+S, G	Generates an Launcher system file (if the system's execution mode is set to Launcher) or generates a command file for a Command Server (if the execution mode is set to Command)
Deploy	none	Displays a submenu for defining deploy scripts. Selecting Definitions from the submenu displays the Define Deploy Scripts dialog to manage deploy scripts for the active system. Selecting a specific deploy script name from the submenu runs the selected deploy script.
Unresolved Settings	Alt+S, U	Processes unresolved settings for the active system definition file

Tools menu

The Tools menu contains commands that initiate actions for defining Integration Flow Designer tools.

Using the keyboard, press **Alt L** to view the Tools menu.

Command	Key	Description
Short Cuts	Alt+L, S	Displays the Shortcut Keys dialog for changing the shortcut key assignments
Options	Alt+L, O	Displays the Options dialog for changing program options
Align to Grid	Ctrl+G	Aligns each selected component to its nearest respective grid intersection point

Window Menu (Alt+W)

The Window menu provides viewing control of the open system windows.

Using the keyboard, press **Alt W** to view the Window menu.

Command	Key	Description
New Window	Alt+W, N	Opens a new system window with the same contents as the active system window. The new system window has a similar name followed by a numeral (1 for the first duplicate, and so on).
Split	Alt+W, S	Splits the active system window into four panes, useful for working on components that are spread out. When the split grid is displayed, click your mouse to position the junction of the boundaries. After the grid is set, click and drag either the horizontal divider, or the vertical divider to a new position.
Cascade	Alt+W, C	Arranges the system windows so that they overlap in a descending pattern
Tile Horizontally	Alt+W, H	Arranges system windows as horizontal non-overlapping tiles
Tile Vertically	Alt+W, V	Arranges system windows as vertical non-overlapping tiles
Next	Alt+W, X or Ctrl+F6	Activates the next system window
Previous	Alt+W, P or Ctrl+Shift+F6	Activates the previous system window
Arrange Icons	Alt+W, A	Arranges system window icons in the main window
Close All	Alt+W, L	Closes all open system windows
Open Windows List	Alt+W, 1 Alt+W, 2 „,	Displays a list of windows that are currently open. Select the one you want to view. A check box indicates which system window is currently active. When ten system windows are open, a More Windows command is displayed to access a dialog to activate any open system window.

Help menu

The Help menu offers information about the IFD version.

Using the keyboard, press **Alt H** to view the Help menu.

Customizing your work environment

You can customize the Integration Flow Designer interface to suit your preferences while working in the application. For example, if you do not want receive confirmation messages upon deletion; you have the ability to turn off that setting. Or, you can create a shortcut for a keystroke you use often.

- [Shortcut keys](#)
- [Options](#)
- [Finding and replacing in the Integration Flow Designer](#)

Shortcut keys

From the Shortcut Keys dialog, you can configure shortcut keys for Integration Flow Designer functions.

Under **Select a macro** is a list of the Integration Flow Designer menu selections. When you click on an item in the list, its description and currently assigned shortcut is displayed. You can create or remove shortcuts as needed.

Refer to Design Studio Introduction documentation for more information about configuring shortcut keys.

Options

From the Options dialog, you can customize options related to viewing, saving, and confirmation messages. To access the Options dialog, select Tools > Options .

Click on each item in the list to view available options.

- [Maps](#)
- [Miscellaneous](#)
- [Navigator](#)
- [Subsystem](#)
- [Confirmations](#)
- [Import and export](#)

Maps

The Maps option specifies how cards are displayed when a map component is expanded.

Miscellaneous

The only Miscellaneous option available is **Backup On Save**, which is enabled by default. When enabled, the Integration Flow Designer automatically creates a backup copy of a system definition file (.msd) when it is saved and places it in the same directory.

Navigator

The Navigator option allows you to do the following:

- Select the font for the text in the Navigator
- Select the style of lines that connect components in the treeview format in the Navigator. Options include **None**, **Solid**, or **Dotted**.
- Enable or disable tooltips to appear when you mouse-over the name of a component that is not fully displayed.

Subsystem

The Subsystems option allows you to specify how cards are displayed when a subsystem component is expanded.

Confirmations

The Confirmations option allows you to enable or disable confirmation messages from appearing upon copy, move, or delete operations. All options are enabled by default, which is the recommended setting.

Import and export

The Import and Export option allows you to enable logging and set up preferences for import and export operations. See [Import and Export Options](#) for more information.

Finding and replacing in the Integration Flow Designer

The Integration Flow Designer supports standard search facilities. There are two find commands:

- **Find** searches for the selected name in the Navigator.
- **More Find/Replace** searches an entire system definition file.

You can perform find and replace operations in the Navigator using the **Find** and **Replace** options separately; or you can perform a complete find and replace operation in a system definition file (.msd) using the **More Find/Replace** option.

Finding and replacing component attributes

A system that you define can include a complex arrangement of components. Subsystems can contain nested subsystems, so executable maps are represented at various locations within the Navigator.

Using the More Find/Replace operation, you can easily locate and modify specific attributes associated with components defined in systems. Use the Find operation to locate card names, path names, or component names within a system; use the Replace operation to change the names. You can also use the Find and Replace operations to change specific settings across a set of components in order to adapt existing systems to new server environments.

Note: You can find and replace component names and path names, however you can only find card names. The replace operation cannot be used to replace card names. The goal of the Find operation is to locate specific attributes associated with system components based on the search criteria that you define. For example, by using the Find and Replace operations, you can change the paths that specify where executable maps are located on target servers. From the More/Find Replace dialog, there are two types of Find options:

- To list only those attributes that match a specific value based on your search criteria, enter a value in the Find What field and click Find.
- To find all the attributes associated with the components in a system that match your specified search criteria, click Find All without entering a value into the Find What field.

Note: The text on the Find All button changes to "Find" when a value is entered in the Find What field.

You can change the display width of a column by moving your cursor on the border between column titles and then clicking and dragging the border to the desired width.

- [Find and replace operations](#)
-

Find and replace operations

About this task

To begin a find operation

Procedure

1. Select the system window from where you want to perform a find operation.
2. Select **Edit > Find**.
The Find dialog is displayed.
3. Enter text in the Find What field, and click Find.
4. To list only those attributes that match a specific value based on your search criteria, enter a value in the Find What field and click Find.

To begin a replace operation

Procedure

1. From the Edit menu, choose Replace.
The Replace dialog is displayed.
2. After you have an entry in the Find what field, enter the new name that is replacing the existing name in the Replace with field.
3. Click Find Next to begin the operation.
4. Click Replace or Replace All to replace the names.

Sorting by column

What to do next

You can sort the results listed in the More Find/Replace dialog by clicking the column headings. When you click a column heading, the list is sorted in alphabetic order. Clicking again reverses the sort order.

Using the more find and replace option

About this task

Use the More Find/Replace option to search an entire system definition file.

- [To find component names](#)
- [To find specific component names](#)
- [To find card names](#)
- [To find path names](#)

- [To find specific path names](#)
- [To replace](#)

To find component names

Procedure

1. From the Edit menu, select More Find/Replace.
2. Enter the component name in the Find What field.
3. Select Component Names from the Search Criteria drop-down list.
4. Click Find.
Results appear under the Component Name heading on the Find tab.
5. To go directly to a resulting item, select it from the list and click Go To.

To find specific component names

Procedure

1. From the Edit menu, select More Find/Replace.
2. Select Component Names from the Search Criteria drop-down list.
3. Click Settings to specify any further search criteria you require.
4. When the Component Name Settings dialog is displayed, enable the components that you would like to find, and click OK.
5. From the Find/Replace dialog, enable Match Case and or Include Referenced Systems as optional search criteria.
6. Click Find to display the search results.
Results appear under the Component Name heading on the Find tab.
7. To go directly to a resulting item, select it from the list and click Go To.

To find card names

Procedure

1. From the Edit menu, select More Find/Replace.
2. Enter the card name in the Find What field.
3. Select Card Names from the Search Criteria drop-down list.
4. Click Find.
The default is to find all card names associated with the system. You can add further settings to find specific card names.
5. To go directly to a resulting item, select it from the list and click Go To.
This allows you to view the component in the associated system definition diagram.

To find path names

Procedure

1. From the Edit menu, select More Find/Replace.
2. Enter the path name in the Find What field.
3. Select Path Names from the Search Criteria drop-down list.
4. Click Find. The default is to find all path names associated with the system. You can adjust the settings to find specific path names.
Results appear under the Component Name heading on the Find tab.
5. To go directly to a resulting item, select it from the list and click Go To.
This allows you to view the component in the associated system definition diagram.

To find specific path names

About this task

Procedure

1. Enter the path name in the Find What field.
2. Select Path Names from the Search Criteria drop-down list.
The Path Name Settings dialog is displayed.
3. Enable or disable path name search options as desired and click OK.
4. From the More Find/Replace dialog, click Find to display the search results.

Results appear under the Component Name heading on the Find tab.

5. To go directly to a resulting item, select it from the list and click Go To. This allows you to view the component in the associated system definition diagram.

To replace

Procedure

1. From the Edit menu, select More Find/Replace.
The More Find/Replace dialog is displayed.
 2. From the Find tab, begin a find operation.
 3. When the results appear in the list, select the check box for each item that you want to change.
 4. Go to the Replace tab.
 5. In the Replace field, enter what is being replaced.
 6. In the With field, enter the replacement text, or select a historical entry from the drop-down list. If you do not enter a value in the With field, the replace operation will substitute a blank string for the string you entered in the Replace field.
 7. Click Find.
- The replace operation completes based on your selection criteria.

Text in a system definition diagram

About this task

You can easily add text to a system definition diagram in order to help document your design.

To add text to a system definition diagram

Procedure

1. From the toolbox, click on the Add Text tool.
2. In the system window, click on the location where you would like to enter text.
3. Enter text. You can move or delete the text by selecting it and choosing the appropriate action from the menu or toolbar.

Printing a system definition diagram

About this task

In the Integration Flow Designer you can print a snapshot of the active system window.

To print system details:

Procedure

1. From the Navigator, select the system you want to print.
2. In the system window, arrange the system components to display how you would like them to print. For example, double-click map source files to expand or hide map components.
3. For best results, select File > Print Preview to view what will print, and then click Print. Otherwise, select File > Print .
The Print dialog is displayed.
4. Select a printer and click OK.

Using the grid

About this task

Components in a system diagram are positioned on a grid that can be viewed by selecting Grid from the View menu or by clicking the grid icon on the tool bar.

- [To view the grid](#)
- [To cause new components to be aligned to a grid point](#)
- [To align existing components to grid points](#)

To view the grid

Procedure

- From the toolbar, click the Grid tool to view or hide the grid.
 - You can also cause subsequent actions that add or move components to position the components on the nearest grid point by enabling the snap to grid mode. Enable or disable snap-to-grid mode by selecting the Snap To Grid Mode tool on the toolbar. When snap-to-grid mode is enabled, existing components are not repositioned.
-

To cause new components to be aligned to a grid point

Procedure

- From the tool bar, click the Snap To Grid Mode tool to enable snap-to-grid mode.
 - When each new component is added, it will be positioned to its nearest respective grid point.
-

To align existing components to grid points

Procedure

1. Select the components to be aligned to the grid.
 2. From the Tools menu, choose Align to Grid or press `Ctrl G`.
Each selected component will move to its nearest respective grid point.
-

How the Integration Flow Designer works

When you use the Integration Flow Designer, you are creating visual process flows and from them creating executable systems that are processed by the Launcher or Command Server.

The Integration Flow Designer enables you to easily manage collections of related maps by graphically organizing them into logical collections of systems. The Integration Flow Designer turns a system into an executable file that is run by the Launcher or Command Server.

- [Theory of operation](#)
-

Theory of operation

You use the Type Designer and Map Designer to produce maps. A map transforms data content from source formats to target formats according to the rules you specify in the map. An executable map is stored in a source map file and built into a compiled map file. Command or Launchers run compiled maps.

The Integration Flow Designer views a map as an indivisible unit, recognizing both source and compiled maps. For design purposes, it also enables you to define placeholders, or pseudo maps, for maps that have not yet been implemented. Consider the Integration Flow Designer as one layer up from the Map Designer.

- [Map components](#)
 - [Command Server or Launcher](#)
 - [Map component execution settings](#)
 - [Systems](#)
-

Map components

A map component is an Integration Flow Designer object that represents an executable map with a defined set of interfaces based on sources, targets, and a surrounding layer of execution settings used at run time.

There are three classes of map components.

A map component references an executable map; it does not consume it. That is, the executable map exists externally and is reusable such that another map component can also reference it. You define an executable map once and then use it as many times as you want in the Integration Flow Designer. Since the Integration Flow Designer treats every map component as a unique instance, you can define multiple map components that reference the same executable map.

The Integration Flow Designer enables you to work from the bottom up. You can roll existing executable maps up into systems. The Integration Flow Designer also enables you to work from the top down. You can start at the top defining systems of maps that have not yet been implemented and you work your way down later to implement these maps. You can also do a bit of both: reference existing executable maps and maps that will be implemented later within the same system.

A map component is an executable unit. The Integration Flow Designer maintains the execution settings that you specify separately with each map component. The referenced compiled map files and source map files are static and are not modified directly with this information. The settings are eventually used on designated servers to execute the maps.

Command Server or Launcher

The Integration Flow Designer manages collections of maps at design time while a Command Server or Launcher manages the execution of maps at run time. The Integration Flow Designer treats a map as an indivisible unit at design time while a Command Server or Launcher treats maps as indivisible units at run time.

The Command Server manages the execution of one system at a time. The Launcher manages the execution of as many systems as you have defined concurrently.

- [Command Servers](#)
 - [Launchers](#)
-

Command Servers

A Command Server executes maps based on commands that you supply using a predefined command-line syntax. You start a Command Server, providing it with one or more commands, and the Command Server terminates when it has completed the last command. The commands for a Command Server can be produced by the Integration Flow Designer from the execution settings that you specify for map components. You can also define the commands manually.

You can use a Command Server to execute one map or multiple maps. A Command Server executes multiple maps in a single-threaded sequential fashion, a scheme that is sufficient for many applications. A Command Server expects all the sources of a map to exist when the map is executed.

Note: Refer to the Command Server documentation for more information.

Launchers

The Integration Flow Designer is the tool you use to create and generate systems for the Launcher to run. A Launcher executes maps based on a sophisticated event-driven model. Maps are launched only when specific events occur and only when required resources to run the map are available. You can specify event triggers, source and target resources, and other settings for a map from the Integration Flow Designer.

For example, on Microsoft Windows systems, the Launcher is a service that runs maps in a multithreaded fashion. The Launcher is started and allowed to run continuously to monitor events and run maps accordingly.

Note: For more information about the Launcher, see the *Launcher* documentation

Map component execution settings

You maintain the execution settings for map components by using the Integration Flow Designer. These settings are eventually embedded into the process control information, which drives the corresponding Command or Launcher. Some execution settings that you specify are used by both Event and Command Servers at execution time, including:

- The location of the map on the server to be executed
 - The source settings for input data
 - The target settings for output data
 - The same map settings available in the Map Designer
 - Retry options that apply if resources (such as work files or log files) that the map requires to execute are in use. Each source and target of the map also has retry options
 - [Launcher settings](#)
 - [Source and target settings](#)
 - [Map settings](#)
-

Launcher settings

Some map component settings are specific to an Launcher, such as time event triggers and input event triggers. Examples of an input event trigger include when a file's timestamp changes, or when a messaging system receives a message.

Note: you are using cluster support for the Launcher, the system definition file (.msd) is a key factor in the behavior of file triggers. To prevent trigger files from being processed more than once, set the OnSuccess card setting to Delete, or configure a keep directory. See the Launcher documentation for details about the keep directory and the OnSuccess setting.

Source and target settings

A source is used to read input data from a file, query a database, retrieve a message from a messaging system, or receive the results of a call to an application. A target is used to write output data to a file, insert or update data into a database, send a message to a messaging system, or call an application to send data to it.

A map component that references an executable map has a default set of sources and targets defined within the referenced source or compiled map file. The sources and targets are the interface points of the map component used within a system. The Integration Flow Designer displays sources and targets of a map component.

You can use the Integration Flow Designer to change a map component's sources or targets by changing its source or target settings. This capability enables you to reuse the functionality of a map and couple it to desired source and target pipelines.

Retry and rollback settings are also available for each source and each target. The retry setting specifies how many attempts will be made to recover from a source or target fault condition that might occur. These attempts are spaced over a specified interval of time. The rollback setting specifies whether source or target data should be rolled back to its original state if the map fails as a transaction unit.

Map settings

Map settings are initially defined for a map in the Map Designer. You can use the Integration Flow Designer to override these map settings. Map settings include definitions for audit log creation, paging values, trace file creation, validation settings, and work file configuration.

Systems

Systems of maps are executable units. The Integration Flow Designer enables you to use a system as a component of another system. This type of system is a subsystem component. A system can contain two types of components: map components and subsystem components. A subsystem component is a reference to another system that you have already defined. As with map components, the Integration Flow Designer displays subsystem components graphically.

A system can consist of map components and subsystem components. Subsystems can also be nested within subsystems. The Integration Flow Designer Navigator displays systems and the contained subsystems in a hierarchical and alphabetical list.

A map component and a subsystem component are conceptually similar. The difference between them is that they operate at different layers. As with a map component, a subsystem is an Integration Flow Designer object. A subsystem does the following:

- Encapsulates an executable system and includes a surrounding layer of execution settings used at run time
- Can include a subsystem component with a defined set of interfaces based on the sources and targets of the various maps that it contains

At design time, you decide which subsystem components you want to add to a system. A subsystem component can reference another system you have defined within a system definition file (.msd).

A subsystem component can also reference a design document that you have produced by using a preferred tool (a type is registered with the Windows platform). This facility helps you to keep track of design-related and implementation-related information at a system level.

As with map components, it is important to recognize that while a subsystem references another system, it does not consume it. The system being referenced is reusable. Another subsystem can also reference the same system.

Systems and the subsystems that reference them have execution settings. The execution settings include the server that will execute the system and the type of Command or Launcher that will run the system.

The following table lists some similarities of maps and systems of maps:

Feature	Map	Systems of Maps
Executable	✓	✓
Contains execution settings	✓	✓
Reusable	✓	✓
Include sources and targets that serve as component interfaces	✓	✓

- [Single-server systems](#)
- [Distributed systems](#)

Single-server systems

You can configure a system to execute on a single server; all maps contained within the system are executed on the designated server. Although all maps are executed on this single server, the actual sources or targets of these maps may cause data to be gathered from and sent to other servers.

A Command Server manages the execution of one system at a time. A Launcher manages the execution of as many systems as you have defined concurrently.

Distributed systems

You can also configure a system so its subsystem components are distributed across a set of servers. Each server has a Command or Launcher that runs the corresponding maps.

Data flows across servers between the distributed system components as indicated in the following example of a distributed system. This data flow is possible because maps can directly communicate data across servers when they execute.

There are four basic source and target types: file, database, message, and application. Within these four types, wide ranges of options are available to retrieve data from a remote location and to send data to a remote location, similar to the following scenarios:

- A map source or target can be a file that is in a shared location, allowing multiple servers to have direct access to it.
- Using the application adapter architecture, you can use any connectivity method to retrieve data from a remote location and to send data to a remote location. For example, you can use sockets, remote procedure calls, or directly call a local application that connects indirectly to another server to pass data. Databases and messages within messaging systems can also be accessed remotely.

The primary benefit of a distributed system is that you decide which subsystem components run on specific servers so that you can balance the overall execution load of the system across the servers in your enterprise. The data flow between servers is managed automatically as maps are executed. You do not need a global manager to

coordinate this data flow.

You can easily add more servers to a distributed system at a later time. The Integration Flow Designer enables you to rearchitect the distribution of subsystem components across a new set of servers.

System definition files

A system definition file contains the definitions for one or more systems and servers.

- [Systems](#)
- [System definition files](#)
- [System definition files and map source files](#)
- [About relocating system definition files](#)
- [Working with system definition files](#)
- [Importing and exporting system definitions](#)

Systems

A *system* is a collection of maps that you organize into a unit. A system can include components that reference executable maps and components that reference other systems. Systems of maps are executable units. The systems you define using the Integration Flow Designer are executed by Command or Launchers.

System definition files

A *system definition file* contains the definitions for one or more systems and the servers on which those systems are to execute.

System definition files and map source files

The following table notes the parallels between a system definition file (.msd) and a map source file (.mms).

system definition file (.msd)...	map source file (.mms)...
Normally contains one or more executable systems. Because a system contains a collection of maps, you can view a system definition file as a level up from a map source file	Normally contains one or more executable maps.
Maintains systems in source format for design purposes. Systems are not executed directly from a system definition file. You analyze and generate process control information for a particular system to execute it	Maintains maps in source format. Maps are not executed directly from a map source file. You build a compiled map to execute it

About relocating system definition files

If you want to copy system files (.msd) from one machine to another, be aware of the dependencies or references to other source map files (.mms), compiled map files (.mmc), and text or Windows-based design documents that you have produced.

The server map location is used to resolve paths specified as relative to the map location, such as the audit log, trace file, work file, and source and target files.

Whenever an .msd file is copied or moved to a different location or a different machine, the set paths for the contained source files (such as map source, compiled map, or subsystem component) change. When you open the system, the source files cannot be found. In this case, you must change the paths to reflect the new file location. You can change paths by either performing a find-and-replace operation or by editing the component.

Working with system definition files

About this task

This section describes the basic procedures for working with .msd files, including opening, creating, closing, and so forth.

- [To create a new system definition file](#)
- [To open a system definition file](#)
- [To display the systems contained in a system definition file](#)
 - To display systems in a system definition file, choose one of the following options:
 - [To close a system definition file](#)
 - [To save a system definition file](#)
 - [To create a system](#)
 - [To copy a system to another system](#)
 - [To rename a system](#)
 - [To delete a system](#)

- [Assigning a server to a system](#)
 - [Modifying a server definition](#)
-

To create a new system definition file

Procedure

- From the File menu, choose New.
 - A new system definition file icon named SystemFile **X** (where **X** is a sequential number) is displayed in the Navigator. A new system window opens with the default name System1.
-

To open a system definition file

Procedure

1. From the File menu, choose Open.
The Open dialog is displayed.
 2. Select an .msd file and click Open.
-

To display the systems contained in a system definition file

To display systems in a system definition file, choose one of the following options:

Procedure

- In the Navigator, click on a system definition file name.
Systems assigned a server of **None** are not executable.
 - In the Navigator, click + to expand the system and view its components.
 - Double-click on the system node or select the system node and press **Enter** to open the system window.
-

To close a system definition file

Procedure

1. In the Navigator, select a system to close.
 2. From the File menu, choose Close.
If you made changes to a system since it was last saved, a confirmation dialog is displayed giving you the option to save changes.
-

To save a system definition file

Procedure

1. In the Navigator, select a system definition file name.
 2. From the File menu, choose Save.
If this is a new system definition file, the Save As dialog is displayed so you can enter a file name.
 3. Enter the name of the file to be saved and click Save.
-

To create a system

Procedure

1. In the Navigator, select the system definition file that is to contain the new system.
 2. From the System menu, choose New.
The New System dialog is displayed with a default name of System**X**, where **X** is a sequential number.
 3. Accept the default name or enter a unique name for the system, and click OK.
A system window is displayed with the new system name and the path name of the system definition file displayed in the title bar.
-

To copy a system to another system

Procedure

1. In the Navigator, select the system that you want to copy.
 2. From the System menu, choose Copy.
The Copy System dialog is displayed.
 3. Enter a unique name and click OK.
The new system name is displayed in the Navigator.
-

To rename a system

Procedure

1. In the Navigator, select the system that you want to rename.
 2. From the System menu, choose Rename.
 3. When the Rename System dialog is displayed, enter a unique name and click OK.
-

To delete a system

Procedure

1. In the Navigator, select the system that you want to delete.
 2. From the System menu, choose Delete.
The Delete System dialog is displayed.
 3. Click OK to delete the system.
-

Importing and exporting system definitions

The Integration Flow Designer permits the import and export of system definition files as XML. When you import or export a system definition file (.msd), the logging option is enabled by default and both the server and system definitions are included.

There are options available for password encryption and for overwriting existing definitions.

- [Exporting system definitions](#)
 - [Importing system definitions](#)
 - [Import and export options](#)
 - [Audit log](#)
-

Exporting system definitions

About this task

For information about the export command line utility, refer to the *Utility Commands* documentation.

The following items are included in the definition when exporting an .msd file:

- deployment scripts
- components (maps, subsystems, external)
- pseudo links
- text components
- component positions within the system window

However, the state of a system window, such as the size or grid setting, is not exported.

Password encryption is an optional setting. To change default settings or for additional information about import and export options, see [Import and Export Options](#).

To export a system definition:

Procedure

1. From the Navigator, select a system to export.
The Save As dialog is displayed.
2. Accept the default or enter a new file name and click Save.
The system definition is saved as an .xml file.

Results

The following XML example displays a simple system definition with one map component:

```

<?xml version="1.0" encoding="UTF-8"?>
<MSDFile FilePath="" ServerCount="0" SystemCount="1" Version="1">
  <System ComponentsCount="1" ExecutionMode="Command" Name="cmndsrvr"
    ScriptCount="1"
    ServerName="Local Server" Version="1">
    <DeployScripts Name="cmndsrvr" Version="1">
      <BuildAndTransferMaps>
      </BuildAndTransferMaps>
      <GenerateAndTransferMslFile FileName="install_dir\systems\evntsvr.msl"/>
      <TransferAdditionalFiles>
      </TransferAdditionalFiles>
    </DeployScripts>
  <MapComponents ComponentName="cmndsrvr" ExecutableMapName="cmndsrvr"
    Expanded="No" LogFileName="install_dir\examples\general\ifd\cmndsrvr\cmndsrvr.log"
    MapCompiledFile="install_dir\examples\general\ifd\cmndsrvr\cmndsrvr.mmc"
    MapSourceFile="install_dir\examples\general\ifd\cmndsrvr\cmndsrvr.mms"
    Type="Source Map" Versions="1">
    <EventServerSettings ConcurrentInstances="0"
      MapServerLocations="install_dir\examples\general\ifd\cmndsrvr\cmndsrvr.mmc"
      Mapdelay="0" Pendinghigh="0" Pendinglow="0" Version="1">
      <Pending_Hour>0</Pending_Hour>
      <EventServer_TimeEvent BeginAfter-Hour="0" BeginAfter-Minute="0"
        BeginAfter-Second="0" SkipIfBusy="Yes" Switch="OFF">
        <Trigger_Once></Trigger_Once>
      </EventServer_TimeEvent>
    </EventServerSettings>
    <ComponentPosition X="281" Y="129"/>
  </MapComponents>
  </System>
</MSDFile>

```

Importing system definitions

About this task

Note: For information about the import command line utility, see the *Utility Commands* documentation.
To change the default settings or for additional information about import and export options, see [Import and Export Options](#).

To import a system definition:

Procedure

- From the Integration Flow Designer menu, select **File** > **Import**.
- The Open dialog is displayed, prompting you to select an .xml file.
- Choose a file and click **Open**.
The Save As dialog is displayed.
- Enter a name for the system and click **Save**.
The system is displayed in the Navigator.

Import and export options

The Integration Flow Designer settings for importing and exporting system and server definition files are located under **Tools** > **Options** > **Import and Export**. Each option is described below.

Enable Logging: Enables or disables logging for the import and export process.

Import

Overwrite Servers: Enable this option to overwrite any server definitions already present in the .msd file. If the option is disabled, the import process fails when a duplicate server name is detected and an error is logged.

Overwrite Systems: Enable this option to overwrite existing system names already present in the .msd file. If the option is disabled, the import process fails when a duplicate system name is detected and an error is logged.

Referenced Servers: Enable this option to import any servers defined within the system to be imported.

Referenced Systems: Enable this option to import any referenced systems defined within the system to be imported.

Export

Encrypt Password: Enable this option to encrypt the server password.

Referenced Systems: Enable this option to include any referenced systems associated with the system definition file to be exported.

Referenced Servers: Enable this option to include any referenced servers defined within the system to be exported.

Audit log

About this task

When the logging option is enabled, the log file is generated by default into the directory of the map that is being imported or exported.

The name of the file begins with the map name, followed by **imexport.log**. For example, **cmndsrvr imexport.log**.

To view the import/export audit log

Procedure

- Select View > Import\Export Results .
- The import/export log is displayed.

Results

The following is an example of an export log:

```
Map cmndsrvr exported successfully.  
System cmndsrvr exported successfully.  
15:23:33, March 02, 2004  
Output File: install_dir\examples\general\ifd\cmndsrvr\cmndsrvr.xml.  
Map cmndsrvr exported successfully.  
System cmndsrvr exported successfully.
```

Map components

A map component is an Integration Flow Designer object that represents an executable map with a defined set of interfaces based on sources, targets, and a surrounding layer of execution settings used at run time.

The Integration Flow Designer treats each map component as a unique object. Consequently, the name, execution settings, corresponding source and target interfaces, and document links are maintained separately for each map component that you add to a system.

Source map components

Source maps reference executable maps defined within a map source file.

Compiled map components

Compiled maps reference executable maps in compiled file format.

Pseudo map components

Pseudo maps reference executable maps that have not yet been implemented.

- [Source map components](#)
- [Compiled map components](#)
- [Pseudo map components](#)

Source map components

About this task

A source map component references an executable map that is defined in a map source file. You can add map components to single-server systems only. Single-server systems run on one server rather than multiple servers and cannot have a distributed server assigned.

A distributed system consists of subsystems that are assigned to run on different servers.

To add a source map component to a system:

Procedure

1. In the system window, place the focus on a system to add a source map component.
 2. From the toolbox, click the Add Source Map tool.
 3. Click on the location in the system window where you want to position the map.
The Add Source Map(s) dialog is displayed.
 4. Enter the name of the map file or click the browse button to locate the file.
The executable map is displayed in the Add Source Map(s) dialog. Note that you can click browse again and open another map file. You can repeat this step as many times as needed.
 5. Enable the check box next to each executable map you want to reference with map components.
After you close the Add Source Map(s) dialog, one map component will be added for every executable map you selected.
 6. Click Select All to add source map components that reference all executable maps displayed in the list.
 7. Click OK.
Each new source map component is displayed in the system window.
- [Modifying a map component name](#)

Modifying a map component name

About this task

You can modify the names of source map components, compiled map components, and pseudo map components.

To modify a map component name:

Procedure

1. Right-click the map component icon and select Edit Map Component from the context menu.
2. Enter the new name in the Component Name field (replacing the old name).
3. Click OK to save changes.

Compiled map components

About this task

A compiled source map component references an executable map within a compiled map file. You can use compiled maps when source maps are not available. You can add compiled map components to single-server systems only.

Use the following steps to add a compiled map component to a system.

Procedure

1. In the system window, place the focus on a system to add a source map component.
2. From the toolbox, click the Add Compiled Map tool.
3. In the system window, click where you want to insert the compiled map.
The Add Compiled Map(s) dialog is displayed.
4. Enter the name of the map file.
The executable map is displayed in the Add Compiled Map(s) dialog. Note that you can click browse again and open another map file. You can repeat this step as many times as needed.
5. Enable the check box next to each executable map you want to reference with map components.
After you close the Add Compiled Map(s) dialog, one map component will be added for every executable map you enabled.
6. Click Select All to add compiled map components that reference all executable maps displayed in the list.
7. Click OK.
Each new compiled map component is displayed in the system window.

Pseudo map components

About this task

Pseudo maps are placeholders for executable maps that have not yet been implemented. You can add pseudo map components to single-server systems.

To add a pseudo map component to a system:

Procedure

1. In the system window, place the focus on a system.
 2. From the toolbox, click on the pseudo map.
 3. In the system window, click where you want to insert the pseudo map.
The Add Pseudo Map(s) dialog is displayed.
 4. Enter a name for the pseudo map component and click Add.
The component name displays in the Component Name column in the Add Pseudo Map(s) dialog.
 5. Continue to add as many names for pseudo maps that you want to include as components in your system definition diagram.
A check mark automatically appears next to the component name to indicate that it will be added to the system file. You can also do the following:
 - Change the component name by clicking Modify Name.
 - Add a document link by clicking Browse Link.Component names must be unique within a system. A warning message appears if you try to add a duplicate component name.
 6. Click OK.
- [Defining sources and targets for a pseudo map](#)
 - [Editing input and output cards](#)

Defining sources and targets for a pseudo map

About this task

After a pseudo map is added to a system file, you can define sources and targets by adding input and output cards.

To add an input card:

Procedure

1. Right-click the pseudo map icon and select Add Input Card from the context menu.
The Add Input Card dialog is displayed.
 2. In the CardName field, enter a unique name for the input card. This is the only required field, however you can specify other values as needed. If you choose to specify the **TypeTree** and **Type** values, they must reference a valid type in an existing tree. See the Map Designer documentation for more information.
 3. Click OK to add an input card.
-

Editing input and output cards

About this task

The settings for an input card or an output card can be modified any time after the card has been added.

- [To edit an input or output card](#)
 - [To delete an input or output card](#)
-

To edit an input or output card

Procedure

1. Right-click the input or output card icon and select Edit from the context menu.
 2. Make your changes to the card settings and click OK to save changes.
-

To delete an input or output card

Procedure

1. Right-click the input or output card icon and select Delete from the context menu.
 2. Click Yes when a dialog is displayed to confirm the deletion.
-

Creating a source map from a pseudo map

Before you begin

Before creating a source map, you must first add at least one output card with a valid type and type tree to the pseudo map. This procedure assumes that you have already added the input and output requirements.

About this task

After the pseudo map component is defined, you can convert it into a source map component. Pseudo maps are the only components in the Integration Flow Designer that allow you to create source maps and add input and output cards.

During source map creation, you can either create a new map source file (.mms) or select an existing map source file. Within the map source file, you can either create a new executable map or overwrite an existing map.

Procedure

1. Right-click the pseudo map icon and select Create Source Map from the context menu.
The Create Source Map dialog is displayed.
2. In the Map Source File field, do one of the following:
 - If you want to create a new .mms file, accept the default map source file or enter a new name.
 - If you selected an existing .mms click GRAPHIC (browse) next to the Map Source File field and choose the file.
3. In the Executable Map Name field, do one of the following:
 - If you want to create a new .mms file, either accept the default executable map name (which is the same name as the pseudo map), or type a new map name.
 - If you selected an existing .mms file and you want to overwrite one of the existing executable maps, click the browse button next to the Executable Map Name field to display the list of executable maps within that file. Select the executable map and click OK.
 - If you selected an existing .mms file and you want to create a new executable map, type the new name in the Executable Map Name field.

4. To edit the input or output cards, select the card from the list and click Edit.
5. To create the .mms file, click Create.
6. When a message is displayed to confirm the map was created successfully, click OK.
The pseudo map component is converted to a source map component (the icon color changes).

Viewing sources and targets of a map component

About this task

When you are working with systems in the Integration Flow Designer, you can view and modify sources and targets (inputs and outputs).

To display sources and targets of a map component:

Procedure

You can display map component sources and targets (inputs and outputs) by doing one of the following:

- Double-click a map component.
- Select the map component and click the Expand/Contract button on the toolbar.
The expanded view of a map component displays (or hides) the input and output cards with corresponding card names and numbers
If the audit log file option is enabled for the map, the audit log file is presented as an output (MapSettings > MapAudit > Switch = ON).

Results

From the system window, after you expand the contents of a map component, you can right-click on a card to view a context menu. From the context menu, you have the option to Open Type Designer or View Card Details.

- If you choose Open Type Designer, the selected card opens in the Type Designer.
- If you choose View Card Details, the View window is displayed for the card.

When a map component is expanded, you can right-click to view a context menu. From the toolbox, you can also use the Override tool to override the source or target of a card with the source or target of another card. Each input and output card is represented by an icon that represents its adapter class.

- [Card tooltips](#)

Card tooltips

About this task

The Integration Flow Designer provides card tooltips that display information about the source of data for an input card or the target of data for an output card. The type of information displayed depends on the adapter type.

To view card tooltips, move the mouse cursor over a card and wait approximately two seconds.

Resource type
Tooltip information

File

Displays the file name specified for the card

Database Adapter

Displays the type of database adapter, connectivity information (connect string, data source name, and so on) and table(s) affected

Messaging Adapter

Displays the type of messaging adapter and the **AdapterCommand** defined for the card

Application Adapter

Displays the type of adapter and the **AdapterCommand** defined for the card

- [Viewing multiple tooltips](#)

Viewing multiple tooltips

About this task

When working in a system definition diagram, it is often useful to view the card tooltips of several of the components simultaneously. You can do this by moving the cursor over each card tooltip you want to display. These card tooltips will continue to be displayed until you click anywhere in the system window or move the cursor over any open area in the system window and wait for several seconds. Performing either of these actions clears the card tooltips and restores the card names.

Working with map components

Three basic characteristics of map components include the component name, execution settings (including source and target interfaces), and document links.

If a map component contains a trigger, the appropriate symbol is displayed on the execution settings button.

The Integration Flow Designer treats each map component as a unique object. The name, execution settings, corresponding source and target interfaces, and document links are maintained separately with each map component that you add to a system.

- [Map names](#)
 - [Execution settings](#)
 - [Overriding map settings](#)
 - [Overriding card settings](#)
-

Map names

You choose a map component name when adding the component to a system. It is common to name a map component the same as the executable map that it references. You can also rename a map component within a system. Duplicate component names are not accepted within a system.

Execution settings

This section presents the basic concepts of map component execution settings and describes the available settings according to the Command or Launcher that runs the map.

Map components are executable units. Using the Integration Flow Designer, you can specify the execution settings for a map component, which in turn are used by the Command Server or Launcher to run the map. Because the Integration Flow Designer treats each component as a unique instance, these execution settings are maintained separately for each map component.

Some of the execution settings that you specify are used by both Launchers and Command Servers at execution time. Settings that apply to both engines include the location of the map on the server to be executed, source settings for input data, target settings for output data, and the same set of map settings available in the Map Designer.

- [Viewing execution settings](#)
 - [MapServerLocation](#)
 - [MapSettings](#)
 - [MapDelay](#)
 - [PendingExpiration](#)
 - [Max Concurrent Map Instances setting](#)
 - [TimeEvent](#)
 - [Pending Instance Thresholds setting](#)
 - [Input and output settings](#)
-

Viewing execution settings

About this task

You can define execution settings for each map component in your system. There are two ways to access execution settings.

To view execution settings:

Procedure

In the system window, do one of the following:

- Right-click the map component icon and select Edit Launcher Settings (or Edit Command Server Settings if the execution mode is Command) from the context menu.
- Click the execution settings button on the map component icon.
The Launcher Settings dialog is displayed (or Command Server Settings dialog if the execution mode is Command).

MapServerLocation

The MapServerLocation setting identifies the path of the executable map file on the server. The default value for the MapServerLocation setting is the path of the selected map.

You can define a resource alias for the MapServerLocation in the Resource Registry. Click Tools > Options > Miscellaneous to enter or navigate to a resource configuration (.mrc) file. When you specify resource alias as the MapServerLocation, the path dynamically resolves at run time. See the Resource Registry documentation for details about resource aliases.

MapSettings

MapSettings specify properties for map execution that are not specific to a particular input or output. These include settings for auditing a map, tracing data content, performance settings, validation settings, and map-specific warnings and errors.

Because maps executed with a Command Server can only override those MapSettings that have corresponding execution commands, some MapSettings are not configurable in the Integration Flow Designer. The following table displays a list of which Launcher and Command Server settings are available in the Integration Flow Designer.

MapSetting	Command Server Settings	Launcher Settings
MapAudit		
Data Log	✓	✓
Execution Log	✓	✓
MapSettings Log		✓
CardSettings Log		✓
MapTrace	✓	✓
WorkSpace	✓	✓
Century	✓	✓
Validation	✓	✓
Retry	✓	✓
Warnings	✓	✓
DocumentVerification	✓	✓

See the Map Designer documentation for information about configuring map settings.

MapDelay

The MapDelay setting defines the amount of time in milliseconds that the Launcher waits, after all event triggers are satisfied, before running the map. The default value for the MapDelay setting is **0**.

PendingExpiration

The PendingExpiration setting specifies the amount of time that a map can stay in an initiation pending state before expiring (that is, being dropped and forgotten). The default value for the PendingExpiration setting is **Hour**.

The PendingExpiration > Value setting specifies how many units in the PendingExpiration setting value (**Hours**, **Minutes**, or **Seconds**) to use for measuring the waiting period. The default value for the **Value** setting is **0**.

If the map associated with a given watch has multiple triggers, and at least one event trigger occurs, the map is placed in an *initiation pending* state until all triggers occur. A *watch* pertains to the map and the set of events that initiate it. Maps in an initiation pending state are reevaluated each time another event trigger occurs. The initiation pending state occurs when any of the following conditions are true:

- The instance of the map is defined as single-threaded and one occurrence of the map is already running.
- The map requires an event trigger that has not yet occurred.
- The maximum number of concurrent maps are already running.

If all preceding conditions are eliminated, then the initiation pending state can be removed from the map; if the PendingExpiration period has not elapsed, then the map can run.

After a map instance is initiated, a `Source not available` message might appear if that source is used by an application unknown to the Launcher and one of the following conditions apply:

- One of the previous source event triggers of a pending map no longer exists
- all event triggers occur and another input is not an event trigger, and that source does not exist

The message `Target not available` may appear if a target message, database, or application adapter does not exist.

Max Concurrent Map Instances setting

The Max Concurrent Map Instances setting, when non-zero, specifies the maximum number of concurrent mappings for the map. This setting overrides the dtx.ini MaxThreads, WatchMaxThreads, and DisableMaxThreads Launcher settings for the map where it is set. This map can consume up to its maximum setting, even if the MaxThreads value for all maps has been reached.

TimeEvent

The TimeEvent settings initiate map components of a system that is time-based. Each map component is run based on a time event, a source event, or a combination of multiple events. If a map component is not assigned an event trigger, the Launcher will not initiate that map to run. The TimeEvent settings are described in the following table.

Note: When you analyze a Launcher system using the Integration Flow Designer, a warning is registered for any source or compiled map component that has no associated event trigger.

TimeEvent Setting	Description
Switch	The Switch setting enables or disables TimeEvent options. The default value for the Switch setting is OFF (Disables TimeEvent options).
BeginAfter	The BeginAfter settings specify the period of time in hours, minutes, or seconds to wait (from the time the Launcher starts) before enabling the time trigger.
	<ul style="list-style-type: none"> • Hour - The Hour setting is used to specify how many hours to wait to begin the map. The default value for the Hour setting is 0. • Minute - The Minute setting is used to specify how many minutes to wait to begin the map. The default value for the Minute setting is 0. • Second - The Second setting is used to specify how many seconds to wait to begin the map. The default value for the Second setting is 0.
Trigger	Use the Trigger setting to define the type of time event trigger. You can trigger a map based on a singular time event or cycle, according to a specified time increment. The default value is Once .
Trigger > Interval	Use the Interval setting to describe the recurring period to use for the trigger. The Interval setting is available only if the value of the Trigger setting is Every . The default value for the Interval setting is 1 Day(s) .
Interval > At	Use the At settings to set a specific time for the trigger to start after the start of the interval defined in Interval settings. The At settings are only available if the value of the Trigger setting is Every . The time periods specified in the Hour , Minute , and Second settings describe a time based on a 24-hour clock set to system time. <ul style="list-style-type: none"> • Hour - The Hour setting specifies the hour in which to run the map. The default value for the Hour setting is 0. • Minute - The Minute setting specifies the minute in which to run the map. The default value for the Minute setting is 0. • Second - The Second setting specifies the second in which to run the map. The default value for the Second setting is 0.
OmitDays	Use the OmitDays setting to set the days to omit.
	<ul style="list-style-type: none"> • Monday - The Monday setting is used to omit Mondays from the time trigger schedule. The default value for the Monday setting is No. • Tuesday through Sunday - These settings work the same way as the Monday setting.
OmitHours	Use the OmitHours setting to set the hours to omit.
	<ul style="list-style-type: none"> • 0 - The 0 setting is used to omit the 0 hour (midnight to 1:00 am). The default value for the 0 setting is No. • 1 through 23 - These settings work the same way as the 0 setting (above).
SkipIfBusy	Use the SkipIfBusy setting to ignore the time event trigger if it occurs when a watch instance is already in process. The default value is Yes .
EventCoordination	Use the EventCoordination setting to control the coordination of time event and input event triggers. The EventCoordination setting is available only if the map has both a time event trigger and one or more input event triggers; and the SourceEvent setting for one of the input cards is ON . The input event trigger can have wildcards. The default value for the EventCoordination setting is FirstAvailable .

Pending Instance Thresholds setting

The **Pending Instance Thresholds** setting enables a listener to pause or resume for a specific watch.

Setting	Description
High	Value (no limit) for the watch to pause the event(s) for that watch. The default value is 0 .
Low	Value (no limit) for the watch to resume the event(s) for that watch. The default value is 0 .
Note: If the InitPendingHigh and InitPendingLow settings in the Launcher section of the dtx.ini file are also set, the Pending Instance Thresholds Launcher settings will take precedence.	

Input and output settings

Because maps executed with a Command Server can only override those input and output settings that have corresponding execution commands, some input and output settings are not configurable in the Integration Flow Designer.

Note: If you use cluster support for the Launcher, the system definition file (.msd) is a key factor in the behavior of file triggers. To prevent trigger files from being processed more than once, set the OnSuccess card setting to Delete, or configure a keep directory. See the Launcher documentation for details about the keep directory and the OnSuccess setting.

Input settings

The following table lists input settings.

Table 1. Table 1. Availability of input card settings in Launcher and Command server

Input Setting	Available in Command Server Settings?	Available in Launcher Settings?
FetchAs	No	Yes

Input Setting	Available in Command Server Settings?	Available in Launcher Settings?
WorkArea	Yes	Yes
Backup	No	Yes
SourceEvent	No	Adapter-dependent
ErrorDirectory	No	Yes
KeepDirectory	No	Yes
Source		
Command	No	Yes
OnSuccess	No	Adapter-dependent
OnFailure	Yes	Yes
Retry	Yes	Yes
Scope	No	Yes
Warnings	No	Yes
FetchUnit	No	Yes

Note: See the Map Designer documentation for information on how to configure these settings.

Output settings

The following table lists output Launcher and Command Server settings.

Table 2. Availability of output card settings in Launcher and Command server

Output Setting	Available in Command Server Settings?	Available in Launcher Settings?
Backup		Yes
Target		
Command	Yes	Yes
OnSuccess		Adapter-dependent
OnFailure	Yes	Yes
Retry	Yes	Adapter-dependent
Warnings		Yes
Scope		Yes

Overriding map settings

About this task

Map settings specify properties for map executions that are not specific to a particular input or output. Map settings defined during the design phase are saved in the map source file (.mms) and the compiled map file (.mmc). Using the Integration Flow Designer, you can override these map settings. Any time you change a map setting from the Integration Flow Designer, it is considered an override. This override value is used during the creation of system files for the Launcher or command files for the Command Server.

When you place an override on a map card, the override propagates to the uppermost system level where that card is visible. When an override is placed on a subsystem card for the corresponding map card, the higher-level subsystem card override takes precedence. The override at the highest level always takes precedence.

To override a map setting:

Procedure

1. In the system window, right-click on a map component and select Edit Launcher settings.
The Launcher Settings dialog is displayed. Select a map setting and choose a new value.
2. Click OK to save changes.
The new map settings will be used during execution.

Overriding card settings

About this task

Card settings, which are specific to input and output cards, define the data object the card represents and how that data is retrieved or routed. A map component that references an executable map has card settings that are defined in the map source file (.mms) and the compiled map file (.mmc). Using the Integration Flow Designer, you can specify execution settings that override the card settings.

Note: You cannot override an input card's Source setting with the static file adapter.

To override card settings:

This procedure assumes that **Launcher** is the execution mode for this system.

Procedure

1. In the system window, double-click on a map component to view the inputs and outputs.

2. On the map component icon, click the execution settings button.
The Launcher Settings dialog is displayed.
3. Select an input or output setting and choose a new value.
4. Click OK to save changes.
The new card settings will be used during execution.

Subsystem components

Systems can contain any combination of map components and subsystem components. A subsystem component is an Integration Flow Designer object that represents or references another system that you have already defined. The concept of a subsystem component is that it enables you to reuse a system. As such, a subsystem is an executable unit for which you can specify execution settings for using the Integration Flow Designer.

The Integration Flow Designer treats each subsystem component as a unique instance. Consequently, the name, execution settings, source and target interfaces, and document links are maintained separately with each subsystem component that you add to a system definition file.

The Integration Flow Designer displays a subsystem component graphically in the system window, as shown in the following diagram.

Subsystem components, which are displayed graphically in the system window, have four basic characteristics: name, execution settings (including sources and targets), and optional document links.

- [Subsystem component name](#)
- [Execution settings](#)
- [Inputs and outputs](#)
- [Working with subsystems](#)

Subsystem component name

When you add a subsystem component to a system definition file, you are selecting a system from a list of systems that you have already defined. By default, the name of the subsystem component is the name of the referenced system.

After a subsystem component is added to a system, you can rename it. The name can be any length and can contain spaces. A subsystem component name must be unique because the Integration Flow Designer does not accept duplicate component names within a system file.

Execution settings

About this task

A subsystem component has a defined set of interfaces that are based on the sources and targets (inputs and outputs) of the various maps that it contains. The inputs and outputs of a subsystem are derived according to the following rules.

- An input of a subsystem is a source that is not internally produced by one of its components.
- An output of a subsystem is a target that is internally produced by one of its components, and is not deleted.

To view execution settings for a subsystem

Procedure

From the system window, do one of the following:

- Click the execution settings button on the subsystem icon.
- Right-click on the subsystem icon and select Edit Execution Settings from the context menu.
The System Launcher Settings dialog is displayed.
- [ServerName](#)
- [ExecutionType](#)

ServerName

The **ServerName** setting specifies the type of server on which the system is deployed. The values include **Local Server**, **Distributed**, and **None**. You can also define additional servers that appear in the drop-down list. The default value for the **ServerName** setting is **Local Server**. Each server option is described in the following table.

Option	Description
Local Server	A system is going to run on the local workstation, usually where the Integration Flow Designer is installed. You might want to assign Local Server to systems to use your workstation as a test environment to verify execution. Or, you may plan to use Local Server as a part of your production environment for system execution.
Distributed	A system is composed of subsystems that are assigned to run on different servers in a coordinated manner to distribute the processing. Components in a distributed system must be subsystems, not maps.
None	

No server selected. Because there is no server assigned, the system is not executable.

Systems that have an assigned server value of **None** do not appear in the **Component** view in the Navigator. These nonexecutable systems can be used as subsystems within a system that has an assigned server.

A subsystem with an assigned server value of **None** derives its server from its parent system that has a server assigned. Subsystems always display in the **Composition** view unless the parent system also has a server value of **None**.

ExecutionType

The **ExecutionType** setting specifies the execution mode for the system. Choices include **Launcher** or **Command**. The default setting is **Launcher**, which indicates that the system is deployed for execution by the Launcher. If **Command** is selected, the system is deployed for execution by the Command Server.

Inputs and outputs

A subsystem component has a set of sources and targets that are based on the sources and targets of the various maps that it contains. The sources and targets (inputs and outputs) are the interface points of the subsystem component used within a system.

In general, a system input is a component input that is not internally produced and a system output is a component output that is not deleted. When a system is presented as a component of another system, the subsystem inputs and outputs serve as interface points, allowing it to be connected to other components in the view.

Double-clicking a subsystem icon expands the view to show inputs and outputs. Double-clicking an input or output card displays the execution settings for the subsystem component.

- [Default settings](#)
- [Saving map card positions](#)
- [Overriding card source or target](#)

Default settings

The default settings for inputs and outputs are based on the inputs and outputs of the various maps contained within the subsystem.

In the system diagram above, the following applies:

- A system input card correlates to a specific input card of a map component that it contains.
- A system output card correlates to a specific output card of a map component it contains.

If any of the inputs can trigger the map, then you will see an input event trigger displayed on the map card icon.

Note: The time trigger icon and input event trigger icon are not displayed on the execution settings button of a subsystem component icon.
The following convention is used to identify the subsystem card:

Saving map card positions

When you initially expand a subsystem component, the input and output cards are cascaded with first card on top by default. Similar to map components, you can move subsystem input or output cards to specific positions and the card positions are retained when you save the file.

The following pertains to card positioning:

- Moving the subsystem component in contracted view to a new position resets the card position to the default.
- If the subsystem component is expanded and it is moved to a new location, the card positions are not changed.

Overriding card source or target

In a subsystem, you can override the source and target of a card with the source or target of another card by using the override function. This works the same as with map component input or output cards.

Working with subsystems

About this task

The following procedure details adding a subsystem to a system.

To add a subsystem component to a system

Procedure

1. Double-click an open .msd file and ensure that it is focused in the system window.
2. From the toolbox, click the Add System tool and then click the location in the client area of the system window where you want to add the subsystem.
The Add System(s) dialog box is displayed.
3. Choose an .msd file and click OK.
In the Add System(s) dialog box, the .msd and a list of systems that it contains is displayed.
4. Do one of the following:
 - Click Select All to reference all systems listed in the new subsystem component.
 - Select only the systems in the list that you want to reference in the new subsystem component.
5. To change the name of a system in the list, click to select it and click Modify Name.
6. To link a document to this subsystem, click Browse Link and navigate to the file.
7. Click OK to save changes.
8. When a message is displayed to confirm that the subsystem was generated, click OK. Recursion is not allowed. The subsystem that you add to a parent system cannot contain the parent system as a component. The Integration Flow Designer alerts you if you try to add a subsystem that contains the system you are defining.

Overview of server definitions and execution modes

The distribution of systems among your enterprise servers plays a key role in the behavior of these systems at execution time. You can define servers using the Integration Flow Designer. These server definitions represent servers within your enterprise that execute systems. After a server is defined, you can assign it to a system. You also assign an execution mode to a system to specify the type of Command or Event Server that will run this system. The server and execution mode that you assign to a specific system provides the Integration Flow Designer information it needs to perform key operations. For example, building maps depends on the target server platform. Also, generating appropriate process control files for execution purposes depends on the type of Command or Launcher that will run the system.

- [Server implementation examples](#)
- [Server definitions](#)
- [Working with system definition files](#)
- [Importing and exporting server definitions](#)
- [System execution modes](#)

Server implementation examples

Use the Integration Flow Designer to define systems of varying complexity. The simplest case involves one system that runs on one server. The following sections describe various examples of systems with increasing complexity.

Multiple independent systems running on one server

You can define multiple systems that have no data dependencies among their components and are all executed on the same server.

Although all systems in this configuration are executed on the same server, data can still be gathered from and sent to remote server locations. This behavior is possible because you can set the sources and/or targets of maps contained in the systems to directly cause data to flow from and to remote servers when these maps are executed.

You can also have multiple independent systems running on multiple servers.

Multiple dependent systems running on one server

You can use the Integration Flow Designer to define systems that have data dependencies among their components and are all executed on the same server.

Data sources and targets can exist on remote servers.

Multiple dependent systems running on multiple servers

You can use the Integration Flow Designer to define distributed systems. A distributed system consists of only subsystem components, not map components directly. These subsystem components are distributed across more than one server. Data flows across servers from one subsystem to another based on the sources and targets of maps that you specify to cause this flow.

Complex combinations of systems

You can define varying combinations of the previously described systems to yield very complex systems. For example, you might have a system that is distributed across servers as well as completely independent systems running on the same servers. The design of your systems depends on your requirements.

Server definitions

The Integration Flow Designer includes three predefined server definitions: **Distributed**, **Local Server**, and **None**.

In addition to the predefined servers, you can create custom server definitions for each system. When you create your own server definitions, they appear on the **Server** drop-down list in the system window.

A new system is automatically assigned the default server of **None** and is considered "non executable". Nonexecutable maps do not appear in the **Composition** view of the Navigator.

Each predefined server type is described in the following table.

Server Definition

Used When

Distributed

A system is composed of subsystems that are assigned to run on different servers in a coordinated manner to distribute the processing. Components in a distributed system must be subsystems, not maps.

Local Server

A system is going to run on the local workstation, usually where the Integration Flow Designer is installed. You might want to assign **Local Server** to systems to use your workstation as a test environment to verify execution. Or, you may plan to use **Local Server** as a part of your production environment for system execution.

None

No server is assigned. The system is not executable, but can be used as a subsystem within a system. A subsystem with an assigned server of **None** derives its server from its parent system that has a server assigned. A new system automatically has **None** assigned by default.

Working with system definition files

About this task

This section describes the basic procedures for working with .msd files, including opening, creating, closing, and so forth.

- [To create a new system definition file](#)
 - [To open a system definition file](#)
 - [To display the systems contained in a system definition file](#)
- To display systems in a system definition file, choose one of the following options:
- [To close a system definition file](#)
 - [To save a system definition file](#)
 - [To create a system](#)
 - [To copy a system to another system](#)
 - [To rename a system](#)
 - [To delete a system](#)
 - [Assigning a server to a system](#)
 - [Modifying a server definition](#)

Assigning a server to a system

About this task

In the Integration Flow Designer, there are two ways to assign a server to a system. You can either copy an existing server and drag it to a new server, or select the system in the Navigator and choose **New** from the Server menu. Both methods are described below.

To copy a server to system (drag-and-drop method):

Use this method if you want to add an existing server to a different system definition file (.msd). You must have both files open in the Navigator. **System File A** is the .msd file with the existing server; **System File B** is the .msd file receiving a copy of the server.

Procedure

1. From the Navigator, click and hold on the server in **System File A**, and press **Ctrl**.
2. Drag the server to the root server node in **System File B**.
The mouse pointer will display a plus sign (+) to indicate correct positioning.
3. Release the mouse to drop the server.
4. When a message is displayed to confirm this action, click **Yes**.

Results

You can also use this procedure to duplicate a server within the same system file. A new server with the same properties is generated, however, it has a unique name.

Modifying a server definition

About this task

The following procedures detail how to add or modify a server definition.

To change or assign a server in a system

Procedure

To change or assign a server for a system, select a new server from the Server drop-down list in the system window.

To edit a server definition

Procedure

1. Select a system containing the server definition that you want to edit.
2. Choose one of the following options:
 - a. From the Server menu, choose Edit.
The Servers dialog is displayed.
 - b. Select the server from the list and click OK.
Or
 - c. From the Navigator, right-click on the server and select Edit from the context menu.
The Edit Server dialog is displayed displaying the current server information.
3. Make changes and click OK.

Importing and exporting server definitions

About this task

The Integration Flow Designer permits the import and export of server definitions as XML files. For information about the Integration Flow Designer setting for the Import and Export operations, see Import and Export Options.

- [To export a server definition](#)
 - [To import a server definition](#)
-

To export a server definition

Procedure

1. From the List view of the Navigator, select the Servers node to include all servers, or select a single server to export.
2. From the menu bar, select Servers > Export.
The Save As dialog is displayed.
3. Enter a file name and click Save.
An XML server definition file is created.

To import a server definition

Procedure

1. From the List view of the Navigator, right-click the Servers node and choose Import. The Open dialog is displayed, prompting you to select an .xml file.
2. Choose a file and click Open. The Import - Servers dialog is displayed. Each server defined in the selected .xml file is displayed under Servers.
3. Under Servers, select the server to import and click the appropriate arrow button. The server names are displayed in the Import list.
4. To replace any existing servers with the same names as those you are importing, enable the Overwrite Servers check box. Otherwise, disable the check box to ensure that existing servers are not overwritten.
5. Click OK to complete the import process. The imported servers are displayed under the Servers node in the List view of the Navigator and on the Server drop-down list of the system window.

System execution modes

About this task

Each system you create has an execution mode. You specify the system execution mode by selecting Launcher or Command from the Execution Mode drop-down list.

The execution mode you select determines the type of execution server that will run the system.

- Selecting Launcher execution mode indicates that your system will run on a Launcher.
 - Selecting Command execution mode indicates the system will run on a Command Server.
-

Generating system files

To run an Integration Flow Designer system, you must generate a command (.txt) or Launcher system file (.msl) from your system definition file (.msd). An .msl file is the process control file for the Launcher. Before generating an .msl file, you should first build all maps and then analyze the system.

- [Building maps](#)
 - [Analyzing a System](#)
 - [Generating executable system files](#)
 - [Unresolved settings](#)
 - [System definition file differences](#)
-

Building maps

About this task

The Integration Flow Designer enables you to easily build maps for a specified system. You can build a single map, a selected group of maps, or all maps referenced within a system. The build process is the same as that performed in the Map Designer.

- [To build all maps referenced by all source map components in a system](#)
 - [To build one map referenced by a source map component in a system](#)
 - [To build a collection of maps referenced by a collection of source map components within a system](#)
 - [To view the last build results at any point in time](#)
-

To build all maps referenced by all source map components in a system

Procedure

1. Open a system.
2. From the System menu, choose Build Maps.
All of the executable maps are built. The Build Maps dialog is displayed displaying the progress of the build process. After the Integration Flow Designer builds all the maps in the system, a dialog is displayed displaying the build results.

To build one map referenced by a source map component in a system

Procedure

1. Place the focus on a system in the system window.
2. Right-click a source map component and choose Build.
The selected map is built.

To build a collection of maps referenced by a collection of source map components within a system

Procedure

1. Place the focus a system in the system window.
2. From the toolbox, click the Select tool and select each source map component to include.
3. Select System > Build Maps.
The selected maps are built.

To view the last build results at any point in time

Procedure

- Select View > Build Results.
 - The results from the last build appear.
-

Analyzing a System

About this task

To ensure that a system will execute properly before actually executing it, use the **Analyze** function. This function analyzes the system for logical consistency and displays the results.

To analyze a system:

Procedure

1. Place the focus on a system in the system window.
 2. Select System->Analyze.
The Analyze System dialog appears.
 3. If errors are detected, click Results to view the details.
The Analysis Results dialog appears.
-

Generating executable system files

About this task

In the Integration Flow Designer, there are two execution modes you can use to create a Launcher system file: **Launcher** and **Command**. **Launcher** execution mode generates system files (.msl) for the Launcher. **Command** execution mode produces command files (.txt) for the Command Server. A Command Server runs one command file at a time.

- [To generate a command file](#)
 - [To generate a Launcher system file](#)
-

To generate a command file

Procedure

1. Place the focus on a system in the system window.
2. From the Execution Mode drop-down list, select Command.
3. Select System->Generate.
The Save As dialog is displayed.
4. Specify the path of the command file to be saved.
The generated command file includes one command for each map specified in the selected system. Options for each map are based on the Command Server settings.

Results

```
; Date: Thu May 13 14:44:46 1999 (Version 2.0)
; File: C:\Examples\Business.msd
; System: Business
;
; Component: SourceMap
; Map File: C:\Examples\Business.mms
; Executable Map: SourceMap
;
E:\business\SourceMap.mmc
-WD
-Z14:18:21:26:27:28:29
;
; Component: business1
; Map File: C:\Examples\Business.mms
; Executable Map: business1
;
E:\business\business1.mmc
-ID1 '-T'
-WD
-Z14:18:21:26:27:28:29
;
; Component: business2

; End System: Business
;
```

The commands within the generated command file are ordered based on the input and output dependencies of the maps in the system. Where no input or output dependencies exist, the commands are ordered based on the physical positioning of the maps in the system definition file.

To facilitate the moving of components to different positions, use the **Align to Grid** option.

To generate a Launcher system file

About this task

Procedure

1. Place the focus on a system in the system window.
2. From the Execution Mode drop-down list, select Launcher.
3. Select System > Generate.
The Save As dialog is displayed.
4. Specify the path and name of the Launcher system file (.msl) to be saved.
Other saving options:

- If you have a Windows share setup between your client and server machines, then you can save the .msl or command file directly to the server.
- You can use the Deploy option to copy the .msl or command file to the server running the corresponding Command or Launcher. (See *Deploying Systems*.)
- You can manually copy the .msl or command file to the server running the corresponding Command or Launcher.
- For Launchers, place a copy of the Launcher system file in your deployment directory.

When the Launcher runs, it manages the execution of all Launcher system files in the deployment directory. See the Launcher documentation for additional information.

Unresolved settings

About this task

If you use the Map Designer to delete or rename an input or output card that has override settings defined in a system, the Integration Flow Designer detects the change after the map source file is saved or after the compiled map file is produced. Within the Integration Flow Designer, settings that are no longer associated with any card are known as unresolved settings.

You know that unresolved settings exist in your system when one of the following scenarios occurs:

- You open a system and the Unresolved Settings dialog is displayed.
- You have a system open in the Integration Flow Designer and you use the Map Designer to delete or rename a card that is referenced by a map component in the system. Unresolved settings are detected when you save the map source file. When you return to the Integration Flow Designer, the Unresolved Settings dialog is displayed.

From the Unresolved Settings dialog, you can immediately delete or assign the unresolved settings to a different map card; or you can close the dialog and access it again at a later time by selecting Unresolved Settings from the System menu.

To view unresolved settings:

Procedure

1. Open the system that contains unresolved settings.
 2. From the System menu, choose Unresolved Settings.
The Unresolved Settings dialog is displayed.
The dialog displays the settings that are unresolved and are no longer associated with any card. These settings were defined in the Integration Flow Designer as the source or target settings for a card that no longer exists because it was deleted or renamed in the Map Designer.
- [Processing unresolved settings](#)

Processing unresolved settings

About this task

You can process unresolved settings by deleting the card or by modifying the card settings by copying the settings to an existing card.

After you display the affected system in the Unresolved Settings dialog, you can immediately modify the card settings or delete the card.

If you modify card settings, you can drag the updated card to a map card in the system window, which updates the existing card settings in the map component.

To resolve map card settings

Procedure

1. From the Unresolved Settings dialog, if you are not familiar with the map component that is displayed in the Unresolved Settings navigation pane, right-click the card and select Go to component.
The map component is displayed as a selected object in the system window.
2. Return to the Unresolved Settings dialog, and modify the card settings as required.
3. When the card settings are correct, click-and-hold on the card (in the navigation pane) and drag it to the corresponding card in the system window.
4. When the card in the system window is highlighted, release the mouse to drop the card.
5. Click Yes when you are prompted to confirm the copy operation.

To delete unresolved settings

Procedure

From the Unresolved Settings dialog navigation pane, right-click the affected card and select Delete.

System definition file differences

The Source Compare feature enables you to view differences between two system definition files.

- [Comparing system definition files](#)
 - [Comparing systems](#)
 - [Comparing servers](#)
 - [Comparing deploy scripts](#)
 - [Comparing components](#)
 - [Comparing compiled map components](#)
 - [Comparing source map components](#)
 - [Comparing a psuedo map component](#)
 - [Comparing subsystem components](#)
 - [Comparing document links](#)
 - [Comparing system definition files](#)
 - [Viewing and printing system definition file differences](#)
-

Comparing system definition files

When comparing system definition files, the files are considered "different" when:

- Any of the systems that exist in one file and do not exist in the second file.
 - Any of the systems are different.
 - Any of the servers that exist in one file and do not exist in the second file.
 - Any of the servers are different.
-

Comparing systems

When comparing systems, systems are considered "different" when:

- Any of the system properties are different.
 - Any of the components of the system are different.
 - A component exists in the system in the first file but does not exist in the same system in the second file.
 - If any of the deploy scripts are different.
 - If a deploy script exists in the file but not in the second file.
-

Comparing servers

When comparing servers, servers are considered "different" when any of the server settings are different.

Comparing deploy scripts

A deploy script is different if any of the script instructions are different.

Comparing components

A component is different if:

- If any of the doc links are different
 - If any of the doc links are present in the component in the first file but do not exist in the same component in the second file
 - If any of the unresolved settings are different
 - If any of the log files are different
 - If any of the input/output cards are different
 - If any of the input/output cards are present in the component in the first file but do not exist in the same component in the second file
-

Comparing compiled map components

A compiled map component is different if:

- File path of compiled map is different.
 - Map settings are different.
 - Launcher or Command Server settings are different.
-

Comparing source map components

When comparing source map components, components are considered "different" when:

- File path of map source is different.
 - Map settings are different.
 - Event or Command sever settings are different.
 - Map name for source map component is different.
-

Comparing a pseudo map component

When comparing pseudo maps, a component is considered "different" when:

- Pseudo map name is different
 - Event or Command sever settings are different
 - Map settings are different
-

Comparing subsystem components

When comparing subsystem components, components are considered "different" when:

- Referenced system name is different.
 - Referenced system definition file path is different.
 - Event or Command sever settings are different.
 - Any of the log files are different.
-

Comparing document links

A document link is different if the paths are different.

Comparing system definition files

About this task

System definition source file differences are compared for the source files that you select. You can view the results after the differences are identified.

- [To compare system definition source files](#)
 - [To view system definition file differences](#)
-

To compare system definition source files

Procedure

1. From the File menu, choose System Definition File Differences.
 2. The Select First File dialog box is displayed.
 3. Choose the first system definition source file to compare and click Open.
The Select Second File dialog box is displayed.
 4. Choose the second map source file to compare and click Open.
The progress of the comparison is shown briefly in the System Definition Source File Differences Analysis dialog and then the System File Differences window is displayed.
-

To view system definition file differences

Procedure

1. From the System Definition File Differences window, select the item you want to compare.

2. Press F8 to view the next difference or F7 to view the previous difference.

Viewing and printing system definition file differences

You can view and print all settings for an element that you select in the compared .msd file, regardless of the differences. For example, if you select a map source file, the Properties, Map Settings, and Launcher Settings display.

- To expand a list of Properties, Map Settings, or Card Settings, right-click on the list and choose Expand All.
 - To print Map Settings or Card Settings, right-click on the list and click Print Properties.
- You cannot edit information from this window.

Links

A link is a connection that the Integration Flow Designer creates between two components in a system definition file.

Links represent the direction of data flow among the components of a system at execution time. One of the linked components produces data and the other component uses it as a source. Links graphically present the source and target dependencies between system components.

- [Internal links](#)
- [External links](#)
- [Pseudo links](#)
- [Doc links](#)
- [Overriding a card source or target](#)

Internal links

The Integration Flow Designer treats a map component as a self-contained indivisible unit. This basic building block is displayed graphically using various visual cues to convey information about it. Double-click on a map icon in the system window to expand or contract the view.

The expanded view of a map component uses links to distinguish its sources from its targets. These links are called internal links because sources and targets are an integral part of a map component. By default, the Integration Flow Designer displays the sources to the left of a map component and the targets to the right. However, you can drag any of the source or target icons to any new location within a system window. A map's internal links always help you to distinguish source icons from target icons regardless of where these icons are placed.

The Integration Flow Designer also displays the audit log of a map as a target if you enable the map's audit log option (`MapAuditLogSwitch = ON`). The audit log file is represented as a target by a dotted internal link.

In general, the Integration Flow Designer automatically derives and displays internal links for an expanded map component. It uses information in the referenced source or compiled map file together with any source and target overrides that may be specified.

If you change the default sources or targets defined within a source or compiled map file using the Map Designer, the Integration Flow Designer will display these modified definitions when you expand the corresponding map component. Also, if you change the source or target (input or output) overrides for a map component by using the Integration Flow Designer, the changed overrides are displayed when you expand the corresponding map component.

The Integration Flow Designer prevents you from deleting internal links as well as the corresponding source and target icons. You must use the Map Designer to change the number and type of inputs and outputs.

External links

About this task

Map components and subsystem components are the fundamental building blocks of a system. The Integration Flow Designer uses links to display data flow relationships among these components. A link that is displayed between two system components is called an external link because the link is not an integral part of either component. An external link represents the fact that one of the components produces a data target and the other component uses this data as a source.

An external link can connect a map component to another map component, or a map component to a subsystem component, or a subsystem component to a subsystem component. External links are represented by a solid, directed line. An example follows. The map components are expanded, indicating that the internal links are visible. A visual clue that indicates a component is expanded is that the name is displayed in bold text. When the component is not expanded, the name text is regular, not bold.

Results

An external link conveys more information when the map components that it connects are expanded. In this example, you can explicitly view which targets of one component feed which sources of the other component. When a link is displayed between contracted map components, the link implicitly displays the data flow relationship between the two components.

The Integration Flow Designer automatically derives and displays an external link between two components that share common resources as sources and targets. As with internal links, the Integration Flow Designer uses information in the referenced source map or compiled map files together with any source and target overrides that you may have specified to determine if any two components in a system definition file have a data flow relationship.

The Integration Flow Designer automatically derives and displays database links, messaging links, and file links.

A database link is drawn between two map components when the Select statement defined in the database source of one of the maps references the table associated with the database target of another map. You can view the links explicitly if both map components are expanded.

A messaging link is drawn between two map components when the messaging source of one of the maps references the messaging target of another map.

A file link is created between two map components when the file named in the source of one of the maps references the same file in the target of another map.

Changing the default sources or targets defined within a source map or compiled map file using the Map Designer, or changing the source or target overrides by using the Integration Flow Designer has a direct effect on the external links that are drawn.

The Integration Flow Designer prevents you from deleting external links that it has automatically derived. You must either delete one of the components or change the source or target settings to remove an external link.

Pseudo links

The Integration Flow Designer automatically derives external links and displays them using solid directed lines. The Integration Flow Designer also enables you to manually define external links between two components. These are called pseudo links. A pseudo link is displayed using a dotted directed line.

Pseudo links represent data flow relationships that cannot be derived statically at design time. They help you to visualize data flow relationships that are established at execution time. The Integration Flow Designer does not embed pseudo links that you define into the process control information, which drives Command or Launchers. Pseudo links serve a visual purpose only.

- [Using a pseudo link](#)
-

Using a pseudo link

About this task

This section contains the basic procedures for working with pseudo links.

- [To add a pseudo link](#)
 - [To delete a pseudo link](#)
 - [To display or hide links within a system window](#)
-

To add a pseudo link

Procedure

1. In the system window, place the focus on the system that contains the components to link.
 2. From the toolbox, click on the Add Pseudo Link tool and click the source component or card in the system window.
The mouse pointer changes to a cross (+).
 3. Click on the target component or card.
A dashed line is displayed between the two components or cards.
-

To delete a pseudo link

Procedure

1. From the system window, select the link to delete.
Both ends of the pseudo link now have small bold rectangles indicating it is selected.
 2. Press Delete.
The pseudo link is deleted.
-

To display or hide links within a system window

Procedure

1. Place the focus on a system in the system window.
 2. From the toolbar, click the Display/Hide Links tool.
All links will be displayed or hidden.
-

Doc links

The Integration Flow Designer includes a feature called Doc Links to assist you in documenting your design. You can link any type of text file or Windows-registered document to a map component. For example, you can link a Microsoft Word document or a project plan to a map component that specifies design information for the map. You can view and edit the document by referencing it through the map component to which it is linked.

- [Using doc links](#)
-

Using doc links

About this task

You can define Doc Links for each map component and subsystem component as well as the sources and targets. A document link associates a document file of your choice, such as a design specification, with the component. For example, it is best to link a design specification to a subsystem component because it specifies information at the system level as opposed to the map level.

- [To add a document link for a component](#)
 - [To view a document link](#)
 - [To delete a document link](#)
-

To add a document link for a component

About this task

Procedure

1. Right-click the component icon where the document is to be linked.
 2. From the context menu select Doc Links > Add and select the document to be linked by clicking Open.
The document is now associated with the component.
-

To view a document link

Procedure

1. Launch the associated application from the Integration Flow Designer to view Doc Links.
 2. Right-click the map icon with the document link and select Doc Links > document.
Clicking the document will launch the associated viewing application provided that it is registered on the machine running the Integration Flow Designer.
-

To delete a document link

About this task

Note: Deleting a document link does not delete the document, only the link between the component and the document.

Procedure

1. Right-click the map icon with the document link and select Doc Links > Remove.
The Remove Doc Links dialog is displayed.
 2. Select the document link and click Remove.
The document link is deleted.
-

Overriding a card source or target

About this task

You can override a card source or target with the source or target of another card; however, the card names cannot be overridden or changed. Links are created automatically between cards when a relationship is established.

To override an input or output card:

Procedure

1. Place the focus on a system in the system window.
2. Double-click a map component to expand the view.

3. From the toolbox, click the Override tool and then click on the card source or target to copy.
 4. Move the cursor to and click on the card you want to override.
The source or target of the first and second cards are now identical.
-

Deploying systems

Using the Integration Flow Designer, you can create and run deploy scripts that automate the process of preparing systems to run on specific servers. For example, you can create a deploy script to build maps, generate system or command files, or transfer files to a designated server.

- [Using deploy scripts](#)
 - [Running a deploy script](#)
-

Using deploy scripts

About this task

Deploy scripts are only available for executable systems (systems with assigned servers).

- [To access deploy scripts](#)
 - [To configure a script command](#)
 - [To add a deploy script](#)
 - [To remove a deploy script](#)
 - [To rename a deploy script](#)
 - [Build and transfer maps](#)
 - [Generate and transfer files](#)
 - [Transfer additional files](#)
-

To access deploy scripts

Procedure

1. Place the focus on an executable system in the system window.
 2. Select System > Deploy > Definitions
If deploy definitions already exist for the system, they will appear in the submenu list.
 3. Enter a name for the deploy script and click OK.
The Define Deploy Scripts dialog is displayed. The Define Deploy Scripts dialog lists the deploy scripts that have been defined. Clicking a deploy script name in the list causes the Script Commands group to be refreshed based on the definition of the selected script.
The Script Commands group has three commands with a check box next to each: Build and Transfer Maps, Generate and Transfer Files, Transfer Additional Files. Enabling a check box implies that the command will be executed when the script is run. Files are transferred by means of file transfer protocol (FTP) as binary data or ASCII text.
-

To configure a script command

Procedure

Under Script Commands, do one of the following:

- Select the script command and click Details.
 - Double-click the script command name.
-

To add a deploy script

Procedure

1. Open the system that requires the deploy script.
 2. From the System menu, select Deploy > Definitions . The scripts listed are associated with the system whose window was active prior to running the Deploy command.
 3. When the Define Deploy Scripts dialog is displayed, click Add.
 4. When the Add Deploy Script dialog is displayed, give the new deploy script a name and click OK. The script name must be unique within the active system.
-

To remove a deploy script

Procedure

1. Open the system containing the deploy script to be removed.
2. From the System menu, select Deploy > Definitions . The scripts listed are associated with the system whose window was active prior to running the Deploy command.
3. Do one of the following:
 - Select the script to be removed, and click Remove.
 - Right-click the name of the script to be removed and select Remove from the context menu.

To rename a deploy script

Procedure

1. Open the system containing the deploy script to be renamed.
2. From the System menu, select Deploy > Definitions . The scripts listed are associated with the system whose window was active prior to running the Deploy command.
3. Select the script to be renamed by clicking on its name and do one of the following:
 - When the Define Deploy Scripts dialog is displayed, click Rename.
 - Right-click the script to be renamed and select Rename from the context menu.
4. Click OK to rename the script.

Build and transfer maps

About this task

By using the **Build and Transfer Maps** script command, you can identify which maps to be built and to where they are transferred.

- [To build and transfer a compiled map](#)
- [To use the Maps Referenced Below option](#)
- [To modify the component list](#)
- [To specify the directory where the compiled map \(.mmc\) is transferred](#)
- [Editing a path](#)

To build and transfer a compiled map

Procedure

1. Select a system and select System > Deploy > Definitions . The Define Deploy Scripts dialog is displayed.
2. Under Deploy Scripts, select a deploy script from the list.
3. Under Script Commands, double-click Build and Transfer Maps . The Build and Transfer Maps dialog is displayed.
4. From the Maps to Process tab, select one of the two options:
 - The All Maps option (the default selection) to indicate that all maps in the selected system are to be built and transferred when this deploy script is run.
 - The Maps Referenced Below option to indicate that only the referenced maps in the list are to be built and transferred when this deploy script is run.

To use the Maps Referenced Below option

About this task

There are two drag-and-drop operations that you can use to move map references into the list: one from the List view and one from the system window. Instructions for both operations are provided in the following procedure.

- [To drag from the List view](#)
- [To drag from the system window](#)

To drag from the List view

Procedure

1. From the List view in the Navigator, click on a map and drag it to the component list on the Maps to Process tab.
2. When the mouse pointer displays a plus sign (+), release the mouse to drop the map component.

To drag from the system window

About this task

To drag a map component from the system window, you must first ensure that the system window is not maximized. One way to make the active system window smaller is to go to the Window menu and select Cascade. Then you must arrange the open dialog boxes in such a way that they do not block your view of the map component in the active system window. Now you are ready to drag-and-drop from the system window.

Procedure

1. From the system window, click on the map component and drag it to the component list on the Maps to Process tab.
2. When the mouse pointer displays a plus sign (+), release the mouse to drop the map component.

To modify the component list

About this task

To modify the list of components in the Maps to Process tab, do one of the following:

Procedure

- Select an item in the component list and right-click to view a context menu.
- Click a column title button to sort by ascending or descending order.

To specify the directory where the compiled map (.mmc) is transferred

Procedure

- From the Build and Transfer Maps dialog, go to the Server Map Directories tab.
- On the Server Map Directories tab, the values in the Server View column are the directories of map server locations for the particular map components referenced on the Maps to Process tab.

Editing a path

About this task

The directories listed in the **Server View** column are for display only and cannot be edited. The **Integration Flow Designer View** column represents the target destination directory for the given source directory (under **Server View**) on the server.

The paths in the **Integration Flow Designer View** column can be edited either one at a time or by replacing text in a selected group of directories. Right-click to view the context menu.

One directory can be edited by selecting **Edit Integration Flow Designer View** (or by double-clicking a directory in the **Integration Flow Designer View** column), which allows inline editing directly in the list control. After the inline-editing mode is started, a box is displayed around the item in the list.

To edit multiple directories:

Procedure

1. Ctrl-click each directory to include and right-click. A context menu is displayed.
2. Select Replace Integration Flow Designer View.
The Replace dialog is displayed.
3. Enter the part of the selected string(s) to be replaced into the Replace field.
4. Enter the replacement string into the With field.
5. Click OK to modify the selected paths in the list.
If a directory cannot be changed based on the With field input, the directory stays highlighted and an error message is displayed.

Generate and transfer files

About this task

You can generate and transfer .msl or command files. Procedures for both are described in this section.

When deploying systems that contain maps with XML types to non-windows platforms, the XML Schema and XML input files must be transferred in binary format.

- [To generate and transfer a Launcher system file \(.msl\)](#)
- [To generate and transfer a command file](#)
- [Moving a map component to the deploy dialog](#)
- [Moving subsystems to the deploy dialog](#)

To generate and transfer a Launcher system file (.msl)

About this task

This procedure assumes that the execution mode of the active system is set to Launcher.

Procedure

1. In the Define Deploy Scripts dialog, select the deploy script.
2. Under Script Commands, select Generate and Transfer Launcher Control File and click Details.
If the server is local, distributed, or undefined, the Event Server control file path on server dialog is displayed. (The Command file path on server dialog is displayed when using Command execution mode.) For this option, select or name the .msl file and click Save. This specifies the name and location of the .msl file that will be created by the deploy script.
If the server is completely defined, follow the prompts to select the target directory.

To generate and transfer a command file

About this task

This procedure assumes that the execution mode of the active system is set to Command.

Procedure

1. From the active system, select System > Deploy > Definitions.
The Define Deploy Scripts dialog is displayed.
2. Under Script Commands, select Generate and Transfer Command File and click Details.
If the server is local, distributed, or undefined, the Command file path on server dialog is displayed. For this option, select or name the file and click Save.
If the server is completely defined, the Command control file path on server dialog is displayed. For this option, select the target directory and click OK. Click OK again from the Command file path on server dialog. This action specifies the name and location of the command file that will be created by the deploy script.

Moving a map component to the deploy dialog

About this task

Moving map components from a system window to the deploy dialogs is an easy drag-and-drop operation. A map component can also be moved from the Navigator to the dialog.

After the map component is moved to the dialog, the list is automatically refreshed.

Source map components as well as compiled map components can be moved to the dialog. When a script runs, the compiled maps are transferred. Pseudo maps cannot be moved; duplicates will be rejected.

Only map components that reside in the system being deployed can be moved into the dialog. For example, if you are defining a deploy script for system **ABC**, then only map components that are contained in the **ABC** system can be moved to the dialog.

Moving subsystems to the deploy dialog

About this task

Moving subsystems from a system window to the deploy dialog is an easy drag-and-drop operation. A subsystem can also be moved from the Navigator to the Build and Transfer Maps dialog. After the subsystem is moved to the dialog, the list is automatically refreshed.

Similar to map components, only subsystems that reside in the system being deployed can be moved to the dialog. If you are defining a deploy script for system **ABC**, then only subsystems that are contained in **ABC** can be moved to the dialog. If you open a system window unrelated to **ABC**, then subsystem components cannot be moved to the dialog.

If a subsystem has already been moved into the dialog, then any map component that the subsystem contains cannot be moved to the dialog. Also, if a map component has been moved to the dialog, then the subsystem that contains the map component cannot be moved to the dialog.

You can click one item in the list to select it or use the Shift and Ctrl keys to select multiple items. Right-click on one or more selected items in the list to display the following context menu.

If multiple items are selected, the Go To Component is disabled. If you select Go To Component, the system window where the component resides is displayed and the component is selected.

Transfer additional files

About this task

You can transfer files other than the compiled map, Launcher system file (.msl), or command file. For example, you can transfer a text file that contains notes about implementing the system. For each file, you can choose either an ASCII or binary transfer mode.

To transfer additional files

Procedure

1. From the Define Deploy Scripts dialog, select Transfer Additional Files and click Details.
The Transfer Additional Files dialog is displayed.
2. Right-click on an item under Source Location or Target Location to view the context.
 - Selecting Edit Source or Edit Target allows inline editing of the source or target location. After the inline-editing mode is started, a box is displayed around the item in the list indicating that it can be edited.
 - Selecting Replace Target Location allows you to do a find-and-replace operation.
 - Selecting Browse Target Location allows you to browse for a target location.
3. To change the transfer mode from the default setting (ASCII) to binary, click on the Mode field, display the drop-down menu, and select Binary from the list.
4. Click OK to save changes and close the dialog.

Running a deploy script

About this task

After you create a deploy script, you can easily select and run it by selecting System > Deploy. Each deploy script listed on the submenu is associated with the active system.

- [To run a deploy script](#)
- [To view deploy script results](#)

To run a deploy script

Procedure

1. Place the focus on a system in the system window.
2. From the System menu, select Deploy *script name*, where script name is the name of the predefined deploy script. The script runs.
3. When the script ends, click the Results button to view all activity. In addition, all activities reported on the Deploy dialog are written to a log created in the installation directory that you can view at a later time.
If a deploy script fails, an error message is displayed.

To view deploy script results

Procedure

- Select View > Deploy Results.
- The Deploy Results file is displayed in a text editor.

Return codes and error messages

- [Return codes and error messages](#)
- [Troubleshooting tips for error messages](#)

Return codes and error messages

This section contains return codes and error messages that result from an analysis of a system.

The System Analyzer checks the internal consistency of your systems to assure that they can be executed.

- [System analysis structure error messages](#)
- [Systems using wildcards analysis structure error messages](#)

System analysis structure error messages

The following table lists the structure error messages that result from a structural analysis of a system:

Return Code	Message
SE100	Map, <i>name1</i> , cannot be a component because system, <i>name2</i> , is distributed. A distributed system cannot have maps as components.
SE101	System, <i>name1</i> , contained in system, <i>name2</i> , must have a server. Each component of a distributed system must be distributed or have a server assigned (i.e., the server for a component of a distributed server cannot be "None").
SE102	System <i>name</i> has unresolved settings that must be resolved - (error). Unresolved settings must be resolved.
SE103	Wildcards are used in map source/target name, but map will be run by Command Server - Map Component <i>name1</i> , Card Name <i>name2</i> (error). Wildcards cannot be used in map source or target names if a Command Server will execute the map.
SE104	Wildcards are used in directory name that is specified in source/target name - Map Component <i>name1</i> , Card Name <i>name2</i> (error). Directories cannot have wildcards in their names.
SE105	Wildcards are used in database source name - Map Component <i>name1</i> , Card Name <i>name2</i> (error). A database source name cannot contain wildcards.
SE106	Wildcard must be used in at least one source trigger because wildcards are defined for non-trigger sources and/or targets - Map Component <i>name</i> (error). If wildcards are used as sources and/or targets, at least one source trigger must have a wildcard.
SE107	Question mark wildcard is used in a target name - Map Component <i>name1</i> , Card Name <i>name2</i> (error). Question marks cannot be used in target names. A target name can contain at most one asterisk.
SE108	Question mark wildcard is used in a source name that is not a trigger - Map Component <i>name1</i> , Card Name <i>name2</i> (error). Question marks cannot be used in sources that are not event triggers. A source that is not an event trigger can contain at most one asterisk.
SE109	Multiple wildcard characters are used in a source trigger name, but other source triggers are defined - Map Component <i>name1</i> (error). Multiple wildcards can be used in a source trigger name of a map as long as there are no other source triggers.
SE110	More than one source trigger name contains a wildcard character and the wildcard character used is different - Map Component <i>name1</i> (error). If more than one source trigger name contains a wildcard, that wildcard must be the same wildcard.
SE111	Wildcards are used in queue manager name and/or queue name specified for WebSphere MQ name - Map Component <i>name1</i> , Card Component <i>name1</i> (error).
SE112	Source map component <i>name</i> references a non-existent MMS file - (error). Unresolved MMS reference by source map components must be resolved.
SE113	Compiled map component <i>name</i> references a non-existent MMC file - (error) . Unresolved MMC reference by compiled map components must be resolved.
SE114	Subsystem component <i>name</i> references a non-existent system - (error) . Unresolved system reference by subsystem components must be resolved.
SE115	A system contains itself as a component - System <i>name1</i> , Subsystem <i>name2</i> (error) . A system cannot contain itself as a component.
SE116	Invalid <i>source/target name</i> - Map Component <i>name1</i> , Card Name <i>name2</i> (error) . Database, messaging and application adapters must have valid source/target names as checked by the individual adapter.
SE117	Asterisk wildcard is used multiple times in a target <i>name</i> - Map Component <i>name1</i> , Card Name <i>name2</i> (error) . Only one wildcard per target name is permitted.

Systems using wildcards analysis structure error messages

Wildcards can be used to specify a variable name for a source or target. The asterisk and question mark characters are used according to the conditions described in the SE103 thru SE110 error messages detailed in [System Analysis Structure Error Messages](#). The System Analyzer verifies that these conditions are satisfied. When a condition is not satisfied, it is flagged as an error.

Note: For more information about wildcards, refer to the Launcher documentation.

Return Code

Message

SE500

Map component *name* has no triggers. [Warning].
Maps that will be executed by a Launcher should have a trigger, otherwise the map will never run.

SE501

System name has no components. [Warning].
A system should have at least one component.

SE502

Pseudo map component *name1* exists in system *name2*. [Warning].
Pseudo maps should be converted to source map components.

SE503

Triggers are defined for a map that will be executed by a Command Server - Map Component *name1*. [Warning].
Triggers should not be defined for a map that will be executed by a Command Server.

SE504

The execution mode of system *name* does not match the execution mode of subsystems that it contains. [Warning].
The execution mode specified for a system should be the same as the execution modes specified for its subsystems.

SE505

Drive letters should not be used in UNIX paths - Map Component *name1*, Card Name *name2*. [Warning].
Drive letters should not be used in UNIX paths.

Troubleshooting tips for error messages

- [Not enough memory to execute error message](#)
- ["Version Mismatch" error message](#)

Not enough memory to execute error message

Problem: A map is running on a UNIX platform but fails on a different platform displaying the following error message:

Not enough Memory to execute (2)

Solution: The most common reason is that the map being run is not built for that platform. Ensure that the executable map corresponds to the correct UNIX system where the engine is running.

"Version Mismatch" error message

If you deploy a system to an incompatible platform, the logged error message might incorrectly indicate a version mismatch, when it should instead indicate a platform mismatch.

The problem causing an incorrect error message is that the version is reverse byte ordering on UNIX (as opposed to Windows). To the Launcher, it is displayed as a version mismatch because it there is no indication that it was meant for Windows. The Launcher can only conclude that it is not appropriate for UNIX systems.

Database Interface Designer

Database Interface Designer overview

The Database Interface Designer is used to import metadata about queries, tables, and stored procedures for data stored in relational databases. It is also used to identify characteristics of those objects to meet mapping and execution requirements such as update keys and database triggers.

The Database Interface Designer is used to:

- specify the databases to use for a source or target
- define query statements
- automatically generate type trees for queries or tables

After defining database queries or tables in the Database Interface Designer, define your map in the Map Designer where, in map cards, you can specify an input source as either a query or a stored procedure and an output target as either a table or a stored procedure.

Database connectivity is supported under the control of Relational Database Management Systems (RDBMS).

The adapters provide the option of using a driver to connect to the platform of your choice so that you can automatically create type trees for database queries and tables. The adapters also provide a test environment on the PC for maps using data stored in a database.

You can also install adapters on additional systems to provide remote database connectivity, such as with ODBC, Oracle, Sybase, or DB2®, on operating systems such as HP-UX, Sun Solaris, AIX®, and so on.

Non-Windows adapters do not require the Database Interface Designer if you plan to only use **mtsmaker** without a database/query file (MDQ) to generate each type tree. For information about using **mtsmaker**, see the Resource Adapters documentation.

Basic steps for using database data

About this task

The following is a high-level description of the steps required to use database data.

To use the Database Interface Designer to import database definitions

Procedure

1. Create a database/query file (MDQ).
2. Define a database.
3. If the database is to be used as an input, define a query for that database.
4. Generate the type tree for the query, table, view, stored procedure, or message from which or to which you want to map.
5. If the database is to be used as an output, set keys and designate columns for performing SQL updates.
6. Save the MDQ file.

To use the Map Designer to configure database sources, targets, or operands in a rule

Procedure

1. From the input or output card(s) in the executable map, select Database as the value for either the GET Source or PUT Target setting.
2. Select the MDQ file that contains the database-specific source or target information.
3. Perform the following for an input and/or an output card:
 - In an input card, select a query from the MDQ file.
 - In an output card, specify a table name or stored procedure.

Database Interface Designer basics

This topic introduces the **Database Interface Designer** window and provides information about working with the graphical user interface.

- [Starting the Database Interface Designer](#)
- [Database Interface Designer user interface](#)
- [Menu commands and tools](#)
- [Configuring the environment](#)

Starting the Database Interface Designer

During installation, an entry for the Database Interface Designer is added to the IBM Transformation Extender program folder (listed under the Design Studio).

When the Database Interface Designer runs, the Startup dialog appears. In this dialog, you can select how the Database Interface Designer program should open. The following options are available:

- [Open an existing database/query file](#)

Browse for the MDQ file you want.

- **Create a new database/query file**

Create a new MDQ file.

- **Open a recently used database/query file**

Select one or more files from the displayed file list. You can also double-click on a file from this list to open it.

The Startup dialog can be disabled by enabling the **Do not show this at startup** check box; however, you can always access this dialog from the **Database Interface Designer** window Help menu by selecting the Startup Window menu option.

Database Interface Designer user interface

The main **Database Interface Designer** window provides a graphical user interface in which to create and maintain MDQ files. These files contain database definitions that include information such as database name, connection information, queries, stored procedures, and so forth.

When you create a database/query file in the Database Interface Designer, a file named **Database_Query File** (which is the default file name) followed by an assigned, sequential number appears in the Navigator. This indicates that you can begin defining databases, queries, and so on. Save this database/query file (a file name with an MDQ extension), providing an appropriate name and location.

- [The Navigator](#)
-

The Navigator

The Navigator graphically presents all of your opened MDQ files and the databases that they contain. It also provides a graphical representation of the queries, stored procedures, message queues, and tables or views that have type trees generated. Also displayed are tables and views with update keys defined, as well as variables that are defined in each MDQ file.

- [Changing the appearance of the navigator](#)
 - [Database Interface Designer icons](#)
-

Changing the appearance of the navigator

About this task

The **Navigator** can be shown or hidden. It also can be presented as either a docked window or a floating window. These choices are available from the context menu of the **Navigator**. To access the context menu, right-click on the border of the **Navigator**.

- [To show or hide the Navigator](#)
 - [To float the Navigator in the main window](#)
 - [To dock the Navigator](#)
-

To show or hide the Navigator

Procedure

1. To show the Navigator, from the View menu, select Navigator.
A check mark appears next to Navigator in the View menu, indicating that the Navigator is displayed.
 2. To hide the Navigator, from the context menu of the Navigator, select Hide.
or
Repeat Step 1 above to disable the Navigator selection from the View menu.
-

To float the Navigator in the main window

Procedure

1. Starting with the Navigator being docked, right-click on the top border of the Navigator.
The context menu appears.
 2. Click **Float In Main Window**.
The Navigator is now a separate window, floating in the main window.
-

To dock the Navigator

About this task

This procedure assumes that the Navigator is floating in the main window.

Procedure

1. In the Navigator, right-click anywhere around the border of the window, except in the title bar.
The context menu appears.
 2. If the Allow Docking option is not available, disable the check mark from the Float In Main Window option.
The Navigator is docked.

or

If the Allow Docking option is available, select it and go to the next step.
 3. After selecting Allow Docking, you can toggle between a docked window and a floating window by double-clicking the top border (below the title bar) of the Navigator. Double-click the title bar so that the Navigator is again docked.
-

Database Interface Designer icons

In addition to the hierarchical structure indicating the contents of each MDQ file, information about entries in the Navigator is visually conveyed using different icon representations defining the object and its state. For example, when a type tree has been generated for a query, the query icon changes to represent the existence of a generated type tree.

Menu commands and tools

Actions can be performed in the **Database Interface Designer** window using menu commands, tools, and shortcut keys. Not all menu commands have corresponding tools, and not all tools are represented in the command menus. When working with database/query files, you can activate commands in several different ways:

- Select functionality using the menu bar.
- Right-click on any entry in the Navigator to display its context menu.
- Click the tools on the toolbar.
- Double-click objects in the Navigator.

Note: Database Interface Designer commands are available using the methods listed above. Most procedural information in this guide uses the menu access as a default method. Use the access method most convenient for you.

- [Menu](#)
 - [Toolbar](#)
-

Menu

The **Database Interface Designer** window menu provides the common menu structure for commands generally used with Windows programs, as well as for commands to accomplish specific Database Interface Designer tasks.

Toolbar

The toolbar is a part of the **Database Interface Designer** window, providing quick access to various tools that invoke Database Interface Designer actions while working with database/query files. The applicability and behavior of each tool depends upon the Database Interface Designer object selected and its current state.

- [File menu](#)
 - [Edit menu](#)
 - [View menu](#)
 - [Database menu](#)
 - [Query menu](#)
 - [Tools menu](#)
 - [Window menu \(Alt+W\)](#)
 - [Help menu](#)
-

File menu

The File menu provides the commands that are generally available in Windows applications.

Using the keyboard, press **Alt F** to view the File menu.

Command	Shortcut Key	Description
New	Ctrl+N	Creates a new MDQ file

Command	Shortcut Key	Description
Open	Ctrl+O	Opens an existing MDQ file
Close		Closes the selected MDQ file
Save	Ctrl+S	Saves the selected MDQ file
Save As		Saves the selected MDQ file with a different name
Source Control > Create Project	Alt+F, L, C	Allows you to begin the process of creating a project using the third-party source control application you have selected.
Source Control > Open Project	Alt+F, L, O	Displays the Project window in which you can begin the process of selecting an existing project in which to work using a third-party source control dialog.
Source Control > Get Latest Version	Alt+F, L, G	Displays the Get Latest Version dialog in which you can select related files that you can get.
Source Control > Check Out	Alt+F, L, E	Displays the Check out file(s) dialog in which you can specify the files to be checked out.
Source Control > Check In	Alt+F, L, I	Displays the Check in file(s) dialog in which you can either only check in or both check in and check out again the selected files.
Source Control > Undo Check Out	Alt+F, L, U	Displays the Undo Check Out dialog in which you can reverse a check out of one or more files without either the check out or the undo of the check out showing up in the archive history.
Source Control > Add to Source Control	Alt+F, L, A	Displays the Add to source control dialog in which you select one or more files to add to your source control project archives.
Source Control > Remove from Source Control	Alt+F, L, R	Displays the Remove from source code control dialog in which you can specify the file(s) to be removed from the specified source control project archives.
Source Control > Show Workfiles	Alt+F, L, F	Displays the Project dialog in which you can view all of the workfiles in this project archive.
Source Control > Add Workfiles	Alt+F, L, W	Displays the Add Workfiles dialog in which you can specify the workfiles to be added to the project archives.
Source Control > Show History	Alt+F, L, H	Displays a third-party, source control application-specific dialog that allows you to define what you want to see in a history report generated by that third-party application.
Source Control > Show Properties	Alt+F, L, P	Displays a third-party, source control application-specific dialog that allows you to view labels and other source control-determined information on a revision-by-revision basis as recorded in that third-party source control application.
Source Control > Refresh Status	Alt+F, L, R	Synchronizes the project information for files displayed in your designer with the archival information in your third-party source control.
Database Query File Differences	Alt+F, D	Displays the Select First File dialog in which you can begin the process of specifying the two database/query (MDQ) files to compare.
Trace	Alt+F, T	Enables trace functionality to create a Database Interface Designer trace file for the selected MDQ file
Print	Ctrl+P	Displays the Print dialog in which to specify and print definitions for the selected database(s)
Print Setup	Alt+F, R	Displays the Print Setup dialog in which to configure printer options
Recent File		Opens the selected MDQ file from this list
Exit	Alt+F, X	Quits the application and prompts to save changes

Edit menu

The Edit menu provides the editing commands generally available in Windows applications. It also contains the **Find** command that can be very useful when viewing trace files in a trace window.

Using the keyboard, press **Alt E** to view the Edit menu.

Command	Shortcut Key	Description
Undo	Ctrl+Z	Reverses the last-performed action
Cut	Ctrl+X	Deletes the selection and places a copy on the clipboard
Copy	Ctrl+C	Copies the selection to the clipboard
Paste	Ctrl+V	Inserts the contents of the clipboard to the cursor location
Find	Ctrl+F	Displays the Find dialog in which to locate specified information in the active trace window
Replace	Ctrl+H	Displays the Replace dialog in which to specify the text upon which to search and the text that is replacing it

View menu

The View menu provides selections to control the appearance of your Database Interface Designer environment.

Using the keyboard, press **Alt V** to view the View menu.

Command	Shortcut Key	Description
Toolbar(s)	Alt+V, T	Displays the Customize dialog for toolbars in which to select the toolbars to be displayed and to adjust the tools displayed on specific toolbars
Status Bar	Alt+V, S	Shows or hides the status bar in the Database Interface Designer window
Navigator	Alt+V, N	Shows or hides the Navigator
Trace File	Alt+V, F	Displays the Database Interface Designer trace file for the selected MDQ file in a separate trace window

Database menu

The Database menu provides commands to initiate actions for a selected database.

Using the keyboard, press **Alt D** to view the Database menu.

Command	Shortcut key	Description
New	Ctrl+D or Insert	Displays the Database Definition window so that you can add a database to the associated MDQ file. Note: You must first select the Databases object in the Navigator to be able to do this.
Edit	none	Displays the Database Definition window that allows you to modify the selected database. Note: There is no shortcut key. But you can double-click the database object name to perform the same function as the tool.
Delete	Delete	Deletes the selected database.
Generate Tree From > Table	Alt+D, G, T	Displays the Generate Type Tree from Tables dialog that allows you to generate a type tree from a table or view in the selected database. Note: You can also double-click the Tables object in the Navigator to perform the same function as the tool.
Generate Tree From > Procedure	Alt+D, G, P	Displays the Generate Type Tree from Stored Procedures dialog for the selected database or stored procedure in which you can specify the generation of a type tree from a stored procedure. Note: You can also double-click the Stored Procedures object in the Navigator to perform the same function as the tool.
Generate Tree From > Queue	Alt+D, G, Q	Displays the Generate Type Tree from Queues dialog in which you can specify the generation of a type tree from a message queue
Set Update Keys	Alt+D, S	Displays the Set Table Update Key Columns dialog in which you can specify update keys and the key columns to update in the selected database

Query menu

The Query menu provides commands to initiate actions for a selected query.

Using the keyboard, press **Alt Q** to view the Query menu.

Command	Shortcut Key	Description
New	Ctrl+Q or Insert	Displays the New Query dialog in which to add a new query. Note: You must first select the Queries object in the Navigator to be able to do this.
Edit	Alt+Q, E	Displays the Edit/View Query dialog in which to modify the selected query. Note: You can also double-click the database query name to perform the same function as the tool.
Delete	Delete	Deletes the selected query
Generate Tree	Alt+Q, G	Displays the Generate Type Tree from Query dialog that allows you to generate a type tree from the selected query
Define Variables	Alt+Q, V	Displays the Define Variables dialog in which to specify pseudo variable values. Note: You can also double-click the Variables object in the Navigator to perform the same function as the tool.
Define Trigger	Alt+Q, T	Displays the Trigger Specification dialog in which to specify the input events that must occur to launch a map using the selected query as a data source

Tools menu

The Tools menu provides options to customize your Database Interface Designer environment.

Using the keyboard, press **Alt L** to view the Tools menu.

Command	Shortcut Key	Description
Shortcuts	Alt+L, S	Displays the Shortcut Keys dialog in which to assign shortcut keys or key combinations to specific Database Interface Designer operations
Options	Alt+L, O	Displays the Options dialog in which to configure Database Interface Designer options for backups, the Navigator, trace windows, tables/views, and confirmations

Window menu (Alt+W)

The Window menu contains commands to provide control of open trace windows.

Using the keyboard, press **Alt W** to view the Window menu.

Command	Shortcut Key	Description
Close All	none	Closes all open trace windows
Cascade	none	Arranges all open trace windows so that they overlap in a descending pattern
Tile Horizontally	none	Arranges all open trace windows as horizontal, non-overlapping tiles
Tile Vertically	none	Arranges all open trace windows as vertical, non-overlapping tiles
Arrange Icons	none	Arranges all minimized trace windows in an orderly fashion
List of recently used files	none	Selecting a specific trace file from this list makes it the active window. A check mark appears next to the trace file that is in the active trace window.

Help menu

The Help menu offers choices to display information about the Database Interface Designer.

Using the keyboard, press **Alt H** to view the Help menu.

Command	Shortcut Key	Description
Contents	none	Displays the contents of the Help system which also lists the Help topics
Startup Window	none	Displays the Startup dialog in which to select whether to create a new or open an existing MDQ file
About Database Interface Designer	none	Displays application-specific information

Configuring the environment

Much of the Database Interface Designer environment can be configured to accommodate your preferred work environment. For example, you can:

- Specify various user interface options (font, line appearance, dialog display)
- Select the tools to display
- Change the look of the tools on the toolbar
- Assign shortcut keys
- [Tools > Options](#)
- [Shortcut keys](#)

Tools > Options

From the Tools menu, select Options. The Options dialog appears. Select choices representing various aspects of the Database Interface Designer environment and configure them as desired.

- [General options](#)
- [Navigator options](#)
- [Trace window options](#)
- [Tables/views option](#)
- [Confirmations options](#)

General options

In the list of options, select General to specify values concerning the backing up and saving of your MDQ files. The fields in this dialog are as follows:

Field	Description
Auto-save files every <i>n</i> minutes (where <i>n</i> represents a number)	This spin button indicates the time interval at which to automatically save opened MDQ files. The default value is 0.
Show Banner	This check box specifies whether to display the banner, which appears between the title bar and the menu bar of the Database Interface Designer window. The default setting is enabled.
Backup on save	This check box specifies whether to create a backup copy of each MDQ file when the file is saved. The default setting is enabled.
Configuration File	Enter the name of the resource configuration (.mrc) file to use to resolve resource aliases.

Navigator options

In the list of options, select Navigator to specify how to display objects in the Navigator.

Trace window options

In the list of options, select Trace Window to specify the font used to display text in the Trace window.

Tables/views option

In the options list, select Tables/Views to determine the objects to be displayed that are associated with the database. The fields in this dialog are as follows:

Field	Description
List tables	This check box determines whether tables are displayed in the database list. The default value is enabled.
List views	This check box determines whether views are displayed in the database list. The default value is enabled.
List synonyms	This check box determines whether database synonyms are displayed in the database list. The default value is enabled.

Confirmations options

In the list of options, select Confirmations to specify the actions for which you want a confirmation dialog displayed before completion of those actions.

Field/Button	Description
Database operations	
Deleting database(s)	This group box displays the options that control whether confirmation dialogs are displayed with regard to database operations. Select any or all of these options.
Copying database(s)	This check box determines whether a confirmation dialog appears when deleting a database. The default value is enabled.
Moving database(s)	This check box determines whether a confirmation dialog appears when copying a database. The default value is enabled.
Table operations	
Deleting table(s)	This check box determines whether a confirmation dialog appears when deleting a table. The default value is enabled.
Copying table(s)	This check box determines whether a confirmation dialog appears when copying a table. The default value is enabled.
Moving table(s)	This check box determines whether a confirmation dialog appears when moving a table. The default value is enabled.
Query operations	
Deleting query(s)	This check box allows you to display the name of each object when the cursor is held over it and the Navigator is sized too small for the name to be completely displayed. The default setting is enabled.
Copying query(s)	This check box determines whether a confirmation dialog appears when deleting a query. The default value is enabled.
Moving query(s)	This check box determines whether a confirmation dialog appears when copying a query. The default value is enabled.

Shortcut keys

You can assign your own shortcut keys for any existing or new menu items. Using the Shortcut Keys dialog, you can:

- Assign shortcut keys.
- Remove shortcut key assignments.
- Restore the shortcut key assignments present at installation.

For information about these procedures, see the Design Studio Introduction documentation.

Database/query files

This topic discusses how to use the Database Interface Designer when working with MDQ files to perform the following types of tasks:

- Create MDQ files and learn about their XML format. (For more information about the XML format, see [Understanding the MDQ XML format](#).)
- Define the various objects included in an MDQ file. (For more information about such objects as queries and variables, see [Defining a query](#) and [Defining Variables in SQL Statements](#).)
- Generate type trees. (See [Generating type trees](#).)
- Print reports and enable trace functionality. (See [Printing reports](#) and [Database Interface Designer trace files](#).)
- [Creating database/query files](#)
- [Defining a database](#)
- [Defining a query](#)
- [Editing or deleting a database or query](#)
- [Understanding the MDQ XML format](#)
- [Comparing database/query files](#)
- [Defining variables in SQL statements](#)
- [Generating type trees](#)
- [Printing reports](#)
- [Database Interface Designer trace files](#)

Creating database/query files

About this task

An MDQ file contains the definitions for one or more databases, as well as queries, stored procedures, and other specifications, that may contribute to the execution of a map. Use the commands on the File menu in the Database Interface Designer to create and save a database/query file with an **.mdq** file extension. This file name and path appears in the title bar of the **Database Interface Designer** window when it is the selected file in Navigator, indicating that it is the active MDQ file.

After starting the Database Interface Designer, the Navigator lists one or more MDQ files depending upon whether your selection was to create a new MDQ file or to open one or more existing files.

When an MDQ file is created, it appears in the Navigator next to the appropriate icon. The **Database_QueryFile** file name is automatically assigned, along with a sequential number.

To save an MDQ file or rename it:

Procedure

1. From the File menu, select Save As.
The Save As dialog appears.
2. Enter the new file name and select the path.
3. Click OK.

Defining a database

About this task

When an MDQ file appears in the Navigator, you can add new database definitions to it or you can modify the name of an existing database. This is done using the Database Definition window. Each **Database Definition** window contains some settings that are common across all platforms and others that are platform-specific. To view more information about each platform-specific setting, refer to either the context-sensitive help available from the dialog itself or to each platform-specific reference guide.

For the purposes of outlining a basic procedure to define a database, the ODBC adapter for the Windows platform will be used. An example follows.

see the following table for a listing of the settings in this window and their descriptions.

Setting	Description
Database Name	This is the name of the database being defined. This name appears in the Navigator.
Adapter	Adapter properties: Type This is a list of adapters that can host the database you are defining. Select one from the list. The default value is ODBC. This selection will affect the list of supported platforms displayed in the Platform list.
Platform	This is a list of platforms upon which the adapter (that you selected in the Type list) is supported.
Access user tables/procedures only	This setting determines level of user access and, to some extent, the presentation of the information being presented. The default value is Yes. If No is selected, all of the names (of tables, views, and so on) in the database are accessible and are presented, including the respective prefix of each associated user ID. If Yes is selected, only the names (of tables, views, and so on) in the databases associated with the current user ID are accessed and presented. Because these are all associated with the same user, no prefix is added.
Surround table/column names with	This setting indicates the character you want to use to enclose table and column names. For example, many databases require that names be enclosed by single or double quotation marks if they have spaces in their names, or when the names are SQL reserved words. When you specify table names in output cards or column names in update keys, these names will be enclosed by the character defined in this setting to provide database compatibility. There is no default value.
Data Source	Data source properties: Database Interface Designer Both this and the Runtime settings are platform-specific settings. On other platforms, you may have different settings. Again, see the platform-specific adapter reference guide or the context-sensitive help for more setting-specific information. This is the name of the data source used to access database information for design-time (pre-production or testing) purposes.
Runtime	This is the name of the data source used to access database information for run-time (map execution) purposes.
Security	Security properties:
User ID	

This is the user ID used to access the database. If you do not know this information, contact your database administrator. There is no default value.
Password

This is the password used to access the database. If you do not know this information, contact your database administrator. There is no default value.

To define a database:

Procedure

1. From the Navigator, select Databases under the MDQ file.
2. From the Database menu, select New.
or
Right-click the Databases object in the Navigator and select New.
The Database Definition window appears.
3. Enter information for the remaining settings as desired.
4. Click OK.
The new database name appears in the Navigator next to the database icon.

Defining a query

About this task

After you have opened an MDQ file in the **Database Interface Designer** window and a database has been defined, you can specify queries. To use a query as a source, define the query by assigning it a name and entering either the SQL SELECT statement or the stored procedure invocation statement.

To define a query:

Procedure

1. In the Navigator, select Queries under the database icon for which you want to add a query.
2. From the Query menu, select New.
The New Query dialog appears.
3. In the Name field, enter a name for your query. Use this name to reference this query using the Map Designer or you can use it in a data source override execution command.
4. In the Query text box, enter an SQL statement that defines how data should be retrieved from the database.
If your SELECT statement includes table names with spaces, you must enclose them with either single or double quotation marks.
5. Click OK.
The new query appears in the Navigator next to the query icon.

Editing or deleting a database or query

About this task

The following procedures describe how to edit and delete a database or a query, respectively.

To edit a database or query

Procedure

1. In the Navigator, select the name of the database or query to be edited.
2. From the Database menu (or Query menu as appropriate), select Edit.
or
In the Navigator, right-click the database or query icon and select Edit.
3. Make any necessary changes and click OK.

To delete a database or query

Procedure

1. In the Navigator, highlight the database(s) or one or more queries you want to delete.
2. From the Database menu (or Query menu as appropriate), select Delete.
or
In the Navigator, right-click the database or query icon(s) and select Delete.
3. To confirm the deletion, click Yes.

Understanding the MDQ XML format

The database/query (MDQ) file is a configuration file that is used by IBM Transformation Extender when accessing databases using database adapters. Some of the information contained within an MDQ file could include the following:

- database logical names (to distinguish among settings for the databases defined in this file)
 - database adapter types
 - database connection parameters
 - user names and passwords
 - information about tables
 - queries and stored procedures accessed by the adapters
 - primary keys for the tables (used for the database updates)
 - event trigger information for the Launcher
- [XML Schema](#)**
[Saving database/query files](#)
[Processing MDQ files](#)

XML Schema

The MDQ files are well-formed, valid XML documents. MDQ files can be created using the Database Interface Designer (DID) or any other utility capable of creating XML documents. The XML Schema file that is used by IBM Transformation Extender to validate MDQ files is **mdq.xsd**.

Note: Do not modify the content of the **mdq.xsd** file. Unexpected results may occur if you do.

If *install_dir* is the directory into which the IBM Transformation Extender product is installed, the **mdq.xsd** file is copied to the following platform-specific directories as part of that installation process:

Platform	Location
Windows	<i>install_dir</i>
UNIX	<i>install_dir /src</i>

Saving database/query files

Note: If you do not use the Database Interface Designer to create MDQ files, verify that the generated XML files are well-formed and valid for the provided **mdq.xsd** XML Schema.

The following topics contain information related to saving MDQ files from the Database Interface Designer (regardless of whether they were originally created in the Database Interface Designer or using another utility):

- [XML prolog text](#)
- [XML data from XML-generated MDQ files](#)
- [Attribute formatting](#)
- [Password encryption](#)
- [Backup copies](#)

XML prolog text

The XML prolog will always be generated as shown below:

```
<?xml version="1.0" encoding="UTF-8"?>
```

This means that the MDQ files saved from the Database Interface Designer use the UTF-8 encoding scheme.

XML data from XML-generated MDQ files

If you have created this MDQ file outside of the DID, the following information is ignored by the DID when it reads the MDQ file and the information is removed from the MDQ file when it is saved from the DID:

- XML comments
- namespace declarations
- CDATA sections and processing instructions

The content from the CDATA sections is preserved. However, it is saved using the XML entity references.

Attribute formatting

Attribute values are always enclosed in double quotes.

Password encryption

The XML schema provides two different password elements:

- `PASSWORD.literal`
- `PASSWORD.encrypted`

In an MDQ file that has not been saved in the Database Interface Designer, only the `PASSWORD.literal` value can be specified, which is not encrypted. When the file is saved in the Database Interface Designer, the password will be encrypted (using the `PASSWORD.encrypted` element).

Backup copies

If the MDQ file was created (and saved) in an earlier version of the DID and when that file is edited and saved from the DID, this newly saved MDQ file is in the current version. In addition, a backup copy of the MDQ file is created for the older version using the ODQ filename extension (instead of MDQ).

Processing MDQ files

The MDQ files can be processed either at runtime or design-time, depending upon how (and where) the files are specified.

- [Runtime execution](#)
- [Design-time execution](#)

Runtime execution

If the `-MDQ` adapter command is used along with the `DBLOOKUP`, `DBQUERY`, `GET` or `PUT` map functions or if it is specified as an adapter command in the database cards, the MDQ file is parsed at runtime.

Design-time execution

If the MDQ file name is specified in the `DatabaseQueryFile` setting of a map card, the MDQ file is parsed when the map is compiled, which is during design time for the map, not at runtime.

Comparing database/query files

Database/query (MDQ) files contain definitions of one or more databases, as well as queries, stored procedures, tables, queues, and variables. The file differentiation process identifies MDQ file differences first at the database-level, and then at the query-, stored procedure-, table-, and variable-levels. See [Creating a database/query file comparison](#).

After you have performed a comparison between two MDQ files, color-coding is used to highlight what is unique between the two:

- Differences are highlighted in red.
- New information is highlighted in blue.

For more information, refer to [Viewing database/query file differences](#).

- [Criteria for analyzing differences](#)
- [Creating a database/query file comparison](#)
- [Viewing database/query file differences](#)

Criteria for analyzing differences

The criteria for analyzing differences for the different entities is as follows:

- MDQ file
 - Any of the database definitions are different.
 - Any of the variables are different.
 - Any of the objects exist in one, but not the other, MDQ file.
- database definition
 - Any of the database definition settings are different.
 - Any of the syntax of the queries, column overrides of the stored procedures, column overrides or update keys of the tables, or any of the values of the variables are different.

- query
 - The syntax of the queries is different.
 - Column overrides of the queries are different.
 - stored procedure
 - Column overrides for the stored procedures are different.
 - table
 - Column overrides for the tables are different.
 - Update keys for the tables are different.
 - variable
 - Values for the variables are different.
-

Creating a database/query file comparison

About this task

Use this procedure to compare database/query file differences between two selected MDQ files. After you have created the comparison, you can view the results.

To create an MDQ file comparison:

Procedure

1. From the File menu, select Database Query File Differences.
The Select First File dialog appears.
 2. Navigate your file system and select the first MDQ file to be compared.
 3. Click Open.
The Select Second File dialog appears.
 4. Navigate your file system and select the second MDQ source file to be compared.
 5. Click Open.
The progress of the comparison is shown briefly in the Database Source File Differences Analysis dialog. When the analysis has completed, the Database Differences window appears.
-

Viewing database/query file differences

About this task

Note: The Database Differences window should already appear. If you do not see it, you must create the file comparison as described in [Creating a database/query file comparison](#).

Differences are indicated using color-coded text:

- Differences are **red**.
- Additions or new information items are **blue**.

To view MDQ file differences:

Procedure

1. Place current focus in the Database Differences window.
 2. Resize any of the four panes as needed.
 3. Select any database, query, stored procedure, table, or variable to view the differences.
The settings display in the two lower windowpanes, depending upon what you select.
 4. Press F8 or F7 to view the next or previous difference, respectively.
In the Database Differences window, you can view all of the settings for the selected element in the compared MDQ file, even though differences may not exist.
- [Database/query file difference results](#)
 - [Database definition setting differences](#)
 - [Query differences](#)
 - [Variable differences](#)
 - [Unique database information](#)
 - [Stored procedure differences](#)
 - [Table differences](#)
-

Database/query file difference results

When database/query source files are compared, they are considered different if any of the database definition settings are different, any of the variables are different, or any of the objects exist in one MDQ file and not the other. Text color is used to provide a visual distinction. see the table below as a guide:

Condition	Upper Panes	Lower Panes
Same name and content	black text	black text on tab, only one pane at a time
Same name, different content	red text	red text on tab, both panes appear, unique text in red

Condition	Upper Panes	Lower Panes
Different name and content	blue text	red text on tab, only one pane at a time, unique text in green (for database settings only, rest have unique text in blue)

Database definition setting differences

If any database definition settings of either of the two compared MDQ files are different, both database names appear in red letters in the Database Differences window.

The **Database Properties** tab in each lower windowpane also appears in red letters. (If there were no differences, this tab would appear in black letters.)

Query differences

If there are differences between the two compared MDQ files with regard to query syntax or column overrides, the name of the query with differences appears in red letters in the Database Differences window. If the query in each MDQ file is uniquely named, each query name appears in blue letters.

If each MDQ file has a query with the same name, but containing unique information, the **Query** and/or **Column Overrides** tabs in each lower windowpane appear in red letters. (If there were no differences, these tabs would appear in black letters and you would only see one display in the bottom pane at a time, depending upon where your cursor is in the upper pane.) When the tabs are red, you can go to each display and see the differences indicated in red letters.

Click the **Query** and **Column Overrides** tabs in each pane to view the differences.

Variable differences

If the variables of the two compared MDQ files have the same name, but different settings, the variable name will appear in red letters in the upper pane and both variables will appear in the bottom panes with the tab letters also in red letters. In the bottom panes, the unique value(s) will appear in red letters. If the variable names of either of the two compared MDQ files are different, the name of each variable appears in blue letters in the Database Differences window. If the variables are exactly the same, the name of the variable in both the upper and lower pane and the **Variables** tab would all appear in black letters.

Click the **Variables** tab in each pane to view the differences.

Unique database information

If the databases of the two compared MDQ files have the same name, but different settings, this tab will appear in red letters. Also, both databases will appear in the bottom panes of the Database Differences window. If the database names of either of the two compared MDQ files are different, the name of each database appears in blue letters in the Database Differences window. If the databases are exactly the same, the name of the database in both the upper pane and the **Database Properties** tab would all appear in black letters. In both of these latter scenarios (with the different-named or duplicate databases), you can view only one tab at a time by clicking on the Database icon in the upper (Navigator-like) portion of the window for the specific MDQ file. The resulting display in this tab is a reproduction of the settings of the Database Definition dialog. To see the respective database differences, you must click alternately on each database icon in each upper half of the Database Differences window.

Stored procedure differences

If the stored procedures of the two compared MDQ files have the same name, but different values, the stored procedure name will appear in red letters in the upper pane and both stored procedures will appear in the bottom panes with the **Column Overrides** tab letters also in red letters. In the bottom panes, the unique value(s) will appear in red letters. If the stored procedure names of either of the two compared MDQ files are different, the name of each stored procedure appears in blue letters in the Database Differences window. If the stored procedures are exactly the same, the name of the stored procedure in the upper pane and the **Column Overrides** tab and columns would all appear in black letters.

The columns on this tab (**Column Name**, **Column Length**, **Presentation**, and **Interpret As**) correspond to fields and list names in the Column Datatype Specification dialog.

Table differences

If the tables of the two compared MDQ files have the same name, but different values for column overrides or update key definitions, the table name will appear in red letters in the upper pane and both tables will appear in the bottom panes with the **Column Overrides** and/or **Update Keys** tab letters also in red letters. In the bottom panes, the unique value(s) will appear in red letters. If the table names of either of the two compared MDQ files are different, the name of each table appears in blue letters in the Database Differences window. If the tables are exactly the same, the name of the table in the upper pane and the **Column Overrides** and Update Keys tabs and related information would all appear in black letters.

Click the **Column Overrides** and **Update Keys** tabs in each pane to view the differences.

The columns on the **Column Overrides** tab (**Column Name**, **Column Length**, **Presentation**, and **Interpret As**) correspond to fields and list names in the Column Datatype Specification dialog.

Defining variables in SQL statements

Elements of SQL statements can be executed as map sources that are determined at runtime. Use the Database Interface Designer to define a statement variable with a pseudo value in an SQL statement and then pass the actual value on the command line at runtime. This technique is beneficial when using the `RUN` function because it allows one map to modify the SQL statement of another map or to build, potentially, an entire SQL statement.

When you generate type trees using the Database Interface Designer, a substitution value must be entered for each variable to ensure that the syntax of the SQL statement is valid. The Database Interface Designer provides a facility for specifying a value for these variables; however, the value you enter for a variable in the Database Interface Designer does not have to be the same value passed at runtime. (Any value can be passed.)

- [Defining a query with variables](#)
 - [Specifying the values at runtime](#)
-

Defining a query with variables

About this task

In the Database Interface Designer Query dialog, variables can be specified in SQL statements as literals enclosed in pound sign (#) characters. For example, you might enter a statement that defines a variable named `ID`:

```
select * from BigTable where Identifier = #ID#
```

Because the value of a variable may be a text string, you can also create larger elements of the statement variable. For example:

```
select * from BigTable where #WhereClause#
```

When you define variables in a query, the Database Interface Designer automatically detects the presence of the variables in the statement and lists each variable in the Navigator, along with a variable icon.

Use the Define Variables dialog to enter the variable values. Note that you cannot generate a type tree for the query until you have specified a value for *each* variable it contains. Also, if the variable you are defining in the Define Variables dialog is a text string, you must enclose the value in single quotation marks.

The pseudo values specified using the Define Variables dialog are used in the Database Interface Designer only when accessing the database to generate the type tree. They are not used when executing a map.

To specify values in the Define Variables dialog

Procedure

1. In the Navigator, select the variable to which you want to add one or more values.
2. From the Query menu, select Define Variables.
The Define Variables dialog appears, listing all the variables in the MDQ file.
3. In the Value field, enter a value for each variable and click OK.
The pseudo values are stored in the MDQ file and can only be changed in the Define Variables dialog. Also, if the variable you are defining is a text string, you must enclose the value in single quotation marks.

To delete a variable

About this task

When a variable is removed from a query statement that was previously defined in the Database Interface Designer, the variable is automatically deleted from the Navigator and no longer displays.

Specifying the values at runtime

Even though you have specified pseudo values for the defined variables using the Database Interface Designer, they are only substitution values that are not referenced at runtime. Values *must* be provided for the variables at runtime; otherwise, the SQL statement will be syntactically invalid.

The correct value for each variable is specified at run time using the Variable adapter command (`-VAR`) in the Input Source - Override execution command (`-ID`). For more information about how to specify values for these variables at runtime, see the Resource Adapters documentation.

Generating type trees

Use the Database Interface Designer to generate a type tree from a table, query, stored procedure, or message queue associated with a particular database. A type tree generated using the Database Interface Designer contains a type for the table, query, stored procedure, or message, as well as a row type and types for each column in that table, query, stored procedure, or message.

As an alternative, use **mtsmaker** on non Windows-based platforms to generate type trees when you cannot use the Database Interface Designer. For more information about using **mtsmaker**, see the Resource Adapters documentation.

- [From a query](#)

From a table or view

About this task

When you generate a type tree for a table or view, information from your database and from the Database Interface Designer is used to create a type tree file (MTT). If you change your database table definition or edit the database definition in the Database Interface Designer, you must generate a new type tree to reflect the new information.

Generated type trees may differ when generated using different database adapters. For example, a date field may be represented differently by different databases. For this reason, use the same adapter type that will be used at run time to generate the type tree with the Database Interface Designer. Or, if you use ODBC, use the Column Attributes Override dialog that is described in the Resource Adapters documentation.

To define the type tree to generate from a table or view, use the Generate Type Tree from Tables dialog or the Generate Type Tree from Views dialog. The following table contains fields and descriptions.

Database Name	This is the name of the database from which you want to generate a type tree. (This name is automatically inserted based upon your selection in the Navigator.)						
Tables/Views	This list displays all of the tables, views, or synonyms that have been defined in this database. Select one or more from this list. Note: If the table, view, or synonym you want is not displayed in this list, add it by right-clicking in the list, selecting Insert, and typing the desired name.						
File name	This field displays a system-generated file name based upon the database selection in the Navigator. The default value is the database name with a type tree extension (MTT) and a default path. To change any of this information, click the browse button.						
Overwrite file	This check box determines whether you want to replace the existing type tree file (MTT) upon saving it. The default value is disabled.						
Override type	This check box determines whether to replace existing types with matching, newly generated types and to add any non-matching new types to the type tree file (MTT). This is useful when you want to add types for additional tables into an existing type tree. The default value is enabled.						
Row group format	<p>This list displays options to determine the row format in the generated type tree. The default value is Delimited.</p> <table border="1"><tr><th>Option</th><th>Description</th></tr><tr><td>Delimited</td><td>Select this option to create rows delimited with a pipe character () or some other user-defined selection. This is the preferred option if you are using large column widths where the values may be smaller than the width of the columns. The pipe character is the default selection.</td></tr><tr><td>Fixed</td><td>Select this option to create rows of fixed size in the generated type tree. There are certain situations in which you would want to select Fixed:<ul style="list-style-type: none">• The query result contains a large number of rows where each row consists of small, fixed-length fields. In this situation, delimiters are unnecessary and they also consume memory.• You need to append fields in the output. This may be true if multiple fields have some meaning when concatenated together.</td></tr></table>	Option	Description	Delimited	Select this option to create rows delimited with a pipe character () or some other user-defined selection. This is the preferred option if you are using large column widths where the values may be smaller than the width of the columns. The pipe character is the default selection.	Fixed	Select this option to create rows of fixed size in the generated type tree. There are certain situations in which you would want to select Fixed: <ul style="list-style-type: none">• The query result contains a large number of rows where each row consists of small, fixed-length fields. In this situation, delimiters are unnecessary and they also consume memory.• You need to append fields in the output. This may be true if multiple fields have some meaning when concatenated together.
Option	Description						
Delimited	Select this option to create rows delimited with a pipe character () or some other user-defined selection. This is the preferred option if you are using large column widths where the values may be smaller than the width of the columns. The pipe character is the default selection.						
Fixed	Select this option to create rows of fixed size in the generated type tree. There are certain situations in which you would want to select Fixed: <ul style="list-style-type: none">• The query result contains a large number of rows where each row consists of small, fixed-length fields. In this situation, delimiters are unnecessary and they also consume memory.• You need to append fields in the output. This may be true if multiple fields have some meaning when concatenated together.						
Delimiter	This is the value for the delimiter to be used when generating this type tree. For a list of available symbols, click the browse button. The Symbols dialog appears, allowing you to select the desired value. The default value is a pipe character ().						
Terminator	This is the value for the terminator to be used when generating this type tree. For a list of available symbols, click the browse button. The Symbols dialog appears, allowing you to select the desired value. The default value is <CR><LF>.						
Release	This is the value for the release character to be used when generating this type tree. For a list of available symbols, click the browse button. The Symbols dialog appears, allowing you to select the desired value. The default value is an exclamation point (!).						
Override Column Definitions	(For ODBC only) This check box indicates whether the database driver (with check box disabled) or a command line override (with check box enabled) is used to interpret columns. The default value is disabled. For more information about this field, see the adapter-specific documentation in each adapter reference guide.						
Generate type trees in 1.4.0 format	(For Oracle adapter only) This check box determines whether you can generate type trees that are compatible with maps for Version 1.4.0. You might enable this functionality if you have legacy 1.4.0 maps that you want to maintain for some reason. The default value is disabled. For more information about this field, refer to adapter-specific documentation in each adapter reference guide.						
Represent date/time columns as text items	If you are generating new type trees, make sure this check box is disabled. The default is disabled. Because of adapter-specific differences in date and time formats, see the adapter-specific instructions in each adapter reference guide.						
Treat text item as	This list displays the languages available in which to handle text items. The default value is Western.						

To generate a type tree from a table or view:

Procedure

1. In the Navigator, highlight the icon of the database containing the table from which you want to generate a type tree.
2. From the Database menu, select Generate Tree From > Table.
or

In the Navigator, right-click the database icon and select Generate Tree From > Table.

The Generate Type Tree from Tables dialog appears, including a list of tables and views.

3. If you need to add a table because it is not displayed in the Tables/Views list, you must insert it using the instructions provided in the Note below.
or

If you see one or more tables in the Tables/Views list that you want to select, if it is one; select it. If it is multiple tables, press either Shift or Ctrl and click the desired table.

If the table or view you want is not displayed in this list, add it by right-clicking in the list, selecting Insert, and typing the desired name.

4. To create a new type tree, in the File name field, specify the path and name (with an .mtt extension).
or

Click the browse button to select a type tree from the Save As dialog. Highlight it and click OK.

5. Specify the remaining options as desired. Refer to context-sensitive help for field-specific information.

6. Click Generate.

The Database Interface Designer and the Type Tree Maker produce a type tree corresponding to the selected database table(s) or view(s).

Results

The generated type tree is represented in the Navigator with the table/view icon next to the name.

From a stored procedure

About this task

Use the Database Interface Designer to generate type trees from the parameters of stored procedures.

An example of the Generate Type Trees from Stored Procedures dialog follows, along with a table describing its fields and their descriptions.

Database Name	(Display only) This is the name of the database from which you want to generate a type tree. (This name is automatically inserted based upon your selection in the Navigator.)						
Stored Procedures	This list displays all of the stored procedures that have been defined in this database. Select one or more from this list. The list of stored procedures includes stand-alone procedures by default. (Procedures that are parts of a package are not listed.) If you need a procedure that is part of a package (whether this functionality is available is dependent upon your database), you may need to insert it into this list before selecting it. To insert a packaged stored procedure, right-click in the list, select Insert, and type the desired name. Use the following format: <i>schema . package . procedure</i> .						
File name	This field displays a system-generated file name based upon the database selection in the Navigator. The default value is the database name with a type tree file extension (.mtt) and a default path. To change any of this information, click the browse button.						
Overwrite file	This check box determines whether you want to replace the existing type tree file (MTT) upon saving it. The default value is disabled.						
Override type	This check box determines whether to replace existing types with matching, newly generated types and to add any non-matching new types to the type tree file (MTT). This is useful when you want to add types for additional stored procedures into an existing type tree. The default value is enabled.						
Row group format	<p>This list displays options to determine the row format in the generated type tree. The default value is Delimited.</p> <table><thead><tr><th>Option</th><th>Description</th></tr></thead><tbody><tr><td>Delimited</td><td>Select this option to create rows delimited with a pipe character () or some other user-defined selection. This is the preferred option if you are using large column widths where the values may be smaller than the width of the columns. The pipe character is the default selection.</td></tr><tr><td>Fixed</td><td>Select this option to create rows of fixed size in the generated type tree. There are certain situations in which you would want to select Fixed.</td></tr></tbody></table> <ul style="list-style-type: none">The query result contains a large number of rows where each row consists of small, fixed-length fields. In this situation, delimiters are unnecessary and they also consume memory.You need to append fields in the output. This may be true if multiple fields have some meaning when concatenated together.	Option	Description	Delimited	Select this option to create rows delimited with a pipe character () or some other user-defined selection. This is the preferred option if you are using large column widths where the values may be smaller than the width of the columns. The pipe character is the default selection.	Fixed	Select this option to create rows of fixed size in the generated type tree. There are certain situations in which you would want to select Fixed.
Option	Description						
Delimited	Select this option to create rows delimited with a pipe character () or some other user-defined selection. This is the preferred option if you are using large column widths where the values may be smaller than the width of the columns. The pipe character is the default selection.						
Fixed	Select this option to create rows of fixed size in the generated type tree. There are certain situations in which you would want to select Fixed.						
Delimiter	This is the value for the delimiter to be used when generating this type tree. For a list of available symbols, click the browse button. The Symbols dialog appears, allowing you to select the desired value. The default value is a pipe character ().						
Terminator	This is the value for the terminator to be used when generating this type tree. For a list of available symbols, click the browse button. The Symbols dialog appears, allowing you to select the desired value. The default value is <CR><LF>.						
Release	This is the value for the release character to be used when generating this type tree. For a list of available symbols, click the browse button. The Symbols dialog appears, allowing you to select the desired value. The default value is an exclamation point (!).						
Override Column Definitions	(For ODBC only) This check box indicates whether the database driver (with the check box disabled) or a command line override (with the check box enabled) is used to interpret columns. The default value is disabled. For more information about this field, see the adapter-specific documentation in each adapter reference guide.						
Generate type trees in 1.4.0 format	(For Oracle adapter only) This check box determines whether you can generate type trees that are compatible with Version 1.4.0 maps. You might enable this functionality if you have legacy 1.4.0 maps that you want to maintain for some reason. The default value is disabled. For more information about this field, refer to adapter-specific documentation in each adapter reference guide.						
Represent date/time columns as text items	This check box determines whether to automatically format this information in its database-specific date and time format (enabled) or as a text string (disabled). If you enable this check box (generating date and time as a text string), you may have to use either the TEXTTODATE or TEXTTOTIME function in a map rule to convert the text string to the database-specific date and time format. If you are generating new type trees, make sure this check box is disabled. The default is disabled. Note: Because of adapter-specific differences in date and time formats, see the adapter-specific instructions in each adapter reference guide.						
Treat text item as	This list displays the languages available in which to handle text items. The default value is Western .						

To generate a type tree from a stored procedure:

Procedure

- In the Navigator, highlight the icon of the database containing one or more stored procedures from which you want to generate a type tree.
- From the Database menu, click Generate Tree From > Procedure.

or

In the Navigator, right-click the database and select Generate Tree From > Procedure.

The Generate Type Tree from Stored Procedures dialog appears, including a list of stored procedures.

3. If you need to add a stored procedure because it is not displayed in the Stored Procedures list, you must insert it following the instructions provided in the Note below.
or

If you see one or more stored procedures in the Stored Procedures list that you want to select, if it is one, select it; if it is multiple procedures, press either Shift or Ctrl and click the desired stored procedures.

Note: The list of stored procedures includes stand-alone procedures by default. (Procedures that are parts of a package are not listed.) If you need a procedure that is part of a package (whether this functionality is available is dependent upon your database), you may need to insert it into this list before selecting it. To insert a packaged stored procedure, right-click in the list, select Insert, and type the desired name. Use the following format: schema.package.procedure.

4. To create a new type tree, in the File name field, specify the path and name (with an .mtt extension).
or

Click the browse button to select a type tree from the Save As dialog. Highlight it and click OK.

5. Specify the remaining options as desired. Refer to context-sensitive help for field-specific information.

6. Click Generate.

The Database Interface Designer and Type Tree Maker produce a type tree corresponding to the selected stored procedure(s).

Results

The generated type tree is represented in the Navigator with the stored procedure icon next to the name.

From a message queue (Oracle AQ)

About this task

Use the Database Interface Designer to generate type trees for a message on an Oracle AQ message queue. An example of the Generate Type Tree from Queues dialog follows, along with a table describing its fields and their descriptions.

Database Name	This is the name of the database from which you want to generate a type tree. (This name is automatically inserted based upon your selection in the Navigator.)						
Tables/Views	This list displays all of the queues that have been defined in this database. Select one or more from this list. If the queue you want is not displayed in this list, add it by right-clicking in the list, selecting Insert, and typing the desired name.						
File name	This field displays a system-generated file name based upon the database selection in the Navigator. The default value is the database name with a type tree extension (.mtt) and a default path. To change any of this information, click the browse button.						
Overwrite file	This check box determines whether you want to replace the existing type tree file (MTT) upon saving it. The default value is disabled.						
Override type	This check box determines whether to replace existing types with matching, newly generated types and to add any non-matching new types to the type tree file (MTT). This is useful when you want to add types for additional stored procedures into an existing type tree. The default value is enabled.						
Row group format	This list displays options to determine the row format in the generated type tree. The default value is Delimited. <table border="1"><thead><tr><th>Option</th><th>Description</th></tr></thead><tbody><tr><td>Delimited</td><td>Select this option to create rows delimited with a pipe character () or some other user-defined selection. This is the preferred option if you are using large column widths where the values may be smaller than the width of the columns. The pipe character is the default selection.</td></tr><tr><td>Fixed</td><td>Select this option to create rows of fixed size in the generated type tree. There are certain situations in which you would want to select Fixed.</td></tr></tbody></table>	Option	Description	Delimited	Select this option to create rows delimited with a pipe character () or some other user-defined selection. This is the preferred option if you are using large column widths where the values may be smaller than the width of the columns. The pipe character is the default selection.	Fixed	Select this option to create rows of fixed size in the generated type tree. There are certain situations in which you would want to select Fixed.
Option	Description						
Delimited	Select this option to create rows delimited with a pipe character () or some other user-defined selection. This is the preferred option if you are using large column widths where the values may be smaller than the width of the columns. The pipe character is the default selection.						
Fixed	Select this option to create rows of fixed size in the generated type tree. There are certain situations in which you would want to select Fixed.						
Delimiter	This is the value for the delimiter to be used when generating this type tree. For a list of available symbols, click the browse button. The Symbols dialog appears, allowing you to select the desired value. The default value is a pipe character ().						
Terminator	This is the value for the terminator to be used when generating this type tree. For a list of available symbols, click the browse button. The Symbols dialog appears, allowing you to select the desired value. The default value is <CR><LF>.						
Release	This is the value for the release character to be used when generating this type tree. For a list of available symbols, click the browse button. The Symbols dialog appears, allowing you to select the desired value. The default value is an exclamation point (!).						
Override Column Definitions	(For ODBC only) This field is not available for message queues.						
Generate type trees in 1.4.0 format	(For Oracle adapter only) This check box determines whether you can generate type trees that are compatible with Version 1.4.0 maps. You might enable this functionality if you have legacy 1.4.0 maps that you want to maintain for some reason. The default value is disabled. For more information about this field, refer to adapter-specific documentation in each adapter reference guide.						
Represent date/time columns as text items	This check box determines whether to automatically format this information as a text string. By default, the checkbox is deselected, and the information is formatted in its database-specific date and time format. If you enable this check box (generating date and time as a text string), you might have to use either the TEXTTODATE or TEXTTOTIME function in a map rule to convert the text string to the database-specific date and time format. If you are generating new type trees, make sure this check box is disabled. Note: Because of adapter-specific differences in date and time formats, see the adapter-specific instructions in each adapter reference guide.						
Treat text item as	This list displays the languages available in which to handle text items. The default value is Western.						

To generate a type tree from a queue:

Procedure

1. In the Navigator, select the icon of the database from which you want to generate a type tree.
2. From the Database menu, click Generate Tree From > Queue.
The Generate Type Tree from Queues dialog appears, including a list of queues.
3. If you need to add a queue because it is not displayed in the Tables/Views list, you must insert it following the information in the Note below.
or

If you see one or more queues in the Tables/Views list that you want to select, if it is one, select it. If it is multiple queues, press either Shift or Ctrl and click the desired queues.

4. To create a new type tree, in the File name field, specify the path and name (with an .mtt extension).
or

Click the browse button to select a type tree from the Save As dialog. Highlight it and click OK.

5. Specify the remaining options as needed.
6. Click Generate.

The Database Interface Designer and the Type Tree Maker produce a type tree corresponding to the selected queue(s).

Note: Type trees generated from queues are not graphically represented in the Navigator.

From a query

About this task

When generating a type tree from a query, information is used from your database and from the Database Interface Designer to create the type tree. If you change the definition of your query in the Database Interface Designer or edit that database definition, you must generate a new type tree to reflect the new information.

When attempting to generate a type tree, if your query is incorrectly specified, an error message from your database is received and a message displays, indicating that the column definitions for that query could not be accessed. In this scenario, a type tree is not generated.

Generating a type tree provides a way to test the syntax of your select statement. If you can successfully generate a type tree from a query, you know that the query has valid syntax.

An example of the Generate Type Trees From Query dialog follows, along with a table describing its fields and their descriptions.

Field	Description
File name	This field displays a system-generated file name based upon the database selection in the Navigator. The default value is the database name with a type tree extension (.mtt) and a default path. To change any of this information, click the browse button.
Overwrite file	This check box determines whether you want to replace the existing type tree file (MTT) upon saving it. The default value is disabled.
Override type	This check box determines whether to replace existing types with matching, newly generated types and to add any non-matching new types to the type tree file (MTT). This is useful when you want to add types for additional stored procedures into an existing type tree. The default value is enabled.
Row group format	This list displays options to determine the row format in the generated type tree. The default value is Delimited .
Delimited	Select this option to create rows delimited with a pipe character () or some other user-defined selection. This is the preferred option if you are using large column widths where the values may be smaller than the width of the columns. The pipe character is the default selection.
Fixed	Select this option to create rows of fixed size in the generated type tree. There are certain situations in which you would want to select Fixed. <ul style="list-style-type: none">• The query result contains a large number of rows where each row consists of small, fixed-length fields. In this situation, delimiters are unnecessary and they also consume memory.• You need to append fields in the output. This may be true if multiple fields have some meaning when concatenated together.
Delimiter	This is the value for the delimiter to be used when generating this type tree. For a list of available symbols, click the browse button. The Symbols dialog appears, allowing you to select the desired value. The default value is a pipe character ().
Terminator	This is the value for the terminator to be used when generating this type tree. For a list of available symbols, click the browse button. The Symbols dialog appears, allowing you to select the desired value. The default value is <CR><LF>.
Release	This is the value for the release character to be used when generating this type tree. For a list of available symbols, click the browse button. The Symbols dialog appears, allowing you to select the desired value. The default value is an exclamation point (!).
Override Column Definitions	(For ODBC only) This check box indicates whether the database driver (with the check box disabled) or a command line override (with the check box enabled) is used to interpret columns. The default value is disabled. For more information about this field, see the adapter-specific documentation in each adapter reference guide.
Generate type trees in 1.4.0 format	(For Oracle adapter only) This check box determines whether you can generate type trees that are compatible with Version 1.4.0 maps. You might enable this functionality if you have legacy 1.4.0 maps that you want to maintain for some reason. The default value is disabled. For more information about this field, refer to adapter-specific documentation in each adapter reference guide.
Represent date/time columns as text items	If you enable this check box (generating date and time as a text string), you may have to use either the TEXTTODATE or TEXTTOTIME function in a map rule to convert the text string to the database-specific date and time format. If you are generating new type trees, make sure this check box is disabled. The default is disabled. Note: Because of adapter-specific differences in date and time formats, see the adapter-specific instructions in each adapter reference guide.
Treat text item as	This list displays the languages available in which to handle text items. The default value is Western .

To generate a type tree from a query:

Procedure

1. In the Navigator, highlight the icon of the query from which you want to generate a type tree.

2. From the Query menu, select Generate Tree.
or
In the Navigator, right-click the query and select Generate Tree.
- The Generate Type Tree from Query dialog appears, displaying the name of the selected type tree.
3. To create a new type tree, in the File name field, specify the path and name (with an .mtt extension).
or
Click the browse button to select a type tree from the Save As dialog. Highlight it and click OK.
4. Specify the remaining options as desired. Refer to context-sensitive help for field-specific information.
5. Click OK.
The Database Interface Designer and the Type Tree Maker produce a type tree corresponding to the selected database query.

Results

The generated type tree is represented in the Navigator with the query icon displayed next to the name.

Printing reports

About this task

You can print reports including detailed information about each specified database and query contained in an MDQ file. Reports contain information about the databases and queries that you designate. They can also include the time when the report was printed, the full path name of the MDQ file, the database definition, and definitions of each query and stored procedure.

You can only specify one database at a time.

To print a report:

Procedure

1. Highlight the database within an MDQ file for which you want to print the information.
2. From the File menu, select Print.
or
In the Navigator, right-click the icon of the database and select Print.
- The Print dialog appears.
3. To print all of the entities displayed, skip to the next step.
or
To select certain entities to not be printed, disable the appropriate check box next to the entity name.
4. To use the default font for the report, skip to Step 6.
or
To change the font for the report, click Font.
- The Font dialog appears.
5. Change the settings as desired and click OK.
The Font dialog is closed and you are returned to the Print dialog.
6. Click OK.
The Print dialog appears.
7. Make any changes as desired and click OK.
The report is printed.

Database Interface Designer trace files

The Database Interface Designer trace is a facility that produces information about accessing your database from the Database Interface Designer and then logs this information to a file. This can be useful in determining problems encountered when generating type trees or setting update keys using the Database Interface Designer.

If trace is enabled, a Database Interface Designer trace file (.dbl) is automatically created when you generate a type tree. This trace file is placed in the same directory as the MDQ file. The newly created Database Interface Designer trace file is named using the full name of the MDQ file with a .dbl extension. For example, if your MDQ file is named **Orders.mdq**, the trace file is named **Orders.dbl** and is located in the same directory. If the MDQ file has been newly created, the trace file is named its assigned name (**Database_QueryFile n .dbl**, where **n** represents the assigned sequential number) and resides in the directory in which the Database Interface Designer is installed.

- [Database Interface Designer trace](#)
- [Viewing Database Interface Designer trace files](#)
- [Finding text in trace files](#)

Database Interface Designer trace

About this task

You can enable or disable trace for any MDQ file listed in the Navigator.

To enable or disable trace:

Note: Because this is a toggle command, use the same procedure for both enabling and disabling trace.

Procedure

1. In the Navigator, highlight the MDQ file for which you want to enable a trace.
2. From the File menu, select Trace.

Viewing Database Interface Designer trace files

About this task

After trace has been enabled and a Database Interface Designer trace file has been generated, the contents of this file can be viewed in a trace window in the Database Interface Designer.

To view trace files:

Procedure

1. In the Navigator, highlight the MDQ file for which you want to view the results of a trace.
2. From the View menu, select Trace File.
A trace window appears, showing the results of the last trace.
Note: If a trace file has not yet been generated, a blank window appears.
3. To define how you want to view multiple trace windows simultaneously, from the Window menu, enable either Cascade, Tile Horizontally, Tile Vertically or Arrange Icons.

Results

In addition to the Database Interface Designer trace that is applicable only when working in the Database Interface Designer environment, you can also generate an additional database trace file that records activities occurring during map execution.

Finding text in trace files

About this task

Use the **Find** command to locate specific text in a Database Interface Designer trace window. This is helpful when analyzing errors or searching for specific information. The **Find** command is implemented as a result of values entered in the Find dialog. An example of this dialog follows, along with a table describing its fields and their descriptions.

Find what	Enter the text upon which to search. The default value is blank.						
Match whole word only	This check box determines whether to use the value entered in the Find what field to match only whole words against in the trace file. (For example, if this was enabled and text was your find value, texts would not be a match.) The default value is disabled.						
Match case	This check box determines whether to use the value entered in the Find what field to exactly match its case in the trace file. (For example, if this was enabled and Text was your find value, text would not be a match.) The default value is disabled.						
Direction	Select the option to determine the direction of the find, that is whether to start at the beginning point and search backward (Up) or forward (Down). The default selection is Down. <table><thead><tr><th>Option</th><th>Description</th></tr></thead><tbody><tr><td>Up</td><td>Select this option to begin the find at this point and go backwards in the trace file. The default value for this is cleared.</td></tr><tr><td>Down</td><td>Select this option to begin the find at this point and go forward in the trace file. The default value for this is selected.</td></tr></tbody></table>	Option	Description	Up	Select this option to begin the find at this point and go backwards in the trace file. The default value for this is cleared.	Down	Select this option to begin the find at this point and go forward in the trace file. The default value for this is selected.
Option	Description						
Up	Select this option to begin the find at this point and go backwards in the trace file. The default value for this is cleared.						
Down	Select this option to begin the find at this point and go forward in the trace file. The default value for this is selected.						

To use the Find command:

Procedure

1. Select the trace window containing the trace file upon which you want to perform a text search.

Note: Ensure the trace window containing the desired trace file is the active window.

or

From the Window menu, select the name of the trace file.

2. From the Edit menu, select Find.

The Find dialog appears.

3. In the Find what field, enter the text you want to find.
 4. Make other selections as desired.
 5. Click Find Next.
If a match is found, the text is highlighted in the file in the trace window. Otherwise, there may be a message asking if you want to continue searching.
 6. Repeat Step 5 until you have finished your search.
 7. Click Cancel.
-

Database type trees

Use the Database Interface Designer or **mtsmaker** to generate a type tree to be used in a map. You can also define your own type tree using the Type Designer. However, for the database adapters to correctly process your database data, your type tree must conform to the format described in this topic. For information about using **mtsmaker** to generate type trees, see the Resource Adapters documentation.

Although you can manually create a type tree for a table or a query using the Type Designer, it is not recommended.

The following examples represent type trees generated by the Database Interface Designer from two queries (one SELECT and one calls a stored procedure), a table, a stored procedure, and a message queue.

As shown in these examples, the type trees generated from tables, views, queries, and stored procedures are very similar, while the type tree generated for message queues differs slightly.

In these example type trees:

- The type tree named **ActvProj.mtt** was created for a query that referenced a Microsoft Access table.
 - The type tree named **Stores.mtt** was created for a table in a Microsoft SQL Server database.
 - Two type trees were created for stored procedures in an Oracle database.
 - The **PymtInfo.mtt** type tree was generated for a query called **GetPaymentInfo** that calls an Oracle stored procedure to be used as a map data source.
 - The **ApplyPmt.mtt** type tree was generated for the **SCOTT.APPLY_PAYMENT** stored procedure to be used as a map output.
 - The type tree named **Paulmsg.mtt** was generated from a message queue on the **PAUL_MSG_QUEUE**.
 - [Table and query type tree structure](#)
 - [Stored procedure type tree structure](#)
 - [Oracle AQ Message type tree structure](#)
-

Table and query type tree structure

Type trees generated for a query and a table closely resemble one another.

Each type tree generated by the Database Interface Designer or **mtsmaker** for a database table or query (or a query that calls a stored procedure) will have the following standard characteristics:

- The root of the generated type tree is named **Data**.
 - The generated type tree contains a category whose name corresponds to any one of the following:
 - the name of the table in the database
 - the name of the query in the MDQ file
 - the name specified using the Category Type (-N) parameter for **mtsmaker**

The types defining the columns and rows returned by the database adapter stem from this type. In the examples, the categories are **ActiveProjects** and **stores**.
 - Stemming from the category named for the table or query are types that define the contents of the table or the results of query execution.
 - Each column in the database table or in the results of the query must have a corresponding item type with a name identical to that of the column in the database. These types stem from an item type (shown in each example) named **Column**.
 - A group type named **Row** represents a single row of data—either the result of a SELECT statement or a row to be inserted/updated in a table or view.
 - An implied group represents a collection of rows reflecting the results of a query, table, or view. This group is named either **DBSelect** for a query or **DBTable** for a table or view (or **DBProcedure** for a stored procedure).
 - [Special characters in type names](#)
 - [Characteristics of the DBSelect or DBTable type](#)
 - [Components and format of the row type](#)
 - [Defining the column type\(s\)](#)
-

Special characters in type names

Some characters used in column names are not valid within type names. The Database Interface Designer replaces these characters when it creates the type name for the column. If you create a type tree without using the Database Interface Designer or **mtsmaker**, you need to replace these characters in the type name.

Again, if you use the Database Interface Designer, these conversions are automatically performed. If you use **mtsmaker**, you must manually convert these characters.

Invalid Character(s)	Conversion to Type Name
space or hyphen (-) example: My_Column_Name	replaced with underscore (_) becomes: My_Column_Name
punctuation (other than ~ # % \ ^ ?) example: ^^Total^Amount	replaced with pound sign (#) becomes: ##Total##Amount
digit (as first character of column name) example: 1st-Game-of-2	prefixed with pound sign (#) becomes: #1st_Game_of_2

Characteristics of the DBSelect or DBTable type

In each type tree generated by the Database Interface Designer or **mtsmaker**, an implied group type represents the results of executing the query or the contents of the table.

- **DBSelect**

The type tree defines a query used as a data source for a map.

- **DBTable**

The type tree defines a table used as a data target for a map.

The **DBSelect** or **DBTable** type is an implied group with a series of row objects as its only component.

Components and format of the row type

As its name implies, the **Row** group represents a row (or tuple). The **Row** type is a group with an explicit format. The syntax of that format is based upon the options specified when the tree was created from the Database Interface Designer or the value passed to **mtsmaker** using the Format **mtsmaker** command (-x).

see the following table for information about specifying the value for the **Row group format** list when generating a type tree for a query or table.

Using

Information

Database Interface Designer

Database/query files

mtsmaker

Resource Adapters documentation

There are two different row group formats:

- delimited row group format
- fixed row group format

You can specify the syntax for each of these when generating the type tree.

- [**Delimited row group format**](#)
- [**Fixed row group format**](#)

Delimited row group format

If you select Delimited as the value in the **Row group format** list in either the Generate Type Tree from Tables dialog, the Generate Type Tree from Query dialog, or the Generate Type Tree from Stored Procedures dialog, the Properties window in the generated type tree indicates that the Group Subclass > Format is an explicit group defined as having a delimited syntax.

In the **Group options** pane, which is located in the dialog for generating the type tree, you can specify the **Delimiter**, **Terminator**, and **Release** setting values to be used in the type tree. The default values are |, None, <CR><LF>, and !, respectively. The **Initiator** value cannot be specified; it is always set to None.

When using the **DBLOOKUP**, **DBQUERY**, **GET** and **PUT** map functions with the database adapter, the adapter will use the default values for the **Delimiter**, **Terminator**, and **Release** settings. This is because the data passed to and from the adapter is, in this case, not represented by the type trees generated in the Database Interface Designer. The adapter will use the default values for the **Delimiter**, **Terminator**, and **Release** settings since it cannot access this information from a type tree.

Each component of **Row** is a type representing a column. These components appear in the component list in the same sequence as they appear in the query or table, as opposed to the type tree, which lists them in alphabetical order. In a delimited **Row**, each of the columns is defined as optional within the **Row** by specifying a range of (0:1) for each column component.

Fixed row group format

If you select Fixed as the value in the **Row group format** list in either the Generate Type Tree from Tables dialog, the Generate Type Tree from Query dialog, or the Generate Type Tree from Stored Procedures dialog, the Properties window in the generated type tree indicates that the **Row** type is an explicit group defined as having a fixed syntax.

In the **Group options** pane, which is located in the dialog for generating the type tree, you can specify the **Terminator** setting values to be used in the type tree. The default value is <CR><LF>.

When using the **DBLOOKUP**, **DBQUERY**, **GET** and **PUT** map functions with the database adapter, the adapter will use the default values for the **Delimiter**, **Terminator**, and **Release** settings. This is because the data passed to and from the adapter is, in this case, not represented by the type trees generated in the Database Interface Designer. The adapter will use the default values for the **Delimiter**, **Terminator**, and **Release** settings since it cannot access this information from a type tree.

Defining the column type(s)

Each named column in the database has a corresponding item type under the **Column** type in the type tree with the same name. For example, if the **DEMO.DEPARTMENT** table in the database has three columns (**DEPARTMENT_ID**, **LOCATION_ID**, and **NAME**), the type tree will have three identically named items (subject to restrictions described in [Special Characters in Type Names](#)) under the **Column** type.

Each item is defined according to the data type and length information returned to the database adapter by the database driver. For more information about the correspondence between database data types and item formats, see the specific adapter reference guides.

The minimum size of item types for columns in a delimited **Row** is 0 unless otherwise specified by the database driver. The minimum size of item types for columns in a fixed **Row** equals the maximum size.

- [Binary column types](#)
 - [Column types for expressions](#)
 - [Specifying column aliases](#)
-

Binary column types

If a database column corresponds to a binary type, your type tree contains additional types so that the binary data can be correctly interpreted. The method used to define binary columns allows a distinction to be made between a **NULL** column and a binary value of 0.

A category called **SizedGroup** is added to the tree. This category has an item subtype called **Sizeof** and group subtypes with the same names as the item types for each binary column.

The following changes are made to the type tree to account for columns representing binary data:

- Two variable length binary items are created as subtypes of the **Column** type to represent the value of the two binary type columns.
- The **Sizeof** item is a subtype of the **SizedGroup** category and is defined as a character integer item.
- Also, as a subtype of the **SizedGroup** category, two groups given the same name as the binary column type are created, each group including two components. The first component of each group is the **Sizeof** item; the second, the variable length binary item (either).
- The formats of those group types defined as subtypes of the **SizedGroup** category are defined in the same way as the format for the **Row** group type.
If the type tree has a delimited **Row** group format, the group types for the binary columns are also defined as delimited groups with the pipe character (|) as an infix delimiter. In this example, the **Sizeof** component is defined as being required in the component list. However, the binary item type is optional (with a range of 0:1).

You cannot generate a fixed **Row** group format type tree for a table or query containing variable length binary data.

If the type tree has a fixed **Row** group format, the group types for the binary columns are also defined as fixed groups. In this situation, both the **Sizeof** component and the binary item type are required.

- In the group type component list, the **Sizeof** component has the **Sized** attribute, indicating that the **Sizeof** item contains the size of the binary item that follows it.
When mapping to a table or view containing binary columns, use the **SIZE** function to assign the size of the binary data to the **Sizeof** data item.
 - The components for the **Row** type are the group types under the **SizedGroup** category for the binary columns.
-

Column types for expressions

Each constant or function specified in a query is given a name based upon the name returned from the database driver to the database adapter. If the database driver does *not* return a name for a column in the results, the item type created for the column is given a name beginning with Expr and is concatenated with a number beginning with 1000 for the first constant or function, 1001 for the second, and so on.

For example, the type tree generated for the following query

```
SELECT MIN(salary), MAX(salary) FROM Employee
```

would have a **Row** with two columns representing the result of the SQL MIN and MAX functions. In the type tree, the items created to represent the results of these functions would be Expr1000 and Expr1001 for the MIN and MAX functions, respectively.

Specifying column aliases

When you want to control the name of the generated item to represent a particular column or expression in a query, use the AS keyword to specify an alias for that column.

For example, you could specify the query as:

```
select min(salary) as min_salary, max(salary) as max_salary from employee
```

which would result in a type tree containing a **Row** with two columns representing the result of the SQL MIN and MAX functions. In the type tree, the items created to represent the results of these functions would be **min_salary** and **max_salary**. An example of this follows.

You can also use the AS keyword to specify an alias for a column having a name containing any of the characters that are invalid in a type name. Or, you can specify an alias for a column having a name longer than 32 bytes in UTF-8 encoding, which is the limit for the size of a type name.

The following example results in a type tree having a **Row** with three columns.

```
Select SomeReallyReallyReallyLongColumnName AS  
SomeLongColumnName,  
    1st-Payment AS Payment#1,  
    2nd-Payment AS Payment#2  
from some_table
```

The items created to represent the results of this query would be **SomeLongColumnName**, **Payment#1**, and **Payment#2**.

Stored procedure type tree structure

The type trees generated by the Database Interface Designer for stored procedures used for outputs from a map are slightly different from the ones generated for tables, queries, and queries calling stored procedures (that are used as the source of data for a map).

Major differences between a type tree for a stored procedure that will be used as output and a type tree for a table that will also be used as output are:

- Whereby table and query type trees have a **Column** item type from which stems all of the individual column types, the type tree for a stored procedure has an **Argument** item type from which stems item types representing each of the arguments passed to the stored procedure.
- Instead of a **Row** group, the type tree for a stored procedure has a **ProcedureCall** type. The **ProcedureCall** group represents the set of arguments passed to the stored procedure for each execution of the procedure.
The **ProcedureCall** group is defined in the same way as a **Row** type for a table or a query in the type tree. Its group format is determined by the value selected in the **Row group format** list in the Generate Type Tree from Tables dialog or the Generate Type Tree from Query dialog, respectively. The selected group format determines the terminator and release characters.
- Similar to the **DBTable** or **DBSelect** types in type trees for tables or queries, the type tree for a stored procedure has a **DBProcedure** type, which is an implied group consisting of a series of **ProcedureCalls**. The stored procedure is called once for each **ProcedureCall** in the **DBProcedure** output.
For information about using stored procedures as a data target, see [Using stored procedures](#). For information about generating type trees for a stored procedure, see [From a stored procedure](#).

Oracle AQ Message type tree structure

The type trees generated by the Database Interface Designer for Oracle AQ messages used as output from a map are different from those generated for tables, queries, or stored procedures. For information about these type trees, see the Oracle AQ Adapter documentation.
